This week, in response to this continuing trend of poor formality of operations, the site office communicated concerns with disciplined operations at WETF to LANL management. The site office noted that disciplined facility operations continue to be undermined with configuration management, pressure safety, safety basis implementation and operational readiness issues. The correspondence included an outline of significant events that have occurred over the past two years. Although the site office commended WETF operations for being transparent in their identification and reporting of these issues, they noted that the number and repetitive nature of the events indicate that extent of condition reviews and corrective actions have been less than adequate.

In an effort to improve disciplined operations at WETF, the site office directed LANL to provide a briefing that outlines the continued programmatic need for WETF operations, additional resources needed to successfully resume facility operations, and steps needed to bring WETF into compliance with its safety basis. The corrective action plan is expected to establish commitments that will ensure appropriate resources are applied to resolve technical issues, achieve readiness, and enable safe and sustainable operations in a timely, effective, and efficient manner.

Plutonium Facility – Safety Basis: LANL submitted three Evaluations of the Safety of the Situation to the site office for approval to address recent Potential Inadequacies of the Safety Analysis associated with the following: 1) non-conservative leak path factor associated with the seismic/fire accident scenario; 2) post-seismic fire in the basement; and 3) vault room shelving seismic requirements. The first two issues were identified by the Board's staff during a review of the Documented Safety Analysis earlier this year and communicated to NNSA by Board letter on June 18, 2012. For the leak path factor issue, an immediate action remains in effect to limit the material at risk for heat source plutonium in two rooms close to the exit doors. LANL is also implementing upgrades to the vault room shelving in question (planned for this month) to meet performance category 3 seismic requirements. LANL concluded that the post-seismic fire in the basement does not represent an Unreviewed Safety Question.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 16, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending November 16, 2012

Area G Drum Venting System (DVS): On Tuesday morning, DVS personnel discovered burned radioactive waste tags on a transuranic waste drum in the DVS area caused by failure of a heater. The heater element failed and hot metal dropped onto the waste drum and tags, which caused the tags to smolder. Subsequent investigation by Area G management identified that manufacturer recommendations on exclusion of combustible materials below these heaters were not being followed. DVS personnel have removed combustibles from beneath the heaters and a standing order has been issued to require a combustible standoff distance. Area G personnel noted that approximately half of the ten heaters of this type used in Dome 33 (the DVS dome) fail on an annual basis. LANL plans to replace the current heaters with a safer design identified by engineering personnel. Area G personnel are completing extent of condition reviews, a lessons learned and other corrective actions for this event.

Plutonium Facility – Seismic Safety: This week, the site office forwarded an update to the TA-55 Project Execution Strategy to NNSA-HQ that addresses seismic upgrades at the Plutonium Facility in response to Board Recommendation 2009-2. This revision includes plans for seismic upgrades of eight basement captured columns in Fiscal Year (FY) 13 and roof girders in FY 14. These upgrades address issues identified in the initial static non-linear seismic analysis that resulted in the declaration of a Potential Inadequacy of the Safety Analysis in August (see 8/31/12 site rep report). For FY 13, the plan also includes developing the critical decision 1 package for the Safety Class, Performance Category-3 active confinement ventilation system and continuing seismic upgrades for the fire suppression system (planned for completion in FY 14). LANL continues additional analysis and testing to ensure the seismic results are adequately bounding as directed by NNSA.

Criticality Safety: LANL recently provided the site office with a corrective action plan to strengthen and improve the criticality safety program and to respond to findings identified by a recent NNSA Criticality Safety Support Group (CSSG) assessment. The plan includes specific actions to address the following two findings in the CSSG report: 1) ownership and monitoring of the nuclear criticality safety program is less than adequate; and 2) inability to close outstanding criticality issues in a timely manner. Actions include hiring a new criticality safety group leader, appointing the Principal Associate Director for Operations and Business (Beard) as the chairman of the nuclear criticality safety committee, strengthening line management ownership and responsibilities, establishing facility-specific and programmatic metrics, establishing responsibilities and expectations to track and close issues in a timely manner, and re-validating criticality safety work priorities.

The CSSG team also identified an opportunity for improvement associated with the loss of LANL nuclear criticality staff. Based on further attrition in this group since the CSSG review, corrective actions to address staffing issues were included in the corrective action plan. In addition, LANL identified the following near-term compensatory measures: 1) establish and communicate the highest priority for limited criticality safety resources (support floor operations); 2) identify resources outside the criticality safety group within LANL that could respond to upset conditions and issues; 3) accelerate training and qualification of contractor staff; and 4) provide an option for an extended work week for criticality safety staff.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 23, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending November 23, 2012

Plutonium Facility – Seismic Safety: LANL recently submitted a safety basis addendum to the site office that addresses the Unreviewed Safety Question associated with facility structural performance (see 10/19/12 weekly). Static non-linear seismic analysis performed by LANL earlier this year indicates that the probability of failure for multiple structural components exceeds the performance goal identified in the safety basis. The safety basis addendum identifies a worst case offsite consequence of approximately 900 rem for a seismic collapse scenario that includes spill, impact and fire release mechanisms. The addendum does not identify new controls or compensatory measures that mitigate the potential consequences for this accident scenario.

LANL has developed conceptual design upgrades for two vulnerable structural components, the basement captured columns and facility roof girders. The addendum indicates that upgrades for these components will be complete in FY 13 and FY 14, respectively. The LANL submittal provides responses to the steps identified under Exigent Circumstances in the DOE memorandum dated September 17, 2012 on Adequate Protection. Consistent with the DOE memorandum, NNSA will “specify a senior level of DOE approval authority for these circumstances, including a Program Secretarial Officer or higher (when appropriate) in consultation with its Central Technical Authority and the Office of Health, Safety and Security.”

Weapons Engineering Tritium Facility (WETF): WETF engineers continue to identify pressure safety issues as a result of extent of condition reviews. Most recently, the following four noncompliances with pressure safety Technical Safety Requirements (TSRs) were identified: 1) compensatory measures for some pressure safety variances do not meet requirements; 2) some system components do not have adequately sized pressure relief devices installed; 3) some system components do not have any pressure relief device installed; and 4) preventative maintenance for some system pressure relief devices is not performed. Facility engineers noted during the critique that extent of condition reviews were almost complete and that all WETF systems will have been fully evaluated to ensure they meet pressure safety requirements in the very near future.

Area G Drum Venting System (DVS): LANL submitted, and the site office approved a Corrective Action Plan supporting the Federal Readiness Assessment (FRA) of DVS operations at Area G (see 10/26/12 weekly). In response, the site office developed and approved a plan of action for a limited scope FRA to evaluate closure of the initial prestart findings. This limited scope FRA will evaluate a select number of core functions based on performance during the original FRA and is scheduled to commence on December 10, 2012.

Certification Requirements Assessment: Earlier this month the Technical Area 55 (TA-55) Facility Operations Director declared a TSR noncompliance based on the failure of control room operators to meet all requirements for their two year re-qualification. In response, the site office has informed LANL that they will be conducting an assessment of certification requirements for operators and supervisors at TA-55. The assessment is scheduled to commence on December 3, 2012, with the overall objective of ensuring the respective Nuclear Facility Training Programs are effectively implemented.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 30, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending November 30, 2012

Kevin Smith recently announced that he will be leaving LANL as the site office manager to become the new manager of the Office of River Protection at the Hanford site. Juan Griego will be acting in his place until a new site office manager is assigned.

Transuranic Waste Operations – Safety Basis: In March 2012, the site office manager approved a major revision to the safety basis for transuranic waste operations at Technical Area-54, the Area G Basis for Interim Operation (BIO). This document will replace the current safety basis that was originally approved in 2003. Following approval, LANL moved forward with implementation plans for the new document; however, there have been significant delays and Area G management now estimates that implementation will not be complete until the second half of Fiscal Year 2013. In the interim, LANL is developing a safety basis strategy (expected in January 2013) that details plans to revise the Area G BIO to improve and simplify this new safety basis. These changes, which will be reviewed and approved by the site office, are expected to help simplify implementation at Area G.

The site office also provided direction to LANL this week to address and respond to the Board letter dated November 19, 2012, that identifies inconsistencies in the Area G BIO. LANL is requested to evaluate the issues identified and enter the Potential Inadequacy of the Safety Analysis process where appropriate and to provide a response on all issues to the site office by December 21st.

Activity-level Work Planning Oversight: This week, the site office Assistant Manager for Field Operations issued direction to all Field Operations personnel regarding their responsibilities for oversight of activity-level work planning. This direction cited DNFSB/TECH-37 and the Accident Investigation Board's report for the contamination event at the Los Alamos Neutron Science Center as examples of the importance of proper and diligent oversight of work at the activity level. The direction requires that all Facility Representative Team personnel complete at least one monthly operational awareness assessment of facility work at the experimental or activity level. These assessments are to be aimed at all aspects of planning and executing the activity being observed, including: work document development and review; coordination of work scheduling; pre-job briefings; work release; performance of work; work package closeout; and post-job brief. This direction also requires all Safety Engineering Team personnel to consider and incorporate this strategy into their formal assessments and operational awareness activities as appropriate.

Weapons Engineering Tritium Facility (WETF): In response to a series of formality of operations issues and recent site office direction to make improvements in this area (see 11/9/12 weekly), the WETF Facility Operations Director (FOD) determined that corrective actions have not been effective at ensuring the desired level of reliable nuclear operations. Based on this determination, the FOD declared the lack of effective corrective actions to be a recurring event and issued an Occurrence Report identifying this fact. Senior LANL management have indicated that the root causes associated with these recurring issues and adequate resources to address them need to be identified and in place prior to completing startup preparations. WETF management is developing a plan for how corrective actions and startup preparations will be integrated.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 7, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending December 7, 2012

Criticality Safety: As a part of LANL compensatory measures to help mitigate the risks associated with the reduction of qualified criticality safety staff (see 11/16/12 weekly), the Associate Director for Nuclear and High Hazard Operations recently communicated guidance and criticality safety priorities to LANL Responsible Associate Directors. The priorities for criticality safety resources are (in order of importance): 1) emergency response; 2) event response (infractions); 3) field support (requests for clarification from floor personnel); 4) procedure reviews; 5) annual process walk-downs; and 6) requests for new criticality safety evaluations. Facility operation supervisors and criticality safety officers are directed to emphasize with operators the need to follow criticality safety limit approvals and that if questions arise, response from criticality safety personnel will be a high priority.

Plutonium Facility – Criticality Safety: Two criticality safety related issues were identified at the Plutonium Facility this week. On Monday, workers identified liquid in a glovebox used to stage plutonium metal and oxide. Appropriate immediate actions to back-off and contact the operations center were taken. Operations personnel with criticality safety staff input developed a path forward to remove the materials from the glovebox and address the liquid. Subsequent investigation indicates that the liquid came from a legacy liquid cooling system associated with a furnace. The furnace and cooling system have not been used in over a decade; however, the system was not removed or placed out-of-service such that a limited amount of liquid remained in the system. Other similar legacy furnaces are being evaluated as a part of the extent of condition review for this issue.

Also this week, Plutonium Facility personnel identified approximately 450 grams of plutonium oxide holdup that was released into two gloveboxes during replacement of glovebox HEPA filters. These HEPA filters are used as housekeeping filters (i.e. not credited as a safety component) in the glovebox ventilation system. The filters are replaced as needed but the replacement periodicity varies depending on the operation in the glovebox and is not rigorously controlled. For the gloveboxes in question, there is a significant amount of plutonium oxide processing that has been performed for several years, however, the informal installation dates identified for one of the filters was 1991. Currently, the criticality safety evaluation for operations in these gloveboxes excludes evaluation of the filter because only limited contamination is expected. As part of the corrective actions, criticality safety will determine if additional evaluation is required. Plutonium Facility management is also pursuing an extent of condition review for other housekeeping filters, re-evaluating the program for filter replacement, and will determine if periodic non-destructive assay is appropriate for these type filters.

Plutonium Facility - Certification Requirements Assessment: The site office presented to LANL the preliminary results of the assessment of certification requirements for operators and supervisors (see 11/23/12 weekly). The assessment team concluded that the Plutonium Facility “does not have a compliant certification program for Operations Center Operators and Supervisors in accordance with DOE Order 426.2, *Personal Selection, Training, Qualification, and Certification Requirements for DOE Nuclear Facilities.*” This conclusion was based on a number of failures of the certification program to meet the requirements of the order. In response to these assessment results, facility management declared a Technical Safety Requirement violation for failure to ensure adequate manning by certified personnel and suspended operations in the Plutonium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 14, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending December 14, 2012

Weapons Engineering Tritium Facility (WETF): Since the discovery of oxygen in-leakage into the WETF hot-inlet system (HIS) in October, 2010, WETF has operated under a Justification for Continued Operation (JCO). Because the source of in-leakage has been difficult to identify and repair, the JCO has been repeatedly extended, with the most recent extension expiring on December 1, 2012. In lieu of extending the JCO, LANL submitted to the site office an Evaluation of the Safety of the Situation (ESS) declaring the HIS inoperable and concluding that with this action WETF is in a safe configuration. The ESS requires that the operational restrictions on the HIS not be removed until the in-leakage is repaired and the HIS is adequately implemented as safety significant.

In response, the site office concurred that because the HIS contains only trace quantities of tritium, the system is safe provided it is completely locked and tagged out. As such, the site office directed LANL to immediately lockout and tagout the tritium sources to the HIS. The site office noted that allowing the JCO to expire without correcting the problems in a timely manner was another example of less than disciplined operations at WETF (see 11/9/12 weekly). Additionally, the site office directed LANL to address the HIS issues and perform a contractor readiness assessment prior to making appropriate recommendations on future operations to the site office manager for approval.

Plutonium Facility – Criticality Safety: LANL submitted an ESS to the site office for approval that addresses a criticality safety issue for storage of fissile materials in vault rooms B and I. Based on questions from site office personnel in October, LANL identified that the Criticality Safety Evaluations (CSEs) for these two rooms did not adequately address the potential for interaction effects between drawer and floor storage locations (see 10/19/12 weekly). Plutonium Facility management suspended operations in vault rooms B and I. These restrictions remain in place. The criticality safety issue was subsequently declared an Unreviewed Safety Question.

The ESS recommends establishing a Technical Safety Requirement (TSR) level control for the minimum spacing between drawer and floor locations. LANL is also pursuing a new CSE for these vault rooms that will appropriately analyze interaction effects. In the interim, LANL recommends approval of the ESS that will allow resumption of vault room B and I operations with the spacing control implemented as a TSR level control. The site office is reviewing the ESS.

Transuranic Waste Facility (TWF) Project: The site office recently provided direction to LANL on the Safety Design Strategy (SDS) and the Preliminary Documented Safety Analysis (PDSA). LANL is requested to re-submit the SDS and PDSA documents in early-2013 to address site office issues including the following: 1) clear description and justification of differences between the Area G and TWF safety basis; 2) re-evaluation of material at risk limits (the site office believes the waste storage building material limits could be reduced by a factor of 2 or 3); 3) include a safety class engineered control that prevents large vehicle impact; and 4) evaluation of safety implications and life-cycle impacts of elevating waste storage containers, fire suppression system and lightning protection system (including support systems) to safety class. The TWF project design is approximately 90% complete.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 21, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending December 21, 2012

Area G Drum Venting System (DVS): A limited scope Federal Readiness Assessment (FRA) for DVS operations was completed this week. The scope of the FRA was to verify closure of core requirements and pre-start findings from a previous FRA that concluded the contractor had not successfully demonstrated readiness for Hazard Category 2/3 drum venting operations in Area G (see 10/5/12 weekly). The limited scope assessment team recommended that upon adequate closure of their one pre-start finding and site office approval of corrective actions for the three post-start findings, the startup of Hazard Category 2/3 drum venting operations be authorized in Area G. The one pre-start finding identified that facility operators, waste operators, and shift operations supervisors were not qualified in compliance with DOE Order 426.2.

The heaters in Dome 33 with a high failure rate and a failure mechanism that includes dropping hot metal from the failed heating elements have yet to be replaced (see 11/16/12 weekly). One compensatory measure in place includes marking exclusion zones beneath the heaters to prevent personnel injury and to prevent another fire in the dome. During the walkdown of Dome 33 in preparation for the DVS FRA, it was observed that there were combustible materials beneath grating and around tanks within multiple exclusion zones. The contractor has committed to clean out the combustible materials and aggressively pursue replacement of the current heaters with a safer design.

Plutonium Facility – Control Room Operator and Supervisor Certifications: On December 10th, 2012, the site office approved a LANL request for a six month extension of certification of Technical Area (TA)-55 operations center operators and supervisors following the discovery that the certification program was not compliant with DOE Order 426.2 (see 12/7/12 weekly). The LANL request identified compensatory measures that include the development of a TA-55 Operations Center Certification/Qualification improvement process. A condition of approval identified by the site office included requesting the Principal Associate Director of Operations and Business to examine the causes and perform an extent of condition review of the non-compliances. LANL is currently performing a preliminary evaluation of all certified positions to identify potential similar issues. A plan for additional extent of condition reviews that could potentially extend to qualification programs at other LANL facilities, such as Area G DVS operations, is being developed.

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition Project: Laboratory personnel continue startup preparations in CMR Wing 9 to support retrieval and disposition of radiological material contained in nine large metal confinement vessels currently stored at TA-55. LANL recently completed a detailed evaluation of startup preparations and status (similar to the red team reviews performed at Area G). This review identified concerns with the amount of floor practice time for facility workers, procedures (including the Integrated Work Document), and the technical baseline (e.g. incorrect quality assurance levels for some credited safety components). CMR personnel are working on corrective actions to resolve these issues. Earlier this month, LANL conducted an Implementation Verification Review for the safety basis associated with the confinement vessel disposition project. Readiness activities and preparation will continue in 2013 with the contractor and federal operational readiness reviews scheduled for March and June, respectively.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 28, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending December 28, 2012

The Los Alamos National Laboratory was on winter break this week. The site reps were out of the office. This report is filed for continuity purposes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 4, 2013

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending January 4, 2013

Plutonium Facility – Seismic Safety: The site office recently provided comments to LANL on the safety basis addendum associated with inadequate structural performance identified in October 2012 (see 11/23/12 weekly). The safety basis review team that is evaluating the addendum includes subject matter experts from LASO, the NNSA Albuquerque Complex, and DOE-Headquarters. The review team provided 20 comments on the addendum that require correction or resolution. The site office memo directs LANL to resubmit the addendum along with a completed comment resolution document by January 18, 2013.

Area G – Safety Basis: LANL has submitted a revised safety basis strategy for Technical Area-54, Area G Basis for Interim Operations (BIO) and Technical Safety Requirements (TSR) to the site office for review and approval. In March 2012, the site office approved a BIO and associated TSRs to replace the current safety basis that was approved in 2003. However, due to a focus of resources on accelerating material at risk (MAR) reduction efforts through the 3706 Campaign, BIO implementation has been delayed to the second half of 2013. This new safety basis strategy proposes to revise the currently approved BIO and associated TSRs to account for the significant reduction in above-ground material at risk as a result of 3706 Campaign waste removal efforts. In addition, the revised BIO and TSRs will address issues identified in the Board letter dated November 19, 2012, that identified deficiencies in the BIO. LANL recently submitted its response to the Board's letter to the site office for review.

LANL expects to submit the revised BIO and TSRs to the site office for approval in April, 2013. This submittal date will facilitate implementation of the BIO and TSRs by September 30, 2013. In order to reduce risk while operations continue as the implementation of the BIO is delayed, LANL is proposing several actions including: relocating MAR to locations more distant from the site boundary; removing several high MAR containers in addition to those of the 3706 Campaign; and paving roads within Area G to eliminate the need for the large gasoline powered water truck currently used for dust suppression.

Los Alamos Neutron Science Center (LANSCE): In December, LANL completed initial corrective actions to support resumption of operations in the Lujan Center, ER-2 flight paths. The Lujan Center flight paths in ER-1 and ER-2 have been shut down since a release of contamination occurred in August 2012. In September 2012, NNSA's Accident Investigation Board (AIB) identified 14 Judgments of Need (see 11/2/12 weekly). The initial corrective actions to support restart of operations in ER-2 address issues identified by the AIB. Operations in ER-1 (the location of the most significant contamination) are not expected to restart until the next beam cycle (July 2013).

The site office has also increased their operational awareness of LANSCE activities during the decontamination and recovery phase including a walk-down of the sample management procedures and processes by the Assistant Manager for Field Operations. ER-2 flight path operations are expected to restart this month and continue through the end of this beam cycle (February 2013). LANL plans to implement additional permanent corrective actions at the Lujan Center and other LANSCE facilities prior to the start of the next beam cycle.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 11, 2013

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending January 11, 2013

Weapons Engineering Tritium Facility (WETF): In November 2012, LANL submitted an Evaluation of the Safety of the Situation (ESS) to address hot inlet system (HIS) oxygen in-leakage issues (see 12/14/12 weekly). At that time, LANL declared the HIS inoperable. The ESS identifies operational restrictions to ensure tritium is not introduced into the HIS and concludes that the system is in a safe configuration for air in-leakage. In December, the site office concurred that the HIS is safe, provided the system is completely locked and tagged out per LANL requirements, and directed such actions. LASO also directed conduct of a contractor readiness assessment and that the HIS remain locked and tagged until approved by the site office manager.

In December, WETF personnel completed the actions and implemented the controls identified in the ESS and directed by the site office. However, based on questions from the facility representative this week, LANL identified that an Implementation Verification Review was not conducted as required by site procedures to ensure controls were appropriately implemented. Additionally, because the ESS controls were not specifically approved by the site office, questions concerning the status of its controls are also being evaluated.

Area G – Safety Basis: The site office responded to the safety basis strategy submitted by LANL for the Technical Area-54, Area G Basis for Interim Operations (BIO) (see 1/4/13 weekly). The site office response generally agreed with the approach proposed by LANL, but cautioned that the proposed scope of and schedule for the revision was aggressive and could jeopardize timely implementation of the revised BIO. The site office directed LANL to revise the scope of the revision to ensure implementation by September 30, 2013. The site office also directed that when limiting the scope, certain revisions must be made, to include: addressing issues identified in the Board's letter dated November 19, 2012; addressing issues identified in the site office's review of the currently approved BIO; and ensuring deposition velocity is reasonably conservative as directed in a previous site office memorandum to LANL.

Plutonium Facility – Emergency Preparedness: In response to direction from NNSA headquarters, the site office has accelerated plans for a table top emergency exercise for a Plutonium Facility collapse scenario in response to a significant seismic event. An extensive series of table top exercises is planned for February 26, 2013. The site office and LANL are working closely together to select challenging scenarios to ensure preparedness of both site personnel and several outside agencies likely to respond to such an event.

Cognizant System Engineer (CSE) Program: This week, LANL submitted its response and corrective actions to the site office's Fiscal Year 2012 assessment of the CSE program. The assessment found that progress continues to be made in achieving a mature and effective CSE program at LANL. The assessment also identified two findings: 1) CSE required training curricula does not meet all requirements of DOE Order 420.1B; and 2) tracking of corrective actions in response to site office assessments of the CSE program is not fully effective. Corrective actions are being maintained and tracked through the LANL Performance Feedback and Improvement Tracking System.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 18, 2013

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending January 18, 2013

Area G – Work Planning and Control: A Radiological Controls Technician (RCT) assigned to source check an area radiation monitor in the High Energy – Real Time Radiography facility in Area G opened a vial containing a liquid Europium-152 (Eu-152) source and emptied its contents on to an equipment cabinet. The RCT mistakenly thought the vial contained a sealed source. The source was actually comprised of 0.53 mCi of Eu-152 suspended in a hydrochloric acid solution. Approximately 1 milliliter of liquid was poured out of the vial contaminating the RCT and a local area in the facility. Actions taken after the spill of material prevented contamination from being spread outside the facility.

In addition to the fact that the RCT did not know that the source being used was in a liquid form, there were a number of work planning and control issues that contributed to this event. Some of the identified issues included: no procedure existed for performing the source check activity; no pre-job brief specific to the activity of conducting the source check was conducted; word of mouth was used to identify the required source for the check; the RCT did not stop when he initially could not get the correct reading on the radiation monitor; and not all of the controls specified in the radiological work permit were followed. Additionally, issues that paralleled the release of contamination event at the Los Alamos Neutron Science Center (LANSCE) in August 2012 were identified. As a result, the Associate Director of Nuclear and High Hazard Operations has directed an additional investigation be performed by managers involved in the investigation of the LANSCE event.

Plutonium Facility – Criticality Safety: Based on questions from site office personnel, a criticality safety infraction was identified in the Plutonium Facility when workers placed containers on a cart that were too small to be restrained by an interference plate. This plate is designed to ensure containers remain in their location during a seismic event as required by the criticality safety limit approval (CSLA). During the critique of the event it was determined that controls that were identified as safety significant in the CSLA were not elevated to the safety basis documents as would have been appropriate. In response to this discovery, the New Information process has been entered and use of the carts has been suspended until appropriate criticality safety controls are implemented.

Safety Basis: The site office granted LANL extensions on the following three significant safety related documents this week to “ensure the necessary quality deliverables and management review”: 1) the PF-4 safety basis addendum to address structural performance (now due February 1st); 2) the final report on the PF-4 service chase joint mock-up testing (now due February 15th); and 3) the Area G safety basis changes to support higher material at risk box line operations (now due January 31st). The site office letter requests LANL to ensure that results from the PF-4 service chase joint testing are appropriately factored into the ongoing alternate seismic analysis.

The site office also recently provided extensive comments to LANL on the August 2012 submittal of the RANT shipping facility Documented Safety Analysis update. The site office identified 66 comments that require correction or resolution and requested LANL to resubmit the safety basis documents in 90 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 25, 2013

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending January 25, 2013

Federal Oversight: Earlier this month, the DOE Office of Health, Safety and Security's (HSS) Office of Enforcement and Oversight released a report on LANL's corrective action effectiveness. The HSS review team in conjunction with a site office assessment team evaluated LANL's corrective actions to address safety system oversight and other assessment findings. The HSS report agreed with the site office conclusion that the LANL process did not ensure effective implementation of corrective actions. The report also notes that previous HSS issues had not been adequately resolved. The HSS forwarding memo states that the "weaknesses call into question the current state of key aspects of the contractor's assurance system...."

Transuranic Waste Operations: LANL recently removed their sole supplier for transuranic waste drums from the approved vendors list based on failure to meet all applicable sections of the nuclear quality assurance standard NQA-1. In October 2012, a Joint Supplier Evaluation Program audit of the vendor was completed and findings were communicated that included failure to meet sections 200 through 900 of NQA-1. The vendor response in November indicated that action would not be taken on implementation of these sections, which resulted in the supplier being removed from the approved vendor list earlier this month. LANL has not noted any significant receipt inspection or performance problems with drums received from this vendor.

This week, LANL entered the site's new information process to evaluate potential safety basis impacts for nuclear facilities that use transuranic waste drums. A recently received inventory of drums is being held until a commercial grade dedication process can be developed and applied to verify that the drums meet applicable safety basis performance requirements. LANL is also evaluating options including continued use of the commercial grade dedication process as an avenue to procure drums from this sole source vendor.

Area G High Energy – Real Time Radiography (HE-RTR): This week, LANL performed decontamination activities at the HE-RTR facility to address the release of Europium-152 from a source that occurred last week (see 1/18/13 weekly). On Thursday, the decontamination was sufficient to release the facility to operations. Area G personnel also located a solid source (versus the liquid source that was released last week) to test the area radiation monitors. LANL is developing a lessons learned document to capture the work planning and control issues associated with this event. In addition, a senior team from the Associate Director of Nuclear and Hazard Operations continues to investigate this event and the corrective actions.

Transuranic Waste Facility (TWF) Project: Based on direction from the site office, LANL is performing engineering studies to evaluate the safety basis strategy for the TWF Project Fire Suppression System, Lightning Protection System and metal containers. The Preliminary Documented Safety Analysis will be revised based on the engineering studies and comments from the site office (currently scheduled to be submitted in March). Last week, LANL submitted a revised aircraft crash frequency analysis based on feedback from the site office. The project had previously been scheduled for Critical Decision-2 evaluation by the Energy Systems Acquisition Advisory Board in December 2012 but this decision has been delayed by NNSA-Headquarters.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 1, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending February 1, 2013

Plutonium Facility – Seismic Safety: This week, LANL submitted a revision to the Plutonium Facility safety basis addendum on the exceedance of seismic performance goals to the field office for review and approval. The revision was submitted to address comments in a memo from the field office on the initial submission of the addendum in November 2012 (see 1/4/13 weekly). The analysis in the addendum identifies a bounding offsite dose consequence of approximately 940 rem for the seismic accident followed by a structural collapse and fire.

In addition to committing to perform structural modifications to reduce the probability of structural collapse by the end of the 2014 calendar year, the addendum identifies four compensatory measures that will be taken while the exigent circumstances identified in the addendum are addressed. These compensatory measures include: reducing the material at risk limit for the laboratory floor; reducing the material at risk limit for the vault; crediting newly-analyzed heat source safety-class containers; and removing one kilogram of heat source plutonium from the first floor by the end of calendar year 2013. The addendum identifies that implementation of these compensatory measures will reduce offsite dose consequences approximately 30% to 60% depending on safety basis assumptions. A NNSA safety basis review team is evaluating the addendum.

Plutonium Facility – Safety Basis: The field office responded to a request by LANL to revise the Documented Safety Analysis and Technical Safety Requirements to address issues with the certification and manning of control room operators and supervisors (see 12/21/12 weekly). In particular, the revision proposed reducing manning requirements and eliminating the requirement for supervisors and operators to be certified. Due to the significance of the activities these personnel are required to perform in order to ensure safety of the facility, the field office did not approve the requested revision. Plutonium Facility operations center operators and supervisors received a 6 month certification extension approved by the field office in December 2012 while LANL upgrades the training and certification process to meet DOE Order 426.2 requirements.

Area G – Startup Activities: There are a number of startup activities ongoing and upcoming in Technical Area-54, Area G. These activities will directly support LANL's efforts to meet commitments of the 3706 campaign to disposition above ground solid transuranic waste. This week, the contractor commenced a checklist readiness assessment of the Dome 231 box repackaging line to allow Hazard Category 3 operations. This review is scheduled to be complete next week.

For the Dome 375 box repackaging line, the fire suppression system passed required hydrostatic testing this week. Following successful completion of ventilation and fire suppression system installation and testing, the facility will move into a series of startup reviews culminating in a federal readiness assessment to support up to and including Hazard Category 2 repackaging operations.

Finally, the contractor submitted a corrective action plan for the federal readiness assessment of drum venting system operations in Dome 33. Following field office approval of the corrective action plan, completion of the necessary pre-start corrective actions, and authorization by the field office to commence operations, Hazard Category 2 drum venting activities will commence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 8, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending February 8, 2013

Plutonium Facility – Criticality Safety: This week, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis (PISA) based on failure to capture criticality safety controls associated with facility transfer carts in the safety basis. LANL had previously declared a criticality safety infraction when containers that were too small to be restrained by an interference plate were identified on these carts, which defeated the control in the criticality safety limit approval (see 1/18/13 weekly). During investigation of the infraction, LANL noted that the criticality safety documents specified the transfer cart controls for inclusion in the safety basis consistent with requirements in DOE-STD-3007 and site procedures; however, no action had been taken to capture these controls in the safety basis. Facility management declared a PISA on Tuesday and terminated normal operations in the facility to remove criticality safety postings and segregate these carts. Following these actions, the Plutonium Facility was returned to normal operations; however, lack of these carts significantly impacts the ability to move nuclear material in the facility. LANL is pursuing safety basis changes to appropriately capture the criticality safety controls and return the carts to service.

Weapons Engineering Tritium Facility (WETF) – Work Planning: During the closeout review of a work package, a work planner identified that an independent verification of a lockout/tagout had not been performed as required. The facility operations director convened a critique that identified work planning improvements for independent verification were necessary to remove ambiguity and to ensure the appropriate checks were completed. These improvements included requiring all lockout/tagouts at WETF to have an independent verification, and that all required independent verifications be procedural steps in the integrated work document vice relying on the lockout/tagout attachment to direct this action.

Area G – Permacon Box Repackaging: A contractor readiness assessment of Permacon box repackaging line operations in Dome 231 of Area G was completed this week. The assessment was performed to ensure readiness for Hazard Category 3 (HC-3) operations in this facility. The assessment team concluded that the facility demonstrated adequate readiness for operations, and that following closure of the one pre-start finding HC-3 box repackaging operations could be performed safely and compliantly.

Area G – Safety Basis: LANL requested a temporary safety basis modification this week to allow disposition of three sealed tanks in the Sort, Segregate and Size-Reduction areas at Area G. The current Area G safety basis does not allow opening of sealed containers due to the potential for the presence of hydrogen. The temporary safety basis change proposes using the following Specific Administrative Controls consistent with the controls used at the WCRR Repackaging Facility: 1) use of non-sparking tools to loosen the lid/flange bolts sequentially; 2) stopping all spark-generating operations while the tank opening is elevated above the horizontal plane – spark generating activities shall not resume until hydrogen levels at the tank opening are measured and demonstrated to be less than 4%; and 3) workers and tanks must be grounded. The LANL request notes that additional sealed containers are expected to be identified that require remediation and notes that a formal change to the safety basis will be requested in the next 60 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 15, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending February 15, 2013

Weapons Engineering Tritium Facility (WETF): Following investigation into elevated tritium levels in a storage area, WETF personnel identified that a safety class tritium container (AL-M1) was leaking. AL-M1 containers are used to capture and store tritium in the Tritium Waste Treatment System (TWTS). After these containers are loaded in the TWTS, they are stored at WETF pending further processing or disposition. LANL believes the maximum allowable working pressure for this particular AL-M1 was exceeded due to pressure buildup from tritium decay and radiolysis of water. This is the second AL-M1 that has developed such a leak within the last few years. Both leaking AL-M1s are currently being stored in a fume hood to mitigate the potential for tritium release.

There are currently twelve loaded AL-M1s stored at WETF. Calculations performed to determine when the remaining canisters will exceed their maximum allowable working pressure indicate that this is possible within the next few years. To preclude additional potential leaks and to disposition the currently leaking containers, all AL-M1s will be overpacked into Flanged Tritium Waste Containers and transported to Technical Area-54, Area G for disposal. In order to perform the overpacking activity, the WETF facility will have to be placed in operations mode which is expected to occur in the next few weeks. LANL is also evaluating the feasibility and safety basis changes needed to support packaging and removal of these and other legacy tritium containers in warm standby mode.

Criticality Safety: This week, LANL began a focused training program (“boot camp”) to provide an intensive learning environment for new criticality safety staff. The program consists of nine modules including: nuclear theory; criticality safety calculation methods; ANSI/ANS, DOE and LANL criticality safety standards and requirements; criticality safety evaluations; and criticality alarm and detection systems. This program along with on-the-job training and performance demonstrations will provide a mechanism for achieving full qualification as a LANL criticality safety analyst. Conduct of the boot camp is part of the LANL corrective action plan for improving the nuclear criticality safety program (site rep weekly 11/16/12).

Plutonium Facility: The field office approved a revision to the Plutonium Facility Documented Safety Analysis and Technical Safety Requirements (TSRs) to address the Potential Inadequacy of the Safety Analysis identified last week associated with facility transfer carts. The safety basis change adds a new safety-significant TSR control for the transfer carts consistent with the nuclear criticality safety evaluation. Plutonium Facility personnel are in the process of implementing the safety basis change to resolve this issue and resume use of the carts.

Technical Area-35 (TA-35): As a part of the corrective actions to address issues with the criticality safety program at TA-35, LANL submitted an update to the Facility Hazard Categorization (FHC) this week. In 2012, a number of criticality problems were identified at TA-35 including fuel rods in Building 27 with active lengths that exceed the length identified in the criticality safety evaluation. Subsequently, LANL updated the criticality safety evaluation to include an inventory reduction for fuel rods to preclude a credible criticality accident scenario. The updated FHC is intended to strengthen controls to ensure “nature of the process” arguments are maintained and consistent with DOE-STD-1027 requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 22, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending February 22, 2013

Transuranic Waste Facility (TWF): LANL submitted a revised Safety Design Strategy (SDS) to the field office this week to resolve comments from NNSA and issues identified in the Board's June 11, 2012 letter. As part of this submittal, the TWF project team performed evaluations and calculations for material at risk (MAR), the lightning protection system, metal containers (e.g. transuranic waste drums) and the fire protection system. Based on the MAR evaluation, LANL proposes to reduce the building MAR limit from 4550 plutonium equivalent-curies (PE-Ci) to 3200 PE-Ci, which reduces the overall facility MAR by approximately 30%. The revised SDS also captures waste storage containers as safety class and calls for a safety significant dry-pipe fire suppression system with passive freeze protection. In addition, the SDS captures the use of safety class vehicle barriers to preclude impact from large vehicles. Following field office review and approval of the SDS, the TWF project is expected to receive Critical Decision-2.

Criticality Safety: Last week, LANL submitted a revision to the corrective action plan and compensatory measures to strengthen the nuclear criticality safety program. This revision updates the previous plan from November 2012 and incorporates comments from the field office. The submittal letter highlights LANL senior leadership, including the laboratory director, involvement and commitment to improving the nuclear criticality safety program. The training boot camp for criticality safety analysts discussed last week continues. LANL also provided an update on the criticality safety program metrics this week. An assessment using these metrics will be performed quarterly and communicated to LANL and field office management.

Area G Drum Venting System (DVS): Following the review and approval of the corrective action plan submitted by LANL in response to the limited scope Federal Readiness Assessment conducted in December 2012, the field office authorized startup of Hazard Category 2/3 drum venting operations in Dome 33. LANL commenced Hazard Category 2/3 drum venting operations this week, representing the first drums to be processed by the DVS for the 3706 campaign.

A spot check of Dome 33 revealed that the problematic heaters with a high failure rate and a failure mechanism that includes dropping hot metal from the failed heating elements have yet to be replaced (see 11/16/12 weekly). Additionally, combustible materials that were previously identified within the heater exclusion zones had not all been removed. Site rep discussions with Area G management revealed that the work to remove the remaining combustibles is in planning; in the meantime the heaters in this area will be de-energized and tagged out. The site reps were also informed that the cognizant system engineer has identified a safer heater design and there is a management push to get the problematic heaters replaced.

Area G – Sort, Segregate, and Size Reduction (SSSR): The field office approved the temporary safety basis modification to disposition the three sealed tanks discovered during SSSR operations in Area G (see 2/8/13 weekly). Following the implementation of safety basis requirements and a verification review, LANL vented all three tanks this week in preparation for size reduction and disposal activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 1, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending March 1, 2013

Emergency Preparedness: On Tuesday, LANL conducted a series of four tabletop emergency exercises at the emergency operations center to evaluate and preplan site actions in response to a significant seismic event at Los Alamos (see 1/11/13 weekly). Participation from LANL and local, state, and federal agencies included approximately 60 personnel. These personnel represented senior field office and LANL management, Los Alamos Fire and Police Departments, local Tribal Organizations, New Mexico National Guard, New Mexico Department of Homeland Security and Emergency Management, Los Alamos Medical Center, and others.

The four scenarios presented to the participants included a collapse of the Plutonium Facility following an earthquake, and a progression of three scenarios following a significant earthquake that included the collapse of the Chemistry and Metallurgy Research Building, followed by the collapse of the WCCR Repacking Facility and finally the collapse of the Plutonium Facility. After a description of the scenario and pertinent data, the participants were divided into three groups including: strategic; response; and public information. Each group then developed solutions to three focus areas that included: rescue; communication/notification; and transportation/evacuation. Following a tabletop evaluation of options and challenges in each focus area, the groups gathered to present their solutions and options.

Conduct of this tabletop exercise highlights the challenges that LANL and the surrounding area would face during a significant seismic event because of the isolation and limited avenues for evacuation. These discussions and lessons learned will be captured in an after action report that will be used to improve procedures and processes for responding to a significant seismic event.

Transuranic Waste Facility (TWF): This week, the field office approved the Safety Design Strategy (SDS) for the TWF project that was recently submitted by LANL (see last week's report). LANL is scheduled to submit a Preliminary Documented Safety Analysis for the project in March that is consistent with the SDS.

Federal Oversight: The facility representatives (FR) for the field office continue to provide important federal oversight at LANL facilities. This week, FRs at both the Weapons Engineering Tritium Facility (WETF) and Area G identified safety issues. At WETF, the field office FR identified a maintenance work package that had conflicting information relative to the need to install a lock-out/tag-out (LOTO) for completion of the maintenance work activity. Although the LANL subject matter expert had reviewed the activity and concluded the LOTO was not required, the work instruction was not revised to remove this requirement. Instead, an email stating that the LOTO was not needed was attached to the work package.

At Area G, the field office FR identified that an operations center operator had not completed all required training and was not qualified to stand watch. This issue was identified on the backshift and resulted in a TSR violation due to failure to meet the safety basis minimum staffing requirements. Field office oversight at Area G is very important right now as LANL potentially increases the pace of operations to meet commitments for disposition of transuranic waste as part of the 3706 campaign.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 8, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending March 8, 2013

Area G – Below-Ground Transuranic (TRU) Waste Disposition: In response to a commitment in the Framework Agreement with the New Mexico Environment Department addressing TRU waste in Area G, LANL has developed a schedule for disposition of the below-ground waste requiring retrieval. The plan includes pacing milestones that will achieve removal of 2,395 cubic meters of TRU waste from Trenches A-D, Pit 9, corrugated metal pipes, and multiple shafts containing hot cell liners, tritium packages and 55 gallon waste drums, by September 30, 2018. The waste contained in these locations represents approximately 110,000 Plutonium Equivalent Curies (PE-Ci) of material at risk (99.9% of retrievable below-ground TRU waste). The plan is paced such that the amount of below-ground waste that is accumulated above-ground is minimized.

The remainder of the below-ground waste is contained within 33 shafts that house approximately 3.4 cubic meters of TRU waste containing approximately 97 PE-Ci of material at risk. The estimated cost and complexity of retrieval are both expected to be very high. As such, LANL has committed to complete an evaluation of the necessity to retrieve the waste contained within these shafts by September 30, 2015. If it is determined that retrieval of the TRU waste from the shafts is necessary, LANL plans to commence these activities in FY 2020 and last through FY 2022.

Technical Area-35 (TA-35): This week, LANL completed a Management Self Assessment (MSA) of TA-35 Buildings 2 and 27 to evaluate implementation of conduct of operations and the nuclear criticality safety program. The MSA was intended to help management evaluate improvements as part of the recovery plan for previous criticality safety issues and was focused on programs that support “nature of the process” controls and arguments for hazard categorization consistent with DOE-STD-1027. LANL recently submitted a revised Facility Hazard Categorization (FHC) that is currently under review by the field office. Activities at TA-35 Buildings 2 and 27 support training programs including nondestructive assay training for International Atomic Energy Association inspectors.

The MSA review team identified 12 findings and 2 observations primarily related to conduct of operations and training including issues in the following areas: lock-out/tag-out program; caution tag implementation; procedural compliance; training; conduct of management observation and verification reviews; building accountability; and operator aids. LANL is working on corrective actions that address the specific issues along with extent of condition reviews to ensure systemic programmatic issues are addressed. LANL is also continuing recovery plan actions and will implement controls identified in the revised FHC following field office approval.

Criticality Safety: LANL completed their quarterly assessment of the criticality safety program metrics last week as part of their overall program improvement plan. The report documents the increase in backlog of criticality safety work due to staffing issues and reiterates the group’s focus on ensuring safe operations in the field. Next week, the Criticality Safety Support Group (CSSG) will be at LANL to assess the program with a focus on capability and capacity of the current LANL criticality safety staff to support nuclear operations. The team will also be looking at the corrective action plan developed in response to the 2012 CSSG review at LANL.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 15, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending March 15, 2013

Plutonium Facility – Seismic Safety: This week, the field office submitted a memorandum to NNSA-HQ recommending that the Deputy Associate Administrator for Infrastructure and Operations approve the Safety Evaluation Report (SER) for the Plutonium Facility safety basis addendum associated with seismic performance. In January, LANL submitted an updated addendum to address review team comments and respond to the steps identified under Exigent Circumstances in the DOE memorandum dated September 17, 2012. The NNSA review team, which included subject matter experts from the field office, the NNSA Albuquerque Complex, and DOE Headquarters, developed the SER that concludes LANL adequately addresses the Exigent Circumstances for the potential post-seismic collapse. The SER also concludes that with implementation of the identified near-term risk reduction measures, the Plutonium Facility can continue to operate safely without any undue risk to the public while longer-term structural modifications are completed.

The near-term risk reduction measures proposed by LANL in the safety basis addendum include: 1) reducing the material at risk (MAR) limit for the laboratory floor; 2) reducing the MAR limit for the vault; 3) crediting newly-analyzed safety-class containers; and 4) removing one kilogram of heat source plutonium from the floor by the end of calendar year 2013. The field office memorandum notes that they plan to provide LANL with the following safety basis direction following NNSA-HQ approval: completion of items 1-3 above within 30 days; accelerated completion of item 4 above by October 1, 2013; completion of structural upgrades to resolve currently identified deficiencies (i.e. strengthen roof girders and captured columns) by March 1, 2016; and accelerated disposal and robust packaging of excess MAR including a plan for FY 13 activities within 30 days. Although the field office intends to direct completion of facility upgrades by March 2016, the LANL safety basis addendum and current schedule indicate the repairs will be complete by the end of calendar year 2014.

Area G – Safety Basis: LANL submitted a letter to the field office providing a scope of proposed changes for the approved, but not yet implemented, Area G Basis for Interim Operations (BIO) for review and approval (see 1/11/13 weekly). The proposed changes are categorized under four objectives including: reflect reduced above ground MAR limits based on waste disposition efforts; support of 3706 campaign goals; improve confidence level for successful and timely BIO implementation; and respond to previous comments (including those in the November 19, 2012, Board letter). When approved, these proposed changes will be made with the continued goal of having the BIO implemented by the end of FY13.

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition (CVD) Project: Following a series of startup delays, the CVD project Management Self Assessment is scheduled to commence on March 18, 2013. Due to the length of time that has elapsed since the start of the project, a System Adequacy Analysis (SAA) has been drafted to evaluate whether items procured as far back as 2002 meet quality assurance requirements that have changed over this time period. This SAA and a criticality safety evaluation for shipping the confinement vessels from their current storage location in Technical Area-55 to CMR will have to be completed prior to commencing operations. The current plan targets June 2013 for operational start-up, with the goal of completing one confinement vessel this fiscal year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 29, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending March 29, 2013

Area G – Conduct of Operations: Area G management is taking a number of actions aimed at improving their conduct of operations as activities in Area G ramp up and operations continue around the clock. These actions include: assigning a second deputy facility operations director; taking a safety pause to reiterate safety and compliance over production; re-emphasizing key elements of good conduct of operations; assigning compliance representatives to observe operations; and scheduling a corporate assist assessment. Further, the management self assessment scheduled as part of the startup preparations for Dome 375 Sort, Segregate, and Size Reduce activities has been delayed one week in order to allow the time to properly execute these conduct of operations improvement actions.

Plutonium Facility: This week, the Associate Director for Plutonium Science and Manufacturing (ADPSM) directed completion of a 90 minute safety pause over the next week for First Line Managers and team leaders to cover radiological contamination issues. There has been a noticeable increase in skin and laboratory contamination events over the last few months (including three continuous air monitor alarms this week). The safety pause will communicate some of the causes involved in these events along with actions and expectations for improving the current trend. In addition to the safety pause, ADPSM is emphasizing self-monitoring, housekeeping, glove breach issues, and the sharps program to improve Plutonium Facility radiological performance.

Safety Conscious Work Environment (SCWE) Training: EM and NNSA SCWE experts conducted three all day SCWE training courses at the field office. This training was prompted by a commitment in DOE's implementation plan for Board recommendation 2011-1. To date, this course has been delivered 40 times across the complex reaching nearly 1000 trainees. The training session was highly interactive and was attended by senior LANL personnel including the lab director and field office manager.

Criticality Safety: The field office recently provided direction to LANL on nuclear criticality safety noting that NNSA is concerned about the insufficient staffing of fully-qualified criticality safety engineers to support the site's current and planned fissile material operations. The letter identifies that LANL is taking actions to address the staffing situation but that it will take more than a year to achieve a mature criticality safety program. Based on the current situation, the field office provided specific direction including the following actions:

- Curtail work on new or significantly revised Criticality Safety Evaluations unless specifically approved by the field office.
- Submit and obtain field office concurrence with the planned time-utilization for qualified criticality safety staff and subcontractors with specific justification for activities not focused on event response, field operations support or training/qualification.
- Submit and obtain field office concurrence with a ranking of fissile material operations based on maturity and level of confidence in the evaluation basis.
- Obtain near-term criticality safety expertise that can provide mentoring to new staff, review complex analytical deliverables and advise senior management on new staff qualifications.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 5, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending April 5, 2013

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition

(CVD) Project: LANL completed the Management Self Assessment (MSA) for the CVD project startup this week (see 3/15/13 weekly). The MSA team identified eight pre-start findings, most of which were related to training inadequacies, integrated work document and procedural compliance deficiencies, and non-conservative radiological work practices. The MSA team concluded that CVD operations adequately demonstrated readiness for the planned Contractor Operational Readiness Review once all pre-start findings have been resolved and the 14 post-start findings have approved corrective action plans. The Contractor Operational Readiness Review is scheduled to begin the week of April 29, 2013 with a subsequent NNSA Operational Readiness Review scheduled to begin in June 2013.

Area G – Dome 375 Box Repackaging Line: LANL commenced an MSA for the box repackaging line in Dome 375 this week. Within Dome 375 there is a large Permacon containment enclosure measuring 48 feet in width and 110 feet in length. This containment enclosure, with HEPA-filtered ventilation and automatic fire suppression, will be used to sort, segregate, and size reduce (SSSR) transuranic waste for repackaging and shipment to offsite disposal facilities.

The startup of the SSSR activity in Dome 375 is crucial to meeting commitments of the 3706 campaign as it will allow LANL to process the largest fiberglass reinforced plywood waste boxes in Area G, some of which are nearly 40 feet in length. Following successful completion of the MSA, and follow-on Contractor and Federal Readiness Assessments, boxes containing up to Hazard Category (HC)-2 quantities of transuranic waste will be processed within this facility. Startup of HC-2 activities are currently planned for August 2013.

Weapons Engineering Tritium Facility (WETF): LANL recently returned WETF to operations mode (previously in warm standby mode) in accordance with the Technical Safety Requirements. Certain gloveboxes that did not pass leak testing remain in warm standby. With this mode change, WETF personnel are moving forward on plans to overpack AL-M1 tritium containers (including the leaking AL-M1 containers noted in the 2/15/13 site rep report) into Flanged Tritium Waste Containers for disposition at Area G. Because of the length of time since previous tritium gas handling operations, LANL is pursuing readiness reviews to support restart of tritium transfer, function test, and processing activities. The MSA to support these activities is scheduled to begin this month followed by Contractor and Federal Readiness Assessments in May 2013 and June 2013, respectively.

Transuranic Waste Facility (TWF): The field office approved extending the schedule for submittal of the Preliminary Documented Safety Analysis for the TWF Project this week from March 2013 to July 2013. TWF project personnel plan to use this time to implement changes in the safety basis approach that are detailed in the safety design strategy approved by the field office earlier this year (see 2/22/13 site rep report). The project also recently received approval of Critical Decision-2, *Performance Baseline*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 12, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending April 12, 2013

The field office announced that Geoff Beausoleil will be assigned as the acting Field Office Manager for 60 days while a permanent manager is being identified. Mr. Beausoleil is currently the Sandia Field Office Manager and was previously the Deputy Manager at the Pantex Site Office.

Plutonium Facility – Seismic Safety: This week, the field office provided LANL with the Safety Evaluation Report (SER) for the safety basis addendum associated with facility seismic performance (see 3/22/13 site rep weekly). The SER was approved by the NNSA Deputy Associate Administrator for Infrastructure and Operations. The field office transmittal letter includes direction for the contractor to “prudently accelerate disposal and robust packaging of excess material-at-risk.” LANL is directed to provide a plan within 30 days on FY13 objectives for this acceleration and the impact on offsite dose calculations. Other compensatory measures, including material-at-risk limits and qualification of a new robust container, are scheduled to be complete within 30 days. NNSA also continues to pursue the alternate static nonlinear analysis.

Criticality Safety: LANL recently published the results of its Criticality Safety Officer (CSO) Program Assessment at Technical Area-55, the Chemistry and Metallurgy Research Building, and Area G. Numerous concerns in the program were self-identified that will be resolved to help strengthen the CSO Program and ultimately the LANL Nuclear Criticality Safety Program. The identified deficiencies included: insufficient CSO staffing; no established training and qualification programs; limited definition of CSO duties and responsibilities; and insufficient CSO operational oversight and field support. LANL is developing corrective actions to address these deficiencies. LANL also continues to pursue broader corrective actions consistent with the criticality safety corrective action plan.

Area G – Dome 375 Box Repackaging Line: This week, LANL completed the Management Self Assessment for the box repackaging line in the Dome 375 Permacon (see last week’s report). LANL is expecting to move on to its next phase of startup activities with a contractor readiness assessment beginning on April 22, 2013.

Safety Basis: On Tuesday, LANL declared a site-wide Potential Inadequacy of the Safety Analysis (PISA) for nuclear facilities because of increased airport traffic at the Los Alamos County Airport. As part of the safety basis, LANL nuclear facilities evaluate the frequency of aircraft crash in accordance with DOE-STD-3014. A recent increase in commercial flights at the airport prompted LANL to review the airport traffic data that is part of the input information for the DOE standard evaluation. In addition to the new commercial flights, review of airport logs indicates an increase in other flight traffic. Based on this information, LANL declared the PISA and will complete an unreviewed safety question for each nuclear facility. Currently, no compensatory measures have been identified. Initial evaluation indicates that the RANT shipping facility, which previously had an aircraft crash probability just below the cutoff frequency, may now require inclusion of an aircraft crash scenario and associated controls in the safety basis. LANL also plans to evaluate this information for the Transuranic Waste Facility Project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 19, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending April 19, 2013

Criticality Safety: LANL paused activities associated with 17 fissile material operations (FMOs) this week at the Plutonium Facility, Area G and within the Packaging and Transportation Division because outstanding field office comments and issues have not been appropriately resolved. A Criticality Safety Support Group assessment completed in April 2012 concluded that LANL demonstrated an inability to close outstanding criticality issues in a timely manner. As part of the corrective action plan for the assessment, LANL performed an extent of condition review to identify if there are legacy issues identified in the criticality safety database. The extent of condition review revealed 17 FMOs where the field office had identified high-level (the most significant) issues with the associated criticality safety evaluations (CSEs), some dating back to 2007, that have not been resolved. A critique on the issue identified that no formal, documented process previously existed to manage field office comments on CSEs. LANL is working to formalize the process and to determine the path forward for each of the 17 paused FMOs.

LANL also completed their evaluation of all FMOs across the site (approximately 500) to determine the confidence level ranking based on the technical basis for the CSE and other factors. In addition to the 17 FMOs identified above, LANL concluded that another 17 FMOs had low confidence (“red”) technical basis that needs to be addressed.

Weapons Engineering Tritium Facility (WETF): This week, LANL commenced a Management Self Assessment to support the restart of tritium transfer, function test and processing activities. The assessment team identified that a two-year re-qualification examination for operators may have been compromised because the examinations were available through the WETF online document management system for nearly a month prior to being administered. Most of the operators had taken a written examination within the required two year time frame and remain qualified. However, an operator that had performed surveillances within the past week had not taken an examination within the past two years and as such could not be considered qualified. As a result, WETF management declared a technical safety requirement non-compliance. Plutonium Facility and Area G management declared TSR non-compliances for similar qualification issues within the last four months (see the 11/23/12 and 3/1/13 weekly reports).

Plutonium Facility: Operators identified two General Purpose Heat Source (GPHS) items contained in a Plutonium Facility glovebox that were bulging due to an apparent internal pressure build-up. The encapsulated GPHS is credited in the safety basis with providing safety-class confinement (damage ratio of zero) for heat source-plutonium (HS-Pu). When discovered, facility management declared the bulging heat source items inoperable, entered a limiting condition for operation based on the potential for exceeding glovebox material limits, and recalculated the inventory in the glovebox using a damage ratio of one (accounting for all of the HS-Pu). The recalculation showed that no material limits were violated. Facility and program personnel are evaluating the history of the bulging items and have entered the new information process as they develop their plan to resolve the over-pressure condition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 26, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending April 26, 2013

Staff members M. Horr and B. Sharpless were onsite this week to observe the Contractor Readiness Assessment (CRA) of oversized container Sorting, Segregating, Size-Reducing, and Repackaging activities in Area G, Dome 375. The staff observed field operations and interviews conducted by the CRA team. Based on feedback from the staff, the CRA team is revising their implementation plan (IP) to include specific criteria for each IP core requirement as required by the LANL readiness procedure. The CRA is scheduled to continue through the end of next week.

Weapons Engineering Tritium Facility (WETF): LANL continues to struggle with achieving sustainable tritium processing capability at WETF, which is needed to support de-inventory activities. The following items highlight recent issues with restarting WETF tritium operations:

- **Management Self Assessment (MSA):** This week, the MSA team completed their review of tritium operations and concluded that WETF is not ready for operations. The team identified that the current gap between the WETF operational readiness status and that required for a Hazard Category 2 Nuclear Facility is too large to recommend startup. From a high level standpoint, the MSA team concluded that there were significant issues associated with the organization structures, work processes (including the backlog of unresolved issues) and plant equipment. In addition to a number of readiness prerequisites that were not met, the team identified 15 pre-start and 14 post-start findings.
- **Safety System Oversight (SSO) Review:** The field office recently completed a SSO review of contractor-approved conduct of engineering variances and alternate methods (mostly related to pressure safety issues at WETF). The review identified five findings including a significant concern with the LANL review and basis for approving variances. The SSO team concluded that many variances: 1) are not compliant with ASME pressure safety requirements; 2) potentially constitute unreviewed safety questions based on the need for compensatory measures and/or operating restrictions; and 3) were inappropriately approved by the LANL Site Chief Engineer. LANL and WETF personnel are reviewing the assessment report.

Criticality Safety: This week, LANL completed a review of the adequacy of closed corrective actions taken in response to previous criticality safety assessments. This review was performed as part of the corrective action plan to strengthen and improve the criticality safety program and to respond to findings identified by an April 2012 NNSA Criticality Safety Support Group (CSSG) assessment (see 11/16/12 weekly). Among other things, the review identified: 1) that 12 issues tracked to closure in the LANL Performance Feedback and Improvement Tracking System lacked sufficient closure documentation; 2) 103 comments received from the field office should be reopened due to insufficient evidence that necessary changes to criticality safety technical documents had been made; and 3) several Criticality Safety Evaluation Documents with comments questioning their adequacy that had not been resolved in a timely manner. LANL is currently working to prioritize all issues that have been identified with the criticality safety program in order to focus available resources on implementing effective corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 3, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending May 3, 2013

Weapons Engineering Tritium Facility (WETF): Last week, the field office provided LANL with comments on the proposed safety basis that was submitted last year. The current safety basis has not been substantially updated since 2002. The comments identify numerous deficiencies including an overreliance on administrative versus engineered controls, inadequate fire protection controls, and issues with the hazard analysis methodology. The field office memo directs LANL to document the planned disposition of all stored tritium including identification of legacy materials and justification for continued storage of this material at WETF. In addition, LANL is directed to submit a path-forward to upgrade the safety basis in a manner that is integrated with mission requirements, projected inventory needs, and appropriate assurance of continued safe operations.

Area G – Dome 375 Box Repackaging Line: LANL completed its contractor readiness assessment (CRA) for Sorting, Segregating, Size Reduction and Repackaging (SSSR) activities in Area G, Dome 375. The CRA team concluded that once the four identified pre-start findings have been closed and corrective actions have been developed for nine post-start findings, Hazard Category (HC) 3 SSSR operations can be safely and compliantly performed in the Dome 375 box repackaging line. One pre-start finding identified that there is a limited ability for the supervisor, who is stationed outside the SSSR enclosure, and workers within the enclosure to communicate. This was also identified by the Board's staff during their recent visit (see 4/26/13 weekly).

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition (CVD) project: This week, LANL commenced the Contractor Operational Readiness Review (ORR) for the CVD project. This Contractor ORR is a prerequisite to the Federal ORR currently scheduled to begin the first week of June that will evaluate the readiness of the CVD project to commence HC 2 operations. This startup activity is necessary to clean out and disposition the confinement vessels currently stored in Technical Area-55 (TA-55).

Conduct of Critiques: The Associate Director for Nuclear and High Hazard Operations recently emphasized with Facility Operations Directors the importance of conducting high quality critiques. This emphasis included reiterating expectations for critiquing all anomalous events, conducting critiques in a timely manner, and ensuring the appropriate personnel, including the involved workers, attend scheduled critiques.

Criticality Safety: Consistent with the corrective action plan, the laboratory completed criticality safety assessments at LANL nuclear facilities this week. The review teams identified 3, 4, and 6 findings for TA-55, CMR, and Area G, respectively. In all cases, the assessment teams concluded adequate implementation of the Criticality Safety Program with the exception of identified findings. Notably, one of the findings at Area G identified that supervisors and operations center personnel did not have an adequate understanding of criticality safety requirements. Area G management paused operations based on this finding and conducted appropriate training to resolve this issue. The assessment team also identified findings related to criticality safety staff formally reporting issues to management and the lack of a formal process to track and close criticality safety issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 10, 2013

MEMORANDUM FOR: S. A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending May 10, 2013

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition

(CVD) Project: This week, LANL completed the Contractor Operational Readiness Review (CORR) for the CVD project. The CORR team concluded that following adequate closure of their 15 pre-start findings, CVD operations could be safely executed. The team also identified 11 post-start findings and 13 observations. Although there were a significant number of findings, the team lead noted that operators and supervisors demonstrated excellent process knowledge and conduct of operations. The review team also concluded that the pre-starts did not represent indications of systemic failures in CVD operations.

Criticality Safety: The LANL Nuclear Criticality Safety Committee (NCSC), chaired by the Principal Associate Director for Operations and Business, met this week to review the status of the corrective action plan, results from recent evaluations and assessments, and progress on criticality safety analyst training and qualification. The committee decided to move forward with selection and inclusion of criticality safety experts (both internal and external to LANL) as part of the NCSC, which is consistent with a recent recommendation from the DOE Criticality Safety Support Group.

Safety Basis: LANL submitted an Evaluation of the Safety of the Situation (ESS) to the field office associated with increased airport traffic at the Los Alamos County Airport (see 4/12/13 weekly). An Unreviewed Safety Question (USQ) for the RANT shipping facility was identified based on the increase in flight traffic causing the frequency of the aircraft crash scenario to cross the threshold from beyond extremely unlikely to extremely unlikely. The evaluation did not identify USQs for other LANL nuclear facilities. In accordance with DOE-STD-3014-2006, *Accident Analysis for Aircraft Crash into Hazardous Facilities*, the RANT Documented Safety Analysis (DSA) must now include an aircraft crash as a design basis accident vice the beyond design basis accident recognized in the current DSA. The ESS identified that LANL will update the DSA to include an aircraft crash as a design basis accident in the next annual DSA revision.

Weapons Engineering Tritium Facility (WETF): This week, LANL began overpacking AL-M1 tritium containers into Flanged Tritium Waste Containers for disposal at Area G. Some of these AL-M1s have a history of leaking and others have been identified as having the potential to leak in the future (see 2/15/13 weekly). Disposal of the AL-M1s represents the first of many activities needed to de-inventory excess tritium currently stored in WETF.

WETF personnel identified expired calibrations for subcomponents associated with the safety significant environmental chamber over temperature protection system (ECOPS). The system was declared inoperable and the appropriate limiting condition of operation was entered. The calibration was checked as satisfactory during the previous annual inspection of the ECOPS last fall; however, WETF personnel did not capture the calibration expiration date to drive the due date for the next surveillance as required by the procedure (the subcomponent has a calibration periodicity of 18 months). During a critique of this event, WETF management identified actions to improve the surveillance procedure and perform an extent of condition review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 17, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending May 17, 2013

Plutonium Facility: This week, LANL provided the field office planned actions for FY 13 to prudently accelerate disposal and robust packaging of excess material at risk. The field office requested this action as part of the approval of the Plutonium Facility safety basis addendum associated with facility seismic performance. LANL commits to robustly repackage and dispose of specific quantities of weapons grade plutonium currently stored in the vault. Although the actions do not significantly reduce potential offsite dose consequence that are evaluated in the safety basis for a challenging seismic accident scenario, the effort will continue to improve the vault storage configuration and provide additional space to relocate material from the laboratory floor.

Technical Area-48 Radiochemistry Laboratory (RC-1): On Wednesday, a worker at RC-1 was splashed with a small amount of uranyl nitrate solution (depleted uranium) when a glass sample container in a hood over-pressurized and burst. Immediate actions were taken to wash the worker's hands and face at an eye wash station. The worker was transported to occupational medicine and was subsequently released with no restrictions. Whole body surveys and nasal smears taken following the event did not identify personnel contamination.

Although similar experiments had been conducted in RC-1, this new activity involved multiple glass containers with limited headspace and varying molar concentrations of nitric acid. The potential for a pressurization hazard was identified in the Integrated Work Document (IWD) and action was taken to vent the containers during the initial stages of the experiment. However, the samples were left in a sealed configuration for an extended period of time when the activity was interrupted. Shortly after the worker returned to the area and relocated the sealed containers to a hood, the overpressure event occurred, breaking 9 of the 11 glass containers. RC-1 management is pursuing corrective actions including lessons learned, improvements in the IWD, and evaluation of engineered containers that will release pressure.

Plutonium Facility – Safety Basis: This week, the field office provided comments to LANL on their proposed annual updates to the Technical Area-55 Documented Safety Analysis (DSA) and Technical Safety Requirements (TSR). The field office directed LANL to revise the DSA and TSRs to incorporate resolution of the provided comments within 90 days of their receipt.

Area G – Lightning Protection System: Sorting, Segregating, Size Reduction and Repackaging activities were paused this week in domes 375 and 231. The pause was due to facility personnel identifying that scaffolding had been erected within the specified arc flash standoff distance without proper bonding to the lightning protection system. This was contrary to an administrative control for combustible loading that is an element of the fire protection program.

Radiological Laboratory, Utility, and Office Building (RLUOB): LANL began their Management Self Assessment (MSA) this week to evaluate the startup of radiological operations at RLUOB. The MSA is scheduled to complete next week. Further startup activities will follow to provide additional less than Hazard Category 3 analytical chemistry capabilities at RLUOB.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 24, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending May 24, 2013

Staff members D. Kupferer, J. McComb, and J. Plauue were on site this week to conduct a review of criticality safety. The review focused on site-wide and facility specific Criticality Safety Program implementation, impacts on limited criticality safety staffing resources, and federal oversight.

Plutonium Facility – Criticality Safety: Over the past week the Plutonium Facility has experienced a number of criticality safety infractions and process deviations. Several of these issues were self-identified and conservative action was taken to respond, critique, and develop corrective actions. However, these infractions and deviations indicate potential conduct of operations and Criticality Safety Evaluation (CSE) issues that emphasize the need for LANL to continue criticality safety improvements.

- During a system walkdown, the Board’s staff identified material located within a workstation that was not allowed by the CSE. This infraction was due, in large part, to inconsistent understanding of criticality safety requirements regarding the boundaries of the workstation and failure to follow good work practices as prescribed in the CSE. Because this is one of multiple infractions that have occurred in this particular room over the past few months (including inconsistent interpretation of requirements between facility and criticality safety personnel), operations have been paused in this room while operators and criticality safety personnel ensure limits specified in CSEs and postings are clear and well understood.
- A criticality control mass limit was exceeded in a vault location. Workers identified that two containers intended to be stored in certain locations had been inadvertently swapped when initially moved to the vault. This transposition resulted in one location exceeding the mass limit prescribed in the CSE.
- A process deviation occurred when liquid level was discovered in a trap tank sight glass for a wet vacuum system. Liquid is not normally expected to be located in this portion of the system. The CSE requires that if liquid is discovered that the source be located and the liquid be returned to the source. The source of the liquid has yet to be determined and the liquid could not be returned to its source regardless due to the system configuration. During review of this issue, Plutonium Facility personnel identified that the system configuration differed from the CSE description.
- During an extent of condition review, liquid was identified in another wet vacuum trap tank sight glass. The source of this liquid has yet to be determined as well.

Plutonium Facility – Personnel Contamination: A Plutonium Facility worker was identified with skin contamination after removal of a temporary foam plug used during a glovebox pressure test. Nasal smears following the discovery of contamination were positive. The foam plug was installed over an existing temporary plug that had been installed more than a decade ago but was not sufficiently airtight to allow the pressure test to pass. During this activity, the two plugs adhered to each other such that when the new plug was removed the old plug was removed as well resulting in the spread of contamination. Facility management is conducting an extent of condition review to determine whether additional “temporary” plugs are being used as contamination boundaries.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 31, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending May 31, 2013

Plutonium Facility – Criticality Safety: Operations remain paused in the room where the Board’s staff identified a criticality infraction during their recent on-site criticality safety review (see 5/24/13 weekly). Operators, engineers, criticality safety and facility operations personnel are walking down each operation within this room to ensure that the criticality safety controls are clearly understood and adequately captured in procedures and postings. Additionally, the walkdowns are being used to verify that procedures can be followed as written and reflect the work as it is actually performed.

Radiological Laboratory, Utility, and Office Building (RLUOB): This week, LANL completed their Management Self Assessment (MSA) to commence radiological operations with less than Hazard Category 3 nuclear materials at RLUOB. The team identified 6 pre-start findings and 4 post-start findings during the review; however, the manageable list of open issues at the start of the MSA included a number of items that the team considered pre-start findings. The MSA team recommended that radiological operations be authorized following closure of all pre-start findings.

During RLUOB construction, a limited number of laboratory rooms included installation of analytical chemistry equipment. The other laboratory rooms have support services (e.g. electrical, water, air) stubbed off and the rooms are empty. As part of the overall plutonium strategy to support analytical chemistry requirements and closure of CMR in 2019, LANL plans to install additional capability in the vacant laboratory rooms and increase the material limit to 38 grams Pu-239 equivalent consistent with the NNSA supplemental guidance on DOE Standard 1027.

Area G – Safety Basis: The field office provided comments from their review of LANL’s revised submission of the Area G Basis for Interim Operations (BIO) and Technical Safety Requirements (TSR). The field office directed LANL to incorporate resolution of these comments within 30 days to support implementation of the BIO and TSRs by September 2013.

Lightning Protection Systems: The field office conducted an assessment of LANL’s Lightning Protection System Program from November 2012 to January 2013. The assessment identified eleven findings, two observations, and one noteworthy practice. The assessment team noted that it was particularly concerned with the lack of rigor placed on maintenance of lightning protection systems and noted instances of system deficiencies that have been identified but not corrected for several years.

Area G – Dome 375 Box Repackaging Line: This week, the field office issued its implementation plan for the Federal Readiness Assessment (FAR) of Hazard Category 2 Sort, Segregate, Size Reduction and Repackaging Operations at Area G Dome 375 (see 4/5/13 weekly). The FRA is currently scheduled to commence on July 8, 2013.

Safety Basis: In January, LANL provided the field office with a safety basis improvement plan to address issues in staffing, training, and qualification and to improve the overall quality and timeliness of safety basis submittals. The field office provided comments on the scope and details of the plan and requested resubmittal of this document in December 2013. Although improvements have occurred in some areas, LANL continues to struggle with the quality of safety basis documents (see 5/3/13 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 7, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending June 7, 2013

Plutonium Facility – Criticality Safety: LANL continues to evaluate fissile material procedures and operations in the room where operations were recently paused (see 5/24/13 and 5/31/13 weeklies). As part of the review this week, Plutonium Facility workers identified two containers stored in a safe that do not comply with criticality safety limits. Appropriate actions were taken to secure the room, inform criticality safety personnel, and conduct a critique. The criticality safety limit approval includes an operational requirement that container outside diameter be greater than 6.5-inches to protect spacing assumptions in the criticality safety evaluation. This requirement is also identified on the posting. During the critique, operators noted that they were focused on the mass limits when storing items in the safe. A criticality safety infraction was declared for two containers that were identified with an outer diameter of less than 6.5-inches.

In addition to the ongoing review of activities for this specific laboratory room, LANL management is also developing a corrective plan that includes an extent of condition review for other areas of the Plutonium Facility. On Friday, the field office provided direction to LANL on improving the criticality safety program implementation and operational performance. The memorandum forwards the Criticality Safety Support Group report from their March 2013 assessment and a summary of issues from the recent Board staff review in May 2013. LANL is requested to review this information along with the results of the extent of condition review at the Plutonium Facility and provide a path forward on improving criticality safety.

Plutonium Facility – Conduct of Operations: During the conduct of a surveillance test procedure plutonium facility personnel recognized that performance of the procedure was not being accomplished as written. The affected operation has been paused until the procedure can be walked down and revised by operators and supervisors to ensure it can be performed as written and accurately describes the work activity.

Weapons Engineering Tritium Facility (WETF): Recently, the WETF function tester glovebox unexpectedly experienced a sharp increase in tritium levels. Levels in the glovebox peaked at approximately 3000 millicuries per cubic meter. The glovebox system functioned as required to purge the glovebox and the tritium was recovered by the Tritium Waste Treatment System (TWTS). There was no release of tritium to the environment. However, tritium levels in the glovebox remained elevated indicating a continuing release. Subsequent investigation identified that a previously tested item that was being stored in the glovebox was the source of the tritium release. WETF personnel plan to overpack the item in the near future; however, the oxygen monitoring system associated with the low pressure receiver in the TWTS is required to be operational to support introducing the overpack into the glovebox. These repairs are on-going.

Area G – Dome 375 Box Repackaging Line: The field office has approved the corrective action plan from the Dome 375 Sort, Segregate, Size Reduction and Repackaging (SSSR) Contractor Readiness Assessment (CRA). LANL has closed all of the pre-start findings from the CRA. Following these actions, the field office approved the startup of Hazard Category 3 SSSR operations in the Dome 375 box repackaging line.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 14, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending June 14, 2013

Staff members M. Horr, T. Hunt, and J. Pasko were on site this week to review the conduct of operations in Technical Area-54, Area G. The staff team evaluated the implementation of conduct of operations elements prescribed in DOE Order 422.1, *Conduct of Operations*, and local LANL requirements, and focused on Sorting, Segregating, Size Reduction, and Repackaging activities.

Plutonium Facility – Criticality Safety: The LANL Deputy Director provided the field office with an action plan to improve conduct of operations and criticality safety this week at the Plutonium Facility. The action plan stems from recent infractions identified in a specific laboratory room by field office and DNFSB staff personnel. The plan includes the following actions: 1) pause of operations in the room (complete); 2) process walkdown of all glovebox operations and activities in this room (complete); 3) identify requirements for resuming operations (due 6/15/13); 4) issue memo to facility workers restating requirement for verbatim compliance to procedures (complete, discussed below); 5) evaluate extent of condition by performing process walkdowns for 13 other process operations at the Plutonium Facility (due 6/28/13); 6) review all assessments and evaluations of Plutonium Facility operations over last 12 months to ensure appropriate corrective actions have been identified (due 6/21/13); 7) develop a comprehensive operations improvement plan based on walkdowns and assessment review (due 7/5/13); 8) assess the effectiveness of the operations improvement plan (1st quarter FY14); and 9) perform a facility centered assessment of criticality safety at the Plutonium Facility (1st quarter FY14).

On Thursday, the Associate Director for Plutonium Science and Manufacturing issued a memo to workers on procedure adherence requirements stating that “two of the most critical elements of safe operations are that written technical procedures define the proper operational parameters and controls and that those procedures are followed as intended.” The memo reiterates that technical procedures (including reference and use every time) are to be followed as written, without exception, and that work should be paused if a procedure step is confusing or difficult to understand.

Weapons Engineering Tritium Facility (WETF): This week, WETF personnel entered a limiting condition of operation (LCO) for the oxygen monitoring system in the Tritium Waste Treatment System (TWTS). The LCO was entered after it was discovered that a pump associated with the oxygen monitoring system had been inadvertently secured while performing corrective maintenance on the TWTS. The pump was secured due to ambiguous language in an attachment to the integrated work document in use that directed the TWTS be shut down. During the critique, it was identified that the operators were unaware that shutting down the TWTS would secure this pump and require entry into the LCO condition. WETF management is pursuing corrective actions to clarify the work documents.

Chemistry and Metallurgical Research (CMR) Facility – Confinement Vessel Disposition (CVD): The field office conducted an ancillary review of the CMR Documented Safety Analysis and Technical Safety Requirements that generated comments related to the CVD project. Comments identified an inadequacy in the design of the safety significant sphere rotation brake system and incomplete performance criteria to ensure the confinement safety function of the CVD workstation/glovebox is satisfied. As a result the Operational Readiness Review scheduled for June 17, 2013, has been delayed until these issues can be resolved.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 21, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending June 21, 2013

On Wednesday, the staff conducted a teleconference with NNSA and LANL personnel to follow-up on Plutonium Facility criticality safety topics.

Criticality Safety: This week, LANL responded to the recent field office request to evaluate and provide a path forward on the following items: 1) summary of DNFSB staff issues identified during the May 2013 review; 2) final report from Criticality Safety Support Group March 2013 assessment; and 3) the ongoing extent of condition reviews at the Plutonium Facility. In addition to the action plan communicated last week, LANL plans to develop a criticality safety roadmap by October 2013 that integrates improvement actions into a comprehensive “get well” plan. The roadmap will include actions to address criticality safety compliance issues identified by past self-assessments and independent assessments, including the DNFSB staff review.

On Thursday, the chairman on the site Nuclear Criticality Safety Committee (NCSC) held a special meeting to discuss plans for conduct of a criticality safety program assessment, which is scheduled to be complete by the end of July, and NCSC membership. Based on discussion during the meeting, the criticality safety group will evaluate the current subjective status in each of the assessment areas identified in DOE Standard 1158, *Self-Assessment Standard for DOE Contractor Criticality Safety Programs*, to determine the most effective areas to focus this assessment. The committee is also moving forward to select internal and external candidates for membership on the NCSC. Based on questions and discussion during the staff visit in May, the NCSC is putting together a study group to determine the LANL institutional positions on inclusion of criticality safety controls into procedures, container labeling, and improvements to the annual fissile material operation walkdowns.

Plutonium Facility – Criticality Safety: LANL paused operations in a facility glovebox based on concerns identified by the field office criticality safety subject matter expert. The current location of tape demarking a pass through lane in the glovebox would not allow compliance with criticality safety limit approval controls. Because the pass through lane has not been used recently, no criticality safety infraction was declared. Plutonium Facility personnel are pursuing a path forward to correct the situation and resume operations, and are developing a lesson learned package.

Weapons Engineering Tritium Facility (WETF): This week, LANL submitted its schedule to resolve field office comments on proposed changes to the WETF Documented Safety Analysis and Technical Safety Requirements (see 5/3/13 weekly). The submission also included a description of a draft project execution plan to dispose of legacy tritium items currently being stored in WETF. These items include: 1) legacy items from closure of various sites that retain no programmatic interest; 2) bulk tritium gas with no programmatic use; and 3) tritium recovered during operation of the Tritium Waste Treatment System. The disposition of this legacy tritium is important as it constitutes nearly half of the tritium inventory in the facility and has been the source of tritium leaks in the past. The execution plan will identify funding sources and facility systems necessary to process the legacy tritium for disposition. LANL intends to use the Integrated Nuclear Planning process to determine whether a partial facility restart aimed solely at legacy tritium disposition is appropriate versus a full facility restart that would also allow resumption of programmatic operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 28, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending June 28, 2013

Staff members P. Foster and A. Gwal were on site this week to review the Technical Area 55 electrical distribution system and the LANL electrical safety program.

Plutonium Facility – Criticality Safety: On Thursday, the Laboratory Director paused programmatic activities at the Plutonium Facility. The pause was directed based on issues identified during procedural and criticality safety reviews and findings from recent assessments. The Director communicated to all LANL personnel the importance of ensuring procedures and operational processes are being executed appropriately. Additionally, the memorandum emphasized the importance for employees to raise concerns and for leaders to take action on those concerns. The Principal Associate Director for Weapons Programs and the senior management team have been tasked to evaluate the way work is executed and to determine what process and procedure improvements are needed as well as determining a path forward to continuous improvement. Individual operations at the Plutonium Facility will be resumed once necessary updates and enhancements have been achieved.

The procedure and criticality safety implementation reviews that led, in part, to the pause of operations continued this week at the Plutonium Facility. These reviews have identified a number of procedural issues and the need for clarification and improvement of criticality safety controls. As a part of this review, Plutonium Facility personnel also identified a safe drawer with dimensions that are not in compliance with the Criticality Safety Limit Approval (CSLA). The drawer dimensions are identified as an engineered feature that should have been verified as a part of implementing the CSLA. This issue resulted in a criticality safety infraction.

Stage 3 Fire Restrictions: Due to the ongoing drought and the current extreme fire danger level in the area, LANL has entered stage 3 fire restrictions. Entering stage 3 fire restrictions limits activities that increase the risk of starting a fire and have a direct impact on LANL explosives testing. Additionally, access to most recreational areas for walking, hiking, jogging, biking and similar activities is prohibited. The fire restrictions are currently expected to be in effect through August 3.

Safety Basis: LANL submitted a revised Evaluation of the Safety of the Situation (ESS) following a site-wide assessment for new air service between Los Alamos and Albuquerque (see 5/10/13 weekly). The revised ESS indicates that the increased air traffic resulted in positive Unreviewed Safety Questions for Technical Area 55, the RANT shipping facility, Area G, and the Nuclear Environmental Sites. The ESS indicates that there is not an imminent hazard associated with the increase in air traffic in the vicinity of LANL and that the affected DSAs will be updated as necessary to reflect this increased risk during the next annual update.

Area G – Safety Basis: In March 2012, the field office approved a major revision to the Area G safety basis to replace the current safety basis that was originally approved in 2003. However, this document was not implemented in the field. Instead, LANL developed a strategy to revise the new safety basis to account for the reduction of material at risk and to improve and simplify the document. This week, LANL re-submitted this new safety basis to the field office for approval. Following field office approval, LANL plans to implement the new safety basis by the end of the fiscal year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 5, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending July 5, 2013

Plutonium Facility – Criticality Safety: Based on direction from the Laboratory Director, fissile material operations at the Plutonium Facility remain paused this week. On Monday, the Associate Director for Plutonium Science and Manufacturing (ADPSM) provided the following guidance and clarifications to Plutonium Facility programmatic personnel:

- All programmatic operations that involve nuclear materials are paused until further notice.
- Material movement and process operations required to place nuclear materials in a safe and stable configuration are allowed but require specific approval from the Principal Associate Director for Weapons Programs.
- Facility support activities (e.g. surveillances, glove changes, filter changes, and removal of low-level waste) are permitted but must be approved by the TA-55 Facility Operations Director (FOD).
- Laboratory construction, reconfiguration, and cleanout activities with no potential to impact the configuration of nuclear materials are allowed with the approval of the TA-55 FOD.
- Laboratory construction, reconfiguration, and cleanout activities with the potential to impact the configuration of nuclear materials are paused; however, release of individual activities with a specific duration may be approved based on rigorous evaluation and justification that includes approval by the Laboratory Director.
- Walkdowns of Plutonium Facility laboratories and processes to evaluate procedures and criticality related controls are permitted provided they can be performed without affecting the safe and stable configuration of nuclear materials.
- Tours of the facility and individual laboratories are permitted.

The memorandum notes that all requests to resume normal operations must be approved by the Laboratory Director and that ADPSM is developing a formal process to obtain this approval.

Area G – 3706 Campaign: Area G personnel recently announced that they successfully completed removal of above ground, non-cemented transuranic (TRU) waste from Area G to meet the FY 2013 3rd quarter goals of the 3706 campaign. This keeps the project on pace to meet commitments in the framework agreement with the state to remove 3706 m³ of above ground, non-cemented TRU waste from Area G by June 30, 2014.

Chemistry and Metallurgical Research (CMR) Facility – Confinement Vessel Disposition (CVD): CMR personnel continue startup activities in CMR Wing 9 to support retrieval and disposition of nuclear materials contained in nine large confinement vessels currently stored at TA-55. LANL submitted proposed resolution of comments generated during an ancillary review of the CVD project safety basis (see 6/14/13 weekly) to the field office for review and approval. This resolution includes a CMR Documented Safety Analysis/Technical Safety Requirement page change to address field office concerns. Following field office approval of the page change and successful completion of an implementation verification review, the project will proceed with the Federal Operational Readiness Review, which is currently scheduled to commence in August 2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 12, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending July 12, 2013

Criticality Safety: The Laboratory Director's pause of fissile material operations in the Plutonium Facility remains in effect. A senior management team, with the active involvement of the Laboratory Director, continues to work on developing a resumption plan. Plutonium Facility personnel continue their process walk-downs to revise and validate procedures and criticality safety-related controls. These walk-downs have identified additional process deviations and criticality safety infractions. For example:

- A Criticality Safety Limit Approval (CSLA) specified a certain type of container could be stored in a specified location. The procedure used to move the containers had been updated to identify an additional type of container for use, but did not receive a review by Criticality Safety Analysts (CSA). As a result containers that had not been approved on the CSLA or evaluated in the associated Criticality Safety Evaluation Documentation (CSED) were being stored in this location.
- Multiple safe drawers have been discovered with dimensions that are not in compliance with the engineered features specified on the CSLA. This is primarily due to the ambiguous term "nominally" being used by the CSLA and CSED to identify dimensions.
- Five solution tanks were found to have different actual volumes than that specified on the CSLA. Again, this was complicated by the use of the term "nominally" by the CSLA and CSED to identify volumes.

This week, LANL submitted a report on the time-utilization of qualified CSAs to the field office for review. The report identifies that the qualified CSAs spent over 85% of their time during the past eight weeks providing floor support for fissile material operations and assisting with the extent of condition review ongoing in the Plutonium Facility. The report states that due to the time being spent assisting with efforts in the Plutonium Facility little progress is being made on performing Criticality Safety Evaluations needed to support other activities.

Fire Restrictions: The Laboratory and surrounding areas have received a significant amount of rainfall over the past week. As such, all fire restrictions (see 6/28/13 weekly) have been lifted.

Safety Basis: LANL recently submitted a revision to the Unreviewed Safety Question (USQ) institutional procedure. In addition to resolving previous field office comments, the revision clarifies the USQ integration with the LANL New Information process. Notably, the procedure now requires LANL to determine whether a Potential Inadequacy of the Safety Analysis exists within nine working days of entering the New Information process.

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF management identified that a required quarterly surveillance (due 7/6/13) associated with facility HEPA filters was not completed as required by the safety basis. The surveillance was successfully completed on Monday with no additional issues identified. RLWTF personnel are developing corrective actions to improve surveillance tracking.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 19, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending July 19, 2013

Plutonium Facility – Seismic Safety: On Thursday, the field office forwarded the DNFSB letter dated July 17, 2013 on Plutonium Facility seismic safety to LANL for action. The field office memorandum requests LANL support for developing and communicating the schedule for the Plutonium Facility alternate seismic analysis.

Plutonium Facility – Criticality Safety: The Associate Director for Plutonium Science and Manufacturing provided the Laboratory Director with a corrective action plan for criticality safety issues identified at the Plutonium Facility that supersedes the previous action plan (see 6/14/13 weekly) and includes the following:

- Immediate Actions (within 30 days): 1) actions to maintain Plutonium Facility operability and compliance; 2) compensatory actions to ensure operations do not impact criticality controls; and 3) deliberate resumption of operations with minimum potential to challenge criticality controls.
- Short-Term Actions (by the end of September): 1) increase number of certified criticality safety analysts (CSAs); and 2) deliberate resumption of operations with low potential to challenge criticality controls and high programmatic impact.
- Mid-Term Actions (by the end of December): 1) further increase pool of CSAs; 2) deliberate resumption of operations with modest potential to challenge criticality controls and high programmatic impact (e.g. FY 13 deliverables); and 3) identify opportunities for continuous improvement of criticality safety.
- Long-Term Actions (extend beyond 2013): 1) deliberate resumption of additional operations; 2) continue comprehensive operational improvements; and 3) independent evaluation of criticality controls and conduct of operations.

Although the majority of the Plutonium Facility programmatic operations remain paused, the Laboratory Director approved limited resumption of heat source plutonium operations this week. Plutonium Facility personnel also continue to walk-down and evaluate facility operations that are paused. These focused efforts continue to identify criticality safety issues and improvements that are appropriately evaluated and dispositioned.

The field office forwarded the DNFSB letter dated July 15, 2013 on LANL criticality safety to the Laboratory Director for action. The field office memorandum requests LANL action by the end of July 2013 to support response to the Board letter, revise the resumption plan (i.e. the plan detailed above) to addresses identified issues, and provide a resource loaded schedule for resumption activities.

Transuranic Waste Facility (TWF) Project: This week, LANL submitted a revision to the Preliminary Documented Safety Analysis (PDSA) to the field office for approval. The TWF Project will provide enduring LANL capability to stage and characterize transuranic solid wastes and is needed to replace Area G transuranic waste capability. Based on resolution of comments with the field office, the project team revised the PDSA to include a dry pipe fire suppression system and larger vehicle barriers. An Independent Project Review is scheduled for December 2013 to support critical decision-3 in February 2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 26, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending July 26, 2013

Staff member L. Lin was on site this week to walkdown LANL defense nuclear facilities.

Plutonium Facility – Criticality Safety: Plutonium Facility personnel identified several criticality safety issues associated with a recent construction activity in the 400 area.

- Work Release – the Associate Director for Plutonium Science and Manufacturing provided guidance on the facility pause that requires Laboratory Director approval to conduct construction activities with the potential to affect the configuration of nuclear materials (see 7/5/13 weekly). The release of this activity was approved by the Facility Operations Director (FOD) as having no potential to affect the configuration of nuclear materials despite the Integrated Work Document (IWD) identifying interface with systems potentially containing 300 gram per liter fissile material solutions. Subsequently, the FOD provided additional guidance on the pause of construction and maintenance activities that could potentially interface with piping and systems that contain fissile material solutions.
- Criticality Safety Evaluation (CSE) – during the critique, facility personnel identified that no CSE was performed for this activity as required by LANL procedures. The IWD for the construction activity was reviewed and approved by the criticality safety group in January 2013; however, the need for completing a CSE was not recognized.
- Criticality Control Implementation – the IWD for this activity required engaging criticality safety for the catch bag design and use of a catch bag with a volume of less than 1 gallon to contain solutions encountered. The actual catch bag being used was approximately 1.4 gallons.

Chemistry and Metallurgy Research Building – Confinement Vessel Disposition (CVD) Project: LANL submitted a corrective action plan for the previously completed CVD contractor Operational Readiness Review (ORR) to the field office for review and approval (see 5/10/13 weekly). The request identified that actions taken to correct the 15 pre-start findings from the contractor ORR have been completed and all other findings have been entered in LANL's performance feedback improvement and tracking system. Actions that must be completed prior to conducting a federal ORR and subsequent startup include: 1) field office approval of a recently submitted safety basis page change; 2) contractor Independent Verification Review of the approved page change; and 3) resolution of technical issues identified by a field office ancillary review (see 6/14/13 weekly). The federal ORR was recently delayed and is now scheduled for September 9, 2013.

Fire Protection: The field office directed LANL to perform a review and develop corrective actions for two recent instances of the Los Alamos Fire Department (LAFD) having difficulty accessing lab facilities to respond to alarms. In one instance, a lightning strike caused a loss of power at the Los Alamos Neutron Science Center which resulted in hot alarms being received by LAFD prompting their response. Upon arrival at the facility, responders were unable to open the access gate due to the loss of power and the absence of manual instructions for opening the gate. In a second instance, a hot alarm was received from a facility in Technical Area-3 that required LAFD response; however, the crew had to wait for the FOD to arrive with the facility keys in order to gain access. The field office has requested the report to be submitted within 14 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 2, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending August 2, 2013

Weapons Engineering Tritium Facility (WETF): LANL submitted a proposed safety basis improvement plan for WETF restart activities to the field office for review and concurrence. The plan is designed to support completion of both Contractor and Federal Readiness Assessments in September and October of this year respectively. The letter from the Associate Director for Nuclear and High Hazard Operations that transmitted the plan acknowledges that there are open NNSA comments on the currently submitted but not approved safety basis, but notes that effectively addressing all NNSA issues will delay startup. The letter suggests that the plan balances safety basis improvements versus expediting risk reduction through restart this calendar year. The plan identifies facility activities (repairs, modification, and testing) and proposed safety basis improvements that must be completed prior to facility restart.

The plan commits to develop a Project Execution Plan (PEP) for disposal of legacy waste items that have accumulated in WETF over the years. These items originated from work that has been done in WETF as well as from closure of tritium-capable facilities at LANL and other DOE sites. The disposition of these legacy items is essential to reducing risk in the facility as it represents nearly half of the WETF tritium inventory, and some of these legacy items have leaked tritium in the recent past (see 2/15/13 and 6/7/13 reports). The PEP will identify the strategies, timelines, program management approach, resources, and budget requirements necessary to dispose of the legacy items. LANL has established a multi-disciplined project team comprised of personnel from Operations, Waste Management, and Programs to develop and manage this project.

Area G – Safety Basis: This week, the field office completed a Safety Evaluation Report (SER) and approved the Area G Basis for Interim Operation and associated Technical Safety Requirements. This safety basis, which was submitted in April 2013 and resubmitted in June 2013 to resolve field office comments, is based on a new Hazard Analysis that provides clear linkage to control selection and includes significant reduction in overall Area G material-at-risk inventory limits. The safety basis also addresses issues identified in the Board letter dated November 19, 2012. The field office approval identifies that not all safety basis comments have been adequately resolved and provides six directed actions including the following four actions that require a proposed resolution by October 2013:

- Identify Specific Administrative Controls for Safety Management Programs where risk reduction (i.e. frequency and consequence) is applied in the hazard analysis.
- Remove plume meander from atmospheric dispersion modeling for the fire accident scenarios.
- Use conservative damage ratios for seismic events or provide adequate justification for the damage ratios selected.
- For the forklift propane tank puncture and resulting blowtorch scenario, evaluate the consequences in the accident analysis to appropriately derive required controls.

The other two directed actions involve use of DOE-STD-3009 control selection hierarchy and resolution of additional field office comments by the next annual update. Two members of the NNSA safety basis review team provided minority opinions that did not recommend approval of the Area G safety basis. LANL plans to implement this safety basis at Area G by the end of September 2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 9, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending August 9, 2013

Criticality Safety: This week, LANL submitted a revision to its system description SD130, *Nuclear Criticality Program*, to the field office for review and approval. The revision to SD130 has been approved by the Laboratory Director and is aimed at relieving the Nuclear Criticality Safety Group (NCSG) from the burden of having to review procedure changes that are editorial in nature. This will allow LANL's limited NCSG resources to more effectively use their time to perform the numerous criticality safety evaluations and procedure change reviews they have been charged with as a result of procedure walkdowns during the Director's pause in Plutonium Facility operations. The revision also defines what constitutes an editorial change and clarifies that it is the responsibility of the Operations Responsible Manager to ensure procedures impacting criticality safety are reviewed by the NCSG prior to use. Although additional changes to SD130 are planned, this revision was expedited in order to support Plutonium Facility resumption activities.

LANL also submitted its assessment report of 3rd quarter FY13 Nuclear Criticality Safety Program metrics to the field office for review. The assessment aims to measure continuous program improvement, efficient utilization of limited NCSG resources, and alignment of NCSG and Associate Director, Nuclear and High Hazard Operation (ADNHHO) work priorities. The report identified that the criticality safety staff has seen a decrease in their workload during this quarter, but anticipates a large increase in their workload for the 4th quarter as annual process walkdowns come due. Additionally, the assessment concludes that the metrics show an increased alignment of work priorities between ADNHHO and the NCSG.

Plutonium Facility: Plutonium Facility management declared a Potential Inadequacy in the Safety Analysis following a field office assessment of the facility Instrument Air System that identified a less than adequate surveillance procedure. A surveillance performed to ensure the Facility Control System will secure ventilation in certain upset conditions does not perform a complete System Function Test as required by the Technical Safety Requirements.

Chemistry and Metallurgy Research (CMR) Building – Confinement Vessel Disposition (CVD) Project: The field office approved a page change to the CMR safety basis that addresses comments from a field office ancillary review of the CVD project (see 6/14/13 weekly). This approval represents the first of three actions that must be completed prior to commencing a Federal Operational Readiness Review and subsequent startup (see 7/26/13 weekly). The Independent Verification Review of the page change is scheduled to begin August 21, 2013.

Weapons Engineering Tritium Facility (WETF): The field office transmitted a letter to ADNHHO directing action on multiple outstanding WETF recommendations for safety basis changes. The letter identified that safety basis deficiencies are contributing to the inability of WETF to resume operations in order to reduce its legacy tritium inventory and to support its national security mission. The letter directs LANL to resolve safety basis issues identified by the field office and notes that a "step-improvement" in the WETF safety basis is needed to support startup activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 16, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending August 16, 2013

Staff members J. Plaue and R. Tontodonato were onsite this week.

Criticality Safety: This week, LANL submitted a letter requesting relief from previous field office direction on time utilization of qualified Criticality Safety Analysts (CSA). Current field office direction limits CSAs to spending up to 15% of their time working on new or significantly revised Criticality Safety Evaluations (CSE). In addition, work on specific CSEs must be approved by the field office. The remaining 85% of the CSA's time is to be spent supporting emergency response, event response, and field support. The request for relief argues that because of the pause of fissile material operations in the Plutonium Facility, the day-to-day field support by CSAs can be reduced. The CSAs will instead use this additional time to train and qualify newly hired CSAs, and to work on CSEs required to support the resumption of activities in the Plutonium Facility. As such, the letter requests relief from the 15% constraint for working on new or significantly revised CSEs and relief from obtaining field office approval to work on specific CSEs. The CSAs will continue to place priority on emergency/event response and technical support to programmatic operations.

Plutonium Facility personnel continue their process walk-downs to revise and validate procedures and criticality safety-related controls. These walk-downs continue to identify process deviations and criticality safety infractions. This week, facility personnel discovered the arrangement of items in two safes did not match the arrangement as specified by their associated Criticality Safety Limit Approval (CSLA). Additionally, a number of safes were found to have dimensions that did not meet the requirements specified by the CSLA engineered controls.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL completed a Management Self Assessment this week at RLWTF to evaluate use of the Waste Mitigation Risk Management (WMRM) tanks for influent low-level waste storage and use of a new chemical feed system. The MSA team identified 6 pre-start findings, 10 post-start findings, and 5 observations. Following closure of the pre-start findings, LANL plans to use two of the six 50,000 gallon WMRM tanks for influent low-level waste storage.

The WMRM Project was originally intended to establish 300,000 gallons of low-level liquid waste storage under emergency conditions (e.g. wildland fire conditions); however, the project was halted in 2007 due to significant project management and quality assurance issues. In 2009, LANL completed a tie-in to the low-level waste system and additional actions to allow use of the WMRM tanks to provide 250,000 gallons of emergency storage capacity. Since 2009, facility upgrades have been performed including installation of mixing pumps for the 2 tanks that will be used for influent storage and piping runs to feed the low-level waste processing system from the WMRM tanks. Completion of this project will allow LANL to discontinue use of older single shell tanks that are currently used for influent storage. Other actions are being taken to eliminate use of all single shell tanks and piping.

LANL has also completed the Zero Liquid Discharge (ZLD) Project that provides a natural evaporation capability for RLWTF purified water discharge and eliminates the need for an evaporator. The ZLD capability will be used after approval of a new wastewater discharge permit.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 23, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending August 23, 2013

This week, DNFSB Chairman Peter Winokur, Vice Chairman Jessie Roberson, Member John Mansfield, and Member Sean Sullivan were onsite along with staff members David Jonas, Steven Stokes, and John Pasko to meet with NNSA field office and LANL personnel. The Board had detailed discussions with site personnel on the Plutonium Facility (including the status of the programmatic pause, criticality safety improvements, and seismic safety), the Chemistry and Metallurgy Research Building, Transuranic Waste Operations, the Transuranic Waste Facility Project, the Weapons Engineering Tritium Facility, and emergency preparedness. The Board toured the Plutonium Facility and the Weapons Engineering Tritium Facility.

Nuclear Startup and Readiness Program: This week, the field office transmitted a report of its assessment of the LANL Nuclear Startup and Readiness Program. The assessment was conducted from July 9 – 18, 2013, and evaluated LANL's program against DOE Order 425.1D, *Verification of Readiness to Start Up or Restart Nuclear Facilities*. The assessment team concluded that the LANL Nuclear Startup and Readiness Program is adequately implemented, effective, and sustained. The team identified seventeen observations and the following three findings: 1) the LANL readiness procedure does not require documentation of team member training, experience, qualification, independence, or availability (this is a repeat of a previous finding that was not addressed); 2) lack of a 1 year notification for some startup/restart activities as required by DOE Order 425.1D; and 3) late submittal of a Plan of Action for a startup activity.

Plutonium Facility – Safety Basis: The field office approved a LANL request to extend the due date for re-submittal of the annual revision to the Technical Area-55 Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs). The revision was initially submitted in September 2012, but the field office directed LANL to revise the DSA and TSRs to incorporate a number of field office generated comments by August 13, 2013 (see 5/17/13 weekly). The request for extension cited the complexity of the necessary changes as well as a number of other issues being addressed by senior safety basis analysts as factors in the delay of the re-submittal.

The Potential Inadequacy in the Safety Analysis that was declared by Plutonium Facility management for an inadequate surveillance of the facility Instrument Air System (see 8/9/13 weekly) has been declared an Unreviewed Safety Question. LANL will submit an Evaluation of the Safety of the Situation for this issue.

Emergency Exercise: On Thursday, LANL conducted an evaluated emergency exercise that simulated a significant release of hydrochloric acid and personnel injuries at the Sanitary Effluent Reclamation Facility due to a malevolent act. The exercise included participation from federal, state, and county representatives. LANL will complete an after action report that evaluates performance and identifies opportunities for improvement.

Transuranic Waste Operations: As part of the 3706 campaign, LANL completed packaging a number of corrugated metal boxes (CMBs) into ten drum overpacks for shipment to the Waste Isolation Pilot Plant. The remaining CMBs require remediation prior to disposition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 30, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending August 30, 2013

Plutonium Facility – Criticality Safety: In the August 15, 2013, letter to the Board from the Acting Administrator, NNSA committed to complete a causal analysis for recent criticality safety infractions. This week, a LANL causal analysis team held its kickoff meeting. The team consists of laboratory personnel from outside of the Plutonium Facility and is led by the Deputy Associate Director for Chemistry, Life, and Earth Sciences. During the meeting, the team concluded that its first course of action will be to clearly develop the scope of the assessment. The team plans to conduct document reviews, walkdowns of all areas where criticality infractions have occurred, and personnel interviews. The team expects to have the final report completed and briefed to the Laboratory Director by October 4, 2013. NNSA has committed to report the outcome of the causal analysis to the Board in a subsequent status report.

Plutonium Facility – Resumption Status: The Laboratory Director’s pause of fissile material operations at the Plutonium Facility remains in effect. Last week, in accordance with the Associate Director for Plutonium Science and Manufacturing memorandum on resuming operations during the pause, the Laboratory Director was briefed on and approved the release of an integrated work document for preparing small quantity fissile material samples to be tested at Sandia National Laboratory. The work on the sample preparations commenced this week. This activity represents the first programmatic operation (other than activities to achieve and maintain safe and stable facility status) at the Plutonium Facility since the June 27, 2013, pause.

The current highest priority for resumption is to revise, and have the Director approve, 29 Plutonium Facility support processes. These processes control the movement, measurement, disposition, receipt, and shipment of nuclear materials. Although the Director had previously approved limited resumption of heat source Plutonium operations (see 7/19/13 weekly), operations have yet to be performed because these support processes have not yet been approved. The LANL resumption approval process also now requires verification of the seven criteria identified in the NNSA letter to the Board dated August 15, 2013.

Conduct of Operations: LANL recently issued a Conduct of Operations Maturity Plan to improve implementation of DOE Order 422.1, *Conduct of Operations*, at both the facility and institutional level. The plan addresses specific gaps between the order and institutional/facility implementation. In addition, the plan identifies other upgrades and improvements in part based on a review of recent events that involved issues with conduct of operations including: criticality safety implementation at the Plutonium Facility; spread of contamination events at the Los Alamos Neutron Science Center and at the Area G High Energy Real Time Radiography unit; and material control issues at TA-35 Building 27. The plan identifies several focus areas including the following: 1) facility level improvements that can be completed in less than one year; 2) clarification of institutional procedure requirements; 3) improvements in procedure quality; 4) baseline and continuing training; and 5) conduct of operations seminars. As part of this effort, LANL will also be using a new self-assessment tool, “Find-it and Fix-it”, that will support specific evaluation of conduct of operations elements at the facility level.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 6, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending September 6, 2013

Area G – Dome 375 Box Repackaging Line: As part of the campaign to remove 3706 m³ of above ground, non-cemented transuranic waste from Area G, LANL has remediated 25 oversized fiberglass reinforced plywood containers (FRPs) in the Dome 375 box repackaging line since startup of hazard category (HC)-3 operations in June 2013. LANL has been successful at decontaminating most of these containers to low level waste, obviating the need to perform size reduction activities, and thereby decreasing the risk to the workers performing this activity.

Recently completed assays of the remaining oversized FRPs show that two of them exceed the DOE Standard 1027 HC-2 threshold quantities. However, these 2 FRPs do not exceed the HC-2 threshold quantities specified in the NNSA supplemental guidance on DOE Standard 1027. As such, LANL convened a Joint Evaluation Team (JET) to determine whether these 2 FRPs can be remediated as a HC-3 activity, which would allow them to proceed with remediation of the remaining above ground FRPs without having to perform a Federal Readiness Assessment (FRA) as previously planned. The JET voted to submit a request to field office to allow the use of the NNSA supplemental guidance and not to conduct a FRA. The FRPs in question contain large gloveboxes which LANL will also attempt to decontaminate and disposition as low level waste.

Criticality Safety: The Associate Director for Nuclear and High Hazard Operations (ADNHHO) recently divided the previously combined Safety Basis and Criticality Safety divisions, which were managed by one division leader. The reorganization will allow the separate division leaders to focus on improvements in their specific area. Currently, the Deputy ADNHHO is acting as the Criticality Safety division leader until a permanent selection for this position is made.

Chemistry and Metallurgy Research Building - Confinement Vessel Disposition (CVD)

Project: Necessary changes to a Criticality Safety Evaluation (CSE) and implementation of additional criticality controls to support the CVD project have been delayed due to the limited availability of qualified criticality safety analysts. As a result, the ADNHHO has requested a delay in the start of the federal Operational Readiness Review (ORR) that was scheduled to commence next week. The proposed start date for the ORR is now September 30, 2013.

Plutonium Facility – Safety Basis: LANL recently submitted an Evaluation of the Safety of the Situation (ESS) to address facility containers that are not “watertight” as described in the CSE. In March, Plutonium Facility personnel questioned whether the vents associated with material containers were watertight as required by the Criticality Safety Limit Approval. This issue was declared a Potential Inadequacy of the Safety Analysis and subsequently determined to be an Unreviewed Safety Question. LANL conducted testing to evaluate water intrusion into containers during flooding and determined that only a small amount of water leaked into two of the fourteen container types tested. The small amount of water in-leakage was determined to be consistent with the assumptions in the CSE. The ESS commits to revising the CSE to address the small volume of water in-leakage and to revise the Documented Safety Analysis to appropriately evaluate flooding scenarios.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 13, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director

FROM: R.T. Davis and R.K. Verhaagen

SUBJECT: Los Alamos Report for Week Ending September 13, 2013

Criticality Safety: LANL continues to work on resumption activities for the paused fissile material operations in the Plutonium Facility. A war-room has been set up to manage and track the resumption activities, and a senior LANL manager has been temporarily assigned to manage this effort. The resumption process continues to evolve, and as such, a revision to the Notice, *Resumption Release Process for Programmatic Activities at PF-4*, was recently issued. This notice was released to update the requirements for the resumption process and to identify compensatory actions being taken to address material management issues.

During reviews of objective evidence packages for resumption of programmatic operations, the site reps identified multiple issues with the proposed procedures, Criticality Safety Evaluations (CSE), and Criticality Safety Limit Approvals (CSLA). These issues included: 1) a procedure did not specify any criticality controls and did not reference the CSLA; 2) a CSE and its associated CSLA specified different controls; and 3) a CSLA was developed without an evaluation. Additionally, recent assessments and reviews have identified issues with the quality of existing CSEs. All of these issues are being addressed and the resumption process is being refined to ensure evaluations are of sufficient quality and that the controls from the CSEs adequately flow down into the CSLAs, postings, and procedures.

Area G – Safety Basis: Area G personnel are scheduled to implement the new Basis for Interim Operation and associated Technical Safety Requirements (TSRs) by the end of this month. As part of the implementation, inventory tracking was recently transitioned from a locally maintained database to the LANL Waste Compliance and Tracking System. This system will be used to perform material at risk surveillances as required by the TSRs. Area G personnel have completed training on the new safety basis. Field implementation of defined areas, liquid berms, and markings has also been completed in accordance with the TSRs. LANL will perform an Implementation Verification Review prior to declaring the new safety basis implemented. Area G management will review and release individual work activities following safety basis implementation.

Plutonium Facility – Safety Basis: LANL recently submitted an Evaluation of the Safety of the Situation (ESS) to address General Purpose Heat Source (GPHS) items that were found to be bulging. In April, Plutonium Facility workers identified two bulging GPHS items and subsequently identified five additional bulging items. The encapsulated GPHS items are credited in the safety basis as safety-class (damage ratio of zero) for heat source-plutonium. When discovered, facility management declared the safety-class feature inoperable and fully counted the materials against facility material at risk limits (damage ratio of one). LANL subsequently concluded the issue represented an Unreviewed Safety Question. LANL testing and evaluation referenced in the ESS concludes that the bulging is likely caused by helium release during storage and will not result in rupture of the items. The ESS also identifies compensatory measures to 1) continue to apply a damage ratio of one for degraded GPHS items, 2) use safety class containers to overpack these items when outside a glovebox, and 3) store no more than two GPHS items together. Additional testing and analysis is planned to better characterize the bulging mechanism.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 20, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director

FROM: R.T. Davis and R.K. Verhaagen

SUBJECT: Los Alamos Report for Week Ending September 20, 2013

The site representatives were out of the office this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 27, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director

FROM: R.T. Davis and R.K. Verhaagen

SUBJECT: Los Alamos Report for Week Ending September 27, 2013

Chemistry and Metallurgy Research Building (CMR) – Confinement Vessel Disposition (CVD)

Project: This week, the CMR Facility Operations Director declared readiness to proceed with the CVD Federal Operational Readiness Review (ORR). This declaration identified that all necessary findings from the previously conducted Management Self Assessment and Contractor ORR have been closed. Additionally, directed changes to the Documented Safety Analysis (DSA) and Technical Safety Requirements (TSR) to address field office comments from an ancillary review have been completed and their implementation verified.

Due to the current field office management structure, the DOE/NNSA Central Technical Authority has been designated the Startup Authorization Authority (SAA) for this activity. The field office has approved and forwarded the request recommending approval to the SAA. Pending this final approval, the Federal ORR is scheduled to commence September 30, 2013.

Plutonium Facility – Safety Basis: The Potential Inadequacy in the Safety Analysis that was declared for the Plutonium Facility Control System/Ventilation System Function Test (see 8/9/13 weekly) resulted in an Unreviewed Safety Question. LANL submitted an Evaluation of the Safety of the Situation (ESS) to the field office this week for review and approval. The ESS concludes that no compensatory measures or operational restrictions are necessary and commits to revise the DSA and TSRs to clarify the appropriate safety function. Additionally, the test procedure in question will be revised to be consistent with the TSRs.

Weapons Engineering Tritium Facility (WETF): This week, LANL submitted a revision to the WETF DSA, TSRs, and Fire Hazards Analysis to the field office for approval. The field office and LANL personnel have conducted multiple workshops to resolve previous comments and identify specific safety basis changes needed to support near term facility restart. Approval of this safety basis change supports closure of Potential Inadequacy in the Safety Analysis issues associated with the oxygen monitoring system, hot-inlet system, and Radioactive Control Safety Management Program. Following field office approval and implementation of the revised safety basis, a contractor and federal readiness assessment are scheduled. Restart of this facility is needed to support disposition of excess tritium inventory and legacy items and to allow completion of function test programmatic missions.

Plutonium Facility – Seismic/Structural: The field office recently approved changes to the Fiscal Year 2013 Performance Evaluation Plan scope associated with Plutonium Facility seismic and structural activities. Specific Technical Area 55 Reinvestment Project scope that has been delayed was replaced with the following tasks: 1) remove 1.9 kg of heat-source plutonium (HS-Pu) from the laboratory floor; 2) dismantle and reprocess 1.8 kg of HS-Pu from rejected fuel clads (completion depends on resumption of associated programmatic operations); 3) analyze building performance against the requirements in DOE-STD 1020-2012; 4) design and install anchorage for two electrical panels; 5) initiate anchorage upgrades for two unit substations; and 6) add loss of 130 VDC power indication associated with the safety-class seismic switches to the Facility Control System.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 4, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 4, 2013

Staff member J. Pasko was onsite this week to observe the Federal Operational Readiness Review of the Confinement Vessel Disposition Project in the Chemistry and Metallurgy Research Building.

Fire Protection: On September 27, 2013, Los Alamos County approved a new 10 year cooperative agreement with NNSA to provide fire department and other services to LANL. The cooperative agreement continues to ensure that the Los Alamos Fire Department (LAFD) is trained and prepared to provide fire and emergency response to LANL facilities. The new agreement also includes establishment of a LAFD Hazmat Team along with response expectations.

Area G – Safety Basis: As directed by the field office, Area G personnel implemented the approved Basis for Interim Operation (BIO) and associated Technical Safety Requirements (TSR) on September 30, 2013 (see 8/2/13 weekly). Following implementation of the BIO and TSRs, Area G management methodically reviewed and approved release of individual Area G operations. All activities have been restarted and operations to continue the removal of 3706 m³ of above ground, non-cemented transuranic waste have resumed. Area G personnel also reported that the 3706 campaign goals for FY13 have been met.

Weapons Engineering Tritium Facility (WETF): The Deputy Associate Director for Weapon Engineering and Experiments transmitted a letter to the field office updating the status of the tritium-containing materials disposition effort (see 8/2/13 weekly). The letter identifies that an integrated project team has been assembled to develop a project plan to evaluate legacy assets to determine items that have programmatic utility and items that can be processed and dispositioned as waste. The letter also identifies activities intended to be completed in calendar year 2014 to include: 1) complete item inventory and define solution packages; 2) develop processing and disposition paths; 3) execute “simple” solution package disposition; 4) establish processes and procure material necessary for bulk gas storage and shipment of non-essential bulk gas; and 5) identify materials, supplies, processes, and safety basis changes necessary to support out-year legacy-item processing and disposal. This effort is necessary to disposition more than 750 tritium containing items that have accumulated in WETF over the years.

Plutonium Facility – Safety Basis: LANL recently submitted a revision of the 2011 Technical Area-55 (TA-55) Documented Safety Analysis and TSRs to the field office for approval. The safety basis revision addresses preparation and assay of transuranic waste outside of the Plutonium Facility but inside the TA-55 protected area. LANL recently completed installation of a high efficiency neutron counter (HENC) on the safe secure transport pad, which is now referred to as the HENC pad, in support of this activity. The major changes in the proposed safety basis revision include: 1) increased material at risk (MAR) limits for the waste pad; 2) a new MAR limit for the HENC pad; 3) classifying pipe overpack containers as safety class; 4) classifying safes on the HENC pad as safety significant; and 5) a new specific administrative control to exclude refueling around the HENC pad. The change is also intended to resolve a Potential Inadequacy of the Safety Analysis identified in March 2012 associated with refueling activities (see 3/16/12 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 11, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 11, 2013

Because of the ongoing lapse in federal appropriations, NNSA has directed LANL to prepare for the orderly closure of all site operations except for activities required to maintain facilities in a minimum safe state. This state includes compliance with safety basis requirements for nuclear facilities (e.g. performance of Technical Safety Requirement surveillances and minimum staffing). Without a resolution to the appropriations, LANL will transition to this closure mode for all operations at the close of business on October 18, 2013. LANL is identifying essential personnel to maintain a safe shutdown mode along with a resumption team that will focus on plans to safely restart operations following the shutdown. The Field Office is also identifying a small number of excepted personnel.

Los Alamos Field Office: Ike White reported for duty this week to be the acting field office manager for the next 60 days. Mr. White replaces Geoffrey Beausoleil who had been acting in this position pending selection of a new manager.

Confinement Vessel Disposition (CVD) Project: This week, the Federal Operational Readiness Review (ORR) for the CVD Project in the Chemistry and Metallurgy Research Building (CMR) concluded. The Federal ORR team identified 29 pre-start and 25 post-start findings. Despite the large number of findings, the ORR team cautioned against over emphasizing the numbers, as they concluded the issues were generally discrete with clear paths to closure. Operations, criticality safety, and engineering were identified as subject areas with the greatest opportunities for improvement. Following adequate closure of the pre-start findings and the development of a corrective action plan for closure of the post-start findings the team concludes that CVD nuclear activities can be safely conducted in CMR.

Plutonium Facility – Criticality Safety: Plutonium Facility management approved a major revision to the Technical Administrative Procedure, *TA55 Nuclear Criticality Safety Program*. This procedure identifies the Roles, Responsibilities, Authorities, and Accountability requirements for the development, implementation, revision, and periodic review of new and existing criticality limits. Changes were made to address issues raised in the Board's July 15, 2013, letter that identified significant non-compliances with applicable DOE requirements and industry standards in the implementation of LANL's criticality safety program. Specific to the Board's issues, the revision clarifies expectations for implementation of criticality controls in procedures, procedure use categories, and material labeling.

Safety Basis: NNSA recently completed an assessment of the LANL safety basis program and provided initial feedback to laboratory management. The assessment identified the following seven findings: 1) lack of an effective process to ensure safety basis documents are reviewed prior to submittal; 2) ineffective process to ensure safety basis deliverables meet NNSA expectations; 3) lack of an effective comment resolution process; 4) inadequate process to implement DOE-STD-1189 in addressing NNSA comments for LANL projects; 5) internal assessments not performed per LANL procedures; 6) inadequate formal process for implementation of new or revised safety basis documents; and 7) cancellation of a safety basis procedure that did not meet LANL requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 18, 2013

MEMORANDUM FOR: S.A. Stokes, Acting Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 18, 2013

Based on the temporary resolution of federal appropriations, the Laboratory Director cancelled the planned suspension of operations that was scheduled to occur on Friday. All LANS employees are expected to report to work as normal. As some LANL operations had already been impacted, the Director emphasized that the resumption of activities should be performed in a methodical and deliberate manner. In the last few weeks, considerable site effort has been focused on the planning and execution of a safe laboratory shutdown. NNSA has communicated to LANL that these plans be finalized over the next few weeks for potential use in the future.

Transuranic Solid Waste Operations: Environmental and Waste Management Operations (EWMO) including Area G, the WCRR repackaging facility, and the RANT shipping facility were placed into a safe shutdown mode last week due to lack of funding. This included suspension of most LANL subcontract work in these areas. EWMO management has developed a resumption plan that will be implemented next week to bring subcontractors back onsite and conduct a deliberate release of programmatic work to support completion of the 3706 campaign.

Plutonium Facility – Safety Basis: Last week, LANL requested an extension for two Evaluations of the Safety of the Situation (ESS) for refueling activities (see 3/16/12 weekly) and ammonium nitrate in the exhaust ventilation (see 7/23/10 weekly). These ESSs were intended to be closed during the 2012 safety basis annual update; however, the safety basis was never approved. These issues are also addressed in the most recent annual update that was submitted in September.

As noted above, LANL submitted the 2013 annual update for the Plutonium Facility last month. The major changes in this safety basis include the following: 1) incorporation of most field office comments from the 2012 annual update; 2) inclusion of additional transuranic waste activities (see 10/4/13 weekly); 3) changes to support closure of ESSs (including two mentioned above) and Potential Inadequacies of the Safety Analysis; 4) resolution of comments in the 2011 Safety Evaluation Report; and 5) re-evaluation of the leak path factor for the seismic accident scenario. The field office is currently reviewing the revised safety basis.

Area G – Safety Basis: There are approximately 25 unvented drums containing transuranic waste in Area G that cannot be processed by the existing drum venting system (DVS) because they are either too large or exceed the DVS weight limit. The Area G safety basis currently prohibits opening unvented drums due to the potential for hydrogen buildup and deflagration. In order to process these drums, Area G personnel submitted a temporary safety basis modification request to the field office for review and approval. The safety basis modification would allow workers to remove potentially unvented 55 gallon drums nested in potentially unvented 85 gallon drum overpacks nested in 110 gallon unvented drum overpacks. In its response, the field office noted that the proposed activity does not have the capability to attach a lid restraint onto the nested 55 gallon drum or the nested 85 gallon overpack and could thereby expose the worker to potential injury from a postulated lid ejection scenario. The field office provided LANL with additional comments and direction to revise and resubmit the safety basis for approval before it will allow this activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 25, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 25, 2013

Transuranic Waste Operations: Operations at Area G, the WCRR repackaging facility, and the RANT shipping facility resumed this week including shipments to WIPP.

Criticality Safety: In an effort to complete a ranking of fissile material operations (FMOs) across the site based on risk from a criticality safety perspective, LANL submitted a list of what it considers low risk FMOs to the field office for concurrence. The list of low risk FMOs was developed using criteria that provides a high level of confidence that adequate controls are in place to prevent a criticality. The list includes nearly half of the FMOs at the site, and all of the FMOs outside of the Plutonium Facility. As directed by the field office, this risk ranking represents a shift from a previous effort (see 3/19/13 weekly) that ranked FMOs primarily by the confidence level in the technical basis for the criticality safety evaluation. LANL has committed to risk rank the remaining Plutonium Facility FMOs in a future submittal. This risk ranking effort will be used to assist in identifying lower risk FMOs within the Plutonium Facility that will be the first to be resumed.

The Nuclear Criticality Safety Division Leader recently issued a memorandum communicating expectations regarding performance demonstrations for newly qualified criticality safety analysts (CSAs). These performance demonstrations are designed to evaluate newly qualified CSA's quality of work and to ensure a high performance standard. Newly qualified CSAs will be required to perform procedure reviews, criticality safety evaluations, annual process reviews, and event response under review of Nuclear Criticality Safety Division leadership until they have adequately demonstrated competency in these areas.

Plutonium Facility – Safety Basis: This week, the field office approved the Evaluation of the Safety of the Situation (ESS) associated with General Purpose Heat Source (GPHS) items that were found to be bulging (see 9/13/13 weekly). The ESS proposed compensatory measures to apply a damage ratio of one to these items, overpack in safety class containers when outside of a glovebox, and store no more than two GPHS items together. The field office did not identify any conditions of approval. Initial investigation appears to indicate that the bulging is caused by internal pressure; however, LANL continues to investigate the issue.

Safety Basis: Earlier this year, LANL developed and submitted a draft of the *Safety Basis Division Technical Bulletin Guidance on the Identification of Other Equipment Important to Safety (OEITS)*. This guidance was developed to comply with DOE Order 420.1B requirements for the identification of systems that perform important defense-in-depth functions. The guidance also identifies how these systems will be managed through facility safety management programs (e.g. engineering, quality assurance). Earlier this month, the field office concurred with this guidance and directed LANL to formally issue the document within 45 days along with an implementation plan. The first phase of the implementation plan will include identification of an initial list of OEITS by January 17, 2014, based on information available in facility safety basis documents and line management judgment. Facility safety basis documents will also be upgraded during the annual updates to comply with the OEITS guidance and refine the list of defense-in-depth systems.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 1, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending November 1, 2013

The Laboratory Director announced that Cheryl Cabbil has been selected to take over as the LANL Associate Director for Nuclear and High Hazard Operations on December 2, 2013. Ms. Cabbil was previously the vice president for Environment, Safety, Health, and Quality Assurance for URS/CH2M Oak Ridge, LLC.

Material Recycle and Recovery (MR&R): The LANL MR&R program is focused on the disposition and management of nuclear materials to meet programmatic needs (including risk reduction activities) and support strategic plans for enduring national missions. In Fiscal Year (FY) 2013, LANL received additional funding to support an accelerated nuclear material disposition project that includes disposal of 1.4 metric tons of nuclear material with “no defined use” by 2018. As part of this project, accelerated vault recovery eliminates legacy vault materials and will provide greater operational flexibility for future laboratory missions. In FY 2013, the LANL MR&R program completed the following accelerated vault recovery items: 1) removal of all non-standard containers from one vault room to allow access without respirator protection; 2) identification of vault items categorized into appropriate disposition campaign categories (includes more than 7000 items); 3) stabilization/disposition of 400 kg Pu-239 equivalent; and 4) disposition of 234 containers. In addition, the MR&R program completed installation of the High Energy Neutron Counter at Technical Area-55 to support transuranic waste disposition.

Area G – Safety Basis: This week, LANL submitted two safety basis addendums for the currently implemented Area G Basis for Interim Operations to the field office for review and approval. The first addendum will allow operators to open sealed inner containers with bolted lids/flanges during Sort, Segregate, Size-Reduction, and Repackaging activities. The addendum for this activity identifies additional specific administrative controls to reduce the likelihood and consequence of a deflagration that include: 1) ceasing spark-producing activities prior to loosening the lid/flange bolts; 2) the use of non-sparking processes and tools; 3) ensuring the workers and drums are grounded/bonded; and 4) loosening lid/flange bolts sufficiently to break the seal allowing the drum to vent without completely removing the bolts. The second addendum will allow gas generation testing (GGT) of a small number of transuranic waste drums to ensure they meet shipping requirements. This addendum credits an existing specific administrative control to ensure that drums processed through GGT have less than 200 PE-Ci.

Confinement Vessel Disposition (CVD) Project: On Wednesday, the field office transmitted the final CVD Operational Readiness Review (ORR) report to LANL for action. In addition to a corrective action plan for the identified findings, the field office requested the following: 1) the list and qualifications of personnel designated as senior supervisory watch; 2) LANL approach to ensure adequate formality of operations and approach for rigorous closure of pre-start findings; 3) LANL actions to ensure and verify sustained performance for formality of operations and criticality safety; and 4) effectiveness evaluation for actions identified in the LANL Continuous Improvement Plan for Conduct of Operations based on the weaknesses identified in the ORR report. The field office also requested LANL to identify lessons learned for application to future readiness activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 8, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 8, 2013

DNFSB Staff Activity: Dr. J. Plaue reported for Site Representative duty on Monday. Staff members R. Arnold and B. Laake were on site to review documentation associated with the technical basis for the W76 weapons response summary document. The staff and site reps also participated in a multi-site video-teleconference concerning implementation of Issue H of the weapons response summary document and falling man hazards at the Pantex Plant.

RANT Shipping Facility – TRUPACT III Loading Enclosure (TTLE): LANL submitted a Safety Basis Strategy for construction of a TTLE at the RANT shipping facility. The TTLE will provide facility personnel a location to load Waste Isolation Pilot Plant (WIPP) - Waste Acceptance Criteria compliant standard large box 2 (SLB2) shipping packages into TRUPACT III Type B containers using a 40 ton bridge crane. The TTLE will be a large Quonset hut type building with the primary function of providing weather protection for TRUPACT III loading operations, which require temperatures to remain above 40° F. The SLB2 is a large shipping container with an equivalent volume of approximately thirty-five 55-gallon drums. As such, the SLB2 provides the capability to ship large intact items, such as gloveboxes, directly to WIPP without having to conduct size reduction activities, significantly reducing risk to the workers and public. The submission of the Safety Basis Strategy includes a preliminary hazards evaluation and a completed questionnaire from Appendix J of DOE-STD-1189 to conclude that construction of the TTLE does not constitute a major modification of the RANT shipping facility.

Weapons Engineering Tritium Facility (WETF): Recently, WETF personnel identified that the Integrated Work Documents (IWDs) that cover radiological control technician (RCT) work (e.g. surveys, monitoring, radiological equipment use and maintenance) were not evaluated by the Unreviewed Safety Question (USQ) process as required by the safety basis. Facility personnel identified corrective actions during a critique on Tuesday that included: 1) ensuring all IWDs and procedures used by RCTs are evaluated under the USQ process; 2) identifying other support organization procedures used at WETF; 3) verifying these support organization procedures are evaluated under the USQ process; 4) evaluating improvements to the WETF work control procedure; and 5) defining the process for authorizing work for support organizations.

LANL management also identified the need to perform an extent of condition review at other nuclear facilities. Based on an initial review, some support organization IWDs and procedures at other nuclear facilities do not receive a USQ evaluation. In addition, there is no systematic institutional process to ensure these procedures are properly evaluated. A LANL team is reviewing this problem to determine appropriate site-wide corrective actions and will recommend changes to institutional procedures.

Electrical Safety: On Wednesday, the LANL Chief Electrical Safety Officer provided the field office with an overview of three recent electrical safety issues that occurred in October. Recommendations and improvements for each of the individual events were identified. In addition, broader lessons learned will be communicated across the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 15, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 15, 2013

DNFSB Staff Activity: On Wednesday, the site representatives and staff members D. Kupferer and J. McComb participated in a video teleconference arranged by the field office to provide the status on resumption activities associated with criticality safety and conduct of operations at the Plutonium Facility.

Criticality Safety: Last week, the field office concurred with minor changes to the listing of fissile material operations (FMO) the contractor determined to have high confidence of low criticality risk (see 10/25/13 weekly). The field office added one FMO associated with plutonium-238 operations and removed two FMOs associated with plutonium chloride operations from the list. Overall, the approved list contains 228 FMOs, including all FMOs performed outside of PF-4. Within PF-4, the list includes all FMOs involving plutonium-238, operations within the basement, and certain other FMOs assessed as low risk (e.g., ≤ 520 g metal or involving essentially all plutonium oxide). The contractor expects to resume these low risk FMOs on a schedule currently in development.

Safety Basis: On November 8, 2013, the field office transmitted the results of an NNSA assessment of LANL's safety basis program (see 10/11/13 weekly). The transmittal stated that "as evident by PF-4 safety basis deliverables last year, progress has been made, but further improvement is needed, particularly in disseminating and applying lessons learned from each safety basis review to subsequent submittals." The assessment team identified that significant improvements in development, maintenance, and sustainability of safety basis documentation are needed and concluded that LANL safety basis program continues to struggle with quality and consistency of safety basis document submittals. As a result, the field office has directed LANL to: 1) self-evaluate the safety basis program; 2) determine causal factors for the findings identified in the assessment; and 3) incorporate necessary corrective actions into a resource-loaded safety basis improvement plan with milestones to be completed in fiscal year 2014.

Plutonium Facility – Safety Basis: The field office recently transmitted comments to LANL regarding a submittal of the evaluation of the safety of the situation (ESS) addressing Plutonium Facility containers that are not "watertight" as described in the criticality safety evaluation (see 9/6/13 weekly). The field office noted that the ESS is considered incomplete due to an inadequate technical justification, but agreed that there is no immediate safety concern. LANL has been directed to resolve field office comments and resubmit the ESS by December 8, 2013.

Radiochemistry Laboratory (RC-1): The field office approved a LANL request to incorporate derived hazard category-3 threshold quantities calculated for 46 radionuclides to be used in RC-1, which is a radiological facility. The field office previously approved the use of NA-1 SD G 1027, *Guidance on Using Release Fraction and Modern Dosimetric Information Consistently with DOE STD 1027-92* for RC-1 (see 9/14/12 weekly). These particular radionuclides are not identified in the guidance and as such their threshold quantities had to be derived using the methodology approved in the supplemental guidance.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 22, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending November 22, 2013

DNFSB Staff Activity: On Thursday, the Site Representatives and staff members B. Caleca, A. Hadjian, and J. Pasko held a teleconference with field office and laboratory personnel. The purpose of the teleconference was to obtain the status of efforts to analyze and upgrade safety-related systems and components (including planned upgrades for the fire suppression and confinement systems) in the Plutonium Facility consistent with the latest probabilistic seismic hazard analysis.

Governance: Three members of the *Congressional Panel on the Governance of the Nuclear Security Enterprise* visited the laboratory. The members met with the field office, laboratory management, the New Mexico Environment Department, and the Site Representatives to discuss the current NNSA governance approach, issues, and potential improvements.

Criticality Safety: This week, laboratory management briefed the field office on the resumption status in the Plutonium Facility following the Laboratory Director's pause of programmatic activities to improve performance in conduct of operations and criticality safety. The laboratory's resumption process prioritizes activities by mission importance and criticality safety risk; plutonium-238 operations and general plant procedures have been the early focus. To date, the Director has released approximately 60 operational procedures. However, LANL has been unable to resume many of these activities due to dependence on other procedures that have yet to be approved. Laboratory management noted that approximately 300 procedures require approval to accomplish the programmatic activities planned for fiscal year 2014.

In addition to the 60 procedures previously approved, this week the Director delegated authority to resume fissile material operations (FMO) involving ≤ 520 g. Currently, 46 FMOs have a material limit of ≤ 520 g of plutonium. Plutonium Facility personnel are also in the process of evaluating individual FMOs to determine the minimum amount of material required for the operation. Laboratory management expects this effort to reduce the fissile mass analyzed in the associated criticality safety evaluations (CSE) and may result in additional FMOs with ≤ 520 g. The Site Representatives note that a further benefit of this effort may be the reduction of the actual material-at-risk (MAR) present in the lab rooms and improved fidelity on the MAR required to be supported in future safety basis updates.

Confinement Vessel Disposition (CVD) Project: Chemistry and Metallurgy Research (CMR) Building personnel continue to work on corrective actions associated with the CVD Operational Readiness Review (ORR). LANL completed a causal analysis for the ORR findings and expects to transmit a comprehensive corrective action plan to the field office in the next few weeks. To help address actions identified in the field office letter transmitting the ORR report (see 11/1/13 weekly), laboratory management identified primary and secondary senior supervisory watch personnel that will initially focus on achieving sustained performance improvements in formality of operations and criticality safety. Laboratory management is also communicating lessons learned from the CVD ORR to other facilities at the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 29, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 29, 2013

DNFSB Activity: On Tuesday, NNSA personnel briefed the Board on the results of the Operational Readiness Review for the Confinement Vessel Disposition Project and the path forward to commencing nuclear operations.

Weapons Engineering Tritium Facility (WETF): On Monday, WETF management declared a Potential Inadequacy of the Safety Analysis (PISA) regarding the as-found calibration check results for the Oxygen Monitoring System (OMS). The approved safety basis credits the OMS with a safety significant function to provide an early warning so operators can take action to prevent the formation of a deflagrable mixture in tritium gloveboxes and certain processing systems. Per the Technical Safety Requirements (TSR), facility personnel perform a semi-annual surveillance on the OMS oxygen sensors that includes an as-found calibration check, sensor replacement, and an as-left calibration. During the October surveillance, facility personnel determined 6 of 12 sensors failed the as-found calibration check in the non-conservative direction (i.e., readings were lower than expected). Subsequent to a written observation by the field office Facility Representative noting these failures and questioning the adequacy of the surveillance frequency, WETF management conducted a critique, determined the OMS was inoperable, and concluded that a PISA existed.

WETF management placed the facility in a safe condition per the TSR and plan to propose a more frequent surveillance interval to obtain improved data and understanding on sensor drifting as part of their evaluation of the safety of the situation. Facility personnel also plan to conduct the surveillance in the near-term to provide drift data near the one month point. The Site Representatives note the following additional pertinent information: 1) the sensor manufacturer recommends a calibration check every 2–4 weeks, and 2) operators must breach the glovebox confinement to access the oxygen sensors for calibration and replacement due to the design of the existing OMS. Facility personnel have initiated a design change package to upgrade the OMS electronics, but have not pursued changes to relocate the sensors to outside of the tritium-contaminated glovebox environment.

Area G – Safety Basis: The field office disapproved LANL's submittal of the two safety basis addendums for the Area G Basis for Interim Operations (BIO) (see 11/1/13 weekly). The addendums would have allowed operators to open sealed inner containers with bolted lids/flanges during Sort, Segregate, Size-Reduction, and Repackaging activities, and to perform Gas Generation Testing under a stand-alone safety basis. The field office directed LANL to resubmit the addendums as page changes incorporated into the existing BIO and TSR.

Plutonium Facility – Safety Basis: Last week, the field office transmitted comments to LANL on a recent safety basis update (see 10/18/13 weekly). A majority of the comments related to the new transuranic waste preparation and assay activities to be performed outside of the Plutonium Facility structure, but inside the TA-55 protected area. The field office directed LANL to resubmit the revision and a consolidated comment resolution document in a timely manner to support programmatic needs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 6, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 6, 2013

DNFSB Activity: Staff members Z. Beauvais, J. McComb, and R. Verhaagen attended a course on criticality safety conducted at LANL this week.

LANL Management: On Monday, Cheryl Cabbil assumed the role of Associate Director for Nuclear and High Hazard Operations.

Plutonium Facility – Criticality Safety: LANL recently submitted a report providing status and the path forward to the field office on the Plutonium Facility programmatic pause. The path forward includes two improvement plans: one focused on the institutional criticality safety program; and the second on Plutonium Facility conduct of operations and criticality safety improvements. The path forward identifies high-level areas for improvement; however, many key details and decisions that are needed to drive resolution of identified deficiencies have yet to be determined.

NNSA Oversight: Last month, the field office and laboratory jointly approved the Strategic Performance Evaluation Plan (SPEP) for fiscal year 2014. NNSA's approach for this SPEP is similar to last year with five performance objectives each supported by several broad contributing factors uniformly applied for all NNSA sites. These objectives are supplemented with a limited number of site-specific outcomes, including the following LANL outcomes of interest:

- Develop the plutonium strategy for the complex and advance recapitalization and modernization of the plutonium infrastructure at LANL.
- Implement revised plutonium disposition program goals and objectives for the complex; complete plutonium oxide production requirements at LANL; and achieve surplus fissile material program objectives.
- Demonstrate measurable improvements/maturation in the LANL safety culture; improve Nuclear and High Hazard Operations safety performance in areas including, but not limited to, formality of operations and safety basis implementation. Complete implementation of corrective actions to ensure long-term viability of the LANL criticality safety program.

Similar to last year, NNSA Headquarters management prohibited the development of additional criteria or metrics to assist in the objective evaluation of performance against the SPEP.

Weapons Engineering Tritium Facility (WETF): This week, the field office completed a Safety Evaluation Report (SER) that approves a revision to the WETF safety basis. The approval letter states that the proposed revision “constitutes an interim [safety basis] revision sufficient to enable restart of the WETF with the interim goal of inventory reduction of legacy radioactive material at risk.” Accordingly, the SER includes a condition of approval that limits the scope of programmatic operations after startup to legacy material disposition only. The current WETF safety basis has been revised numerous times but relies on a hazard and accident analysis approved in 2002. A new safety basis has been submitted and the field office has provided many comments; however, this document has not been approved (see 5/3/13 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 13, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending December 13, 2013

DNFSB Staff Activity: On Thursday, the staff conducted a teleconference with laboratory and field office personnel. The teleconference covered the status of actions taken in response to concerns with the safety basis for Area G described in a letter from the Board dated November 19, 2012.

Plutonium Facility–Criticality Safety: This week, a team of operations and criticality safety personnel visited Lawrence Livermore National Laboratory to benchmark best practices for a number of open issues (e.g., container labeling and postings). R. T. Davis observed the visit. Next week, the team will travel to the Y-12 National Security Complex for a similar visit.

On Wednesday, PF-4 personnel conducted a critique for a process deviation involving the presence of a geometrically unfavorable vessel (an inverted work/step platform) located in an aqueous plutonium processing room. An observer identified the platform during a tour conducted as part of last week's criticality safety course. The observer notified a facility criticality analyst; however, no actions were taken. The observer later notified the NNSA instructor who in turn notified the field office. The next day, field office personnel walked-down the location, identified the deviation, and notified the Operations Center. During the critique, PF-4 personnel determined the following key corrective actions: (1) perform an extent-of-condition review of the facility to identify other geometrically unfavorable portable vessels, (2) establish a systematic method to control such vessels in the facility, and (3) revise training to reinforce the expectation to notify the Operations Center for any potential anomalous condition.

Plutonium Facility–Seismic Safety: This week, PF-4 personnel began wrapping the captured columns with a fiber-reinforced polymer to improve the structural performance during a seismic event. LANL identified these columns, along with the roof girders, as deficient during the 2012 static non-linear seismic analysis. PF-4 personnel plan to complete the captured column upgrade in early-2014. Upgrade design for the roof girders, including peer review, is ongoing with plans to begin these upgrades in 2014. NNSA also continues to pursue the alternate static non-linear seismic analysis that may identify the need for additional facility upgrades.

Area G–Safety Basis: LANL recently responded to four field office directed actions that were captured in the Safety Evaluation Report (SER) that approved the Area G Basis for Interim Operation (BIO) in August 2013 (see 08/2/13 weekly). During the next BIO revision, LANL committed to eliminate risk reduction credit for safety management programs and instead identify appropriate specific administrative controls or safety structures, systems, and components. LANL also requested a delay of the next BIO submittal from February 2014 to March 2014.

RANT Shipping Facility–TRUPACT III Loading Enclosure (TTLE): Last week, the field office responded to the LANL's safety basis strategy and concluded that the TTLE represented a major modification per DOE-STD-1189 (see 11/8/13 weekly). The field office directed submittal of a preliminary documented safety analysis and a tailoring strategy for DOE-STD-1189. The field office also requested changes to institutional procedures to ensure an early formal determination for major modifications that is readily visible to federal oversight.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 20, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending December 20, 2013

Weapons Engineering Tritium Facility (WETF): This week, facility management announced the completion of the inventory of legacy tritium-containing items. This is an important first step in their effort to disposition tritium-containing items (see 10/4/13 weekly). Facility personnel continue to work on required restart activities including procedure finalization and operator training. Facility restart is necessary to disposition many of the tritium-containing items through the Tritium Gas Handling System. LANL has scheduled restart activities, including a management self-assessment, contractor readiness assessment, and a federal readiness assessment for early calendar year 2014.

Following a series of self-identified issues with work control, the WETF Facility Operations Director called for a safety pause on Wednesday morning. The issues were related to procedural compliance by both facility and non-facility contractor personnel. In one instance, a wall penetration was being performed without a prior ground penetrating radar scan as required by the work package. In another instance, workers completed steps of a preventive maintenance instruction without using a specified tool.

This week, the field office also provided direction to LANL regarding pressure safety issues that were identified during a safety system oversight review (see 4/26/13 weekly). The direction letter noted that many LANL approved variances for WETF safety significant systems may not be compliant with pressure safety requirements of ASME B31.3, *Process Piping*. As a result, LANL is directed to submit to the field office a list of variances that cannot be otherwise closed and will require DOE approval for either an equivalency or exemption from applicable codes requirements.

Contract Management: This week, the field office sent LANL direction regarding contractual implementation of DOE Order 420.1C, *Facility Safety*. DOE issued this version of the Order on December 4, 2012. LANL's original implementation plan included actions extending to September 2019. The field office requested a revised implementation plan by June 2, 2014, to include acceleration of the schedule, inclusion of the order revision into the code of record for new projects beginning this fiscal year, and revision of the Engineering Standards Manual for structural work and hazardous processes this fiscal year, among several other actions.

Federal Oversight: Last week, the field office transmitted to LANL the results of a vital safety system assessment for credited vehicle barriers at the WCRR Repackaging Facility, the RANT Shipping Facility, and Area G. The field office identified that vehicle barriers were not present for a ~25' length at RANT and at one pit location at Area G, contrary to the approved safety bases. They noted that these issues were discovered in early September 2013 and that LANL has yet to critique or enter the new information process. The field office also noted several safety basis issues, including concerns with the flow-down of requirements, non-specific or missing performance criteria, and inadequate surveillance requirements. The field office requested LANL's issue tracking system numbers associated with these issues within 15 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 27, 2013

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 27, 2013

LANL operations closed on Tuesday night for the annual winter holiday break. Operations will resume on January 2, 2014. The Site Representative office was closed Wednesday through Friday.

Chemistry and Metallurgy Research (CMR) Building–Exit Strategy: In guidance issued nearly two years ago (see 2/17/12 weekly), NNSA identified a revised target of approximately 2019 to complete the orderly phase out of programmatic activities from CMR. LANL planners currently indicate that the critical path to achieving this target includes actions to repurpose certain rooms in the Plutonium Facility (PF-4) to support analytical chemistry and materials characterization activities. LANL requires this repurposing because the new Radiological Laboratory Utility Office Building (RLUOB) will not provide all of the capabilities and associated capacities required to meet anticipated program commitments. The repurposing of PF-4 rooms will require: (1) removal of contaminated equipment from at least three rooms, (2) procurement and installation of new equipment into these rooms, (3) completion of readiness activities, and (4) validation of results against parallel testing performed on existing equipment in CMR.

The Site Representatives note that accomplishing the repurposing in the remaining five-year period will be challenging in an operating nuclear facility. In addition, recent Congressional direction may constrain the amount of repurposing work LANL can undertake until a line item project is established. If LANL cannot accomplish the repurposing in time, they will need to examine tradeoffs between continuing programmatic activities in CMR, utilizing off-site vendors, and limiting support to the program. In early 2014, NNSA expects to issue high-level program direction for this effort and an execution plan covering the RLUOB installation activities for the remainder of fiscal year 2014.

Radioactive Liquid Waste Treatment Facility (RLWTF): The field office recently issued a Safety Evaluation Report that approved a new Documented Safety Analysis (DSA) and Technical Safety Requirements. The RLWTF is a hazard category 3 nuclear facility that collects, stores, and processes low-level and transuranic liquid wastes. The new DSA replaces a safety basis that was developed and approved in 1995. Based on the analyzed potential consequences to the public and workers, no safety-related structures, systems, or components are identified; however, defense-in-depth controls in the DSA are identified as Other Equipment Important to Safety (OEITS) consistent with the LANL technical guidance (see 10/25/13 weekly). The safety basis also includes an overall facility material-at-risk limit of 55 Ci of americium-241 equivalent. RLWTF management is now pursuing implementation, including conduct of an Implementation Verification Review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 3, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 3, 2014

The laboratory was closed Monday through Wednesday this week for the annual holiday break.

Weapons Engineering Tritium Facility (WETF): LANL submitted a Justification for Continued Operation (JCO) based on the discovery of an increased probability of WETF Oxygen Monitoring System (OMS) failure to the field office for review and approval (see 11/29/13 weekly). The submitted JCO evaluates the safety of the situation and concludes that the facility is in a safe condition based on the immediate actions taken, which include placing the Tritium Gas Containment System and the Tritium Waste Treatment System low-pressure receiver in warm standby mode. The JCO specifies that a monthly as-found calibration check of the OMS will now be performed in addition to the semi-annual Technical Safety Requirement calibration check. During the first monthly as-found calibration check that was performed in December, several OMS sensors were again found out of calibration. WETF personnel continue to evaluate the OMS to determine the appropriate calibration method and frequency.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL recently submitted a request to the field office to use the Waste Mitigation Risk Management (WMRM) facility for influent low-level liquid waste storage in addition to its intended function of providing emergency space for low-level liquid waste. This request follows WMRM facility system modification and a Management Self Assessment to ensure readiness (see 8/6/13 and 9/14/12 weekly reports). Approval of the request will allow replacement of aging RLWTF tanks that do not meet regulatory requirements while maintaining sufficient capacity for low-level liquid waste storage under emergency conditions requiring facility or site evacuations (e.g. wildland fire conditions).

Plutonium Facility – Safety Basis: In December, the field office directed LANL to resubmit the 2013 annual update of the Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs) within 45 days. Although LANL submitted annual updates to the DSA and TSRs in 2012 and 2013, the field office has not approved an annual update since 2011. The 2013 annual update includes the following changes:

- Resolution of field office comments from the 2012 annual update that was not approved and comments included in the safety evaluation report
- Changes to address Potential Inadequacies of the Safety Analysis, Evaluations of the Safety of the Situation, and JCOs that have been identified for the Plutonium Facility
- Re-evaluation of the leak path factor for the seismic accident scenario and identification of new material at risk limits
- Incorporation of changes to address the Transuranic High Efficiency Neutron Counter (TRU HENC) operations (see 10/4/13 weekly)

The field office response requested LANL to remove the changes associated with the TRU HENC operations (the field office previously provided comments on these changes) and changes associated with a PISA for the ventilation and facility control system, which require additional analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 10, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending January 10, 2014

Criticality Safety: Last month, LANL released its *Criticality Safety Infractions Causal Analysis*, performed largely in response to the Board's July 15, 2013, letter to DOE on criticality safety at the Plutonium Facility. A six-person causal analysis team was appointed by the Laboratory Director to analyze a series of criticality safety infractions that occurred in the Plutonium Facility from January to August 2013. The team conducted interviews, performed walk-downs, and reviewed documents related to criticality safety infractions or process deviations that occurred during that time period. Overall, the team identified five root causal factors supported by 22 contributing causes, many of which appear applicable to other facilities and functional areas. The following is a list of some of the key contributing causes:

- Current efforts appear reactive, rather than executing to a strategic plan with prioritized actions
- Lack of robust communications reflects insufficient management attention to the causes of infractions and needed corrective actions
- Roles and responsibilities are not consistent, not flowed down, and not well communicated
- Unclear requirements and terminology identified during critiques have not been effectively evaluated and corrected
- Conduct of operations issues evident in criticality safety events are not probed to determine issues and corrective actions, including improvements needed in management
- Documented hazard analyses did not account for collocated hazards and controls
- Critique process and output is insufficient to drive enduring improvements
- Internal assessments are not used to self-identify issues and resolve them
- Corrective actions are vague and focus on actions that are near-term and easier to achieve
- Lessons learned information does not provide clear operational insight, nor is it adequately communicated and implemented

Training: This week, the site reps observed an oral board for a criticality safety analyst (CSA) qualifying in the 300 area of the Plutonium Facility. The qualification process for CSAs at LANL is a three part process that includes a training curriculum for criticality safety technical knowledge, a requirement to demonstrate facility specific knowledge, and a practical exercise to demonstrate competency at performing criticality safety evaluations. The board conducted a thorough examination of the qualifying CSA's knowledge of general facility and 300 Area specific process and criticality safety. The board concluded that the qualifying CSA demonstrated acceptable knowledge.

Plutonium Facility – Safety Basis: The field office provided feedback to LANL this week on resolution of two conditions of approval from the 2011 Safety Evaluation Report associated with process descriptions and Hazard Analysis (HA). The latter requires LANL to revisit the process hazard analyses for operations at the Plutonium Facility to ensure a comprehensive evaluation of accident scenarios. The HA development process and results were submitted to the field office in September 2013 and include hazard scenario development, hazard identification, and control identification. Following resolution of field office comments, the HA results will be used to support the 2014 safety basis annual update that is scheduled to be submitted in September 2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 17, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending January 17, 2014

Criticality Safety: Dr. Jerry McKamy completed his first two-week onsite visit to support the field office and LANL Director on criticality safety issues. His detail runs through June 2014.

Last month, LANL issued an update to their staffing plan for criticality safety. For fiscal year 2014, the plan shows an analyzed need of 20.75 full time equivalent personnel with 13.25 currently acquired. As of this week, the qualification status includes one full-time analyst qualified for all facilities, two analysts qualified for individual portions of the Plutonium Facility, and one analyst qualified for the Chemistry and Metallurgy Research Building. In addition, there are six new hires currently qualified to perform calculations along with seven part-time and sub-contractor personnel with various qualifications to supplement these analysts.

Training: On Tuesday, the Site Representatives observed a demonstration of virtual facility familiarization and training software in development by LANL for Los Alamos County Fire Department personnel. LANL is using modern commercial software used by the video game industry to create realistic, high fidelity models of high-hazard facilities. The training contains pre-defined tours, as well as interactive, multi-person capability that includes simulated glovebox firefighting and contamination control. LANL representatives believe this capability is the first in the DOE complex and expect to release the software for the Plutonium Facility at the end of February 2014. The Site Representatives note the potential to utilize these software models for a variety of other training applications.

Plutonium Facility: LANL convened its Joint Evaluation Team this week to review certain paused activities to determine their potential need for readiness assessments prior to restart. Three hazard category 2 activities were evaluated and assessed to require federal readiness assessments if they are not resumed within one year of their last performance. These activities include: pyrochemistry processing, last performed in May 2013; foundry operations, last performed in June 2013; and aqueous processing, last performed in January 2014. Plutonium Facility personnel are evaluating the appropriate scope for these activities.

Radiological Laboratory, Utility, and Office Building (RLUOB): This week, RLUOB management received approval to begin cold (non-radiological) chemical operations in the laboratory areas. Pre-start findings applicable to cold chemical operations that were identified in the Management Self-Assessment completed last year have been closed (see 5/31/13 weekly). RLUOB personnel plan to start these operations next week and continue worker training, procedure improvements, and equipment qualification. Currently, radiological operations are scheduled to commence this summer. During RLUOB construction, only a limited number of laboratory rooms were outfitted with analytical chemistry equipment. LANL continues to pursue plans for outfitting additional laboratory space and increasing the facility material limit to 38 grams of plutonium-239 equivalent consistent with the NNSA supplemental guidance to DOE Standard 1027.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 24, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending January 24, 2014

Federal Oversight: This week, the acting field office manager announced that on an interim basis, the Assistant Managers for Safety Operations and Field Operations will be combined under a single manager. To support this larger group, NNSA is pursuing a deputy position that will be initially filled as a local detail assignment. In addition, the acting manager identified that an expression of interest will be released for a detail assignment as the senior safety and technical advisor position. This position is expected to be permanently assigned in the near future. The field office also released a report that determined the need for 15 facility representatives with a current staffing of 11.

Confinement Vessel Disposition (CVD) Project: Last Friday, LANL submitted to the field office for review and approval a corrective action plan for the CVD Operational Readiness Review completed in October 2013. LANL personnel conducted a causal analysis in order to inform the identified corrective actions (see 11/22/13 weekly). Of note, the causal analysis attributed a large number of the findings to management guidance and expectations not being clearly defined, understood, or enforced. LANL management is tracking to closure all pre-start and post-start findings using the Performance Feedback and Improvement Tracking System. All pre-start findings are currently scheduled to be complete by April 15, 2014. Chemistry and Metallurgy Research Building management evaluated all post-start findings and concluded that none pose risks that would require additional compensatory measures or mitigating actions to support startup of CVD operations.

Weapons Engineering Tritium Facility (WETF): On Wednesday, LANL personnel briefed the field office on the status of their efforts to disposition legacy items containing tritium. WETF personnel noted that their cataloging effort revealed more than 1100 items requiring disposition. As part of this effort, workers photographed, analyzed, and researched each item in order to support binning into one of several disposition solution packages. LANL plans to disposition about 150 tritium items, containing a total of less than 10 g of tritium, in the remainder of fiscal year 2014. As explained during the briefing, LANL will be unable to achieve substantial inventory reductions until the facility completes readiness activities and receives field office authorization to resume operations, which is currently scheduled to occur in the next few months. WETF personnel will then need to remove tritium from the Tritium Load-in Glovebox to facilitate installation of new mercury removal traps and load-out equipment. This equipment is required to process many of the bulk-tritium containing items into a form acceptable for shipping to the Savannah River Site. Design of the traps, which may require additional safety basis changes and readiness activities, is currently underway.

Last Friday, LANL submitted to the field office a revised Justification for Continued Operations (JCO) regarding the Oxygen Monitoring System (OMS) (see 1/3/14 weekly). The revised JCO continues to propose a monthly surveillance and calibration check of the system as a compensatory measure for the observed decrease in OMS sensor reliability. The JCO notes that the system would not be declared operable until WETF management ensures the sensors will remain in calibration for at least 30 days. To-date, WETF personnel have performed two 30-day calibration checks and observed calibration issues with several sensors during each check. WETF engineers are attempting to troubleshoot and resolve these problems. An operable OMS will be needed to support the disposition of legacy items discussed above.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 31, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 31, 2014

DNFSB Staff Activity: This week, staff members Dunlevy and McCoy conducted a review of the Area G safety basis. As a result of questions raised by the staff, Area G management declared a Potential Inadequacy of the Safety Analysis (PISA) and entered a second issue into the New Information process to screen it for status as a PISA. On Wednesday, the Site Representatives attended a meeting of the Northern New Mexico Citizens' Advisory Board focused on transuranic waste disposition activities at Area G.

Federal Oversight: Effective this week, Ms. Kimberly Davis Lebak is the manager of the field office. On Wednesday, the field office issued the annual workforce staffing analysis for the safety engineering team. The analysis indicates a full on-board complement of four safety system oversight engineers, one technical training specialist, and one maintenance manager; however, the analysis also identifies a shortfall of two fire protection engineers.

Contract Management: On Wednesday, NNSA released the fiscal year 2013 Performance Evaluation Report that details the basis of the fee determination for LANL. Overall, LANL earned an 89 % with a 49 % for Operations and Management, which covers most nuclear safety related topical areas.

Plutonium Facility–Seismic Safety: PF-4 personnel completed actions to wrap the captured short columns with fiber-reinforced polymer (see 12/13/13 weekly). This action improved the ability of the facility to withstand a seismic event. Design activities are underway to wrap the roof girders, which is the next significant structural improvement planned to commence later this year.

Plutonium Facility–Safety Basis: On Monday, the field office forwarded to NNSA Headquarters for approval a revised Safety Evaluation Report (SER) for the *TA-55 Documented Safety Analysis Addendum in Response to Nonlinear Seismic Analysis Results*. The field office recommended approval of the revised SER, which incorporates the results of LANL analysis of the facility structural performance against Section 9.3.6 of DOE-STD-1020-2012. The field office also noted that LANL's analysis methodology of combining fragilities may go beyond the intent of the standard for existing facilities and therefore may warrant additional Headquarters guidance.

Plutonium Facility–Criticality Safety: Last Friday, LANL submitted to the field office for approval a listing of 45 fissile material operations (FMOs) assessed to have an adequate technical basis to support resumption. This list builds upon the previous list of 228 FMOs approved by the field office last November (see 11/15/13 weekly). For these FMOs, LANL has concluded that there is adequate technical basis to have high confidence that the currently identified criticality safety controls are adequate. Several of the FMOs in these lists rely on alternative evaluations types that do not meet DOE expectations for criticality safety evaluations. LANL personnel are currently developing modern technical bases intended to facilitate rapid issuance of compliant evaluations; however, they do not intend to use these bases to develop compliant evaluations for the low risk operations until sometime after operations have resumed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 7, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending February 7, 2014

DNFSB Staff Activity: On Thursday, R. T. Davis deployed to the Waste Isolation Pilot Plant to monitor the investigation of the underground fire involving a salt handling truck.

Chemistry and Metallurgy Research (CMR) Building–Exit Strategy: Last month, the NNSA Office of Defense Programs issued a memorandum transmitting the government’s strategy for plutonium infrastructure investments at LANL. The strategy consists of three steps: (1) maximizing the use of the Radiological Laboratory Utility Office Building (RLUOB), (2) reusing space in the Plutonium Facility (PF-4), and (3) evaluating options to extend the lifetime of PF-4 through modular additions. The strategy notes that the first two steps are required to cease programmatic operations in CMR. These steps entail implementing NNSA’s Supplemental Guidance for DOE-STD-1027 to increase the material-at-risk limit in RLUOB from 8.4 g to 38.6 g of Pu-239 equivalent, outfitting about 11 laboratory rooms in RLUOB with analytical chemistry capabilities, and removing existing equipment and re-equipping four rooms in PF-4 with analytical chemistry and materials characterization capabilities (see 12/27/13 weekly). The strategy indicates that initial funding will be used to develop pre-conceptual design documentation and a resource-loaded schedule. NNSA does not specifically commit to an acquisition approach and notes that the use of operating expense funds or the more rigid Major Item of Equipment approach (an acquisition type included in DOE Order 413.3 for equipment with little installation cost) provides the execution speed needed to reduce risk exposure in CMR before it either needs additional infrastructure investment or simply fails.

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a Technical Safety Requirement (TSR) violation after personnel discovered three secondary tritium containment vessels with open valves. These safety class vessels cannot perform their credited containment function with open valves. WETF received these legacy vessels in the 1990’s from another technical area at LANL. Personnel discovered the first vessel with an open valve in October 2013 during an inventory of legacy tritium items and did not recognize that this condition represented a safety basis issue. Following discovery of a third vessel with an open valve in January 2014, a worker notified a WETF manager, who then directed capturing the issue for later review. In February, the WETF Management Review Board tasked a safety basis analyst to consider the need to declare a Potential Inadequacy of the Safety Analysis (PISA). Subsequent to declaring the PISA, WETF management critiqued the issue and determined that the condition represented a TSR violation. The critique revealed that personnel had verified 30 additional similar vessels have closed valves, but identified the need to verify other vessel types have closed valves and to revise procedures to ensure that valves are closed following all work with containment vessels.

Safety Basis: Last Friday, LANL submitted to the field office a safety basis improvement plan (see 11/15/13 weekly). The plan identified the need to develop several products including: a staffing strategy, upgraded qualification standards for analysts, revised institutional processes and procedures, a performance assurance plan, a site-wide safety basis to encompass all safety management programs, a Management Review Team to focus on communications and issue management with the field office, a revised technical document examining dispersion analysis for the site, a laboratory safety basis council, and a nuclear facilities risk assessment to facilitate resource allocation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 14, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 14, 2014

DNFSB Staff Activity: R. T. Davis remained deployed to the Waste Isolation Pilot Plant (WIPP) to monitor the accident investigation of the underground fire involving a salt handling truck.

Chemistry and Metallurgy Research (CMR) Building–Criticality Safety: LANL personnel identified two criticality safety infractions during the past two weeks. In one instance, workers were unable to determine readily whether material quantities complied with nuclear criticality safety limit approval (CSLA). In another instance, a supervisor identified that the combination of material types in a staging location did not comply with the applicable CSLA. In both cases, facility personnel took appropriate actions and facility management conducted critiques of the event. Facility management directed additional causal analysis to formally evaluate the root causes of these infractions. Facility management also requested an external team to conduct an extent of condition review. The review team is to determine whether issues identified in a causal analysis of criticality safety issues in the Plutonium Facility extend to CMR, as well as to evaluate the effectiveness of the flow-down and implementation of institutional criticality safety requirements.

CMR–Confinement Vessel Disposition (CVD) Project: This week, the field office approved LANL’s corrective action plan for the CVD Operational Readiness Review (see 1/24/14 weekly).

Plutonium Facility–Criticality Safety: On Monday, the field office concurred with the listing of 275 fissile material operations judged to have an adequate technical basis (see 1/31/14 weekly). The field office acknowledged compliance issues with some of these operations, but noted the issues do not have a substantive impact on nuclear safety due to the inherent criticality control provided by material mass, form, container requirements, and geometry.

Recently, criticality safety analysts completed a technical document defending the sub-criticality of 520 g of plutonium-239 in any form. This document is the first of several general case limits intended to provide a robust technical underpinning and an accelerated development time for new or revised criticality safety evaluations.

Startup and Restart: On Thursday, the field office approved the quarterly startup notification report with direction to LANL to conduct a federal readiness assessment (checklist type) for retrieval and storage operations of the corrugated metal pipes (CMPs). The CMPs are 20-foot long metal pipes that contain cemented nuclear materials and are currently in buried locations at Area G. The CMPs will ultimately require size reduction prior to disposition at the WIPP.

Area G–Safety Basis: On Thursday, facility management requested and received dispensation from the field office to the LANL requirement to evaluate New Information for applicability of a Potential Inadequacy of the Safety Analysis (PISA) within nine working days. In this instance, facility management entered the New Information process after a recent staff review (see 1/31/14 weekly) raised questions on the adequacy of vehicle barriers for stopping certain pieces of heavy moving equipment. Engineering staff require additional time to complete revised calculations to determine whether a PISA exists. In the interim, facility management restricted the movement of all heavy moving equipment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 21, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 21, 2014

DNFSB Staff Activity: R. T. Davis remained deployed to the Waste Isolation Pilot Plant to monitor the accident investigation of the underground fire involving a salt handling truck and the separate radiological contamination event.

Plutonium Facility–Criticality Safety: Last Friday, LANL released a *Resumption Strategy and Schedule* to the field office, headquarters, and various program sponsors. The strategy outlines a number of actions to strengthen, standardize, streamline, and sustain improvements to criticality safety and conduct of operations. A central element of many of these improvements is the development and use of robust technical basis documents analyzing sets of common material limits and conditions (see 2/14/14 weekly). In the near term, management intends to conduct pilots for each of the six currently identified standardized conditions, which will involve revisions to criticality safety evaluations, limit approvals, postings, and procedures, as appropriate. From a schedule standpoint, the strategy provides projections for a number of programmatic activities. Management believes this schedule is conservative and expects to achieve efficiencies, particularly through the implementation of the new standardized conditions. The first projected start date is March 31, 2014, for an enriched uranium metallography operation. The last projected milestone is the resumption of electrorefining operations by February 24, 2015. The schedule does not cover aqueous operations.

Criticality Safety: On Tuesday, LANL transmitted a revision of the institutional Nuclear Criticality Program document (SD130) to the field office for approval. The primary changes associated with this revision include: (1) establishing *de minimis* values for requiring a criticality safety evaluation, (2) clarifying requirements for postings, (3) making limit approval documents optional, (4) requiring criticality controls in procedures, and (5) allowing criticality limits to be set below the values established in the governing evaluation.

Weapons Engineering Tritium Facility (WETF): On Tuesday, the field office issued their Safety Evaluation Report for the deficiencies associated with the oxygen monitoring system (OMS) (see 1/24/14 weekly). The field office noted several quality problems with the submittal and provided further directed actions to the laboratory. The directed actions primarily require WETF personnel to utilize technically defensible trending data to verify the OMS remains in calibration during the 31-day period prior to declaring the system operable. The Site Representatives note that WETF instrumentation systems are not capable of providing trending data on the state of OMS calibration. Absent the ability to automatically collect this data, WETF management plans to take as-found calibration readings around the 21 and 31-day marks, the first of which should occur next week.

Readiness Reviews: Last week, LANL submitted a change to the laboratory procedure governing the conduct of readiness reviews (P115) to the field office for review and approval. This change was developed in response to lessons learned from the Federal Operational Readiness Review of the Confinement Vessel Disposition Project (see 10/11/13 weekly). Specifically, the change was made to ensure that adequate actions are taken to maintain operational readiness when an excessive amount of time elapses between readiness reviews.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 28, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending February 28, 2014

DNFSB Staff Activity: R.K. Verhaagen relieved R.T. Davis at the Waste Isolation Pilot Plant for the continued monitoring of recovery actions associated with the radiological contamination event.

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF personnel identified that three of eight sensors were out of specification during a calibration check of the Oxygen Monitoring System (OMS). This was the first calibration check since personnel made adjustments to the system earlier in the month. The calibration check is performed against the oxygen content of normal room air (~21 %) and a 3 % oxygen calibration gas. The failed sensors read as high as 25 % and as low as 6 % for room air. In accordance with field office direction (see 2/21/14 weekly), LANL is no longer authorized to continue restart activities for tritium processing and is required to submit to the field office a technical strategy for resolving the OMS problems. Based on the 26-year-old age of the system hardware, the observed failures in both directions, the inconsistencies in the sensors that are failing, and the lack of success with attempted corrective actions, WETF management has determined to upgrade the system hardware to digital. The Site Representatives note that the digital system will continue to rely on electrolyte-based sensors and such sensors have been problematic in similar applications at the Savannah River Site.

Criticality Safety: On Monday, the field office approved without condition the revision to the institutional Nuclear Criticality Safety Program document (SD-130) (see 2/21/14 weekly).

Plutonium Facility–Criticality Safety: On Monday, the LANL Director approved a request to delegate resumption release authority for 106 fissile material operations (FMOs) to the Principle Associate Director for Weapons Programs. These 106 FMOs were part of the 275 FMOs recently approved by the field office as having adequate technical bases despite some known non-compliances (see weekly 2/14/14). These FMOs involve vault locations and the storage, staging, non-destructive assay, and certain glovebox operations involving a single pit or containerized items. Previously, the LANL Director delegated release authority for all FMOs involving less than 520 g of plutonium to the Associate Director for Plutonium Science and Manufacturing (see 10/22/13 weekly). Overall, the number of delegated FMOs represents about 160 of the more than 400 FMOs in the Plutonium Facility. To support these delegations, Plutonium Facility management intends to revise the release resumption process to allow these FMOs to defer certain corrective actions related to criticality safety to post-resumption as long as the actions are captured in the Performance Feedback Issues Tracking System.

Area G–Safety Basis: Last week, the field office approved without conditions revision 2.3 of the Basis for Interim Operations and associated Technical Safety Requirements. This week, LANL personnel independently verified the revision as implemented. Notably, this revision allows Area G personnel to vent certain sealed pencil tanks that require processing as part of the 3706 Campaign. Overall, Area G management expects to complete processing of all 3706 waste by mid-March and complete final assay and certification in April. At that point, all 3706 waste will be ready for offsite shipment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 7, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 7, 2014

DNFSB Staff Activity: R. T. Davis returned to the Waste Isolation Pilot Plant to relieve R.K. Verhaagen for the continued monitoring of recovery actions associated with the radiological contamination event.

Criticality Safety: On Wednesday, LANL transmitted to the field office a project management plan for *Nuclear Criticality Safety Program Upgrades*. This institutional plan consists of a compilation of criticality safety issues and their associated Performance Feedback and Issues Tracking System numbers going back to 2005. Each issue is grouped within five separate sub-projects focused on the following areas: (1) developing the Nuclear Criticality Safety Program (NCSP), (2) establishing a revitalized Nuclear Criticality Safety Committee, (3) establishing a strong partnership between operations and the NCSP, (4) implementing checks and balances to ensure the NCSP attains and maintains full compliance with applicable requirements, and (5) implementing a performance assurance plan to support NCSP evaluation and continuous improvement. LANL is currently working to develop a resource-loaded schedule for each of the five sub-projects, which cumulatively contain about 200 separate actions.

Plutonium Facility: This week, program personnel nearly completed the last aqueous operations required to place the facility in a safe and stable configuration as part of exempted activities under the Director's pause. Specifically, personnel cemented the evaporation residuals from several hundred liters of low plutonium concentration solutions generated during an ion exchange operation that completed at the onset of the pause in late June 2013. The work crew encountered numerous difficulties associated with their procedures, training, and equipment, which resulted in the protracted time line. They expect to complete the final two cement drums next week.

Radiological Safety: Last week, the Confinement Vessel Disposition (CVD) project personnel received a briefing from a Six Sigma Blackbelt regarding the results of a recent study aimed at decreasing the number of glovebox glove breaches. The study focused on the causes of the 65 glove breaches that occurred at the Plutonium Facility from July 2011 to September 2012. The study identified that the leading cause of breaches was latent sharps, in particular work involving bolts, corroded/oxidized metal, and tube cutters. Plutonium Facility personnel are currently developing corrective actions based on the findings. The Site Representatives note that facilities other than the Plutonium Facility would benefit from corrective actions, including training based on the results of the study that provides more than awareness. For example, the identified latent hazards are prevalent during the CVD operation.

Area G–Radiological Safety: On Monday evening, a worker who had cleared multiple radioactive contamination surveys detected contamination on his boots during a final elective survey he performed for peace of mind. Follow-up surveys then detected contamination on his cheek. Radiological control personnel were able to decon both areas. On Tuesday afternoon, facility management conducted a critique of the incident. The critique identified issues with protective clothing doffing, survey practices and responses by radiological control personnel, and worker positioning in contamination survey equipment. Notably, the critique identified that documentation did not include the expectation that radiological control assistance be provided during the entirety of the doffing process for individuals when contamination is detected on outer protective clothing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 14, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 14, 2014

DNFSB Staff Activity: R. T. Davis remained deployed to the Waste Isolation Pilot Plant for the continued monitoring of recovery actions associated with the radiological contamination event.

R.K. Verhaagen and J.W. Plaue were at DNFSB Headquarters to provide the Board with a periodic status briefing on the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 21, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 21, 2014

DNFSB Staff Activity: R.T. Davis, R.K. Verhaagen, and B. Broderick continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant.

Plutonium Facility–Criticality Safety: On Tuesday, facility management declared a Potential Inadequacy in the Safety Analysis based on New Information in the form of completed calculations that indicate the potential to flood a glovebox from sprinkler water through either a burned glove or an inlet filter. Criticality analysis and current inventory information further indicate about 24 locations that may not remain subcritical in a flooded condition. Immediate compensatory actions taken include: (1) ensuring immediate orderly exit from the facility upon receipt of a fire indication, (2) advising responding fire fighters of the situation, and (3) prohibiting the aggregation of more than 4500 g of fissile material in a single location. Personnel are also determining whether additional physical actions are needed to achieve a safe and stable configuration in the 24 locations.

Plutonium Facility–Safety System Degradation: On Monday, facility management reported and then critiqued the discovery of breached elastomeric sealing boots on a glovebox used to perform equation-of-state measurements. During the critique, personnel discussed the fact that these boots were not recognized as part of the safety significant confinement boundary. As a result, specification information, preventative maintenance protocols, and critical spares were not available. Critique personnel did not discuss what contributed to this gap or the need to perform an extent-of-condition review to determine if other unique pieces of confinement equipment were similarly uncontrolled. Program personnel discussed the desire to proceed with a temporary modification to the degraded boots involving tape, plastic bags, and additional radiological controls to support measurements for a near-term milestone.

At the Plutonium Facility, gloveboxes are considered Design Features and are not provided with Limiting Conditions for Operations (LCO). The Site Representatives note that other sites (e.g., LLNL) provide LCO coverage for Design Features as a best management practice.

Plutonium Facility–Unique Capabilities: The Special Recovery Line (SRL) is a unique capability within the NNSA complex to process an inadvertently boosted pit. Recently, LANL managers briefed the results of a study on the future of the SRL to NNSA Headquarters. The study, completed last summer, recommends processing the items currently stored at LANL during the next few years and then no longer maintaining the capability. LANL noted that about 5 to 7 years would be necessary to reconstitute a SRL-like capability once lost and further recommended that NNSA establish the equipment, procedures, and trained personnel to respond in the event that a pit is inadvertently boosted.

Weapons Engineering Tritium Facility (WETF): WETF personnel completed the second week of their management self-assessment in preparation for upcoming readiness reviews. Meanwhile, engineering staff continued efforts to replace the modules for the inoperable Oxygen Monitoring System (OMS) (see 2/28/14 weekly). Last week, WETF submitted to the field office a revised Justification for Continued Operations that asserts the OMS can be declared operable following replacement of the modules without further in-service testing, despite no firm evidence that the replaced modules were the cause of previous failures. WETF has also yet to declare whether operability of the OMS will be a prerequisite to commencing the contractor readiness assessment projected to start on March 31, 2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 28, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 28, 2014

DNFSB Staff Activity: R.K. Verhaagen continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant (WIPP). M.P. Duncan and P.J. Foster observed the weeklong Construction Project Review (CPR) for the Transuranic Waste Facility project. On Thursday, B.A. Laake and R.P. Arnold met with LANL personnel to discuss weapons response.

Area G–Operations: Last week, Area G personnel completed processing the final waste packages associated with the 3706 Campaign. Final assay for these packages should occur in early April. Next week, Area G personnel plan to commence shipping transuranic waste packages to Waste Control Specialists in Andrews, Texas for interim storage until the WIPP can resume accepting waste.

Area G–Safety Basis: Last Friday, Area G personnel submitted to the field office an Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy in the Safety Analysis (PISA) concerning unanalyzed pool fires involving drums containing 100 % combustible waste. This PISA was declared subsequent to the Board’s staff review (see 1/31/14 weekly). The ESS notes an operational restriction on the receipt of newly generated waste and anticipates resolution as part of a safety basis page change expected to be submitted to the field office next week.

Plutonium Facility–Criticality Safety: Facility personnel completed additional analysis of the current conditions related to the PISA concerning unanalyzed flooding (see 3/21/14 weekly). Based on this analysis and as part of further immediate compensatory actions to achieve a safe and stable condition, facility personnel plan to move fissile material from about eight locations and place further restrictions maintaining containerization and prohibiting the addition of fissile material to several other locations.

Weapons Engineering Tritium Facility: Facility personnel completed installation of the new digital modules for the Oxygen Monitoring System and briefed the field office on their proposal to declare the system operable following post-maintenance testing (see 3/21/14 weekly). The field office did not agree with this basis and is expected to direct in-service testing prior to an operability declaration as a condition of approval for the revised ESS. As a result, the contractor readiness assessment will be delayed until early May. Separately, facility personnel requested and received from the field office a 15-day extension to the 9-day requirement for processing New Information related to potential errors in the hydraulic calculations underpinning the required riser pressure limit.

Transuranic Waste Facility (TWF): This week, NNSA performed a CPR to ensure the TWF project is ready to complete construction to meet the baseline technical scope within the approved cost and schedule. The CPR team identified a number of specific recommendations that require resolution and provided the following summary conclusions: (1) the project is ready for final preparations for Critical Decision-3, *Approve Start of Construction*; (2) the project can be completed by January 2018 within the current total project cost; and (3) additional resources are needed for both the federal and contractor project teams. NNSA review of CD-3 is scheduled to occur in May or June 2014.

Criticality Safety: On Tuesday, the LANL Director approved a charter for a revised Institutional Nuclear Criticality Safety Committee. Notably, the committee includes an external member from LLNL.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 4, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending April 4, 2014

DNFSB Staff Activity: R.T. Davis and R.K. Verhaagen continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant (WIPP).

Area G–Operations: Area G completed five shipments of transuranic waste packages to Waste Control Specialists in Andrews, Texas for interim storage until the WIPP can resume accepting waste. Area G personnel also completed the last offsite shipment of low-level waste associated with 3706 Campaign.

Plutonium Facility–Criticality Safety: Facility and program personnel continued planning for additional immediate actions associated with achieving a safe and stable configuration (i.e., removing excess fissile material from about eight locations) required by the Potential Inadequacy in the Safety Analysis (PISA) declared on March 18, 2014. Personnel expect the material movements to require at least another week resulting from difficulties finding movement paths and receipt locations caused by locations filled to their limits.

Weapons Engineering Tritium Facility (WETF): On Thursday, WETF management declared a PISA resulting from errors discovered by the field office in the hydraulic calculations supporting the safety significant fire protection system (see 3/28/14 weekly). The PISA indicates that the minimum riser pressure required by the Technical Safety Requirements may not be sufficient to support the most limiting demand. WETF personnel declared the system inoperable and entered the Limiting Condition of Operation, which requires a 24-hour fire watch performed on an hourly basis. During the critique required for the PISA, WETF personnel identified that: (1) calculations require update, (2) drawings require verification of as-built pipe sizes and lengths to support accurate revised calculations, (3) trending of water supply data indicates degradation and the need to investigate, and (4) upstream water supply valve lineups needed an expedited annual verification and an improperly sized component in the line requires analysis.

WETF personnel observed greater than expected electronic noise in the system associated with the newly installed digital modules for the Oxygen Monitoring System (OMS). For some modules, the magnitude of the noise was sufficient to result in spurious alarms. WETF personnel consulted with the manufacturer and determined that modifications to the electronics are necessary. The impact of this situation on the schedule for the contractor readiness assessment is unclear as the submitted plan of action does not list operability of the OMS as a prerequisite.

Conduct of Engineering: On Thursday, field office management concurred with LANL's declaration of implementation of the core elements of Conduct of Engineering at WETF. This action completes the final nuclear facility to achieve this status under the *Integrated Formality of Operations at LANL Project Plan* issued in November 2006.

Radiological Facilities: Last month, LANL personnel completed a study of the 124 previously identified radiological facilities across the laboratory. Conclusions of note include: (1) the listing was inaccurate, (2) more than half of the facilities could be delisted if surveys were performed to confirm that no legacy radioactive materials remained, (3) a need to establish a *de minimus* threshold for Radiological facility status, and (4) an additional 30 percent could be delisted by applying the *de minimus* threshold, creating a temporary Radiological facility provision, and creating a mechanism to consolidate operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 11, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 11, 2014

DNFSB Staff Activity: R.T. Davis continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant.

Plutonium Facility–Criticality Safety: On Tuesday, LANL transmitted to the field office for approval a combined Evaluation of the Safety of the Situation and Justification for Continued Operations (ESS/JCO) in response to the criticality concerns associated with firewater flooding (see 3/21/14 weekly). The ESS/JCO notes the potential to flood a glovebox through burned gloves during a fire and through inlet air filters or compromised windows during an actuation of the fire suppression system. The document further acknowledges that LANL has not analyzed more than 200 fissile material operations for this credible off normal event, as required by LANL and DOE requirements. The ESS/JCO proposes safe continued operations for this scenario with two compensatory control sets; one based on a 4500 g limit with some additional restriction and the other based on a 520 g limit. The ESS/JCO does not articulate how LANL will integrate these compensatory limits into their overall resumption process.

On Wednesday, program personnel completed the first movements of fissile material required as an immediate action for the Potential Inadequacy in the Safety Analysis associated with flooding. Also on Wednesday, facility operators received the timely order associated with additional immediate actions.

Chemistry and Metallurgy (CMR) Building–Safety Basis: On Monday, CMR management transmitted to the field office for approval safety basis changes required to resolve pre-start findings from the Operational Readiness Review for the Confinement Vessel Disposition project.

CMR–Exit Strategy: On Monday and Tuesday, the NNSA Associate Administrator for the Office of Acquisition and Project Management (APM) visited LANL to initiate planning activities associated with implementation of the plutonium strategy. In a memo dated March 27, 2014, the Acting NNSA Administrator tasked APM with the responsibility of managing investments in plutonium infrastructure. The memo included a reaffirmation of the commitment to cease programmatic operation in the CMR building by the end of calendar year 2019 and notes that all 3 phases of the plutonium strategy will be executed in a manner fully compliant with DOE Order 413.3B, *Program and Project Management for the Acquisition of Capital Assets*. The memo tasks APM with providing an initial execution plan by June 30, 2014. LANL and field office personnel have begun forming integrated project teams in support of this effort. Based on discussion during the visit, NNSA expects to execute the first two steps of the strategy as new subprojects to the existing Chemistry and Metallurgy Research Replacement project line item. During the summer, NNSA plans to evaluate these steps as part of a reaffirmation of CD-1, *Approve Alternate Selection and Cost Range*. These steps are (1) equipping additional laboratory rooms in the Radiological Laboratory Utilities Office Building and (2) repurposing laboratory rooms within the Plutonium Facility.

Weapons Engineering Tritium Facility (WETF): On Wednesday, the field office formally rejected the revised ESS/JCO associated with the Oxygen Monitoring System (OMS) issues (see 3/21/14 weekly). The field office noted that the upgrade of the modules from analog to digital did not automatically resolve the issue and that post-upgrade trending was necessary to support an operability declaration. The field office directed LANL to determine the root cause of the OMS issues, demonstrate resolution through data trending, and request field office approval prior to declaring the OMS operable.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 18, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 18, 2014

DNFSB Staff Activity: R.K. Verhaagen and B.P. Broderick continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant.

Emergency Management: On Thursday, Plutonium Facility personnel participated in the annual emergency response exercise required by DOE Order 151.1C, *Comprehensive Emergency Management System*. This year's scenario was a nuclear criticality. Accordingly, the exercise also fulfilled the exercise requirement in ANSI/ANS-8.23-2007, *Nuclear Criticality Accident Emergency Planning and Response*. In addition to the immediate evacuation of personnel from the facility, the scenario included two injured workers, radiation levels encountered at a muster point, and a vehicle access gate that did not open as intended to facilitate response by the Los Alamos County Fire Department. During the post-exercise critiques, participants noted numerous opportunities for improvement, particularly with respect to communications between the Facility Incident Command, Incident Command, Facility Operations Center, and simulated Emergency Operations Center. Emergency Management personnel will develop an after-action report detailing these observations and providing corrective actions.

Plutonium Facility–Criticality Safety: On Monday, Plutonium Facility personnel briefed members of the institutional Nuclear Criticality Safety Committee on the implementation approach for the Evaluation of the Safety of the Situation/Justification for Continued Operations submitted to the field office last week. The committee expects to issue a formal position on this approach. On Wednesday, program personnel completed movements of fissile material required as immediate actions to place the facility in a safe and stable configuration (see 4/11/14 weekly).

Plutonium Facility: On Monday, facility personnel identified 13 containers that were potentially not included in the material-at-risk (MAR) surveillance required by the safety basis. Facility management entered the applicable limiting condition for operation until the containers could be included and verified to comply with the surveillance limits. During investigation of the issue, the system engineer determined that the software used to perform the surveillance (MAR Tracker) does not properly evaluate containers that are nested beyond a certain level. A software correction has been implemented.

Chemistry and Metallurgy Research (CMR) Building–Safety Basis: On Wednesday, the field office approved revision 3.2 of the CMR safety basis required to support startup of the Confinement Vessel Disposition project. CMR management briefed the field office that they expect to initiate disposition of the first sphere by June 14, 2014.

Transuranic Waste Facility Project: On Thursday, the field office transmitted to LANL a letter approving the exemption request from the requirement in DOE Order 420.1B, *Facility Safety*, to provide fire protection to the safety-class seismic switches. The safety function of these seismic switches is to isolate electrical power from certain portions of the facility during a design basis seismic event to prevent an electrical fault fire. NNSA-HQ approved the request with the concurrence of the Central Technical Authority and provided the following recommendations: (1) verification that the as-built conditions reflect those stated in the exemption request, (2) marking the area around the switches using paint and signage, and (3) implementing an administrative control for combustible materials prior to operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 25, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending April 25, 2014

DNFSB Staff Activity: D.N. Kupferer, J.C. McComb, and J.A. Pasko conducted an onsite review of progress made toward resolving the criticality safety and conduct of operations issues in the Plutonium Facility. J.A. Pasko and the Site Representatives also walked-down the recently completed seismically strengthened columns and work sites for near-term upgrades to the roof girders in the Plutonium Facility. R.T. Davis continued monitoring the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant.

Nuclear Environmental Sites: On Monday, LANL transmitted to the field office the results of a positive Unreviewed Safety Question Determination (USQD) regarding the planned demolition of a water tower in TA-21. The water tower, a 175 ft tall and about 1452 ton structure, sits in proximity to Material Disposal Area T and Material Disposal Area A, known as the General's tanks. The DOE Office of Environmental Management has separately contracted to demolish the water tower and tasked LANL to perform the USQD given the collocated Nuclear Environmental Sites. The USQD identified the planned demolition could increase the probability of occurrence and consequences of postulated accidents, as well as an increase in the probability and consequences of malfunction of safety equipment. The field office is determining a path forward.

Criticality Safety: Last week, LANL responded to the field office regarding the institutional *Nuclear Criticality Safety Program Upgrades* plan (see 3/7/14 weekly). This institutional plan is one of the two plans that collectively constitute the overall improvement effort documented in NNSA's response to the Board dated December 6, 2013. LANL indicated they will submit a revision of the institutional plan addressing the field office comments, including the need for a resource-loaded schedule, by June 30, 2014.

Plutonium Facility–Criticality Safety: Facility personnel performing a confirmatory neutron measurement on a standard waste box (SWB) identified that the measured value exceeded the limits specified by the criticality safety evaluation by a factor of nearly two. The measured value also exceeded the combined, individual measured values of the items inside the SWB by a factor of nearly four. Workers took the correct immediate actions to secure the area, back off, and make notifications. During a critique, facility personnel questioned the adequacy of the calibration of the equipment and agreed to reconvene to determine a path forward for confirming the contents of the SWB. The Site Representatives note that critique personnel did not bring or review as part of the critique the calibration procedure, the procedure for assaying the waste, or the procedure for loading the SWB.

Weapons Engineering Tritium Facility (WETF): On Thursday, LANL submitted to the field office the Evaluation of the Safety of the Situation (ESS) regarding the potentially inadequate firewater riser pressure (see 4/4/14 weekly). The ESS notes that a revised hydraulic calculation supported by new field measurements indicates the current required minimum pressure is adequate as currently written. The facility remains in a 24-hour fire watch performed hourly until the field office approves the ESS.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 2, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 2, 2014

DNFSB Staff Activity: R.T. Davis turned over to DNFSB Headquarters personnel the continued monitoring of the recovery associated with the radioactive material release event at the Waste Isolation Pilot Plant (WIPP).

Area G: On Thursday, the WIPP contractor declared a potential inadequacy of the safety analysis (PISA) concerning the postulated role of untreated nitrate salt waste materials contributing to the radioactive material release event. Given the nitrate salt waste originated at LANL, Area G management conducted a critique on Friday to review the situation. Critique participants determined about 105 waste containers potentially holding nitrate salts are currently stored at Area G. Area G management conservatively decided to control these containers as if they were unvented and transferred all of them except those currently in shipping containers and those that have not been remediated to a dome with a functional fire suppression system. In addition, Area G personnel will perform periodic thermography to determine the presence of any exothermic chemical reactions until the situation at WIPP is understood.

The critique participants also discussed the processing history for these salts, which are bottoms from an evaporator used in the aqueous nitric acid process at the Plutonium Facility. They confirmed that workers treated these materials in accordance with a procedure consistent with direction from WIPP's Difficult Waste Team. Separately, LANL management intends to standup a war room and deploy a senior management liaison to WIPP to facilitate the ongoing investigation.

Weapons Engineering Test Facility (WETF): This week, WETF personnel completed the 30-day surveillance associated with the PISA (see 4/11/14 weekly) on the oxygen monitoring system (OMS) and observed continued problems with the system. WETF personnel now believe there are problems with the recently installed new digital modules and are working with the vendor to develop a path forward. The OMS system has been inoperable since November 2013. WETF personnel continue to evolve their solutions without the aid of systematic root cause methodology. As a result of this week's failed surveillance, the team leader delayed the start of the laboratory readiness assessment that was scheduled to commence next Monday for at least 45 days. WETF has not operated since 2010 and operations are necessary to reduce the risk associated with a large inventory of legacy tritium-containing items.

WETF personnel also continued to resolve field office concerns with hydraulic calculations performed in response to a PISA on the fire suppression system (see 4/25/14 weekly). The facility continues in the fourth week of 24-hour fire watches performed hourly.

WETF-Emergency Management: On Friday, LANL transmitted to the field office the after-action report from a recent exercise involving a postulated glovebox deflagration. LANL identified nine opportunities for improvement including the following: telephone numbers need posting; additional telephones or roll-over capability are needed in the Facility Incident Command (FIC); operators need training on evacuating the Operations Center; the WETF radio system needs improvement; the FIC needs to develop a line of inquiry to provide appropriate initial information to the fire department; the exercise design process need to ensure realism; and stay-times and entry criteria for a tritium area need to be developed and provided in an easy to use reference for the fire department.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 9, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 9, 2014

DNFSB Staff Activity: M.P. Duncan, P.J. Foster, and J.A. Pasko conducted an onsite review of the Transuranic Waste Facility project on Tuesday and Wednesday. On Thursday, P.J. Foster and A.K. Gwal followed up on previous questions regarding electrical systems at the Plutonium Facility. R.G. Quirk supported the Site Representative office all week.

Plutonium Facility–Criticality Safety: On Tuesday, LANL issued a memo that retracts and replaces a previous memo that outlined the approach to identify criticality safety controls as part of the resumption process. The previous approach involved using new technical reference documents to develop or revise compliant criticality safety evaluations for higher mass operations prior to resumption. This process would address known safety margin concerns and insufficiently analyzed abnormal conditions (e.g., flooding and seismic events) in order to ensure the appropriate controls. The new approach centers around the firefighting water Evaluation of the Safety of the Situation and Justification for Continued Operations (ESS/JCO) and includes following paths: (1) requesting field office concurrence that an adequate technical basis exists for operations not covered by the ESS/JCO, (2) utilizing the ESS/JCO control set for covered operations and requesting additional field office concurrence, and (3) developing new criticality safety evaluations for those operations not covered by 1 or 2.

On Wednesday, LANL submitted to the field office a second revision of the firefighting water ESS/JCO (see 4/11/14 weekly). The revision includes enhanced technical basis information and commits to evaluate each operation to determine whether flooding or flooding-derived upsets require additional controls. This week, program personnel began determining whether additional immediate actions are necessary associated with small pieces and turnings of plutonium metal. The ESS/JCO places additional restrictions on these items, which were not reflected in the 4500 g criterion used for the initial immediate actions (see 3/21/14 weekly). On Thursday, facility and program personnel conducted a hot wash for the immediate actions and were unable to determine improvements that could have expedited the nearly month-long effort.

Weapons Engineering Tritium Facility (WETF): This week, WETF management assembled a team of engineering experts from across the laboratory to assist with restoring operability of the oxygen monitoring system (OMS). Operability of the OMS is necessary for facility restart (see 5/2/14 weekly). The engineering team intends to identify and repair the root causes of the OMS inoperability through a systematic troubleshooting process. The team has identified two separate issues it will focus troubleshooting efforts on: system noise and instrument drift. The team will also evaluate the calibration procedure and techniques to determine whether improvements are needed. Benchmarking of other oxygen monitoring systems on site and at the Savannah River Site will also be performed to see if additional insights can be gained into OMS reliability and maintenance.

Area G: LANL stood up a war room to triage information and actions associated with the potential that nitrate salt waste contributed to the radioactive release event at the Waste Isolation Pilot Plant (see 5/2/14 weekly). In addition to locating and controlling drums from this waste stream, laboratory personnel began performing chemical and radiological analyses to evaluate the current conditions of these materials.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 16, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.T. Davis, R.K. Verhaagen, and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 16, 2014

DNFSB Staff Activity: R.T. Davis completed his assignment as a site representative at LANL this week. J.W. Plaue attended the Nuclear Materials Management Team meeting in Denver, CO. R.K. Verhaagen was out of the office Wednesday to Friday.

Area G: On Friday, Area G management declared a Potential Inadequacy of the Safety Analysis (PISA) based on the unknown hazards and hazard frequency associated with nitrate salt wastes that have been treated with an organic based absorbent. During the investigation of the radioactive material release event, Waste Isolation Pilot Plant (WIPP) personnel identified a breached drum in the underground. Based on the location, the breached drum was narrowed down to one of two drums created at LANL that contain nitrate salt waste treated with organic cat litter.

Area G management received this new information on Thursday night and took immediate action to overpack a drum that is very similar to one of the suspect drums in the WIPP underground. This similar drum was created at the WCRR repackaging facility from the same parent drum as one of the suspect drums identified at WIPP. The following additional immediate actions and operational restrictions were identified for the PISA:

- Overpack all treated nitrate salt waste drums into standard waste boxes or pipe overpack containers (action in progress on Friday)
- Relocate all treated nitrate salt waste materials to a location with a fire suppression system (action in progress on Friday)
- Perform temperature monitoring of these waste items (currently being performed daily)
- Conduct headspace sampling and analysis of the standard waste box overpacks as needed

All sampling and intrusive evaluation of treated nitrate salt waste is on-hold pending evaluation of the PISA and identification of a safe path forward. LANL personnel continue to use a war room at Technical Area-63 to triage information and actions associated with this issue.

Plutonium Facility–Criticality Safety: This week, Plutonium Facility management held two critiques to evaluate the details and corrective actions associated with an item identified as an oxide material in the facility inventory database (LANMAS) that was located in a glovebox with criticality controls that specified metal only materials. Field office personnel pursued this issue in detail because the fissile material operation was recently evaluated by an annual walkdown and as part of the resumption process, neither of which identified the database discrepancy. Plutonium Facility personnel subsequently self-identified this issue as part of an extent of condition review that was completed prior to approving the operation for resumption.

During the critique, Plutonium Facility management identified that personnel performed the field evaluations without details from the inventory database in-hand, which is not consistent with facility management expectations. As part of the corrective actions, the procedure that includes the annual field walkdown will be revised to clarify that the LANMAS information should be specifically included and reviewed (the same checklist is used as part of the resumption process). Plutonium Facility management is also performing an extent of condition review for other fissile material operations that have been through the resumption process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 23, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 23, 2014

Area G–Nitrate Salt Waste: Today, the LANL Director named Dr. Terry Wallace as the laboratory’s lead for coordinating efforts related to understanding the radiological release event at the Waste Isolation Pilot Plant (WIPP) and the associated implications for the transuranic waste currently stored at Area G. Dr. Wallace is the Principal Associate Director for Global Security.

In addition to the immediate actions taken in response to last week’s declared Potential Inadequacy of the Safety Analysis (see 5/16/14 weekly), LANL personnel have taken the following measures:

- Completed the relocation of all over-packed treated nitrate salt waste drums into a Permacon enclosure that affords fire suppression, a metal confinement structure, continuous air monitoring for airborne radioactive material, temperature control, and HEPA-filtered ventilation.
- Elected to also relocate all untreated (those without added organic kitty litter) nitrate salt waste drums into a Permacon.
- Strengthened emergency preparedness planning for the nitrate salt waste, including issuing standing orders to guide hourly operator rounds, development of a pre-incident response plan, and starting targeted walkthroughs with fire department and emergency response personnel.
- Established two independent teams of subject matter experts to review the available information, as well as initiated outreach to experts from the other national laboratories.
- Conducted a fact finding to determine whether the nitrate salts were treated and shipped in accordance with the WIPP waste acceptance criteria. Results are pending.

Plutonium Facility–Criticality Safety: Today, the field office transmitted to LANL a letter disapproving the submitted firefighting water Evaluation of the Safety of the Situation and Justification for Continued Operations (ESS/JCO) (see 4/11/14 weekly). Field office personnel and external federal criticality safety experts generated eleven comments. The more significant comments from the field office direct LANL to revise the ESS/JCO to: elevate certain compensatory measures to technical safety requirement level controls; prohibit certain fissile material operations that were not adequately analyzed; clearly define soluble compounds; and clearly identify which compensatory measures apply to which fissile material operations.

Plutonium Facility–Safety Basis: Also today, the field office transmitted to LANL a revised Safety Evaluation Report (SER) for the *TA-55 Documented Safety Analysis Addendum in Response to Nonlinear Seismic Analysis Results*. The SER incorporates the results of LANL analysis of the facility structural performance against Section 9.3.6 of DOE-STD-1020-2012 (see 1/31/14 weekly), and was approved by the NNSA Deputy Associate Administrator for Infrastructure and Operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 30, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 30, 2014

Management: Field office and laboratory management resources are challenged with a number of significant efforts:

- Operations at the Plutonium Facility remain mostly paused due to criticality safety and conduct of operations issues. The war room is expected to support seven day a week efforts to resume a large number of fissile material operations before the end of June 2014.
- LANL continues to maintain its war room for Area G and has separately appointed a recovery manager to organize efforts to investigate the hazards of the nitrate salt wastes and support safe recovery both locally and at the Waste Isolation Pilot Plant.
- Weapons Engineering Tritium Facility management has a task force underway to resolve operability issues with the Oxygen Monitoring System that have lingered since October 2013. Operability is required to restart tritium gas handling activities necessary for risk reduction efforts that have been dormant since 2010.
- Chemistry and Metallurgy Research building management is working through closure of 29 pre-start items in order to commence nuclear operations for the Confinement Vessel Disposition project.
- Management has initiated an investigation of a fire event and associated response at the LANSCE accelerator facility. Though not a defense nuclear facility, this event touches on several safety management programs that impact the entire site (e.g., fire protection, conduct of operations, and maintenance).

Area G–Nitrate Salt Waste: Area G personnel completed the relocation of the unremediated nitrate salt drums into the Dome 231 Permacon. All known nitrate salt drums at LANL are now located in Permacons. Chemistry and Weapons Experiments division experts have also initiated an experimental program to gain an understanding on the potential formation of energetic materials involving the nitrate salts, wheat-based kitty litter, nitric acid, and a neutralizing agent that were utilized as part of the remediation process.

Fire Protection: Last month, the field office transmitted to LANL management the results of a triennial assessment of the Fire Protection Program. Overall, the field office determined that three of six objectives were met and identified 15 findings and 20 observations for corrective action. Findings of particular interest include the following: the Fire Protection Program does not appear to have adequate resources to maintain a compliant program; fire protection engineers are not part of formal structured training plan to improve and maintain necessary job skills; reviewers continue to find many repeat issues from previous triennial assessments; a mechanism has not been implemented to ensure fire protection requirements are properly incorporated into new design and construction projects; corrective maintenance does not support timely restoration of impairments; the Radiological Laboratory Utility Office Building does not meet or exceed applicable building code; certain glovebox fire suppression systems are not UL-listed or otherwise approved for Class A fires; the baseline needs analysis has not been updated since 2009 contrary to the three year update requirement; and pre-incident plans do not contain all of the necessary information to support timely and effective response.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 6, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 6, 2014

DNFSB Staff Activity: On Wednesday, the Site Representatives and DNFSB Headquarters staff held a discussion at Sandia National Laboratories with the lead of the Department of Energy's (DOE) Technical Assistance Team for the Waste Isolation Pilot Plant recovery effort. On Thursday, Headquarters staff conducted a teleconference with field office and LANL personnel regarding emergency response planning for the nitrate salt wastes.

Area G–Nitrate Salts: LANL management announced they will not complete the 3706 Campaign on schedule and are working to relocate all remaining campaign wastes (i.e., combustible and dispersible forms) into Dome 230 for storage under fire suppression. In addition, Area G management suspended all legacy transuranic waste repackaging, treatment, and remediation activities. This suspension excludes drum venting, replacement of degraded components, non-destructive assay, and similar actions that improve the safety posture. On Wednesday, Area G personnel conducted a tabletop exercise involving the nitrate wastes that resulted in the identification of several important improvements. Area G and Chemistry Division personnel have also initiated development of a “safing” process to treat the nitrate salt wastes using a water addition followed by eventual cementation.

Plutonium Facility–Criticality Safety: On Wednesday, the field office unconditionally approved revision 3 of the Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) regarding the potential for criticality due to firewater flooding (see 5/23/14 weekly). The field office noted in their Safety Evaluation Report (SER) that the ESS/JCO is to be implemented by June 30, 2014, and that implementation will include: (1) evaluation of each applicable fissile material operation (FMO) in the context of firewater introduction as a credible abnormal condition, (2) evaluation to ensure that any new credible upsets beyond flooding (e.g., increased reflectivity from graphite) are analyzed, and (3) the criticality controls, procedures, and postings are updated accordingly. The SER notes approval of the ESS/JCO expires on May 30, 2015, and that the termination condition for each FMO is the development and implementation of an updated process-specific criticality safety evaluation that addresses both firewater and seismic induced upsets. Program personnel have initiated implementation efforts with the first Implementation Verification Review expected to occur as early as this weekend.

Contract Management: Last week, LANL transmitted to the field office for approval a revised implementation plan for DOE Order 420.1C, *Facility Safety* (see 12/20/13 weekly). DOE issued this version of the Order on December 4, 2012. LANL's revised plan projects implementation of the last action by end of September 2016 with the next updated probabilistic seismic analyses to occur by September 2018.

Confinement Vessel Disposition (CVD) Project: This week, LANL transmitted a letter to the field office indicating closure of all pre-start findings from the CVD Operational Readiness Review and requesting Startup Approval Authority to commence CVD operations. CVD personnel plan to transport and receive the first confinement vessel from TA-55 next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 13, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 13, 2014

DNFSB Staff Activity: J.C. McComb observed resumption activities at the Plutonium Facility. D.J. Campbell performed site familiarization activities. On Wednesday and Thursday, R.K. Verhaagen observed causal analysis activities performed by the DOE Accident Investigation Board for the radiological release event at the Waste Isolation Pilot Plant.

Area G–Operations: On Friday, Area G management paused all transuranic waste movements until a safety stand-down briefing is completed next Monday. Observations by NNSA Facility Representatives indicating procedural adherence issues, including improper response to a dropped Standard Waste Box, triggered the stand-down.

Plutonium Facility–Criticality Safety: Facility and program personnel entered a period of high tempo of activities in support of resumption. During the past week, personnel conducted a total of at least 12 Annual Operating Reviews and Independent Verification Reviews.

Confinement Vessel Disposition (CVD) Project: On Tuesday, the field office granted LANL approval to commence CVD nuclear operations. On Wednesday, CVD personnel successfully transferred the first sphere from TA-55 to Wing 9. CVD personnel anticipate commencing cleanout activities next week.

Weapons Engineering Tritium Facility (WETF): On Wednesday, WETF management briefed the field office on the status of task force activities associated with the Oxygen Monitoring System (OMS). Management reported that procurements were underway for new sensors, cables, and modules and that testing was scheduled to be completed by July 2, 2014. Based on those actions, management anticipates submitting a revised Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) to the field office by July 14 and commencing contractor readiness activities by July 21. Field office management reiterated their skepticism regarding any attempt to declare the OMS operable without a successful 30-day demonstration. The Site Representatives note that an approved ESS/JCO does not exist for the potential inadequacy of the safety analysis declared on the OMS in November 2013 (see 11/29/13 weekly). In some instances, LANL's approach of combining a JCO with the ESS tends to result in delayed submittals.

Emergency Management: LANL recently issued the after-action report for the April 17, 2014, nuclear criticality exercise at TA-55 (see 4/18/14 weekly). The report notes four findings and seven opportunities for improvement (OFI) to be screened for potential corrective actions. The OFIs include:

- Operations in the Facility Incident Command (FIC) lacked formality, including personnel not following checklists, providing sporadic briefings, and confusion with seating and phones
- At least 12 individuals walked past injured victims without offering assistance
- Radcon technicians were not wearing proper personnel protective equipment (PPE)
- The FIC did not provide timely PPE advice to fire department, which delayed response to patients
- Emergency Management did not receive timely notification of the event
- The TA-55 Operations Center does not have a comprehensive phone list for the FIC

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 20, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 20, 2014

Area G–Nitrate Salt Wastes: This week, Area G personnel completed the relocation of all remaining 3706 Campaign transuranic wastes (i.e., combustible and dispersible) into Dome 230 for storage. Dome 230 is equipped with a fire suppression system.

On Wednesday, Area G personnel conducted an emergency exercise involving the remediated nitrate wastes currently stored in the Dome 375 Permacon. The scenario was supposed to involve an operator that was surprised by contacting a high temperature Standard Waste Box (SWB) and subsequently trips and is rendered unconscious, while a second operator observes and reports evidence of smoke and fire from the SWB. A key controller failed to inject evidence of smoke and fire from the SWB, reducing exercise effectiveness. Consequently, the event did not trigger an Operational Emergency status resulting in several significant exercise objectives that could not be evaluated.

Last Friday, LANL submitted to the field office the Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis regarding waste drums containing remediated nitrate salts (see 5/16/14 weekly). The ESS argues that immediate actions and compensatory measures put in place, primarily overpacking and monitoring the wastes in SWBs, provides a safe configuration until a path forward for disposition is developed and implemented. Specifically, the ESS assigns a damage ratio of 0.1 to the overpacked drums in SWBs for a fire in accordance with DOE-STD-5506. This damage ratio is used to mitigate the consequences to the public from a postulated fire involving all remediated nitrate salt drums in SWB overpacks in the Dome 375 Permacon from 10.6 to 1.06 rem. DOE-STD-5506 cites engineering judgment as the technical basis for this damage ratio.

Emergency Preparedness: On Thursday, LANL conducted a functional exercise of the Emergency Operating Center. The scenario for this exercise was a seismic event that resulted in the collapse of two wings and a fire at the Chemistry and Metallurgy Research Building and a partial collapse of the Plutonium Facility. The exercise also challenged communications by simulating the loss of landlines and saturation of cell phones. LANL's Emergency Response Organization, the Los Alamos County Fire Department and Emergency Management personnel, LANL's Media Center, and the field office were full participants in the exercise. Exercise notifications were made to the New Mexico Department of Homeland Security and Emergency Management and to the DOE Forrestal Watch Office. Field operations were simulated through a concurrent tabletop exercise. Although a full critique of the exercise has not been completed, during the hot wash potential improvements to communications between the emergency directorate and support section personnel were identified.

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF personnel completed a multi-day evolution to package 112 legacy items containing tritium into a Flanged Tritium Waste Container (FTWC) for disposal at Area G. These items were identified during the hands-on inventory completed earlier this year (see 1/24/14 weekly) as a subset of over 1100 legacy items requiring disposition from WETF. This is the fourth FTWC packaged for disposal at Area G and represents another step forward in the legacy item disposition project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 27, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 27, 2014

DNFSB Staff Activity: This week, D. Kupferer assisted the Site Representatives in oversight of resumption activities in the Plutonium Facility. On Wednesday, the staff conducted a teleconference with Plutonium Facility and field office personnel to discuss the implementation of criticality safety controls.

Area G–Nitrate Salt Wastes: This week, Area G personnel sampled an empty parent nitrate waste drum and provided briefings to the DOE Technical Assistance Team (TAT). LANL personnel reported that more than 700 experiments have been conducted to-date. LANL senior management has released some of these results to the TAT and Accident Investigation Board. On Tuesday, the Associate Director for Environment Programs appointed a team to perform a causal analysis to evaluate processing problems that resulted in a potentially non-compliant drum at the Waste Isolation Pilot Plant. The team will out brief results by July 31, 2014.

Radioactive Liquid Waste Treatment Facility: Facility personnel commenced operations of the Waste Mitigation Risk Management tanks for storage of low-level radioactive liquid influent (see 1/4/14 weekly).

Plutonium Facility–Criticality Safety: A year ago today, the LANL Director Paused programmatic operations in the Plutonium Facility due to concerns with criticality safety and conduct of operations. In order to commence fissile material operations, program personnel must complete: (1) the resumption process culminating in release by the LANL Director or designee, (2) an Implementation Verification Review, if the operation falls under the Justification for Continued Operations, and (3) screening for applicability, and completing as necessary, a readiness review. As of today, Plutonium Facility personnel could not provide specifics on the numbers of operations that had completed each of these three steps and executed operations with fissile materials, but they expect to release refined resumption metrics next week.

Plutonium Facility: Last week, during a routine inventory, Plutonium Facility personnel discovered a tank believed to be empty that actually contained approximately 50 liters of a solution with a low plutonium concentration. The solution was generated and transferred to this tank during aqueous operations required to place the facility in a safe and stable configuration (see 3/17/2104 weekly) and was intended to be cemented for disposal. Multiple previous inventories failed to identify the location of the liquid due to the site glass being completely full. During this inventory, a slight change in color of the solution made its presence detectable. Plutonium Facility personnel critiqued the event and determined that the procedure and processes used to dispose of this solution did not contain sufficient detail or require the necessary formality to ensure operators were keeping track of all solutions and complete disposition of these wastes. Personnel significantly revised the procedure during the Director's pause to include direction that is more specific on how to account adequately for solutions.

Area G–Criticality Safety: This week, during an assessment of fissile material operations in Area G, facility personnel identified that they had not performed a criticality safety evaluation (CSE) for handling and storage of sealed sources. Personnel previously identified the need for a CSE for this operation in a May 2012 assessment, but they had not completed the CSE beyond draft form due to competing priorities. Facility management conducted a critique of the event and discovered that operators relied upon informal guidance from criticality safety personnel to control the mass of sources brought into Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 4, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 4, 2014

Plutonium Facility–Criticality Safety: On Monday, the field office transmitted a letter to LANL requesting a status update associated with the resumption of programmatic activities. The field office noted that in accordance with DOE Order 425.1D, *Verification of Readiness to Startup or Restart Nuclear Facilities*, activities that have not resumed by June 27, 2014, may represent an extended shutdown and therefore could require readiness reviews prior to restart. The field office requested by July 14, 2014, a list of programmatic fissile material operations that: (1) resumed as of June 27, 2014; (2) LANL considers in extended shutdown; and (3) did not resume as of June 27, 2014, but that LANL does not consider in extended shutdown. For those operations that LANL does not consider in extended shutdown, the field office requested a detailed discussion of the rationale for this conclusion.

On Tuesday, the field office received a copy of the LANL Director's memo dated June 18, 2014, delegating resumption release authority for all remaining programmatic operations to the Principal Associate Director for Weapons Programs. The scope of this delegation excludes electrorefining, casting, and aqueous processing.

Also on Tuesday, program management informed the Site Representatives that program personnel would begin to place turnings and small pieces of plutonium metal into water resistant containers during the next few weeks. LANL's approved analysis in the Justification for Continued Operations demonstrates that accumulations of these materials in quantities greater than 500 g can result in a criticality, thus a water resistant container is required. Currently, multiple locations in the facility do not meet this requirement and do not have other compensatory measures implemented to ensure safety until these materials can be repackaged to comply with the Justification for Continued Operations controls.

RANT Shipping Facility–Fire Protection: On Tuesday, RANT management declared a Potential Inadequacy of the Safety Analysis (PISA) regarding fluctuations in the pressure of the firewater supply. As part of a lab-wide assessment on fire water supply, field office personnel obtained the results of system pressure monitoring performed by the Utilities and Institutional Facilities division and completed in April that indicated multiple instances during work hours where the water pressure dropped below the minimum specified in the Technical Safety Requirements (TSR). RANT encountered a similar issue in 2012 when pressure fluctuations in the firewater supply (see 8/3/2012 weekly) occurred whenever the facility toilet was flushed. Reportedly, the results of this monitoring were provided to RANT personnel; however, PISA related actions were only initiated after field office action on June 18. The field office assessment also preliminarily identified issues with maintenance and control of pressure reducing valves in the water supply, including a concern as to whether LANL was maintaining components supplying water to a nuclear facility fire suppression system with the appropriate consensus standard (National Fire Protection Association or American Water Works Association).

RANT management conducted a critique and determined that no compensatory measures were necessary with the facility currently in cold standby mode. The only other outcome was to execute the PISA process and determine whether TSR changes would be required. The Site Representative notes that critique participants did not bring the pressure data nor other related procedures or documentation and performed only a cursory effort to gather facts or otherwise discuss the apparent related issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 11, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 11, 2014

DNFSB Staff Activity: D. Campbell augmented the Site Representative office and performed cognizant engineer familiarization activities. He and the Site Representatives walked down the Weapons Engineering Tritium Facility, the Chemistry and Metallurgy Research Building, and the Plutonium Facility.

Plutonium Facility–Safety Basis: Late last month, the field office approved LANL’s request to extend the expiration date of three safety basis documents. The documents include a temporary modification involving fire rated containers from 2012, an Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) for refueling activities from 2012, and an ESS/JCO associated with ammonium nitrate in the ventilation ducting from 2010. The field office notes that implementation of the 2013 safety basis will close these documents and that implementation of the 2013 safety basis is currently scheduled to be completed by May 31, 2015.

The Site Representatives note the importance of executing timely annual updates to the safety basis in order to minimize confusion regarding the safety basis. For example, the safety basis document list for the Plutonium Facility currently indicates that in addition to the Documented Safety Analysis and Technical Safety Requirements, 13 sets of documents (including submittals, associated field office approvals, and extensions) are currently implemented. These documents sets include 10 ESS/JCOs, 2 temporary modifications, and the seismic addendum.

Plutonium Facility–Seismic Safety: Last week, LANL transmitted to the field office a progress report on seismic/structural upgrades for the Plutonium Facility. The report provides status of progress made on achieving milestones in the FY14 Project Execution Strategy for facility upgrades, as well as new scope added to the strategy as additional FY 2014 funds became available. Progress on all milestones are either on track or ahead of schedule. Notable 2014 accomplishments include completion of:

- Vault column modifications to correct captured column structural deficiencies
- Attic fire suppression seismic modifications
- 106 out of 122 identified non-standard fire suppression seismic modifications
- Facility corridor fire suppression seismic modifications
- Basement standard fire suppression seismic modifications
- 90% design for modifications to improve shear capacity of interior roof girders

Additional milestones to the execution strategy for FY14 include completion of:

- Anchorage upgrades for uninterruptable power supply automatic transfer switches
- Anchorage upgrades for electrical distribution system unit substations
- Installation of seismic upgrades for bleed-off ductwork
- Anchorage of basement flammable material storage cabinets

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 18, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 18, 2014

DNFSB Staff Activity: Deputy Technical Director R. Tontodonato performed his annual observation of site representative operations.

Transuranic Waste Facility (TWF) Project: Last Thursday, the NNSA Deputy Administrator for Defense Programs provisionally granted the project Critical Decision 3, *Approve Start of Construction*. The provision requires approval of an updated safety design strategy, which project and field office personnel expect to complete shortly. The project team also issued a lessons learned report for development of the preliminary documented safety analysis. Among the numerous suggested procedure changes include actions to formalize management involvement in the comment resolution process, promote effective communication with the field office by documenting results of project team interactions, and document expectations that safety basis personnel work directly for the project engineering manager.

Plutonium Facility–Safety Basis: On Tuesday, the field office approved the 2014 annual update to the safety basis. This update was minimal and primarily included a previously directed action regarding changes to the technical safety requirements. The field office expects LANL to implement the 2014 update with the 2013 update by May 31, 2015 (see 7/11/14 weekly).

Plutonium Facility–Criticality Safety: On Monday, LANL submitted a response to the Field Office's request for a status update associated with resumption of programmatic activities (see 7/4/14 weekly). LANL's response identified three resumption status bins including operations that were: actively resumed as of June 27, 2014; in extended shutdown and require a formal readiness assessment for restart; and not resumed by June 27, 2014, but not considered in extended shutdown and as such do not require a formal readiness assessment for restart. NNSA headquarters personnel were onsite to assist the field office in assessing compliance of the proposed submittal with DOE Order 425.1D, *Verification of Readiness to Startup or Restart Nuclear Facilities*.

Plutonium Facility–Work Control: During a walk-down of operations, NNSA personnel raised questions that resulted in the pause of two jobs. In one instance, fissile material handlers were in the process of loading containers of enriched uranium into a safe posted as an abnormal operating condition due to a suspected criticality deviation. The safe had been posted since August 2013 and after review at that time was determined to represent a level 5 infraction due to discrepancies with the dimensions. Management held a critique of the event and discussed a number of areas for improvement including failure to execute the recovery plan from the infraction, confusion on work authorization and release mechanisms, posting accuracy and effectiveness, and conduct of operations issues. The Site Representatives note that critique effectiveness improved from clearly presenting appropriate documentation to the entire audience.

Confinement Vessel Disposition Project: Chemistry and Metallurgy Research Building personnel moved the first confinement vessel into the Wing 9 enclosure in preparation for cleanout. Once inside the enclosure, personnel paused the activity to allow a procedure change necessary to replace improperly sized rigging equipment that had been previously installed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 25, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 25, 2014

Area G–Nitrate Salt Wastes: On Monday and Tuesday, members of the DOE Waste Isolation Pilot Plant (WIPP) Technical Assistance Team and the Accident Investigation Board conducted a workshop to review the hypotheses and research efforts that LANL personnel have completed regarding the radiological release event at WIPP.

Criticality Safety: Last Friday, LANL transmitted to the field office their revised plan for the *Nuclear Criticality Safety Upgrades Project* (see 4/25/14 weekly). The project plan contains several hundred actions and indicates completion in October 2016.

RANT Shipping Facility–Safety Basis: Last week, the field office conditionally approved the 2013 Documented Safety Analysis (DSA) and Technical Safety Requirements (TSR). The conditions include within 45 days: (1) removing all references of the TRUPACT III capability; (2) designating vehicle barriers between the facility and adjacent parking lot as defense-in-depth; (3) designating vehicle barriers protecting the container storage area as safety significant features; (4) correcting inconsistencies for the fire suppression system and water supply system throughout the DSA/TSR; (5) ensuring consistency throughout chapter 4 of the DSA with respect to safety system functions, and functional requirements, and performance criteria; and (6) revising chapter 7 to reflect new organizational names. The field office further directed implementation of the DSA/TSR within 90 days. Implementation of this DSA/TSR will move RANT from its status as a limited life facility to recognition of its status as the enduring transuranic waste shipping facility for the laboratory.

Continuous Improvement: Last week, the field office requested that LANL formally submit a sustainment plan for safety culture by August 27, 2014. The plan is to include a list of tools, their descriptions, and the plan and schedule to implement the tools. In addition, the field office invited a LANL participant to attend a NNSA-HQ sponsored safety culture workshop to be held in early August at the Nevada Field Office.

Plutonium Facility–Criticality Safety/Conduct of Operations: Last week, facility personnel identified material stored in a glovebox that did not comply with newly posted criticality safety limits. In this case, plutonium metal turnings in excess of 500 grams were being stored in non-watertight containers contrary to the posting derived from the controls specified in the Justification for Continued Operations (see 7/4/14 weekly). During an Annual Operational Review two weeks prior, with different criticality limits posted, it was noted that the contents of the glovebox did not comply with the limits established in the Justification for Continued Operations and that action would have to be taken to package the material prior to posting the new limits. During a critique of the event, operations personnel reported that subsequent to the AOR they incorrectly concluded that an informal analysis performed by a criticality safety analyst to show the condition in the glovebox was currently safe was sufficient to allow them to violate the posting. As a result, the glovebox was posted with the new controls in a known infringed condition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 1, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 1, 2014

Emergency Preparedness: LANL hosted its annual HAZMAT Challenge this week with 13 teams participating, including five from local entities that LANL may call upon for aid in the event of an emergency. All eight of this year's scenarios were based on a postulated seismic event.

Plutonium Facility–Criticality Safety: On Thursday, the field office responded to LANL's summary of resumption status and proposed readiness activities (see 7/18/14 weekly). The field office concurred with the list of activities that LANL considered in extended shutdown and require a formal readiness assessment for restart, but directed that readiness activities be performed for the activities that LANL considered to not be in extended shutdown. Using LANL's groupings of activities, 14 are actively operating, 12 will require federal readiness assessments, and four will require contractor readiness assessments.

On Tuesday, Plutonium Facility management reported that personnel have replaced 38 of 58 legacy wooden housekeeping filters with new metal versions, including 19 with new "rain caps" to prevent intrusion of water. This work continues on schedule and significantly improves the safety posture of the affected gloveboxes.

Plutonium Facility–Conduct of Operations: In response to issues identified by NNSA personnel (see 7/18/14 weekly), Plutonium Facility management directed that all program managers are to perform at least two management observations on the work floor each week. One observation is to focus on work within the workgroup and the other on an outside workgroup.

Confinement Vessel Disposition (CVD) Project: Late last week, CVD personnel paused work during an evolution to sample and vent the atmosphere within the sphere when they unexpectedly found the sphere to be under vacuum. Procedure changes are underway.

Area G–Safety Basis: On Wednesday, the field office approved the Evaluation of the Safety of the Situation (ESS) for the new information concerning the nitrate salt waste (see 5/16/2014 weekly). However, the field office disapproved LANL's revision of the ESS that provided for changing out the vent plugs in the Standard Waste Boxes. The ESS expires within one year.

Also on Wednesday, the field office approved LANL's request to delay submittal of the revised safety basis to February 20, 2015, from August 1, 2014. The safety basis revision will address field office directed actions (see 8/2/2013 weekly), including elevating aspects of safety management programs to Specific Administrative Controls and re-evaluating the selection of credited controls using the hierarchy of controls.

RANT Shipping Facility: On Tuesday, LANL submitted a letter to the field office indicating that they have determined a TRUPACT III loading function is no longer required. LANL also indicated that no changes were required to institutional procedures to ensure major modification determinations were performed early in the design process and readily visible to federal oversight (see 12/13/2013 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 8, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 8, 2014

DNFSB Staff Activity: Staff members C. Berg, D.J. Campbell, R.T. Davis, M.W. Dunlevy, and M.M. McCoy conducted a review of the safety bases for Area G and the RANT Shipping Facility. A.H. Hadjian observed geophysical testing underway in support of the effort to update the probabilistic seismic hazard analysis. R.K. Verhaagen was on leave.

Plutonium Facility–Worker Safety: Earlier this summer, a programmatic operations group lead restricted use of a glovebox line used for thermal treatment of Pu-238 oxide powders after operators expressed concern about its material condition. The glovebox originated from the old DP Site Plutonium Facility and is at least 30 years old. Material condition concerns include multiple windows with cracked glass, gaskets taped and painted for unknown reasons, corroded water-filled shielding that has likely leaked dry, and significant amounts of abandoned in-place legacy equipment. Use of the glovebox line is essential for all Pu-238 products, including deliverables for the Office of Defense Programs. The group lead is working to resolve these issues.

The Site Representatives note that the current System Health Report for these gloveboxes does not capture most of these degraded conditions despite evidence the conditions have existed for many years. The report further indicates that all the gloveboxes are operable per the safety basis, which credits gloveboxes as safety significant with a performance criterion to maintain primary confinement of dispersible radioactive materials during process operations, upon loss of ventilation, and during or after performance category 2 seismic events. System engineers indicated that they believe these degraded conditions do not challenge the ability of these gloveboxes to perform this function, but had informed safety basis personnel on the need to provide greater engineering detail in the safety basis for this important safety system.

Plutonium Facility–Criticality Safety and Conduct of Operations: Last Friday, Plutonium Facility management directed that personnel execute most work-authorizing documents as Use-Every-Time documents irrespective of the approved level-of-use. In addition, the work authorizing documents are to be present on the floor with any references available within 15 minutes. On Thursday, LANL management provided a status of resumption activities to NNSA senior management.

RANT Shipping Facility: Last Thursday, LANL submitted to the field office the Evaluation of the Safety of the Situation (ESS) regarding the fluctuations in the firewater system pressure (see 7/4/14 weekly). The ESS argues that the facility is safe given the operational restriction of Cold Standby mode and indicates that additional investigation on the firewater system is required prior to proposing a path forward.

Area G–Safety Basis: Last Friday, LANL submitted the third revision of the ESS for fuel pool fires involving combustibles waste (see 3/28/14 weekly). The ESS considers a single drum of combustible waste in a fuel pool fire and establishes a control to limit receipt of drums at Area G to less than 80 Pu-239 Equivalent Curies. In accordance with the ESS, Area G personnel successfully over-packed the only existing combustible drum that exceeds this value on Wednesday. The ESS analysis does not examine multiple drums of combustible waste or other accident types.

Area G–Nitrate Salt Wastes: On Thursday, Area G personnel obtained samples of salt residues from the empty parent of the drum known to have breached at the Waste Isolation Pilot Plant.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 15, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending August 15, 2014

DNFSB Staff Activity: R.K. Verhaagen remained on leave and J.W. Plaué began leave Wednesday.

Plutonium Infrastructure Strategy: Late last month, the field office approved the Safety Design Strategy (SDS) for the new Plutonium Equipment Installation (PEI) sub-project of the Chemistry and Metallurgy Research Replacement project line item. PEI is one of two new subprojects included in a revised *Mission Need Statement* and a *Program Requirements Document*, which NNSA approved on July 3, 2014. The other sub-project is RLUOB Equipment Installation Phase 2 (REI2). PEI and REI2 constitute the first two phases of the Plutonium Strategy and are necessary to establish appropriate enduring analytical chemistry and materials characterization capabilities and capacities and to facilitate termination of programmatic operations in the existing Chemistry and Metallurgy Research building.

The PEI sub-project will repurpose several rooms in the Plutonium Facility by the removal of existing equipment and installation of new gloveboxes and associated equipment. The SDS notes the sub-project was screened against the criteria in DOE-STD-1189 and determined not to represent a major modification. The Chief of Defense Nuclear Safety concurred on the SDS and provided several comments for consideration, notably including the need to improve discussion on the challenges and the controls needed to perform PEI scope in an operating nuclear facility and the need to discuss anticipated demands of new equipment on the capacities of existing safety-related support systems.

Weapons Engineering Tritium Facility (WETF): Last Friday, LANL submitted to the field office the third revision of the Evaluation of the Safety of the Situation (ESS) for the issue associated with the Oxygen Monitoring System (OMS). The ESS was accompanied with the final report from the Root Cause Failure Analysis Team (see 6/13/14 weekly). The ESS asserts that the OMS can be declared operable based on a successful seven day calibration check, but proposes restricting tritium processing until completion of the first monthly as-found calibration check and completion of both the contractor and federal readiness assessments.

Startup and Restart: On Tuesday, LANL's Joint Evaluation Team (JET) convened to review the readiness review determinations for the restart of loading activities for UC609 tritium shipping containers at WETF and the restart of the TBase 2 lathe in the Plutonium Facility. The latter restart represents the first of likely ten upcoming readiness assessments to support full resumption of programmatic operations. The JET determined that both activities require federal readiness assessments pending approval by the field office.

Emergency Preparedness: LANL personnel recently issued the after-action report for the functional exercise of the Emergency Operations Centers (EOC) involving a significant seismic event (see 6/20/14 weekly). Overall, LANL met 76 of the 80 established exercise objectives with one finding and three objectives either not observed or applicable. The finding involved the lack of familiarity of one of the section chiefs with the EOC chain of command. EOC personnel investigated the issue and determined that the chief had not received either initial or refresher training. Additional follow-up revealed several other members of the Emergency Response Organization that were unfamiliar with basic EOC processes. Other notable opportunities for improvement include a field office identified issue to develop predetermined situational awareness information for display on the large electronic wall, the need for training on aspects of WebEOC, and the need to strengthen the conduct and physical arrangements for tabletop field play.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 22, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 22, 2014

DNFSB Staff Activity: E.M. Gibson observed geophysical testing performed in support of the update for the probabilistic seismic hazard analysis.

Field Office: The field office continues to experience difficulties maintaining adequate staffing. Currently, there are 21 federal employee vacancies. These vacancies include many key safety-related positions such as the Deputy Manager, Senior Technology Safety Advisor, Deputy Assistant Manager for Operations, Quality Assurance Manager, three Facility Representatives, and two capital project managers.

Plutonium Facility–Americium Recovery Project: Last week, LANL submitted to the field office a request for approval of the Plan of Action for a Contractor Readiness Assessment (CRA) to establish an americium-241 production capability in the Plutonium Facility. The chloride extraction and actinide recovery (CLEAR) line will recover americium-241 from waste streams that are newly generated or previously stored in the Plutonium Facility. One product of the CLEAR line process will be americium oxide that meets industrial customer specification requirements as directed by the DOE Office of Science. Americium oxide is used by the natural gas and crude oil well logging industry, as well as use in smoke detectors. LANL desires to commence the CRA in September 2014 pending approval of the request and successful completion of a Management Self-Assessment of readiness. Successful completion of the CRA would facilitate a Federal Readiness Assessment currently planned for November 2014.

Nuclear Environmental Sites: This week, a federalized project team successfully completed demolition of the two legacy water towers at TA-21 (see 4/25/14 weekly).

Transuranic Liquid Waste Subproject: Last week, the field office disapproved revision 3 of the Safety Design Strategy for the project. Substantive comments included the need to provide a technical basis for the volumes of liquid to be treated and to clarify the material-at-risk values.

Weapons Engineering Tritium Facility (WETF)–Restart Activities: This week, LANL submitted to the field office an implementation plan (IP) for the conduct of the CRA to restart gas transfer operations at WETF. The field office previously approved a Plan of Action for the CRA that directed LANL to submit the IP prior to the start of the assessment. The CRA team will evaluate WETF readiness to perform gas transfer operations from the function tester glovebox to the load-in glovebox. Additionally, based on the time elapsed since the last gas transfer and function test operations, these previously authorized activities will be evaluated as well. The start date of the CRA is contingent on field office approval of the recently submitted Evaluation of the Safety of the Situation for the issues associated with the Oxygen Monitoring System (see 8/15/14 weekly). The IP notes that following successful completion of the CRA and a follow-on Federal Readiness Assessment, the scope of activities to be authorized will be limited to those operations necessary to maintain facility safety/operability and to disposition legacy nuclear material at risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 29, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending August 29, 2014

DNFSB Staff Activity: On Tuesday, a staff team discussed with the field office concerns with the safety bases for Area G and the RANT Shipping Facility. On Thursday, the staff team out-briefed the results of their review to field office and laboratory management.

Radiological Laboratory Utility Office Building (RLUOB): Last Thursday, LANL management authorized operations with radioactive materials. This Thursday, RLUOB received the first set of radioactive samples.

Plutonium Infrastructure Strategy: Last week, the Deputy Secretary of Energy approved reaffirmation of Critical Decision 1 for the Chemistry and Metallurgy Research Replacement facility project. The project now includes sub-projects for RLUOB Equipment Installation Phase 2 and Plutonium Facility Equipment Installation (see 8/15/14 weekly).

Plutonium Facility–Criticality Safety: Last Wednesday, program operations personnel conservatively questioned whether oil in their glovebox was covered by a provision for “cleaning liquid” on the posting. Criticality safety staff determined the oil was not sufficiently covered and management initiated an extent-of-condition review. The review concluded this week and identified 36 locations impacted by this condition and subsequently posted as out of service. Many of these locations had been through all steps of the resumption process. The path forward is to develop a technical basis to support a revised requirements document.

Emergency Preparedness: Last Thursday, LANL personnel conducted the annual full-scale emergency exercise. This year’s scenario involved an acetylene gas explosion and subsequent fire in Wing 5 of the Chemistry and Metallurgy Research building. The scenario included multiple trauma victims with radioactive contamination. The Site Representatives noted good self-assessment during the controller critique where LANL personnel identified exercise conduct concerns including an inadequate number of exercise controllers in key areas and insufficient preparation time with the scenario and evaluation criteria. From a performance side, the controllers discussed significant concerns with command and control and communications between response assets. For example, communications were poor between Incident Command and the Facility Incident Command. LANL personnel plan to issue an after-action report in early October. While field office personnel participated in the exercise, no personnel observed field play or the controller critique, though DOE Directives do not necessarily require it.

Following the exercise, the Site Representatives conveyed to managers that an over-reliance on simulation limited the benefits of field play. For example, though victims had been prepared with high quality *moulage*, fire department protocol prohibited transporting “unconscious” victim actors, who were permitted to walk from the scene around the outside of the building into the ambulances. Similarly, fire department constraints resulted in personnel not wearing breathing apparatus as expected for a fire involving radioactive material. In addition, the Site Representatives discussed the adequacy of provisions for handling contaminated patients when the limited capacity of the local medical facility is exceeded.

Weapons Engineering Tritium Facility (WETF): On Wednesday, the field office conditionally approved the Evaluation of the Safety of the Situation for the Oxygen Monitoring System (see 8/15/14 weekly). The field office directed WETF to perform three 31-day monitoring periods to demonstrate proper operation of the system prior to startup. The contractor readiness assessment is planned to commence on September 8.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 5, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 5, 2014

DNFSB Staff Activity: J.W. Plaue was on leave this week.

Environmental Waste Management Operations (EWMO): On Tuesday, the EWMO Facility Operations Director (FOD) paused all waste container movements in Area G, the RANT Shipping Facility, and the Waste Characterization, Reduction and Repackaging Facility. This pause followed a series of events dating back to May 2014 in which waste shipments were found to be inadequately performed. The specific occurrences that led the FOD to pause operations included two instances where a required surveillance was not performed prior to moving waste drums and two instances where the receipt inspection was improperly performed. The FOD has ordered an extent of condition review be conducted for all receipt inspections performed in these three facilities since April 2014, as well as a causal analysis to assist in determining necessary corrective actions.

Weapons Engineering Tritium Facility (WETF): On Wednesday, WETF management briefed the field office on the status of efforts to meet calendar year 2014 project commitments for disposition of legacy items containing tritium (see 10/4/13 weekly). Project personnel indicated that most commitments were on track to be met, including exceeding the goal for dispositioning simple solution packages, but that the commitment to complete upgrades to the load-in glovebox will not be complete until next calendar year due to delays in facility startup (see 5/2/14 weekly). These load-in glovebox upgrades are essential to disposition the bulk tritium gas in the facility which represents the majority of the legacy tritium inventory.

On Thursday, WETF facility operations personnel completed the Implementation Verification Review (IVR) for the Evaluation of the Safety of the Situation (ESS) for the oxygen monitoring system (see 8/29/14 weekly). Operations personnel expect to work through this weekend to complete corrective actions from the IVR for ESS implementation, declare the oxygen monitoring system operable, and perform necessary system modifications and testing. These actions are prerequisites for LANL to declare readiness for the Contractor Readiness Assessment of tritium gas transfer operations, scheduled to start Monday, September 8, 2014.

Plutonium Facility–Criticality Safety: Last week, the field office disapproved a LANL request to close a Potential Inadequacy of the Safety Analysis (PISA) declared in September 2011 (see 9/23/11 weekly) and the associated ESS. The PISA was declared due to the potential for backflow of plutonium-bearing solutions from process tanks, through piping, into a bulk nitric acid tank that resides outside the Plutonium Facility's credited confinement boundary, which presents both safety basis and criticality safety concerns. The field office letter disapproving the request cited an inadequate evaluation basis in the modified criticality safety evaluation as the reason for disapproval. Additionally, the letter stated that an extension of the ESS, which expired last Friday, will not be approved and the operation identified as the source for backflow will have to cease until such time that an operational readiness assessment is successfully completed. Finally, the field office letter noted that LANL's submittal of the request to close the PISA provides another data point in the increasing trend of inadequate quality submittals.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 12, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 12, 2014

DNFSB Staff Activity: A.H. Hadjian and E.M. Gibson observed field activities in support of an effort to update the probabilistic seismic hazard analysis. A.H. Hadjian also met with site personnel to discuss details associated with planned roof girder structural upgrades in the Plutonium Facility.

Continuous Improvement: On Thursday, the field office submitted to the NNSA Acting Associate Administrator a Safety Culture Sustainment Plan for the Los Alamos Site (see 7/25/14 weekly). The submittal combined separate plans from both the field office and LANL proposing safety culture sustainment tools to be approved by the Programmatic Secretarial Office with concurrence from the Chief of Defense Nuclear Safety. The submittal noted that LANL linked its safety culture process to the Voluntary Protection Program and will share common safety culture sustainment tools. Field office identified focus areas include: communications, employee involvement, inadequate staffing levels, and feedback and improvement. LANL identified focus areas include: leadership, organizational learning for performance improvement, and employee engagement.

Plutonium Facility–Readiness Activities: On Monday, program personnel commenced the management self-assessment for the Americium Recovery Project (see 8/8/2014 weekly).

Last Friday, the field office formally provided comments to LANL management regarding the Plan of Action (POA) for the T-Base 2 machining activity. This activity will be the first readiness assessment associated with the resumption process and consists of a single glovebox containing equipment used to machine plutonium metal. The field office directed LANL to: (1) expand the scope to include all safety management programs, (2) perform actual procedural evolutions using surrogate material or use of a cold line, and (3) recommended the POA include a review of Vital Safety System Assessments and System Health Reporting to ensure any previously identified issues have been tracked to closure. The revised POA is due by September 15, 2014. Program personnel currently anticipate commencing their management self-assessment later this month.

Weapons Engineering Tritium Facility–Readiness Activities: On Monday, LANL commenced their contractor readiness assessment for gas transfer operations (see 9/5/14 weekly). On Friday, facility management declared a Potential Inadequacy of the Safety Analysis after a readiness assessment team member from the Savannah River Site identified that the lower flammability limit for mixtures of hydrogen in air is reduced when argon is also present. The safety basis allows the use of argon for glovebox work. As an immediate action, management prohibited the use of argon.

Confinement Vessel Disposition (CVD) Project: CVD personnel continue the deliberate and methodical cleanout of the first confinement vessel of this project. On Monday, the Site Representatives observed the successful completion of the first bag-out of waste material from the CVD glovebox to an attached waste drum.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 19, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 19, 2014

Weapons Engineering Tritium Facility (WETF): On Friday, a LANL review team concluded the Contractor Readiness Assessment (CRA) of WETF operations (see 8/22/14 weekly). The stated purpose of the CRA was to provide a confirmatory review of WETF readiness to commence gas transfer operations in order to maintain facility safety/operability and to disposition legacy nuclear material-at-risk. This CRA followed the completion of two management self-assessments and an independent Red Team Review. During Friday's outbrief, the team noted that they had identified 19 prestart and 15 post-start findings representing weaknesses in WETF readiness. Notable findings include:

- Facility personnel were not effective in demonstrating the ability to properly plan, conduct, or respond to off-normal conditions during performance of an emergency exercise
- Facility component labeling nomenclature is inconsistent in the field and may compromise personnel and facility safety
- Operators failed to demonstrate procedure performance proficiency
- Technical issues and inaccuracies were identified in several procedures
- Management has not evaluated open issues (e.g., non-conformances, repair work orders, performance improvement action, etc.) for potential impact to facility and gas transfer operations
- Workers exhibited complacency with radiological control practices during the performance of procedures and the emergency exercise

The review team noted facility performance was insufficient to ensure gas transfer and associated operations could be safely and compliantly performed within WETF. Specifically, operational readiness was not demonstrated in the areas of management systems and safety culture, facility and equipment readiness, and conduct of operations. Additionally, the team noted that the findings and observations identified during the CRA indicate that additional work is required to achieve necessary standards of operational excellence.

Transuranic Waste Storage Facility Project: Project personnel commenced site ground preparation activities this week.

Plutonium Facility–Readiness Activities: On Thursday, facility management suspended the management self-assessment for the Americium Recovery Project after significant procedure and labeling issues were identified. Program personnel completed preparations for the management self-assessment on the T-Base 2 machining activity, which is planned to commence next week. Of note, program personnel acknowledged that modern criticality safety evaluation documents that fully comply with DOE Standard 3007 will not be completed to support the management self-assessments for either of the above startup activities. The current goal is to have these modern evaluations with any associated changes to equipment, postings, and procedures in place prior to the start of the CRAs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 26, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending September 26, 2014

Federal Oversight: On Thursday, the Secretary of Energy requested a plan by November 14, 2014, to transition management of the contract for the legacy environmental cleanup work at LANL from NNSA to the Office of Environment Management.

Plutonium Facility–Safety Systems: Last month, a team from the DOE Office of Enterprise Assessments (EA) completed a review of the ventilation system and facility control system. During the review, the EA team questioned whether the facility surveillance procedure that implements the ventilation system functional test fully meets the technical safety requirement surveillance. Specifically the EA team challenged whether the system functional test procedure ensured “The injection of a simulated or actual signal as close to the sensor as practicable to VERIFY OPERABILITY, including required alarms, INTERLOCK(s), trip functions, and failure trips” as specified in the functional requirements of the documented safety analysis. Last week, following a series of discussions on the subject between the field office, LANL, and the EA team, the field office transmitted a letter to LANL requesting additional information. The field office directed LANL to (1) prove that the performance of the implementing procedure(s) meet the surveillance requirement and (2) provide evidence that the implementing procedure(s) demonstrate how performance of the surveillance requirement ensures that the functional requirements specified in the safety basis for the ventilation system and facility control system are being met. The field office requested this evidence, including any necessary revisions to the implementing procedure(s) and safety basis by September 29, 2014.

Plutonium Facility–Criticality Safety: Last month, one of the program groups completed a pilot demonstration to assist operators in complying with criticality safety requirements by posting printouts from the LANMAS database at the workstation. The current practice requires operators to obtain inventory information from a LANMAS workstation that is not necessarily in proximity to the workstation. This pilot was based on a perceived best practice from the Lawrence Livermore National Laboratory, where operators have successfully used printouts at the workstation for many years. The group leader noted that the use of the printouts served as a quick verification that the fissile material within a location complied with applicable limit. Nonetheless, the group did not recommend proceeding with the use of printouts, primarily citing concerns that operators may forget to update the printouts creating “audit traps.” Producing a printout would require one additional action in the already mandated procedure for LANMAS transactions.

Emergency Management: Last week, LANL issued their after action report from an August 2014 tabletop exercise involving response to contaminated patients. The report notes that all exercise objectives were satisfactorily met, but provides the following opportunities for improvement: (1) only a single LANL medical provider is authorized to perform hands-on assistance at the local hospital, (2) thresholds for respiratory protection and vehicle decontamination have not been established, (3) a memorandum of understanding (MOU) is not in place to ensure helicopter transport of contaminated patients to regional care centers with advanced trauma capabilities, (4) a MOU is not in place with Sandia National Laboratories to facilitate radiological control technicians for patients that may need hospital treatment in Albuquerque, and (5) wider participation should be considered for the DOE provided Radiation Emergency Assistance Center/Training Site. LANL personnel are evaluating the need for corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 3, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 3, 2014

DNFSB Staff Activity: R.K. Verhaagen observed an Integrated Nuclear Planning workshop held at DOE Headquarters. The objectives of the workshop were to validate the projected mission set for LANL nuclear facilities, provide an update on plutonium operations, and provide an update on line-item facility projects.

Area G–Nitrate Salts: On Wednesday, as part of hazards analysis discussions, a chemist raised concerns about the efficacy of the instant temperature measurements on the lids of the Standard Waste Boxes to detect reliably the presence of elevated temperatures within the nested drums. Safety analysis assumed this temperature monitoring would provide sufficient indication of a potential reaction to protect operators who need to enter the Permacon environment to conduct rounds and take headspace gas samples. Recent modeling questioned this assumption by highlighting the insulation capabilities of the wheat-based kitty litter and cardboard drum liners. After hearing the concern, Area G management paused activities in the Permacon until work control documents were revised to include respiratory protection. Rounds and headspace gas sampling resumed Thursday evening.

Plutonium Facility–Safety Systems: On Monday, LANL submitted their response to the field office request regarding the Facility Control System (see 9/26/14 report). Field office personnel are reviewing the detailed response and are planning to meet with personnel from the DOE Office of Enterprise Assessments next week to discuss the path forward. In the response, LANL noted that the September 2013 version of the safety basis reflects an improved description of the systems and their relationship to the credited surveillance procedure.

Plutonium Facility–Worker Safety: Programmatic operations remain restricted in several plutonium-238 laboratories while the operations group continues to investigate and repair gloveboxes with material condition concerns (see 8/8/14 weekly). The group recently replaced several longstanding cracked glovebox windows. Post replacement inspection revealed damage to both layers of glass, contradicting previous assessments by the system engineers. Separately, the group identified a failed gasket on a spool piece attached to the only glovebox capable of bagouts in this area. The group identified this failure when the joint obviously failed a smoke test (i.e., considerable smoke passed through the joint into the glovebox). This condition likely contributed to several recent instances of unexpected contamination in this room. Radiation protection staff used tape to restore this joint temporarily to support an upcoming campaign of waste bagouts needed to reduce combustible loading. The group's investigation also revealed that several abandoned conduits and tubes that remain in communication with glovebox environments are only sealed with tape. The group is actively pursuing engineered solutions to all these problems. The Site Representatives note that LANL management has not considered any of these conditions significant enough to declare these safety significant systems as inoperable.

Transuranic Liquid Waste (TLW) Subproject: Last week, LANL transmitted to the field office revision 3.1 of the Safety Design Strategy. The revision addressed field office comments (see 8/22/14 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 10, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 10, 2014

DNFSB Staff Activity: D.J. Campbell and R.C. Eul reviewed work planning and control.

Management: On Monday, the TA-55 Facility Operations Director (FOD) assumed control of the Chemistry and Metallurgy Research (CMR) building. The move is intended to facilitate the transition of CMR operations to the Radiological Laboratory Utilities Office Building, which is also under the control of the TA-55 FOD. The Science and Technology Operations FOD absorbed the remainder of the facilities under the former Radiological Chemistry Operations FOD.

Emergency Management: Last month, division personnel completed a six-sigma improvement initiative regarding emergency response with a particular focus on incident command and control. The initiative revealed the following key barriers to achieving success: (1) the process is inconsistent, often informal, disjointed, leading to added complexity, (2) lack of credibility and cooperation, (3) lack of formality of operations, (4) unclear roles and responsibilities, (5) poor integration between responders, and (6) emergencies are not reported or are not reported in a timely manner. Improvement actions include the development and training to standardized response processes and building emergency plans, as well as development of a standard line of inquiry for notification of emergencies with associated metrics. The schedule to implement these and other corrective actions runs through early 2015.

Plutonium Facility–Worker Safety: Recently, the programmatic operations group leader for actinide processing began developing improvement actions for two cases in one of the aqueous processing laboratories of gloveboxes with degraded material conditions. In one case, the group believes there is a breached gasket or similar failure on a spool piece associated with a glovebox line to be used for americium-241 production. The group has been troubleshooting spurious contamination events near this spool piece since a worker received an uptake in March 2013. The spool piece is currently draped with taped plastic sheeting and a radiological work permit is required for work in the associated glovebox; however, this glovebox remains operable per the safety basis (see 10/3/2014 weekly). In the other case, an entire wall of legacy gloveboxes, including some that housed a former incineration process for plutonium-238 contaminated rags, contains degraded conditions that workers suspect has contributed to multiple contamination events during the past few years. LANL management does not currently have a plan to remove these gloveboxes in order to both eliminate the hazard and free up the considerable space for new programmatic work.

Plutonium Facility–Criticality Safety: Operators recently initiated efforts to repackage plutonium metal turnings into water resistant containers to achieve compliance with the approved criticality safety limit under the Justification for Continued Operations (see 7/4/2014 weekly). The repackaging delays resulted from three criticality safety infractions in one of the two locations that contain more than 500 g of turnings and competition for the operators' time, since the operators are essential to the ongoing effort to resume the T-Base 2 machining activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 17, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 17, 2014

DNFSB Staff Activity: J.W. Plaue was on leave this week.

Plutonium Facility–Readiness Activities: On Wednesday, a Red Team kicked off a review of Safety Management Program (SMP) implementation in the Plutonium Facility. The Associate Director for Plutonium Science and Manufacturing is sponsoring this review with the stated objective of assessing the functional implementation of SMPs for compliance gaps between regulatory drivers and Plutonium Facility implementing documents, as well as to evaluate field implementation. The team is comprised of an independent group of senior professionals with expertise in relevant disciplines and will accomplish its review primarily through document reviews, interviews, and field observations. The SMPs that will be reviewed include those identified in 10CFR 830, as well as additional SMPs credited in the Plutonium facility safety basis.

The approved evaluation plan indicates that a necessary outcome of the review will be an endorsement of each SMP's technical adequacy, formality of operations performance, and whether implementation supports moving to the next phase of the readiness process for the Plutonium Facility. For those SMPs that cannot be endorsed by the team, specific details of the compliance gaps are requested. In addition to evaluating the health of Plutonium Facility SMPs, the review results will be used to develop the scope of future Contractor Readiness Assessments (CRA) for Plutonium Facility resumption.

The field office approved the Plan of Action for a CRA to establish an Americium-241 production capability in the Plutonium Facility (see 8/22/14 weekly). Of note, the management self-assessment of this activity is currently suspended due to identified procedure and labeling issues (see 9/19/14 weekly). The field office approval letter noted that due to the timing of this CRA and identified issues during other recent readiness activities, additional scrutiny is necessary, in particular with ensuring the relevant SMPs and the implemented safety basis adequately support this activity.

Radiological Laboratory Utility Office Building (RLUOB)–Radiological Operations: This week, LANL briefed the field office on plans for near-term radiological operations in RLUOB. RLUOB radiological operations commenced on August 28, 2014, at the current material-at-risk limits specified in DOE-STD-1027 for a Radiological Facility. LANL intends to increase the material-at-risk limits from the current 8.4g to 38.6g of Pu-239 equivalent as allowed by NNSA's supplemental guidance to DOE-STD-1027. This increase is targeted to occur in July 2015 and will accommodate transition of some additional analytical chemistry capabilities from the Chemistry and Metallurgy Research Building to RLUOB.

Weapons Engineering Tritium Facility (WETF): WETF personnel reported satisfactory results for the second 31-day monitoring period of oxygen monitoring system performance (see 8/29/14 weekly). One additional satisfactory 31-day monitoring period is necessary to declare the system operable prior to startup. Facility personnel continue to work on corrective actions from the issues discovered during the recent CRA (see 9/19/14 weekly). The facility startup plan includes completion of a checklist CRA to verify corrective actions are effective prior to the federal readiness assessment currently scheduled to commence in December.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 24, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 24, 2014

DNFSB Staff Activity: On Tuesday, D.J. Campbell and R.C. Eul presented their observations on work planning and control to site management.

Field Office: On Monday, the field office reported to NNSA Headquarters the quarterly status on the Technical Qualification Program and associated staffing needs. The analysis, performed in accordance with DOE Order 426.1, *Federal Technical Capability*, indicates an overall staffing capability shortfall of 28. This shortfall includes two Senior Technical Safety Managers, four Nuclear Safety Specialists, six Facility Representatives, one Safety System Oversight engineer, and three Quality Assurance engineers. NNSA is currently allocating staffing based on the Capabilities Based Field Office model, which remains conceptual. As a result, the field office currently has only 11 authorized vacancies.

Emergency Management: Early this month, LANL issued the after action report for the annual full-scale exercise (see 8/29/14 weekly). Their findings included: (1) direct communication between facility incident command and the fire department was never established, (2) the Emergency Operations Center (EOC) was assumed to initially be habitable; however, modeling later showed it to be within the plume and protective actions were not re-evaluated, and (3) field office public affairs was not represented. They also identified 12 opportunities for improvement, including the following of note: (a) additional radiological controls experts should be trained as controller/evaluators, (b) the Emergency Manager needs to communicate protective actions using actionable geographical reference points rather than distances, (c) the full screen monitor in the EOC needs repair, (d) the EOC needs more than one information technology support person, and (e) Los Alamos Medical Center warrants improvements with training on protocols and communications between the decontamination room and emergency room.

Plutonium Strategy: Last Thursday, the NNSA Deputy Administrator for Defense Programs issued a memorandum to the Field Office Manager and LANL Director requesting an analysis to examine the potential to increase the radioactive material inventory in the Radiological Laboratory Utility Office Building (RLUOB) to up to 400 g of Pu-239 equivalent. The analysis is to consider RLUOB as a Hazard Category 3 nuclear facility and is to examine impacts on safety, cost, and schedule. The Deputy Administrator expects results within five months.

Confinement Vessel Disposition (CVD) Project: This week, CVD personnel completed cleanout and robotic wire brushing of the first confinement vessel of the project. Project personnel intend to perform activities to de-mate the glovebox and robotic arm, as well as performing neutron assay of the cleaned out sphere, prior to shipment to Area G for final processing for disposition.

Plutonium Facility-Resumption Activities: The Red Team review of Safety Management Programs (SMP) concluded Friday. The team reported 41 issues and concluded that the programs are generally technically sound, but require improvements in implementation. The most significant of the identified issues concluded that the criticality safety SMP required significant attention, in particular with the development of compliant criticality safety evaluations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 31, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 31, 2014

The Site Representatives participated in briefings at DNFSB Headquarters this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 7, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 7, 2014

Plutonium Facility–Seismic Safety: R. K. Verhaagen observed a meeting in Albuquerque of a Seismic Expert Panel charged by the field office to review two separate analyses of Plutonium Facility performance during a seismic event. The panel has been assembled to identify similarities and differences between LANL's existing structural analysis of the facility and an alternate analysis sponsored by NNSA as committed by the Deputy Secretary in his memorandum to the Board dated September 28, 2012. The panel is expected to issue a report in January 2015, addressing points of concern directly impacting the Plutonium Facility's seismic adequacy as well as other points of perspective. During this initial meeting the panel identified some significant differences between the results of the two analyses that they deemed appropriate for additional investigation to better understand the root of the inconsistencies. The panel expects to meet again in San Francisco during the first weekend in December to further their deliberations.

Plutonium Facility–Quality Assurance: Late last month, facility management declared two separate violations of the Technical Safety Requirements (TSR) associated with failures to properly execute limits on material-at-risk (MAR). The facility monitors MAR limit compliance using a software program known as MAR Tracker, which management declared implemented in the summer of 2011. A review of the facility's database indicates that at least 14 critiques concerning the implementation of MAR Tracker have been performed since that time, including four associated with TSR violations. Last month's violations appear to stem from Software Quality Assurance (SQA) issues between the beta and production versions of the software. Three previous critiques going back to June of 2013 identified similar concerns and included an action to formalize MAR Tracker data change management. Further, a TSR violation in April of 2012 resulted in an extent-of-condition review and an overall assessment on MAR Tracker implementation including SQA. Preliminary planned corrective actions for the current TSR violations include to: (1) ensure MAR Tracker is compliant with SQA requirements by December 15, 2014, (2) execute a plan to identify gaps in MAR requirements and MAR Tracker by December 1, 2014, and (3) conduct a SQA assessment on MAR Tracker led by an institutional expert by May 15, 2015.

Plutonium Facility–Safety Systems: On Tuesday, the field office responded with direction to LANL management regarding the Facility Control System issue (see 10/3/14 weekly). The direction is to revise the credited surveillance procedure to require injection of a simulated or actual signal as close to the sensor as practicable upstream from the FCS and to fully verify the interlocks, trip functions and failure trips of the ventilation system fans downstream of the FCS. LANL personnel are directed to execute this revised procedure within four weeks with a provision for field office personnel to shadow its performance.

Confinement Vessel Disposition (CVD) Project: This week, CVD personnel experienced two events where continuous air monitors alarmed during bag-off operations associated with the removal of the robotic arm. In both instances, personnel were using air-purifying respirators, and responded appropriately. Radiation protection personnel are reviewing the events and determining what additional actions and measures are required prior to resuming operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 14, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 14, 2014

Corrective Action Management–Nuclear Criticality Safety: In their December 6, 2013, response to the Board, NNSA highlighted a corrective action associated with the revitalization of the institutional Nuclear Criticality Safety Committee (NCSC). The response states that a goal of the NCSC is to “provide the necessary oversight to ensure issues are properly addressed and provide continual improvement of the program.” The LANL Director signed a new charter for the NCSC in March 2014 (see 3/28/14 weekly). The revitalized NCSC held their fifth monthly meeting this Thursday. Discussions included labeling requirements and a proposed revision to the infraction severity levels. The NCSC also discussed scheduling their first semi-annual briefing to the LANL Director, establishing a replacement external member, conducting the first operational walk-down, and beginning a review of the completion and effectiveness of corrective actions. Separately, the NCSC continues to work on developing their procedures, annual operations plan, and quarterly schedule.

Plutonium Facility–Nuclear Criticality Safety: On Wednesday, Plutonium Facility management reported to the Field Office that the plutonium metal turnings in excess of 500 g had been repackaged into water resistant containers in two of the three glovebox locations (see 7/4/14 weekly). This brings these locations into compliance with the Field Office approved Justification for Continued Operations.

Plutonium Facility–Safety Systems: In the facility, there are currently at least two glovebox lines containing windows with significantly degraded transparency. In one location associated with plutonium-238 operations, the opacity resulted years ago from an operator’s mistaken use of hydrofluoric acid for window cleaning. In the other location, the installed window glass appears to be incompatible with the chemical dissolution operations housed inside. The opacity of these windows prevents effective periodic visual inspection of these locations (e.g., combustible loading, criticality compliance, maintenance). Within both lines, only one glovebox in the second line remains in active service. Operations personnel are working to schedule window replacements.

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a Technical Safety Requirement (TSR) violation due to issues encountered during the conduct of the third and final 31-day monitoring period of Oxygen Monitoring System (OMS) performance (see 8/29/14 weekly). First, during re-assembly of an OMS cell housing for the Tritium Waste Treatment System (TWTS), a clamping screw broke off rendering the system inoperable. During the successive repair and testing, personnel failed to realize that delays had caused the required periodicity to be exceeded for the TSR surveillance on the OMS associated with the Tritium Gas Containment System (TGCS). When operations personnel discovered this discrepancy, they entered the appropriate Limiting Condition for Operations. During the critique facility personnel discussed issues with the processes used to control system operability when performing surveillances, operator confusion caused by the complexity of safety basis and procedure interaction, and tracking TSR completion. A causal analysis will be performed to better understand and fix these issues.

Plutonium Facility–Safety Basis: Last week, LANL submitted a revision of the Plutonium Facility safety basis to the Field Office for review and approval. Changes included increasing the material-at-risk (MAR) limits outside of the Plutonium Facility but within the boundaries of Technical Area 55 protected area to allow operation of the Transuranic (TRU) Waste High Efficiency Neutron Counter. LANL notes that although the MAR limits are increased, as the process to assay and ship TRU waste offsite is implemented, there will be a net reduction in MAR inventory at Technical Area 55 as a result. Additionally, the MAR limit for confinement pressure vessels stored outside of the Plutonium Facility has been reduced due to recent shipments of the vessels from the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 21, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 21, 2014

Board Visit: This week, DNFSB Chairman Winokur and Vice Chairman Roberson visited the laboratory along with staff members R.E. Tontodonato and D.J. Campbell. The Board received briefings from site personnel and walked down several facilities, including the Plutonium Facility.

DNFSB Staff Activity: On Thursday, staff members P.J. Foster, E.M. Gibson, and R.L. Jackson reviewed the status of the Transuranic Waste Facility project. The staff team held discussions with field office and LANL personnel regarding worker safety, the construction schedule, and planned oversight activities. The staff team and Site Representatives also walked down the construction site for familiarization and training purposes.

Plutonium Facility–Configuration Management: On Thursday, program personnel declared a process deviation for nuclear criticality safety when an operator discovered about 30 L of unexpected liquid in a horizontal pencil tank array. Program and facility personnel conducted a fact-finding for the event and determined that management had posted the tank array out of service in 2007 because of concerns with wall thinning. In addition, operators last rewrapped the tank flanges, which contain the sight glasses, in 2009. The fact-finding participants were unable to characterize the liquid or determine a potential source, in large part due to the lack of an engineered piping diagram for this system. Corrective actions include the development of a plan to safely sample and relocate the liquid to robust tanks. Management also determined the need for an extent of condition review to examine other out of service tanks in the facility, since these do not currently receive any type of periodic inspection.

Plutonium Facility–Resumption Activities: Plutonium Facility management authorized the commencement of the management self-assessment for the Balance of Machining activities.

Emergency Management: This week, LANL personnel conducted Emergency Radiological Responder Training (ERRT) for a class of recruits for the Los Alamos County Fire Department. The initial ERRT consists of multi-day classroom instruction on radiation protection fundamentals, unique materials fires, ventilation system fires, and glovebox fires. The ERRT also includes drill evolutions covering establishing perimeters, contaminated patient handling, and doffing contaminated protective gear, in addition to a training evolution on glovebox firefighting. An evaluated drill evolution is required annually, which is particularly important because firefighters often simulate these actions during drills and exercises in the nuclear facilities. For example, firefighters typically simulate use of breathing apparatus because of staffing constraints associated with rehabilitation time and limited overtime for extra shift coverage. Similarly, firefighters typically do not handle actual people or anthropomorphic dummies during contaminated patient handling exercise scenarios due to safety concerns for the people and the firefighters. The Site Representative observed portions of the training and found it to be generally of high quality; however, he discussed with management an inconsistency with the staged graphite containers used in the glovebox firefighting training and the containers found in the Plutonium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 28, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 28, 2014

Plutonium Facility–Conduct of Operations: Last Friday, two workers entered a room under an active loss of ventilation alarm and proceeded to perform work in the restricted area for about an hour. At the time, the entire half of the facility they were working in was under restricted access in support of maintenance activities on the ventilation system. Management discovered their presence when one individual requested support after alarming a contamination monitor while surveying his head. During the fact-finding, personnel discussed issues with three barriers that should have prevented the incident. First, the workers heard the alarm, but did not recognize it and respond appropriately. Personnel noted that in recent years, the samples of the audible alarms were removed from the required facility access training. Second, communication of the status of the facility was insufficient. Specifically, postings and barriers were not placed at the appropriate locations to warn workers of entry into the wing. Third, work scheduling and release processes did not identify the conflict because the work activity was included in a generic work activity that is captured on the plan of the day as ongoing most days. Management tasked corrective actions associated with alarm training and improving communication of the status of the facility.

Emergency Management: On Monday, LANL personnel conducted an emergency exercise at the Weapons Engineering Tritium Facility (WETF). The exercise scenario involved a glovebox explosion and fire that injured and contaminated a worker. The Site Representatives noted good constructive criticism during the exercise hot wash with some of the more pertinent issues discussed including:

- Fire department response to the injured worker took more than 30 minutes, largely resulting from communications issues between the Emergency Operations Center, the Facility Incident Command (FIC), and the fire department.
- The fire department staged at a nearby firehouse and assumed the role of Incident Command prior to arriving on scene and without having received a status briefing from the FIC.
- The FIC initially determined that protective actions were unnecessary; however, the Incident Commander nearly an hour later declared a shelter-in-place for a 2100-meter box zone.
- Responders had trouble with the function and availability of radios and telephones.
- Personnel noted the lack of decontamination and monitoring equipment staged in locations outside of the main operating buildings that are typically evacuated in emergencies.
- Controllers provided inject information for facility-instrumented indications that used incorrect units and did not cover all relevant locations.
- WETF personnel indicated that they had identified many of these issues during previous exercises, but they remain unresolved.

The Site Representatives note that despite these fundamental issues, exercise personnel preliminarily determined that nearly all (~63 of 68) of the exercise objectives were met. This result strongly suggests that the exercise objectives are insufficiently challenging to effectively drive needed improvements. Examples of the objectives used in this exercise include: workers obeyed instructions, the FIC ensures 911 is called, the fire department establishes Incident Command, the Emergency Manager approaches the scene with care and uses the proper forms, and an exercise plan was developed. In contrast, not a single objective assessed the timeliness of the response or the correctness of protective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 5, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 5, 2014

Plutonium Facility–Safety Systems: On Thursday, the facility returned to Operations Mode for the first time in three weeks following the successful completion of a revised surveillance test of the Facility Control System (see 11/7/2014 weekly) and multiple repairs to one of the credited diesel firewater pumps.

Plutonium Facility–Resumption: On Wednesday, LANL management decided to delay the start of the contractor readiness assessment for the T Base II lathe from next Monday to January. The decision was largely based on the need ensure that the controls from the new compliant criticality safety evaluations could be implemented and integrated into operating procedures.

Weapons Engineering Tritium Facility (WETF): Last month, WETF management issued a letter to the NNSA program manager providing the program plan for activities under the Tritium Legacy Project. The project aims to reduce the current inventory of tritium from about 220 g to less than 100 g in order to align the inventory with future programmatic needs. The letter indicates the project will take 5–7 years with bulk tritium gas shipments expected to occur in the first 4–5 years. The plan does not provide specific out-year milestones, but current fiscal year elements include facility restart, equipment and program upgrades, shipment of at least one AL-M1 molecular sieve to the Savannah River Site, and loading of at least one Flanged Tritium Waste Container. Also, late last month, WETF notified the Field Office of successful completion of the third month of required monitoring on the Oxygen Monitoring System (see 10/17/2014 weekly).

Area G–Quality Assurance: This week, Area G personnel identified two occurrences where the field conditions of material-at-risk (MAR) did not match what was contained in the quality records of the MAR tracking database used to ensure compliance with safety basis limits. Area G personnel monitor MAR limit compliance using a software tool known as the Waste Compliance and Tracking System (WCATS), which was implemented in August 2013. In the first instance, in an effort to overpack remediated nitrate salt waste drums into standard waste boxes, operators did not follow the normal processes and procedures for accounting of MAR. This resulted in the volume of waste recorded in the system exceeding the actual volume of waste in the facility. In the second instance, a waste drum was discovered that was not recognized by WCATS. During the critique of this event, Area G personnel identified that during a transition of MAR tracking databases this drum had a location code that was not captured in the new WCATS. Area G personnel declared a violation of the technical safety requirements and are conducting an extent of condition review to ensure that the issues with quality records for tracking MAR in Area G are isolated to these instances.

Area G–Safety Basis: On Wednesday, Area G management declared a Potential Inadequacy of the Safety Analysis (PISA) due to the discovery of an unanalyzed accident scenario in the safety basis. This PISA is focused on newly generated transuranic waste in 55 gallon drums because there are no controls in place to limit the combustible composition of the waste. The Board’s staff identified this issue during follow-up of a related PISA (see 3/28/14 weekly). During the new information process, analysts determined that multiple combustible drums involved in a fuel pool fire may not be bounded by the current accident analysis. As a result, management suspended receipt of newly generated 55 gallon drums in Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 12, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 12, 2014

Emergency Management: During the past weekend, LANL and field office personnel conducted a multi-day full-scale emergency response exercise involving several hundred people. While the scenario focused on a security event, the Site Representatives note a number of positive elements associated with the exercise conduct that could benefit future drills and exercises. In particular, exercise designers chose a scenario unique from those previously exercised and attempted to minimize simulation in several areas. For example, operators physically deployed unmanned aerial systems to provide video surveillance of the event and support personnel physically moved security barriers around the lab site. In addition, assurance personnel utilized about 30 video cameras, including some mounted to response personnel and controllers, to record interactions with the intent of ascertaining factual evidence for after-action analysis, as well as generating training materials. Finally, the exercise designers included greater emphasis on typically underplayed elements of the response, including a full mock press conference and about a day of recovery planning.

Plutonium Facility–Emergency Management: Last Thursday, the Nuclear Criticality Safety Division issued a memo providing a revised calculation for the Immediate Evacuation Zone for the facility. The results indicate the zone extends into the Operations Center necessitating its evacuation. However, the memo concludes that personnel may remain in the Operation Center provided that: (1) they acknowledge and accept the associated risk, (2) the radiation levels are acceptable, and (3) the presence is made with continuous radiation monitoring equipment. Facility personnel will need to implement the revised conclusion through updates to alarm and emergency response procedures, training, and drills/exercises. The Site Representatives note that an ideal solution would be to ensure facility indications are repeated to the Facility Incident Command center in the Radiological Utility Office Building. The Criticality Alarm System upgrade as part of the TA-55 Reinvestment Project includes some of this scope; however, recent efforts to reduce costs may put this functionality in jeopardy.

Weapons Engineering Tritium Facility (WETF)–Configuration Management: Last week, during performance of an integrated work document to replace relief valves on the WETF high and low pressure nitrogen systems, facility operators secured a facility ventilation fan due to an unexpected system response. Upon investigation, WETF personnel observed that the ventilation system inlet and outlet dampers for a WETF process room were inadvertently shut. The resultant pressure drop actuated a ventilation system differential pressure alarm causing operators to respond appropriately by securing the supply fan. During a critique of the event, WETF personnel identified that the ventilation system had been modified in 2006 to use the high-pressure nitrogen system to provide a motive force to pneumatically hold open the dampers. When the nitrogen system was tagged out for maintenance the motive force was lost and the dampers closed. The use of the nitrogen system to provide this function was an unauthorized modification made when decommissioning the Emergency Tritium Cleanup System and associated compressed air system. This modification was made prior to WETF personnel implementing a conduct of engineering program so there was no configuration control of the alteration. As a result, nitrogen and ventilation system drawings do not reflect the actual system configurations, associated procedures are not developed with this configuration in mind, and operators have not been trained on the modifications or the operational interfaces between these systems.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 19, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 19, 2014

DNFSB Staff Activity: J.W. Plaue was at the Lawrence Livermore National Laboratory (LLNL) this week to assist with a site familiarization visit by the new DNFSB staff LLNL cognizant engineer.

Plutonium Facility–Resumption Activities: This week, the field office approved a LANL request to remove the T-Base 2 machining operation from the scope of the Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) regarding the potential for criticality due to firewater flooding (see 5/23/14 weekly). The LANL request identified that all required actions established in the ESS/JCO approval letter necessary to remove the ESS/JCO compensatory measures had been completed. These actions included field office approval and LANL implementation of a comprehensive Criticality Safety Evaluation Document.

RANT Shipping Facility: On Wednesday, facility management declared a potential inadequacy in the safety analysis (PISA) for the RANT Shipping Facility. Safety basis personnel were following the new information process in response to an issue raised in the Board's December 9, 2014, report to NNSA detailing deficiencies in the facility's approved, but not yet implemented, Documented Safety Analysis (DSA). The Board's letter questioned whether the RANT Shipping Facility's seismic analysis demonstrates that the structure meets its credited seismic performance criteria. The same analysis is cited as demonstrating adequate seismic performance in the currently implemented Basis for Interim Operations. The LANL calculation supporting this analysis concludes that the facility does not meet its safety basis credited seismic performance. RANT engineering and safety basis personnel are evaluating this information through the Unreviewed Safety Question Determination (USQD) process. Today, the field office transmitted a letter to LANL rescinding approval of the DSA and directing the facility remain in cold standby until authorized by the field office to change modes.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): This week, WCRRF personnel identified that a procedural change for processing waste in the WCRRF glovebox was made without an adequate USQD being performed. The procedural change was made over two years ago and removed the requirements to stop waste processing and inform management if, among other things, Class 1 oxidizers (such as nitrates), flammable metals or pyrophoric materials were encountered. The currently implemented Basis for Interim Operations does not allow processing of these types of materials. The WCRRF is in cold standby.

Confinement Vessel Disposition (CVD) Project: CVD personnel completed de-mating the robotic arm and glovebox workstation from the first processed confinement vessel (see 10/24/14 weekly). Port covers have been installed in place of the robotic arm and workstation. These actions followed procedural and process changes needed to enhance contamination controls within the enclosure when de-mating these items. The confinement vessel will remain in this safe configuration within the enclosure until the New Year when it will be assayed and shipped to Area G for final processing and disposition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 26, 2014

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 26, 2014

LANL's annual winter closure began Wednesday evening with operations resuming on January 5, 2015.

Conduct of Engineering: Last month, LANL issued the report from a recent Parent Organization Functional Management Review. The review concluded that there has been significant improvement in the Conduct of Engineering since 2006 and noted seven noteworthy practices. Opportunities for improvement included the need for: (1) processes to support continuous improvement, (2) assignment of system engineers earlier in projects, (3) increased focus on configuration management, (4) safety basis awareness training for design engineers, and (5) a more focused effort to keep standards up to date. One of three additional performance feedback items noted that some engineering efforts performed in program groups have not fully embraced Conduct of Engineering and suggested bolstering this interface to ensure that activities that may impact safety bases are appropriately elevated.

Area G–Nitrate Salts: Area G personnel initiated a series of thermal tests to determine the rate of heat removal from a 55-gallon drum containing remediated nitrate salt wastes. The tests will utilize instrumented drums containing a surrogate mixture of wheat-based cat litter and a commercial ice-melt compound consisting of calcium and magnesium chlorides. A robust understanding of the cooling and warming rates is necessary to support the safety of the planned final treatment process, which will rely on temperature control to minimize heat generation from microbial species and slow chemical kinetics.

Plutonium Facility–Work Planning: Last Thursday, a group of eight workers, with five simultaneously working in gloveboxes, experienced a contamination event while performing corrective maintenance on the trolley in the plutonium-238 area. Radiological surveys identified greater than two million disintegrations per minute (dpm) in several locations in the room and on multiple areas of the coveralls of two individuals. One of these workers also had about 500 dpm on the skin. Overall, three workers started special bioassay. The continuous air monitor alarmed about 1.5 hours into the event; however, its filters and those of other fixed air samplers revealed only low levels of airborne contamination. Management conducted a fact-finding for this event on Monday where follow-up actions revealed a V-shaped tear about the size of a quarter in one of the gloves; however, potential causes of the tear remain undetermined. Other points discussed include the need for extra monitoring equipment, reinforcement of surveying following glove exit, and a request for continuous presence of a radiological control technician (RCT) during complicated trolley jobs. The participants noted excellent responses by the RCTs. The Site Representatives note that many of the RCTs in the facility, including the involved RCTs, recently conducted drills for similar scenarios as part of readiness preparation activities, which may have contributed to the strong response.

Plutonium Facility–Worker Safety: On Monday, the programmatic operations lead released restrictions on the plutonium-238 oxide thermal treatment line (see 8/8/14 weekly). The release comes after a significant improvement in the safety posture of these old gloveboxes, including the replacement of several compromised windows, engineered closure of previously taped openings, repairs to shielding, and correction of electrical safety issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 2, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 2, 2015

The Year on a Page: The key happenings of 2014 and a look at the year ahead as distilled by the Site Reps:

- The Field Office gained a permanent Manager; however, several key management and safety related positions remain vacant. LANL created a new Associate Deputy Director position and appointed a new Deputy Director, a new Principal Associate Director for Operations, and several new managers associated with transuranic waste operations.
- Plutonium Facility (PF-4) operations remain largely dormant 18 months after the LANL Director's pause stemming from criticality safety and conduct of operations issues. PF-4 personnel spent much of the last six months preparing for the expected 10 federal readiness assessments (FRA) required to restart the complete suite of programmatic operations. The first contractor readiness assessment (CRA) is set to begin on January 12, 2015, with the entirety of the restart effort planned to span the duration of the year.
- The PF-4 safety posture improved with the completion of reinforcements to eight vault columns and strengthened seismic anchorages to the fire suppression, electrical, and ventilation systems. The year 2015 is set to include planned reinforcements to the roof girders, additional safety system upgrades, and perhaps the completion of the alternative seismic analysis of the facility, which is currently stalled.
- In May 2014, photographic evidence revealed a transuranic waste drum originating from LANL contributed to the radiological release at the Waste Isolation Pilot Plant. Since then, LANL personnel have spent considerable effort investigating how processes failed and allowed nitrate salts to be mixed with wheat-based cat litter, how a chemical reaction initiated in this mixture and breached the drum, and how similar drums can be safely treated to rectify the situation. Treatment operations are likely to commence later in 2015; meanwhile, transuranic waste operations remain largely curtailed.
- Following nearly a year of troubleshooting the Oxygen Monitoring System, the Weapons Engineering Tritium Facility (WETF) conducted a CRA to restart gas transfer operations, which have not occurred since 2010 and are required to support risk reduction efforts. The CRA identified that facility performance was insufficient to support safe operations. In early 2015, WETF management plans to re-perform the CRA ahead of a FRA. In parallel, personnel continue to achieve minor gains in risk reduction through direct-discard of tritium contaminated legacy items into Flanged Tritium Waste Containers for disposal at Area G.
- After a period of uncertainty on the approach to terminate programmatic operations in the Chemistry and Metallurgy Research building by 2019, NNSA and LANL moved forward with the first two steps of the Plutonium Strategy. Facility work supporting these steps is to commence in early 2015.
- In June 2014, LANL closed all the pre-start findings from the October 2013 Operational Readiness Review for the Confinement Vessel Disposition project. Since then, project personnel successfully cleaned out the first of nine vessels. They plan to process another two in the remainder of fiscal year 2015.
- The Nuclear Criticality Safety Division gained a new manager, three new experienced analysts, and four new junior analysts. The Division issued about 100 new criticality safety evaluations in the past year and will need to generate several hundred more to support the full restart of PF-4.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 9, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 9, 2015

Plutonium Facility–Safety Systems: Late last month, LANL transmitted to the field office for review and approval the major modification determination for the Active Confinement Ventilation Upgrade Project (ACVUP). Based on feedback from the field office, LANL concluded that the ACVUP constituted a major modification to the safety basis. However, since the system’s safety function will remain to provide airflow via cascading differential pressures, LANL intends to submit a safety basis strategy at the end of this month that relies upon a graded approach. This will involve submittal of safety basis page changes developed against DOE-STD-1189 in lieu of a preliminary documented safety analysis. The ACVUP is a subproject under Phase III of the TA-55 Reinvestment Project with a pre-conceptual completion date of fiscal year 2024.

Also late last month, LANL transmitted a revision of the TA-55 Project Execution Strategy (PES). The PES serves to help integrate the scope, high-level schedules, and funding associated with the numerous capital and program-funded projects associated with actions necessary to reduce the mitigated offsite consequences from seismically-induced events to below the DOE Evaluation Guideline. The PES identifies the following scope for fiscal year 2015:

- Modify the sewer vent in the Bleed-off system to prevent the formation of ammonium nitrate on the ventilation system HEPA filters
- Seismic qualification for numerous replacement and spare components for safety systems
- Evaluation of options to equip gloveboxes with fire suppression in accordance with DOE and national consensus standards
- Modify the anchorages for various electrical and ventilation system components
- Improve the shear capacity of the interior roof girders
- Upgrade six stands of gloveboxes containing furnaces to meet Performance Category 3 requirements during the next two years

Emergency Management: On Thursday, LANL personnel conducted the annual emergency exercise at the Radioactive Liquid Waste Treatment Facility (RLWTF). This year’s scenario involved a postulated crash of a delivery truck carrying poisonous gas in the facility’s yard area. The event triggered an immediate facility evacuation to the outdoor muster point and response by the fire department and hazardous material team. This year, coordination of facility response was improved through an area-wide announcement transmitted from the TA-55 Operations Center alerting facility responders to assemble at the Facility Incident Command at the Radiological Laboratory Utility Office Building, which is down the block from RLWTF.

Plutonium Facility–Quality Assurance: This week, facility management declared another violation of a Technical Safety Requirement associated with material-at-risk (MAR) limits (see 11/7/14 weekly). In this instance, an extent of condition review revealed two locations that were not included in the MAR tracker database used to track limit compliance. Facility personnel attempted to correct the deficiencies in the database and to complete the required surveillance within 24 hours to maintain operability as allowed by the Documented Safety Analysis. Performance of the surveillance failed when MAR tracker was unable to process all necessary input data. As a result of the failure to complete this surveillance in the required time, normal facility operations had to be terminated. A causal analysis is being performed and the facility is implementing a configuration management plan to address MAR tracker software changes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 16, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 16, 2015

Plutonium Facility–Restart Activities: On Monday, LANL commenced their contractor readiness assessment (CRA) of the T-Base II machining activity. The scope of the activity includes a single glovebox housing the lathe machine and a supporting glovebox and is conducted by two machinists and their first line manager. LANL management proposed using this activity to assess the health of the safety management programs. As a result, more than half of the CRA lines of inquiry are focused on these programs. The CRA is expected to conclude next week and will overall include about 70 interviews, a performance demonstration, and an emergency drill; the latter two occurred this week.

Plutonium Facility–Safety Systems: On Wednesday, a Plutonium Facility cognizant system engineer for the safety significant fire suppression system identified that a Technical Safety Requirement surveillance had not been performed as required. Specifically, sprinkler heads within two areas in the facility were not inspected to ensure they could function as required. In the first instance, maintenance personnel could not enter a laboratory room because they were unable to coordinate the Radiological Control Technician support required to enter the room with its existing contamination issues. In the second instance, maintenance personnel incorrectly interpreted the requirements and believed that sprinklers above the vault did not need to be inspected because they would need to access the top of the vault to examine the subject sprinkler heads. In both cases, the maintenance supervisor inappropriately determined that the areas were inaccessible and therefore the inspection of these sprinkler heads was not necessary to satisfy the surveillance. During a critique of the event, personnel determined that the subjectiveness of the term “inaccessible” in the procedure contributed to the misinterpretation.

Area G–Safety Basis: Safety basis personnel have yet to complete the Unreviewed Safety Question Determination (USQD) and the Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis (PISA) associated with combustible waste composition (see 12/5/14 weekly). DOE guidance indicates that the USQD should be completed within “hours or days, not weeks,” though the LANL procedure specifies 15 days and includes a provision for extension. Similarly, DOE guidance indicates that the ESS should be completed “as soon as practicable and not take more than a month,” which LANL implements with a 30 day limit and provision for extension through the Field Office. In this case, the PISA was declared on December 3, 2014, and neither extension provision was executed. Timely issuance of the USQD and ESS is important because they provide the analysis necessary for the Field Office to determine whether the operational restrictions LANL imposed are adequate to ensure worker and public safety. During 2014, three of the five PISAs declared within this organization did not meet LANL’s expectations, including a similar PISA concerning combustibles declared about a year ago (see 1/31/14 weekly) that took nearly 2 months to complete the USQD and ESS.

Chemistry and Metallurgy Research Building (CMR)–Criticality Safety: On Wednesday, LANL provided the Field Office with the results of a criticality safety review conducted by a LANL review team at the CMR. The review was performed to evaluate whether criticality issues similar to those identified in the Plutonium Facility also existed at CMR, as well as to improve the overall criticality safety performance at CMR. The review identified a number of opportunities to improve operator performance, operator training, and criticality safety postings. This review is one of many criticality safety improvement initiatives underway at LANL, the results of which have been compiled into one coordinated Criticality Safety Project Management Plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 23, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 23, 2015

Transuranic Waste Management: Last week, the field office requested a plan from LANL for sustaining operations during the shutdown of the Waste Isolation Pilot Plant (WIPP). The response provided an outline of waste generation and storage status and commits to providing a quarterly status report. The quarterly reports will assume LANL shipments to WIPP commence by October 1, 2016. The response also notes that the current inventory at Area G is at 28k of the 57k Pu-239 equivalent curie limit in the safety basis and that Area G personnel expect to implement use of pipe overpack containers in the safety basis later this spring. The use of pipe overpacks allows for a 90 % reduction in material-at-risk (MAR).

Plutonium Strategy: On Wednesday and Thursday, NNSA and LANL personnel conducted a working meeting in support of development of a final recommendation on whether to upgrade the Radiological Laboratory Utilities Office Building to a Hazard Category 3 nuclear facility to be operated at a limit of 400 g Pu-239 equivalent (see 10/24/14 weekly). The team expects to present their recommendation to senior NNSA leadership next month.

Plutonium Facility–Emergency Management: Last week, personnel conducted a facility-level drill for the readiness assessment team. The drill scenario involved a continuous air monitor alarm and an injured contaminated patient. In contrast with institutional-level exercises, responders donned respirators, performed field decontamination techniques, and physically loaded and moved the contaminated patient without simulation. In the last few months, facility personnel have initiated these style drills in preparation for upcoming readiness assessments (RA). Eventually, this effort will need to translate into a documented drill program to cover the full spectrum of potential abnormal events, locations, times of day, and personnel.

Plutonium Facility–Restart Activities: On Friday, the contractor RA team for the T-Base II machining activity out-briefed their results to management. The team identified two pre-start findings associated with the quality of evidence packages for the assessment prerequisites and the inability of planning and resource allocation processes to preserve the integrity of the facility safety envelope. The team identified three post-start findings associated with non-compliant material labeling practices for criticality safety, non-compliant criticality safety evaluations, and incomplete criticality self-assessments. In addition, there were 25 opportunities for improvement. Of note, the team commended the work crew associated with the machining activity as a model for others to follow. The federal RA for T-Base II is currently scheduled for May. The next contractor RA will cover the balance of machining operations and is scheduled to begin in mid-February.

Plutonium Facility–Quality Assurance: During the past several months, Plutonium Facility management declared multiple Technical Safety Requirement (TSR) violations associated with the failure to properly execute surveillances of MAR limits using the MAR Tracker software tool (see 11/7/14 weekly). In response to these failures, Plutonium Facility personnel performed an extent of condition review that identified additional issues with the MAR Tracker software (see 1/9/15 weekly). LANL recently reported to the field office that the exhaustive extent of condition review was completed and all surveillances have been performed to ensure the facility safety envelope is intact. Based on these actions, Plutonium Facility management reports that there is a high level of confidence that the related MAR Tracker issues have been resolved. Assurance personnel are continuing the latest of several causal analyses for these issues to ensure corrective actions are implemented that prevent future MAR Tracker configuration issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 30, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending January 30, 2015

RANT Shipping Facility: On Tuesday, LANL management transmitted to the field office for approval the positive Unreviewed Safety Question and the Evaluation of the Safety of the Situation (ESS) for an incorrect assumption in the seismic analysis for the facility structure (see weekly 12/9/2014 report). The ESS indicates that the RANT structure does not meet DOE-STD-1020-2002 criteria for an existing Performance Category 1 facility, contrary to its credited function to withstand a Performance Category 2 seismic event. The ESS notes that the operational restriction to maintain RANT in Cold Standby will continue (the Field Office has also withdrawn approval of the safety basis) and discusses several options to be studied in the next 90 days. The options include seismic bracing for the facility, seismic cutoff switches for electrical power, seismic cages to protect material-at-risk, or only performing loading operations outdoors via the mobile loading unit.

Plutonium Facility–Configuration Management: On Wednesday, operations personnel discovered about 3.5 L of unexpected solution in two pencil tanks. The tanks, and nearly all of the operations in the room, have been out of service since May 2013. This room has had frequent contamination issues and has been under restricted access, which resulted in the recent missed surveillance (see 1/16/15 weekly). This discovery occurred during the extent of condition review directed following the unexpected discovery of about 30 L back in November (see 11/21/14 weekly). While personnel expect both sets of liquids to be lean in nuclear material, they have yet to determine the composition of the liquid or a suspected source.

Weapons Engineering Tritium Facility (WETF)–Formality of Operations: In response to questions from the Facility Representative, WETF management convened a fact-finding to investigate an improperly performed maintenance activity that resulted in a facility evacuation alarm. The fact-finding revealed that in December, an operator was performing a surveillance on the tritium monitoring system when he operated an incorrect switch on the back of a tritium monitor. The fact-finding identified that switches on the back of the monitor are unlabeled and that the operator did not have visual access to the switches because he did not use a ladder. After determining the incorrect switch was functioned, the operator incorrectly repositioned the switch without stopping and informing management as required. This action also activated the facility evacuation alarm and all personnel evacuated to the control room. The operator informed control room personnel that the incorrect repositioning of the tritium monitor high voltage switch caused of the alarm. In response, control room personnel failed to complete the appropriate alarm response procedure.

Also this week, management convened two fact-findings after it was discovered that unauthorized modifications had been performed on a safety significant fire door credited as a one-hour fire barrier. In this instance, vagueness in the work instruction led maintenance personnel to believe they could add washers they had on hand to shim a strike plate on the door so it would engage a latch. Significant issues identified included: (1) the door latch had been inoperable for some time and in certain circumstances the door was being held in place with a wooden wedge, (2) the strike plate on the door was a modification made numerous years ago that was undocumented and did not appear to use appropriate materials, and (3) instructions provided by safety basis personnel in the integrated work document were not followed. LANL management has acknowledged they will need to address issues with formality of operations within WETF prior to resuming readiness activities. They plan to employ additional mentors, similar to the ones used to prepare the Plutonium Facility for its recent successful contractor readiness assessment, to assist facility operators.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 6, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 6, 2015

Area G–Conduct of Operations: On Wednesday, Area G management issued a standing order to clarify terminology and the expected response to certain abnormal conditions associated with the nitrate salts. Management previously developed a special *Response Plan* for these waste materials; however, an event late last month revealed weaknesses in the plan and an overall lack of awareness amongst key responders. Specifically, Area G experienced an electrical power transient on a Saturday afternoon, which apparently caused the control management unit for the Continuous Air Monitors (CAM) in the Dome 375 Permacon to go into audible alarm. The control management unit remained in audible alarm for more than 17 hours until Sunday morning when a radiological control technician (RCT) entered the Dome, noticed the alarm, and responded per normal procedures for a CAM alarm. However, given the circumstances with the nitrate salts, the *Response Plan* dictates a different response approach involving additional assets for a CAM alarm and other abnormal conditions. The standing order reminds operators of the *Response Plan* until management can convert its elements into an Abnormal Operating Procedure to define clear entry conditions, response actions, and associated responsibilities.

Waste Characterization Reduction and Repackaging Facility (WCRRF)–Emergency Management: On Wednesday, WCRRF personnel conducted their annual emergency exercise. This year’s scenario involved a postulated explosion and fire associated with processing of nitrate salt waste. The exercise employed a wide spectrum of artificiality. On the realistic side, safety class vehicle barriers were lowered to allow fire department apparatus and personnel directly into the facility complex, hoses were pulled, and responding RCTs arrived in full protective equipment and respirator. On the artificial side, glovebox workers wore modesty clothing instead of coveralls and fire department personnel were pre-approved to simulate supplied air use and contaminated patient handling. At the hotwash, a manager indicated there was a need for the entire Technical Area 55/50 complex, which includes three nuclear facilities, to better integrate responses and participate in joint exercises. WCRRF has been in cold standby since last summer, but facility personnel have recently been working to develop a drill program that they expect to deploy at Area G in coming months.

Confinement Vessel Disposition (CVD) Project: Assay results for the first processed confinement vessel have been obtained (see 12/19/14 weekly). The results indicate that the remaining nuclear material in the sphere exceeds the decontamination goals identified in the procedure by nearly three times. Project personnel are considering alternate paths forward including modifying the procedure decontamination goals to allow the sphere to be shipped without further decontamination to Area G for final disposition. In parallel, project personnel are moving forward with activities necessary to move the second sphere from Technical Area 55 to the Chemistry and Metallurgy Research Building for its cleanout.

Transuranic Waste Management: LANL submitted to the field office for review and approval a revision to the Area G technical safety requirements. This revision will allow up to 90 percent more material-at-risk risk under existing inventory limits for waste stored in pipe overpack containers (see 1/23/15 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 13, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 13, 2015

DNFSB Activity: New Board Member Santos, accompanied by Board Member Sullivan and staff member D. J. Campbell, visited the lab for familiarization. The visit included walk-downs all of the primary defense nuclear facilities and introductions with key federal and laboratory management.

Plutonium Facility–Criticality Safety: Plutonium Facility management unveiled revision 13 to the local administrative procedure for nuclear criticality safety. Notably, this revision requires workers to post a hardcopy of the inventory at each fissionable material operation and to update this hardcopy as soon as practicable following any change to a parameter important to criticality safety. This change addresses a post-start finding from the recent contractor readiness assessment, several findings from internal and NNSA assessments, and the Board letter dated July 15, 2013. While this change moves LANL into compliance with the DOE Directives, the inventory tracking process remains fallible to human error. To address this vulnerability in the longer term, Plutonium Facility management initiated an effort to explore technological solutions (e.g., barcodes or radiofrequency identification tags) to enable workers to obtain direct measurement of the inventory at the time of material movement. These mainstream technologies are currently cost effective; however, challenges remain with security requirements.

Weapons Engineering Tritium Facility (WETF)–Safety Systems and Conduct of Operations: Last week, a series of safety system and conduct of operations failures created a situation where operations personnel could not comply with a limiting condition for operation (LCO), forcing them to enter the generic LCO. During a surveillance in June 2014, a ventilation damper was identified to be broken such that it could not perform its safety function to isolate the control room upon activation of the halon fire suppression system. In response, facility personnel installed a blank over the damper to seal the ventilation duct. This modification caused the differential pressure between the control room and an adjacent hallway to change such that a safety significant fire door would not operate as required (see 1/30/15 weekly). Failure of the door to function properly rendered the fixed wet-pipe fire sprinkler system inoperable necessitating a fire watch to comply with a LCO. While in this LCO, a low-level tritium alarm occurred in the facility, preventing operators from performing the fire watch and resulting in the TSR violation. Investigation into the cause of the tritium leak revealed that during performance of a routine surveillance two steps of the use every time procedure were skipped that resulted in a valve being left open and a fitting left uncapped.

Safety Basis: On Wednesday, management paused all Unreviewed Safety Question (USQ) activities at the lab after a management assessment identified multiple instances where analysts incorrectly applied the USQ process to maintenance activities performed on credited Design Features. In several occasions, these instances resulted in TSR violations. USQ operations resumed following special training to analysts that emphasized the need ensure that safety bases appropriately cover maintenance activities on Design Features. In the opinion of the Site Representatives, providing LCO coverage for Design Features—a best management practice utilized by Lawrence Livermore National Laboratory—would prevent this situation and similar situations that may temporarily impact credited systems (i.e., emergency exercises).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 20, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending February 20, 2015

Plutonium Facility–Restart Activities: The federal readiness assessment (RA) team for the T-Base II machining operation was onsite this week to receive an in-briefing, tour the facility, and establish administrative logistics. The team plans to commence field activities on March 23, 2015. Separately, activities supporting the contractor RA for the balance of plutonium machining operations continue with the field office approving a revised plan of action for the contractor RA and LANL submitting a request to exit the justification for continued operations for the associated fissile material operations. The contractor RA team plans to commence their review the week of March 9.

Plutonium Facility–Criticality Safety: Last week, facility personnel completed facility-wide installation of the rain caps—engineered features that preclude water ingress from external sources (e.g., fire sprinklers and pipe leaks) into gloveboxes through inlet filters. In addition to the caps, the work also included replacement of wooden filters with modern metal units.

Transuranic Waste Operations–Restart Activities: Last Friday, LANL submitted a proposed plan for the restart of legacy transuranic waste operations to the field office. The plan discusses the need for safety basis modifications at Area G, the Waste Characterization Reduction and Repackaging facility, and the RANT shipping facility. The safety basis modifications are needed to resolve pre-existing issues, as well as enable implementation of a cooling control strategy for the final treatment of the remediated nitrate salt wastes. The plan indicates the need for actions in several Focused Improvement Areas including roles and responsibilities, procedure control, process control, conduct of operations, quality assurance, training, and sub-contractor management. It also acknowledges that adjustments may be needed after receipt of the final report from the DOE Accident Investigation Board. LANL currently anticipates the need to conduct federal RAs for a sampling campaign and then again for final treatment operations. With respect to the nitrate salts, the proposed schedule shows sampling operations commencing in the 4th quarter of fiscal year 2016 and treatment operations completing in early fiscal year 2019. NNSA and DOE-EM are reviewing LANL's proposed plan.

Area G–Nitrate Salts: On Wednesday, the chemistry team issued their report entitled *Chemical Reactivity and Recommended Remediation Strategy for Los Alamos Remediated Nitrate Salts*. The report represents a key technical input to the restart plan discussed above and provides an understanding of the chemical and biological processes that may have led to the breach of drum 68660. However, the report notes that additional experimental work under nuclear quality assurance practices is needed to support safety basis modifications.

Last week, LANL transmitted information to the state regulator in support of a proposal to remove the 29 unremediated nitrate salt waste drums from the Dome 231 Permacon. In the opinion of the Site Representatives, moving these drums could make the Permacon a viable and more robust alternative to the current plan to conduct sampling operations in the plastic tent within Building 412.

Transuranic Waste Storage Facility Project: On Thursday, project personnel completed the first nuclear quality concrete placement for one of the storage buildings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 27, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 27, 2015

DNFSB Staff Activity: T.L. Hunt was on site this week to observe the conduct of a self-assessment of the local NNSA facility representative program and to discuss staffing plans with Field Office management. R.K. Verhaagen observed a meeting of the seismic expert panel focused on LANL's Plutonium Facility in San Francisco during February 22–23, 2015.

Weapons Engineering Tritium Facility (WETF)–Restart Activities: WETF personnel continue to work through corrective actions to address findings from the September 2014 contractor readiness assessment (CRA) and to prepare for facility restart and follow-on readiness activities (see 9/19/14 weekly). Notably, the acting Principal Associate Director for Operations (PADOPS) is holding weekly meetings with involved senior lab management, facility management, and program management to discuss the status of corrective actions necessary to prepare for the re-performance of a full scope CRA scheduled to start the week of March 16, 2015. These meetings aim to ensure the schedule is upheld and to ensure resources are being employed to address emerging issues. The PADOPS will also chair a Management Review Board designed to have all Safety Management Program owners attest to the readiness of their individual programs prior to commencing the CRA.

On Monday, WETF implemented a completely revised Facility Radiation Protection Requirements (FRPR) document to address several CRA findings. The implementation followed training that included a required reading, a mandatory short demonstration, and a second required reading following revisions stimulated by discussion during the demonstration. Notably, the new FRPR includes more stringent personal protective equipment requirements for all activities in the facility. Accordingly, implementation of the FRPR has resulted in the need to modify numerous facility operating procedures that personnel will have to exercise to ensure proficiency prior to restart.

WETF management recently released the report from a causal analysis performed to address the numerous issues encountered during the September 2014 contractor readiness assessment. The causal analysis team evaluated results of the contractor readiness assessment as well as two reports issued by the NNSA facility representative relating to readiness and conduct of operations. The causal analysis team concluded in their report that improvements were needed in management expectations and performance standards, event investigations to prevent recurrence, management monitoring, and operator proficiency and performance. The causal analysis noted that the current CRA corrective action plan addresses both individual issues identified during the CRA as well as the overarching issues identified in the report.

Management: The PADOPS recently reinvigorated the format of the weekly Executive Management Risk Review meetings to include more in-depth discussions on the LANL Director's top priorities. For example, this week's meeting included about a half hour of detailed discussion, largely led by the Director, on the progress and impediments to WETF restart. Future recurring topics of interest to the Board include Plutonium Facility restart activities, nuclear criticality safety stability, Plutonium Strategy execution, nitrate salt recovery, RANT shipping facility capability, and wild land fire management.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 6, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 6, 2015

Field Office: On Monday, the field office Manager announced that Mr. John Krepps is the new Senior Technical Safety Advisor. This assignment fills a vacancy that has existed for multiple years. Additionally, she announced temporary fills from other field offices for the Acting Deputy Manager and Assistant Manager for Operations while permanent assignments for these key safety-related positions are processed.

Plutonium Facility–Safety Systems: Last Friday, LANL submitted to the field office for review and approval a Safety Design Strategy (SDS) for the Plutonium Facility Active Confinement Ventilation Upgrade Project (ACVUP). This upgrade to the Plutonium Facility ventilation system is a commitment from DOE in the implementation plan for Board Recommendation 2009-2 to reduce the risk of a seismically induced fire. The SDS notes that the ACVUP is in the conceptual design phase and that final configuration for the construction and operation of the active confinement ventilation system is in development. The SDS reiterates that the ACVUP constitutes a major modification to the existing Plutonium Facility safety basis and provides the graded approach intended for development of safety basis documents (see 1/9/2015 weekly). Notably, the SDS indicates that LANL will design the system under the requirements of DOE Order 420.1B, *Facility Safety*.

Weapons Engineering Tritium Facility (WETF)–Emergency Management: On Wednesday, WETF personnel conducted an emergency exercise in preparation for upcoming readiness activities. The exercise scenario postulated that a worker executing a delivery on the loading dock experienced a medical condition and dropped a legacy tritium container breaching its contents. Overall, WETF personnel acknowledged that although some improvements were realized, the fire department's approximately 30 minute response time to the patient should be quickened. In particular, in this scenario a radiological control technician immediately reported airborne tritium measurements from the scene of $90 \mu\text{Ci}/\text{m}^3$ —levels that do not prohibit immediate approach. In the opinion of the Site Representatives, while the overall response was somewhat improved compared to recent WETF exercises, difficulties persist with fundamental elements including command and control, and communications indicating that completed corrective actions may not have fully addressed the underlying problems. In addition, simulation continues to create challenges. For example, one of the workers on the dock simulated a call to 911 and then actually called the operations center. In reality, the worker would likely need to stay on the line with 911, which would have entirely changed the flow of information to the facility operations center and the Facility Incident Command.

Area G–Nitrate Salts: On Tuesday, LANL submitted to the field office for approval a revised Evaluation of the Safety of the Situation (ESS) for the storage of nitrate salts. The revision addresses the need to include two additional remediated nitrate salt containers that Area G personnel recently identified as part of an extent-of-condition review. Following approval of the ESS, Area G personnel plan to relocate these pipe overpack containers to the Dome 375 Permacon. In addition to accounting for these new containers, the ESS clarifies the specific controls relied upon to justify continued operations. This clarification helps to address questions that arose after two recent snowstorms prevented completion of hourly rounds for visual inspections and temperature readings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 13, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending March 13, 2015

Plutonium Facility–Restart: On Thursday, the contractor readiness assessment team commenced their review of the Balance of Machining activity. Balance of Machining includes the DMU35 milling machine, the Precitech machine, drill and press operations, and the robotic lathe. These operations span three different rooms and involve eight fissile material handlers and two first line supervisors. This represents considerably larger scope than the T Base 2 activity, though there is some overlap with personnel. The team observed performance demonstrations and a drill on Friday and plans a full slate of interviews through the weekend prior to additional activities next week.

Plutonium Facility–Seismic Safety: Last week, facility personnel completed the initial carbon fiber wrapping on the first roof girder. They initiated wrapping the second girder this week.

Plutonium Facility–Safety Basis: This week, LANL submitted several safety basis documents to the field office for approval:

- A request to extend the implementation declaration date for the 2014 safety basis from February 27 to August 7, 2015. They note the critical path to implementation is rework associated with the MAR Tracker inventory database following recent extent of condition issues. LANL also notes they will have an interim implementation declaration for use of additional types of fire-rated containers by April 27, 2015.
- A request to extend the Justification for Continued Operation (JCO) associated with the Facility Control System by one year to March 31, 2016. Closure of this JCO requires approval of page changes to the safety basis. LANL notes that there are currently two other sets of page changes that have been submitted and suggest awaiting their approval and implementation prior to submitting the additional page change so it can be made to an updated and approved safety basis document.
- A request for a temporary modification to allow reuse of catch tube apparatus parts for surrogate shots on the Isotope Fuels Impact Tester. The safety basis currently specifies these parts as safety significant and prohibits reuse. LANL has an insufficient supply of replacements to support the demonstrations needed for upcoming readiness activities.

Area G–Safety Basis: On Monday, LANL submitted to the field office for approval the JCO concerning the receipt of newly generated transuranic waste containing higher combustible fractions than the 3 % fraction assumed in current analysis. Facility management declared a Potential Inadequacy of the Safety Analysis for this issue on December 5, 2014. The JCO includes a new Specific Administrative Control to either (1) close the road in the vicinity of the transportation vehicle during waste receipts or (2) limit the radiological content of shipments to less than 85 Pu-239 equivalent curies (PE-Ci) Equivalent Combustible Waste for direct loaded containers or less than 350 PE-Ci Equivalent Combustible Waste for doublepacked containers.

On a related issue, the field office approved on Wednesday the fourth revision of the JCO associated with single drum pool fires. The approval codifies a new Specific Administrative Control to doublepack drums containing greater than 80 PE-Ci. The Board's staff first raised the questions that resulted in both of these JCOs during a review in late January 2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 20, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 20, 2015

DNFSB Staff Activity: The Site Representatives participated in briefings at DNFSB Headquarters this week. Staff member P.J. Foster was onsite to observe the NNSA Construction Peer Review (CPR) of the Transuranic Waste Facility (TWF).

Transuranic Waste Facility: This week, NNSA performed an annual CPR to ensure the TWF project is on path to complete construction and meet the approved technical scope within the project's cost and schedule. The CPR team identified a number of specific recommendations that require resolution and provided the following summary conclusions: (1) the project has sufficient management reserve and contingency to finish on time and budget; (2) safety basis development is on the project's critical path and a coordinated submittal and review effort is necessary between the Field Office and the project; and (3) the project needs to incorporate commissioning activities in the integrated project schedule. The Critical Decision 4 for TWF is scheduled for January 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 27, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 27, 2015

DNFSB Staff Activity: Staff member D.J. Campbell was on site this week to observe a federal readiness assessment (FRA) in the Plutonium Facility and to augment site rep activities.

Federal Oversight: On Monday, the DOE Office of Environmental Management stood up a local Field Office to oversee work scope performed at LANL. For an interim period, the NNSA Field Office will continue to perform primary nuclear safety approval and oversight functions with some documents requiring concurrence from Environmental Management Headquarters.

Area G–Nitrate Salts: On March 13, the NNSA Field Office approved the revised Evaluation of the Safety of the Situation (ESS) for the continued storage of the remediated nitrate salt wastes (see 3/6/15 weekly). The Field Office approval determined that LANL's proposed Specific Administrative Controls for temperature monitoring and headspace gas monitoring were no longer necessary.

Last week, the LANL Explosives Review Committee issued a memo indicating that certain surrogate mixtures for the remediated nitrate salt wastes were sensitive to electrostatic discharge at levels of 25 mJ when tested in bounding physical forms (i.e., finely ground powders). The memo notes that the Faraday shielding provided by the drums will mitigate this concerns for storage applications, but recommends the use of non-sparking tools and electrical bonding for intrusive work with these materials. Area G management has reviewed this information and is incorporating the recommendations into planning for the final treatment process.

Plutonium Facility–Restart Activities: The FRA for the T-Base II machining operation commenced this week. This is the first FRA to occur as a part of the restart activities to resume operations following the LANL Director's pause in June 2013. Notable activities included the observation of a machining performance demonstration, the conduct of an evaluated operations drill, personnel interviews, facility and system walk-downs, and document reviews. The FRA will continue through next week with an out-brief scheduled to occur on Friday.

Weapons Engineering Tritium Facility (WETF)–Safety Systems and Conduct of Maintenance: WETF personnel continue to struggle to complete the maintenance and testing necessary to restore operability of a safety significant fire door, the halon fire suppression system, and the fixed wet-pipe fire sprinkler system (see 2/13/15 weekly). Most recently, a series of work packages were used to adjust and test the fire door as well as to troubleshoot and repair an intermittent halon system fire panel alarm. Following completion of the work packages and their specified testing, facility personnel restored the operability of the systems and exited the fire watch necessitated by the limiting conditions for operations. During a review of the completed work package for the fire door, the NNSA Facility Representative noted issues with the performance and documentation of the post maintenance testing. Additionally, a subsequent NNSA Facility Representative review of the work package for the halon system identified that it was incomplete. The systems were again declared inoperable and the fire watch re-entered.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 3, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending April 3, 2015

Area G–Nitrate Salts: On Monday, Area G personnel successfully relocated into the Dome 375 Permacon the four newly identified drums thought to contain remediated nitrate salt wastes (see 3/27/15 weekly). Last Friday, LANL submitted to the NNSA Field Office a study on temperature control options for the Permacon. The study notes that there is no compelling technical justification for additional cooling; however, the LANL Director determined that additional cooling will be implemented as a defense-in-depth measure. The selected option involves installation of a supplemental chiller into the existing ventilation system to cool the Permacon to about 5 °C. LANL expects the system to be operational by the end of May 2015.

Plutonium Facility–Restart Activities: On Thursday, the federal readiness assessment team out-briefed the results of their review on the T-Base II machining operation. The team identified four pre-start findings: (1) the nuclear criticality safety evaluation inappropriately relied on an upper subcritical limit that was not supported by the validation report and the independent review was inadequate; (2) the procedure does not implement criticality safety controls consistent with DOE requirements; (3) an inconsistency between the safety basis and the fire hazards analysis concerning glovebox firefighting media was not entered into the New Information process; and (4) the Field Office lacks a documented basis for a safety basis condition of approval concerning the glovebox support stand. The team identified 10 post-start findings. Notable items involve the lack of an established drill program, inadequate procedural implementation of labeling, problems with the Unreviewed Safety Question process, and inadequate Field Office oversight. The team also noted that their detailed report contains additional concerns and non-compliances that did not rise to the agreed upon threshold for a finding, but that management ought to consider for improvement.

Plutonium Facility–Nuclear Criticality Safety: Last Friday, the Field Office directed LANL to: (1) review for sufficiency all legacy criticality safety evaluations applicable to restart activities, (2) evaluate the ability of the criticality staff to support operations given the ratio of operations under compliant evaluations versus those operating under compensatory measures, and (3) update their program improvement plan to reflect resolution of legacy issues and actions to develop evaluations for operations with current compensatory measures. These actions are due in 60 days. In addition, the Field Office directed LANL to develop compliant evaluations for all operations under legacy Augmented Limit Reviews prior to restart.

Plutonium Facility–Configuration Management: On Monday, facility personnel conducted a fact-finding after operators discovered 10–15 L of unexpected liquid in a vacuum trap in one of the aqueous processing rooms. The operators were conducting additional monitoring of vessels directed after previous unexpected liquid discoveries (see 1/30/15). This is the fourth discovery of unexpected liquid in the last year. While operators previously sampled the liquid in those cases, management has yet to receive results or otherwise determine the source(s) of liquid associated with the past two discoveries dating back to November. During the fact-finding, personnel indicated that the previous extent of condition review excluded process support vessels such as vacuum traps. However, field office personnel questioned the need to examine all vessels that are in communication with certain vessels that are geometrically unsafe from a criticality perspective. Subsequently, facility personnel took an action to verify the administrative lockout on the geometrically unsafe vessels in the near-term and seek a longer-term solution to isolate physically these vessels from the system. Facility personnel also indicated that they were developing as-built drawings on a schedule to support future readiness assessments, but they would not develop drawings for systems slated for eventual removal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 10, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 10, 2015

Fire Protection: Last week, the NNSA Field Office approved the fiscal year 2015 Baseline Needs Assessment (BNA). The BNA identified the following issues: (1) current pre-incident plans do not contain much of the information mandated by DOE Order 420.1B, *Facility Safety*, and NFPA 1620 needed to support timely and effective response; (2) the Los Alamos County Fire Department procedure for minimum staffing requires update; and (3) the roles, responsibilities, accountabilities, and authorities (R2A2) between the NNSA Field Office, LANL, and the fire department are not well defined. The BNA notes that two of these issues are long-standing. Notably, the deficiency in pre-incident plans was previously identified in the 2009 BNA, as well as subsequent self-assessments and a DOE/NNSA assessment. In addition, a 2013 DOE/NNSA assessment previously identified the issue with R2A2s.

Plutonium Facility–Safety Systems: Recently, the facility experienced a number of events concerning degraded safety systems resulting in unanticipated entries into action statements specified in the Limiting Conditions for Operation (LCO). The recent events include: (1) last Tuesday, personnel performing a weekly surveillance identified that the heater unit on one of the safety class firewater pumps had failed; (2) on Saturday, a compressor on the safety significant Instrument Air System failed; and (3) the safety significant Facility Control System failed briefly on Tuesday evening then fully crashed on Wednesday evening. Fact-findings revealed questions on proper unit sizing and quality concerns for parts for the first two, respectively. On Tuesday, the facility also experienced an unanticipated LCO entry due to a momentary transient out of the required pressure differentials associated with the safety significant ventilation system. Facility personnel have been troubleshooting this issue following an unusually high number of events (e.g., they logged about 50 such entries from September 2014 through February 2015). Facility management believes the high number may be attributed to increased operator formality leading them to log even brief transients, some potential equipment problems, and the impact of high winds on the external pressure sensor.

Weapons Engineering Tritium Facility (WETF)–Comprehensive Causal Analysis: The Associate Director for Nuclear and High Hazard Operations (ADNHHO) appointed a team to conduct a comprehensive causal analysis and extent of condition review for a missed in-service inspection (ISI) on a tritium containment vessel. During a critique of the event facility personnel identified that procedural deficiencies and an inadequate tracking system were the main contributors to the missed ISI that resulted in a Technical Safety Requirement (TSR) violation. The team's appointment letter from ADNHHO directs them to determine the causes that contributed or lead to this incident, as well as to review a number of other recent similar events that have been reported in the Occurrence Reporting and Processing System to identify common contributors. The team is also chartered to expand the review to evaluate all currently implemented TSR controls using the causal analysis results and to validate all implemented TSR controls are appropriately identified and incorporated into processes or programs that adequately manage and maintain these controls. The team is actively performing this review and intends to have their report with recommended corrective actions completed in the next few weeks.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 17, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 17, 2015

Plutonium Strategy–Radiological Laboratory Utility Office Building (RLUOB): On Wednesday, LANL submitted to the field office for review and approval a safety design strategy for upgrading RLUOB to a Hazard Category 3 nuclear facility. The strategy proposes increasing the radioactive material inventory to up to 400 grams of Pu-239 equivalent. This increase will allow relocating additional analytical chemistry and material characterization processes from the Chemistry and Metallurgy Research (CMR) facility that had previously been slated for the now deferred CMR Replacement nuclear facility. The increase in radioactive material inventory limits, as well as completion of the RLUOB Equipment Installation Phase 2 and Plutonium Facility Equipment Installation (see 8/15/14 weekly), will accommodate the transition of all analytical chemistry and materials characterization processes currently performed in CMR to RLUOB and the Plutonium Facility.

Area G–Nitrate Salts: This week, LANL chemists and energetic materials experts initiated a series of experiments at the request of the DOE Accident Investigation Board in an attempt to recreate the event associated with Drum 68660 in the Waste Isolation Pilot Plant. These experiments are being conducted at full scale within four 55-gallon drums with their contents prepared to resemble as closely as possible the known conditions within Drum 68660 without using radioactive materials. The experiments will be conducted in two temperature controlled transportainers with two 55-gallon drums in each. These LANL experts will now focus on planning and executing a limited set of experiments to support the safety basis for future sampling and treatment activities for the remediated nitrate salt wastes. These experiments will be performed under quality assurance appropriate for nuclear facility applications, whereas the full-scale tests are considered research and development and will not be used to inform safety bases.

Plutonium Facility–Restart Activities: Numerous Plutonium Facility restart activities were completed over the preceding week, including:

- The final report for the T-Base 2 machining federal readiness assessment (FRA) was issued. The assessment team found that fifteen out of sixteen functional area objectives were met, with the criticality safety objective being unmet. The FRA team concluded that upon correction of the pre-start findings (see 4/3/15 weekly) T-Base 2 machining would be ready to restart operations.
- The final report for the Balance of Machining contractor readiness assessment (CRA) was issued (see 3/13/15 weekly). Three pre-start findings were identified relating to an inadequate startup plan, improper use of a machining plan as a work control document, and software quality assurance issues. Seven post-start findings identified issues with conduct of maintenance, transient combustible loading, beryllium hazards, and training and qualification. The CRA team concluded that following satisfactory resolution of pre-start findings Balance of Machining would be ready to restart operations. The FRA is currently scheduled to start in early June.
- A management self assessment for the Isotopic Fuels Impact Tester was completed. The follow-on CRA and FRA are currently scheduled to be completed this fiscal year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 24, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 24, 2015

DNFSB Staff Activity: R.K. Verhaagen attended offsite training on quality assurance and software quality assurance.

Plutonium Facility–Nuclear Material Management: On Thursday, facility personnel conducted a fact-finding after an Implementation Verification Review team identified that several Conflat-type containers of nuclear material were improperly listed in the nuclear materials management database as a certified type. The safety basis credits certified containers to reduce the damage ratio for the container and its resulting contribution to an accident source term. In reality, there is only one size of a Conflat-type container that is certified even though a variety of sizes are present in the facility. Notable points discussed by participants included:

- There are at least four different procedures governing types of containers with multiple requirement drivers including material-at-risk reduction and criticality safety. Procedure content and associated training were not adequate to ensure worker performance.
- The certified Conflat-type containers are not currently in use, but are available in the warehouse.
- The database contains about 200 types of containers, yet provides little information regarding a container's characteristics or specialized function. In addition, some container varieties are available in certified and non-certified forms.
- Configuration management processes for the database and linkage to the procedures was unclear.
- Most certified containers were dropped tested to survive a fall from 11 feet; however, some storage and handling locations in the facility exceed this height.
- The database expert recently retired and chronic staffing shortages resulted in a lack of readily available and qualified individuals to troubleshoot this problem.
- Engineering staff had spot-checked the correct use and listing of other certified containers.

The Associate Director for Plutonium Science and Manufacturing and his Deputy attended the critique, recognized that the situation was untenable for the workforce, and directed the utilization of external resources to conduct a Six Sigma like process analysis to eliminate by redesign rather than patch many of these problems.

Area G–Safety Basis: The safety basis limits material-at-risk to an overall aboveground inventory of $\leq 57,000$ Pu-239 Equivalent Curies (PE-Ci) and a composite source term of ≤ 1.06 PE-Ci. This composite source term accounts for the composition of the waste and assumes that 93.04 % of the waste is noncombustible-nondispersible material, 3.89 % is noncombustible-dispersible, and 3.06 % is combustible-dispersible. Recently, several issues have emerged associated with the composite source term. Last Friday, workers recognized that the remediated nitrate salt wastes were actually combustible, but were coded as noncombustible-nondispersible. As a result, Area G management declared a Potential Inadequacy of the Safety Basis and restricted receipt of new generated wastes. Prior to this event, Area G personnel were struggling to accept newly generated wastes and maintain compliance with the composite source term, since newly generated wastes typically include a higher fraction of combustible materials.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 1, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 1, 2015

DNFSB Staff Activity: On Wednesday, staff members T.A. Chapman and D.J. Campbell held a teleconference with field office and LANL personnel to discuss the status of an emerging nuclear facility drill program.

Area G–Nitrate Salts: Last Thursday, LANL scientists obtained the first result associated with the full-scale drum experiment (see 4/17/15 weekly). Specifically, the contents of the sealed 55-gallon drum in a 60° C environment initiated a thermal runaway reaction, pressurized the drum, and forcefully ejected the drum's lid. This experimental result was anticipated, given the elevated temperature and non-vented conditions. LANL scientists are analyzing the data from the experiment and continue to monitor the other three drums.

Plutonium Facility–Fire Protection: For the T Base II activity, one of the federal readiness assessment team's pre-start findings concerned the fire extinguishing agent available within the glovebox. Specifically, the team noted that the use of graphite was inconsistent with the fire hazard evaluation which indicated the need for magnesium oxide. In addition, the team noted that the volume of agent was half of that required and its placement was not within reach from the location where plutonium metal turnings were handled and stored. In response to this finding, facility personnel have revised the fire hazard evaluation to indicate that graphite is acceptable even though magnesium oxide is preferred, consistent with DOE Handbook 1081-2014, *Primer on Spontaneous Heating and Pyrophoricity*. Facility personnel have also developed a plan to eventually transition to the use of magnesium oxide across the plant and to strengthen the processes used to ensure appropriate staging, inspection, and use of the agent. The Site Representatives note that this effort provides an ideal opportunity to correct the inconsistencies between the actual conditions in the plant and the mock-up used for training with the fire department (see 11/21/14 weekly).

Transuranic Waste Management: Last Friday, LANL submitted to the field office its first quarterly status report on efforts to support sustained laboratory operations during shutdown of the Waste Isolation Pilot Plant (see 1/23/2015 weekly). The report included a list of projects for which transuranic (TRU) waste generation forecasts have been developed, current Area G waste inventories, and a set of initiatives aimed at prioritizing TRU waste generation and storage. LANL identified that 155 containers of TRU waste were received in Area G for storage between June 1, 2014 and March 31, 2015. Of note, these receipts increased the material-at-risk composite source term (CST) from 0.35 Pu-239 Equivalent Curies (PE-Ci) to 0.94 PE-Ci, approaching the limit of 1.06 PE-Ci. Additionally, the report acknowledges that the impact to the actual CST from the Potential Inadequacy of the Safety Analysis relating to remediated nitrate salts that was declared last week (see 4/24/15 weekly) is not yet fully understood. Current projections indicate the limit for CST could be reached as early as September of this year.

Plutonium Infrastructure Strategy: This week the field office approved a revision to the Safety Design Strategy (SDS) for the Plutonium Facility Equipment Installation sub-project (see 8/15/2014 weekly). The revision was made to address Chief of Defense Nuclear Safety and field office comments on the previously approved SDS.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 8, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 8, 2015

DNFSB Staff Activity: J.W. Plaue attended offsite leadership development training on building high performance teams.

Los Alamos Neutron Science Center (LANSCE): On Wednesday, NNSA's Cognizant Secretarial Officer for Safety and the Los Alamos Field Office Manager issued a letter authorizing the establishment of a joint NNSA and Management and Operating partner Accident Investigation Board to investigate a May 3, 2015, accident that occurred at a LANSCE facility electrical sub-station. Of note, the letter indicates that the joint investigation team is modeled after a highly successful investigation conducted at Sandia National Laboratories in 2014. Accident Investigation Board personnel arrived on site and commenced their investigation on Wednesday.

Plutonium Facility–Criticality Safety: On Wednesday, the field office transmitted to LANL a letter outlining concerns with criticality safety infraction management in the Plutonium Facility. The field office notes that there are currently more than 60 unresolved infractions, many of which have been resident for months, or even years. Of greatest concern are the multiple infractions involving unknown liquids discovered in process equipment that have not been properly characterized or addressed (see 4/3/2015 and 1/30/2015 weekly reports), and present an inherently higher criticality risk than non-aqueous operations. In light of these issues, the field office directed LANL to: (1) characterize and ensure the safe stabilization of the unknown liquids, (2) categorize and prioritize identified emergent conditions, and (3) develop a risk-based plan to resolve outstanding infringed conditions. The field office requested a brief on resolution of the unknown liquids in two weeks and a brief on a revised prioritization and recovery plan by May 31, 2015.

Weapons Engineering Tritium Facility (WETF)–Comprehensive Causal Analysis: On Friday, the Associate Director of Nuclear and High Hazard Operation's appointed team issued their report on the comprehensive causal analysis and extent of condition review performed for the missed in-service inspection on a tritium containment vessel (see 4/10/2015 weekly). This comprehensive review identified a number of findings within six functional components, including: (1) effective management oversight, (2) knowledgeable, trained and qualified personnel, (3) formality of operations, (4) nuclear safety culture, (5) System, Structure, and Components performing credited functions, and (6) cross-functional operational planning. Eighteen of the findings are considered pre-start findings to WETF readiness for operations and are being tracked and corrected as part of the WETF resumption plan.

Area G–Safety Basis: LANL safety basis personnel determined that the Potential Inadequacy of the Safety Analysis declared for the remediated nitrate salt waste composite source term (CST) resulted in a positive Unreviewed Safety Question (see 4/24/2015 weekly). Specifically, after recoding the remediated nitrate salt wastes as combustible, the recalculated CST material-at-risk (MAR) value for the existing inventory exceeded the safety basis limits. Facility personnel entered one Limiting Condition for Operation action statement by restricting receipt of all waste and are working on completing the second applicable action statement by revising the safety basis to allow the application of damage ratio for certain containers to lower the calculated CST MAR to below the allowable limits.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 15, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 15, 2015

DNFSB Staff Activity: On Thursday and Friday, E.M. Gibson and R.L. Jackson conducted a review of quality assurance processes used for the construction of the new Transuranic Waste Facility. The review included observation of reinforced concrete placement activities, a walk-down of the concrete batch plant, and record reviews.

Safety Basis: This week, a three-person team from one of the corporate partners conducted a Parent Organization Functional Management Review (POFMR) of safety basis development and management. The team reviewed a number of safety basis division procedures; conducted interviews with analysts, facility and program personnel, the Field Office, and the Site Representatives; and performed a cursory review of recently submitted safety bases for the Weapons Engineering Tritium Facility (WETF) and the Plutonium Facility. The POFMR report is expected in about a month.

Area G—Conduct of Operations: On Wednesday, Area G management released for training an abnormal operating procedure (AOP) governing response to abnormal conditions associated with the remediated nitrate salt wastes stored in the Dome 375 Permacon. Upon completion of training, the AOP will cancel a standing order issued in early February 2015 intended to clarify roles, responsibilities, and actions associated with postulated abnormal events for these wastes (see 2/6/2015 weekly). The Field Office provided numerous comments and suggestions on the nine-page procedure. The Site Representatives note that neither DOE nor LANL provide guidance on the format and content of AOPs.

Area G—Safety Basis: On Thursday, LANL management transmitted to the Field Office for approval an Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) concerning the composite source term (CST) issue (see 5/8/15 weekly). The ESS/JCO identified an inadequacy in the implementation of the CST limit, which when corrected resulted in the exceedance of a safety basis limit. The lack of an executable action statement associated with the applicable Limiting Condition for Operations further exacerbated the situation. The ESS/JCO notes that the safety basis uses the CST to establish the bounding unmitigated consequences for the wildland fire and seismic events. As such, Specific Administrative Controls other than the CST limit are relied upon to mitigate consequences to acceptable levels. The ESS/JCO proposes continuing operations through exclusively receiving pipe overpack containers and assuming the contents of these containers, including those in the existing inventory, are unaffected by the wildland fire and seismic event, as supported by DOE-STD-5506. In addition, LANL proposes an extent-of-condition review to ensure proper characterization of the inventory, an effort to overpack high combustible drums, and future changes to the safety basis to derive properly a control set. While waiting on ESS/JCO approval, LANL continues to restrict receipt of transuranic (TRU) waste, but otherwise continues normal operations at Area G. The Site Representatives note that the about two thirds of the unmitigated consequences associated with the wildland fire event are associated with aboveground storage of tritium. The approved safety basis prohibits shaft disposal of this tritium, eliminating an effective risk reduction tool at Area G and hindering risk reductions efforts at WETF.

Transuranic Waste Management: On Tuesday, LANL and Field Office personnel held a meeting to discuss options to allow continued disposition of TRU waste given speculation of a prolonged resolution process for the CST issue. A functioning TRU waste disposition capability is required to continue numerous risk-reduction activities such as the Confinement Vessel Disposition project, the Accelerated Vault Cleanout, and day-to-day elimination of wastes and other combustibles from gloveboxes in the Plutonium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 22, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending May 22, 2015

DNFSB Staff Activity: On Monday, M.R. Bradisse, D.J. Campbell, P.J. Foster, and M.T. Wright conducted a teleconference with Field Office personnel to discuss questions with the safety basis for the new Transuranic Waste Facility.

Plutonium Facility–Criticality Safety: On Tuesday, results from a non-destructive assay (NDA) of a recently generated waste drum indicated operators had exceeded a limit in the criticality safety evaluation (CSE). During the fact-finding, facility and Field Office personnel identified several issues related to conduct of operations and implementation of criticality controls. These issues included: (1) NDA operators used an incorrect criticality safety limit approval (CSLA) for a fissile material operation they were performing; (2) multiple CSLAs exist for different waste drum operations creating operator confusion; (3) the quantity of material in a drum being moved could not be verified to be within the limits specified on the CSLA; (4) the drum being moved was not labeled with the specific contents and form of material as required; (5) assumptions used to develop an associated staging CSE may not have been conservative; and (6) assumptions in the staging CSE were not properly captured as part of the control set in the CSLA. As a result of these identified issues, facility management paused all drum movements. The Site Representatives note that these issues are very similar to the issues that contributed to the LANL Director's decision to pause operations in June 2013. Following the pause, waste handling and NDA activities were resumed through LANL processes that did not require formal readiness assessments.

Plutonium Facility–Emergency Management: On Thursday, facility personnel conducted their annual emergency exercise as required by DOE Order 151.1C, *Comprehensive Emergency Management System*. This year's scenario was a postulated nuclear criticality in one of the machining laboratories involving two injured workers that required extraction from the air lock. Participants noted several areas for improvement, including strengthening the procedures that guide the response of the criticality safety group. Notably, facility management requested a follow-on tabletop exercise to work through evaluation and recovery of the facility to include a discussion on the use of robots. The Site Representative observed noticeable improvement compared to last year (see 4/18/14 weekly) with the integration between facility management, fire department, and emergency management personnel, likely driven by the recent initiation of routine drills involving the Facility Incident Command. LANL expects to conduct another exercise with a different scenario at the Plutonium Facility later this year.

Plutonium Infrastructure Strategy: On May 19, 2015, the Field Office approved with direction the Safety Design Strategy (SDS) for upgrading the Radiological Laboratory Utility Office Building to a new Hazard Category 3 nuclear facility. The SDS will be part of the package NNSA leadership will use to soon decide whether to proceed with the upgrade effort. Field Office direction concerned the use of the DOE Order 420.1 C, *Facility Safety*, vice its predecessor document and expectations regarding hazards analysis for seismic events and natural gas explosions. Separately, the Field Office provided comments on the SDS for the PF-4 Active Confinement Ventilation System upgrade project (see 3/6/15 weekly). Notably, the Field Office directed LANL to specify DOE Order 420.1C as the code of record for the project and use the seismic design performance categories as specified in DOE-STD-1189, *Integration of Safety into the Design Process*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 29, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 29, 2015

Plutonium Facility–Criticality Safety: On Wednesday, the Field Office approved LANL’s request to extend the Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) concerning the potential for nuclear criticality due to firewater intrusion (see 6/6/14 weekly). The new expiration date is May 30, 2016. In their approval, the Field Office noted that their performance expectations have not been met in that the original ESS was approved over a year ago and still has not been completely implemented. The Field Office further directed LANL to:

- Submit the Nuclear Criticality Safety Program Upgrades Project Plan for approval by July 10, 2015
- Submit safety basis changes referencing the approved plan by November 30, 2015
- Implement the revised safety basis prior to expiration of the extended ESS/JCO

Plutonium Facility–Restart: Facility personnel continued the second week of the management self-assessment for Pit Flowsheet operations. These operations include the various welding, assembly, and inspection activities needed to produce a pit for the stockpile. LANL management hopes to accelerate the start of the contractor readiness assessment to late July. The baseline schedule shows a request for restart authorization by January 5, 2016.

Area G–Conduct of Operations: Area G personnel have recently exhibited some difficulty properly managing technical safety requirements (TSR). In one instance, operators in the operations center were unaware of the fact that the TSR limit for composite source term material-at-risk was currently exceeded (see 5/8/15 weekly). Although the operators were aware that transuranic waste shipments were on hold, they did not know that this was the result of facility management direction to enter the associated limiting condition for operation (LCO) action statement. The Site Representatives believe that the following contributed to this event:

- Weaknesses in the process for how facility management notifies operations personnel of changes in facility status
- A poorly written LCO
- Failure of the system used by operations personnel to track material-at-risk limits to indicate that the composite source term limit was exceeded
- A shift turnover process that does not ensure operators are informed of facility conditions

This week, operations personnel chose to first inspect the storage area rather than entering the appropriate LCO after the material-at-risk tracking system indicated that numerous waste drums in the storage area were non-compliant. LANL management has indicated that a senior supervisory watch will be stationed to assist and mentor operations personnel in proper implementation of the TSRs and that a review will be performed of the process used by management to inform operations personnel of changes in facility status.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 5, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 5, 2015

DNFSB Staff Activity: D.K. Andersen, R.L. Jackson, and J.L. Shackelford were onsite this week to receive an overview of design and construction activities associated with Plutonium Infrastructure Strategy, attend safety basis training, and discuss the Chloride Extraction and Actinide Recovery process.

Safety Basis: On Monday, LANL transmitted to the Field Office for information an updated version of the Safety Basis Improvement Plan. Notable future deliverables include: (1) a revised staffing analysis; (2) instituting the Safety Task/Action Tracker for the New Information process; (3) incorporating the “Do it Right the First Time” storyboarding for the development of safety basis deliverables; (4) updating the Technical Safety Requirements for each facility to incorporate material-at-risk applicability statements, limiting conditions for operations-like action statements and completion times, operability determinations/performance criteria to facilitate placing credited design features out-of-service for maintenance or emergency exercises (5) studying the need for similar action to #4 for Specific Administrative Controls; and (6) ensuring security and emergency exercise/drill plans are evaluated through the Unreviewed Safety Question process.

Plutonium Facility–Safety Systems: Last Thursday, LANL provided the NNSA Deputy Administrator for Defense Programs with their scope analysis and recommendations for Phase III of the TA-55 Reinvestment project. In accordance with NNSA direction, LANL considered the following sub-projects: (1) fire alarm system replacement, (2) upgrading the active confinement ventilation system to safety class, and (3) separating non-seismically qualified structures from the safety class fire water supply loop. Of the three subprojects, LANL recommended only pursuing the fire alarm system replacement based on increased cost estimates, completion of structural modifications and implementation of operational practices to reduce risk in recent years, and the potential to transfer programmatic activities to future modular additions. The briefing notes that repair/update of the ventilation system will be required independent of the active confinement decision. NNSA management is expected to make a decision within the next month.

Area G–Safety Basis: Field Office, DOE-EM, and LANL personnel conducted several meetings this week to discuss the validity of crediting the pipe overpack containers (POC) with a damage ratio of zero, as indicated in DOE-STD-5506 (see 5/15/15 weekly). The experimental basis referenced in DOE-STD-5506 includes a single fire test performed with four POCs in 1997. Three of the POCs utilized polyethylene-housed drum filters and the fourth used a metal-housed drum filter (note that there is a separate metal-housed filter on the pipe component on all POCs). During the test, the poly housing failed, which provided a sufficient vent path for fire insulation to off-gas. The pipe components in these containers were unaffected and experienced peak temperatures of less than 200 °F. In contrast, the metal housing did not fail and pyrolysis products pressurized the drum sufficient to blow off the lid within three minutes. This resulted in direct exposure of the pipe component to the fire and subsequent degradation of the pipe O-ring and filter gasket. LANL has exclusively utilized the metal-housed filters causing Federal personnel to question the use of a damage ratio of zero. The Field Office has enquired about using the poly filters or a plastic bung plug as a type of fusible vent path.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 12, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 12, 2015

DNFSB Staff Activity: On Wednesday, E.M. Gibson conducted a teleconference with LANL and NNSA personnel to discuss the status of efforts on the 2017 update to the probabilistic seismic hazards analysis.

Plutonium Facility–Restart Activities: Members of federal readiness assessment (RA) team for the Balance of Machining activity conducted their pre-visit this week. They plan to commence their full review on June 22, 2015. On Monday, the contractor RA team commenced their review of the Isotope Fuels Impact Tester. Last Friday, LANL submitted their request for startup approval and the associated corrective action plan for closure of the findings from the federal RA for the T Base 2 machining activity.

Plutonium Facility–Configuration Management and Conduct of Operations: On Monday, facility personnel conducted a fact-finding after the NNSA Facility Representative questioned the conduct of a liquid transfer. Workers had transferred liquid to facilitate sampling of one of the liquids of unknown origin (see 4/3/15 weekly). Participants discussed concerns regarding performance of the transfer using a procedure that expired a year earlier and did not include valve lineups, as required by institutional procedure. The workers noted that they have not historically used valve lineups to support liquid transfers due to the complexity of the system and the fact that most transfer piping and valves in the facility do not possess unique identifiers and are not captured in controlled engineering drawings. Instead, the practice had been to conduct a group walk-down to ensure the correct transfer path. Facility management indicated future transfers would need to rely on completion of formal labeling for enduring systems and use of temporary labeling for those systems planned for removal.

Plutonium Facility–Safety Basis: On Wednesday, LANL personnel briefed the Field Office on the state of the safety basis and their proposed remedy. The situation includes: three approved safety basis documents, with only the 2011 version fully implemented; four safety documents that have been submitted, but are not yet approved; and at least six known changes to be submitted in the near future. LANL's proposed remedy is to discontinue implementation efforts for the 2014 documents while pursuing at-risk implementation of the 2015 version, which they submitted to the Field Office in late May. Assuming timely approval from the Field Office, LANL hopes to have the 2015 version implemented in early fall. They anticipate the need to submit a future revision to the 2015 version that will further consolidate outstanding documents and comments.

Area G–Conduct of Operations: Last week, in response to a number of recent conduct of operations issues (see 5/29/15 weekly), LANL management appointed a senior supervisory watch (SSW) for Area G, the RANT Shipping Facility, and the Waste Characterization, Reduction, and Repackaging Facility. The SSW commenced his duties this week, which include critical and objective oversight of operations and mentoring to operations personnel. LANL management is continuing to study the need for improvements on how management communicates safety basis and facility status decisions to operations staff.

Weapons Engineering Tritium Facility (WETF): WETF personnel successfully loaded a Flanged Tritium Waste Container with about 5000 Ci of tritium-containing materials. This evolution was conducted to support risk reduction activities and maintain proficiency ahead of the one-year anniversary from the last evolution (see 6/20/14 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 19, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 19, 2015

Area G–Safety Basis: On Thursday, Field Office, DOE-EM, and LANL personnel discussed the status and path forward regarding the Potential Inadequacy of the Safety Analysis concerning the composite source term (see 6/5/15 weekly). LANL personnel presented the result of an extent-of-condition review on the composition of the existing waste. They now believe that the 3.1 percent combustible fraction assumed in the approved safety basis for the aboveground waste population should actually be 12.2 percent and will use 20 percent in future analyses as a bounding value. This change affects 17 of the 29 design basis accidents, which includes nine that have unmitigated doses in excess of the Evaluation Guideline. LANL analysts presented their preliminary analysis indicating that five additional operational restrictions (beyond the current prohibition of new receipts) are necessary to mitigate these accidents, except for the aircraft crash, to acceptable levels. These restrictions involve reduced material-at-risk limits and all but one are currently reflected in the as-found configuration of the site. Area G management expects to relocate inventory from one of the domes to implement all the restrictions and then formally protect them via standing order.

LANL analysts also presented a case for moving forward with a few new additional controls to accept receipt of newly generated wastes (with a limit of 5000 plutonium-239 equivalent curies) from the Plutonium Facility as part of a revised Evaluation of the Safety of the Situation. If approved, the transfer would likely allow a few extra months of waste generation, though personnel did not provide specific projections. LANL anticipates submitting the revision in mid-July and estimates the ability to resume waste receipts at Area G this September.

Plutonium Facility–Restart Activities: On Thursday, the contractor readiness assessment (CRA) team out-briefed the results of their review of the Isotope Fuels Impact Tester. The team found that all 21 objectives were met, but identified seven pre-start and 16 post-start findings. The findings generally included issues with procedures, postings, training, drill program execution, and a suspended load path above an operator's limbs.

Weapons Engineering Tritium Facility (WETF): This week, a CRA team commenced and completed their review of UC609 shipping container operations. The UC609 is currently the only certified container available to ship bulk quantities of tritium, which WETF personnel will need to support risk reduction efforts later this year. The CRA team found that all 17 objectives were met, but identified four pre-start findings and one post-start finding. The findings involved procedure content, procedure execution, glove removal, and a suspended load path above an operator's limbs.

Nuclear Criticality Safety: On Tuesday, the institutional Nuclear Criticality Safety Committee (NCSC) convened for the first time after the LANL Director approved a revised charter on May 28, 2015. The new charter, which is the third in three years, seeks to improve the group's work by emphasizing field observations. The NCSC issued a work plan that includes five fieldwork activities. Additionally, the NCSC leader has gained unescorted access to the Plutonium Facility and has initiated observations related to criticality safety related events (e.g., fact-findings, worker training, interactions with operations).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 26, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 26, 2015

DNFSB Staff Activity: Z.S. Beauvais augmented the Site Representative office this week and observed portions of the federal readiness assessment (RA) for Balance of Machining activities.

Plutonium Facility–Restart Activities: On Monday, the federal RA team commenced their review of the Balance of Machining activities. Their review is expected to conclude on July 1st. Notably, in their report documenting verification of prerequisites, the Field Office included a caveat that while the actions taken and closure documentation for the contractor’s RA were adequate for commencing the federal RA, the plan and execution were not currently adequate to approve operations and would be carried forward as a manageable pre-start. The Field Office report states that numerous and widespread concerns with the post-start corrective actions contributed to this decision, such as actions not addressing causal factors and superficial extent-of-condition reviews. Separately, the management self-assessment team completed their review of the Pit Flowsheet activity. The contractor plans to conduct their RA at the end of August.

Area G–Nitrate Salts: On Thursday, the Field Office directed LANL to consider the profusion of New Information relative to the safety basis for continued safe storage of the remediated nitrate salts contained in the DOE Accident Investigation Board and the Technical Assistance Team reports on the radiological release at the Waste Isolation Pilot Plant. In particular, the Field Office stated that these sources provide information suggesting that an accident of a different type occurred and with a greater airborne respirable release fraction than assumed in the existing safety basis. These changes have the potential to increase significantly the consequences and therefore may warrant additional compensatory measures. The Field Office requested LANL’s evaluation and any subsequent safety basis changes for approval within 60 days.

Emergency Management: Last Thursday, LANL personnel conducted an exercise utilizing their alternate Emergency Operations Center (EOC). LANL’s alternate EOC is a mobile capability that they can establish at any road accessible location. In last week’s exercise, they setup the EOC in one of three pre-determined locations in the town site.

Work Control: This week, the Associate Director for Nuclear and High Hazard Operations (ADNHHO) issued a memorandum to all facility operations directors (FOD) outlining expectations for necessary improvements in the formality of work operations. This direction follows a number of recent incidents relating to poor work control practices, the most recent of which involved an event last Monday where a maintenance worker contacted and subsequently brought down a 13.8 kV powerline with his dump truck. Following this incident, LANL management paused all maintenance work activities for a one day safety stand-down. Areas specifically identified by the ADNHHO for needed improvement include: (1) oversight and control of work execution; (2) person-in-charge responsibilities for the validation, coordination, execution and proper closeout of the activity; and (3) pre-job briefings to ensure workers clearly understand their scope of work and associated hazards prior to commencing work. The memorandum reiterates the roles and responsibilities of all levels of management for the safe accomplishment of work, and includes additional expectations for the FODs when reviewing work documents and subsequently releasing work.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 3, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 3, 2015

DNFSB Staff Activity: On Tuesday, the Site Representatives briefed the results of their efforts to identify opportunities to reduce risk at the Plutonium Facility via actions associated with material-at-risk to Field Office and LANL management. Overall, the Site Representatives identified that 21 percent of the material-at-risk on the laboratory floor has been idle for more than three years, leading to questions regarding whether this material could either be eliminated from the facility or moved to hardened storage locations such as the vault or safes. In addition, the Site Representatives identified opportunities that site personnel could explore to improve the utilization of certified containers and strengthen practices for the lifecycle management of nuclear materials.

Plutonium Facility–Nuclear Materials Management: Last month, Plutonium Facility personnel initiated a six-sigma improvement effort to streamline the process to select and log containers used to store nuclear materials within gloveboxes. Management directed this effort as a corrective action from a fact-finding associated with improperly selecting a container type in the nuclear material management database (see 4/24/15 weekly). This effort has the potential to remedy some of the container issues identified by the Site Representatives. For example, only about 13 percent of the containers in use are specified in the database as certified to reduce the radiological source term generated from certain insults.

Plutonium Facility–Restart Activities: On Wednesday, the federal readiness assessment (RA) team completed their review and delivered their report for the Balance of Machining activities. The team presented six pre-start and seven post-start findings. Notably, in addition to the findings, the team recommended that an independent federal team perform an assessment of facility implementation of the criticality safety program prior to commencing the ARIES/Furnace/Casting contractor RA scheduled for December 2015.

Area G–Safety Basis: On Wednesday, LANL responded to an NNSA extent of condition data request for information regarding the use and performance assumptions for pipe overpack containers (POC). This request followed a LANL submittal of an Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) that proposed crediting POCs with a damage ratio (DR) of zero as indicated in DOE-STD-5506 (see 5/15/15 weekly). Following several meetings, NNSA, DOE-EM, and LANL personnel determined that a DR of zero for the POCs is not technically defensible. The response to the request for information indicates that LANL currently has five facilities that package, ship, and/or stage POCs. None of these facilities currently credit the POC with a DR of zero; however, the Plutonium Facility is currently using a DR of 0.1 and Area G and the RANT Shipping Facility are approved, but not implemented, to use a DR of 0.1. Additionally, the Transuranic Waste Storage Facility, currently under construction, had planned to use a DR of zero.

Largely due to the conclusion that applying a damage ratio of zero to the POCs is inappropriate, the Field Office has yet to approve the ESS/JCO submitted on May 14, 2015. LANL is expected to withdraw and resubmit a revised ESS/JCO in mid-July. Subsequent to additional review of the technical safety requirements, Area G management determined that it is appropriate to enter the generic limiting condition for operation that requires the facility to shift to a safer mode. As such, operations personnel commenced transitioning Area G to warm standby yesterday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 10, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 10, 2015

DNFSB Staff Activity: On Thursday, D.K. Andersen, D.J. Campbell, P.J. Foster, and R.L. Jackson conducted a teleconference with LANL and field office Transuranic Waste Facility project personnel to follow up on construction quality issues identified during a prior DNFSB staff review (see 5/15/15 weekly).

Area G–Fire Protection: This week, crews initiated remedial actions under the vegetation control element of the Fire Protection Program. These remedial actions included brush and vegetation removal, and were taken in response to results of last month’s required periodic inspection. The inspection indicated all Defined Areas within Area G had unsatisfactory control of grasses and weeds, 4 had unsatisfactory control of shrubbery, and 4 of the primary waste storage domes had grass and weeds growing on all sides. Additionally, all of the defensible areas outside of the fence had grass, weeds, and shrubs within their clearance areas. Of note, the Fire Protection Program vegetation control element is credited as an administrative control in the Area G safety basis to reduce the frequency of certain design basis accidents.

Area G–Nitrate Salts: Area G personnel are in the process of installing increased capacity cooling equipment for the Dome 375 Permacon (see 4/3/15 weekly). This is a significant modification, to include installation of a large chilling unit, associated piping and electrical connections, and additional cooling coils within the Permacon’s existing ventilation ducting. This effort is a compensatory measure to provide improved cooling of the remediated nitrate salt waste, while also serving as a backup for the primary systems were they to fail.

Plutonium Facility–Restart Activities: This week, LANL submitted, and the field office concurred on, a revised corrective action plan for the previously completed Balance of Machining contractor readiness assessment. The plan was revised to address field office concerns that corrective actions in the initial submittal were inadequate to fully address all post-start findings (see 6/26/2015 weekly). On Wednesday, the management self-assessment team issued the final report of their Pit Flowsheet activity review and concluded that upon satisfactory resolution of identified pre-start findings, Plutonium Facility personnel could safely support Pit Flowsheet operations. The contractor and federal readiness assessments for Pit Flowsheet are scheduled for August and October of this year respectively.

LANL Management Responsibilities: On Tuesday, the LANL Director communicated his expectations for management responsibilities in support of employee safety and security to all LANL personnel. This direction follows a number of recent safety and security incidents that have highlighted a need for improvement in these areas. The Director emphasized that there is nothing more important than ensuring every reasonable step is being taken to ensure workforce safety and security. The mechanisms through which these steps are expected to be accomplished include a visible and active leadership presence in the field and increased access to Environment, Safety, and Health experts. In addition to communicating the expectation for increased presence in the field, training on how to effectively observe activities and communicate observations was provided to the leaders expected to perform these duties.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 17, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending July 17, 2015

DNFSB Staff Activity: On Wednesday, D.K. Andersen, B.K. Caleca, R.L. Jackson, A.P. Poloski, and J.L. Shackelford conducted a teleconference with Field Office and LANL personnel in an attempt to identify the technical basis associated with LANL's recommendation to de-scope the upgrade of the Active Confinement Ventilation System for the Plutonium Facility (see 6/5/15 weekly).

Weapons Engineering Tritium Facility–Configuration Management: On Monday, facility personnel conducted a fact-finding following the declaration of a Potential Inadequacy of the Safety Analysis (PISA) associated with the uninterruptible power supply (UPS) to a portion of the oxygen monitoring system (OMS). Specifically, as part of troubleshooting an error message, the system engineer discovered one of the safety significant OMS appliances to be plugged into the non-UPS power strip on its instrument rack. Notable points discussed include the following: (1) unlike other UPS outlets in the facility, this UPS strip had no obvious indication (e.g., red color receptacles) and was identical in appearance to the non-UPS strip located next to it; (2) the work package used to install this appliance in March 2014 specified only to ensure the cord reached the UPS strip, rather than ensure that workers connected it with the UPS strip specified by its identifier; (3) the previous version of the Technical Safety Requirements for the OMS included an operability statement associated with UPS power; however, this requirement was removed in the current version and apparently was never translated into a specific surveillance action; and (4) there is not a configuration managed list of safety loads to the UPS. Facility management directed an extent of condition review for the tritium monitoring system, which also uses safety significant plug-in appliances required to be on the UPS.

Waste Characterization Remediation and Repackaging Facility–Maintenance: On Monday, facility personnel conducted a fact-finding regarding the PISA associated with degradation of the facility roof resulting from flooding. Last week, after observing standing water within the facility, personnel observed about 8–10" of standing water on the roof and requested a priority maintenance response. The facility is currently in COLD STANDBY mode. Maintenance personnel resolved a plug in the roof drain and performed mitigation efforts within the facility. Notable points discussed include the following: (1) no preventive maintenance routines are currently in place for the roof; (2) management initiated a work order for corrective maintenance to repair the leaking roof in October 2014; however, the package was never finalized; and (3) a separate effort to replace the roof this spring was cancelled due to conflicting construction in the area. The Site Representatives note that the formal in-service inspection does not explicitly direct review of roof drains and that effective drainage is necessary to prevent the accumulation of rain and snow loads that may exceed the structure's design basis. Facility management is working to replace or repair the roof, initiating additional repairs for damage to the drywall ceiling, increasing the frequency of rounds while in COLD STANDBY, and starting qualification processes to increase the number of operators for these rounds to more than one.

Plutonium Facility–Emergency Management: On Thursday, Plutonium Facility management participated in a tabletop exercise with Los Alamos Fire Department and LANL emergency management and security personnel to work through evaluation and recovery of the facility following a criticality accident (see 5/22/15 weekly). Participants identified a number of meaningful improvements and worked through potential pitfalls of managing the recovery following the initial evacuation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 24, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 24, 2015

DNFSB Staff Activity: J.L. Shackelford was at LANL this week to perform site cognizant engineer familiarization activities. On Thursday, C. Berg, M.W. Dunlevy, R.C. Eul, and N.M. George conducted a teleconference with Field Office and LANL personnel regarding the remediated nitrate salt (RNS) wastes.

Plutonium Facility–Restart Activities: In a letter dated July 16, 2015, the Field Office approved the restart of nuclear operations associated with the T Base II machining activity. Operations personnel intend on machining a plutonium part before the end of the fiscal year. The ability to perform additional machining operations is currently constrained by limited availability of suitable feed materials and dependent on successful restart of predecessor and downstream activities.

Area G–Nitrate Salts: On Friday, the NNSA Field Office provided LANL relief from the technical safety requirements related to the WARM STANDBY mode condition resulting from the composite source term issue (see 7/3/15 weekly). Specifically, Field Office direction allows Area G personnel to: (1) sample the seven drums containing cemented inorganic wastes known to contain liquid; (2) perform real-time radiography of approximately 150 similar drums that may contain liquid; (3) sample the unremediated nitrate salts currently stored in the Dome 231 Permacon; and (4) conduct other activities needed to support the above actions. The first two actions mainly facilitate resolution of outstanding environment compliance issues and the third action facilitates development of the safety basis for final treatment of the RNS wastes. The Field Office also directed LANL to doublepack the four pipe overpack containers currently containing RNS wastes (containing water absorbent polymer rather than wheat-based cat litter) and prohibited LANL from crediting reductions in damage ratios for the pipe overpacks.

Plutonium Infrastructure Strategy: On July 10, 2015, LANL transmitted the revised safety design strategy for the upgrade of the Radiological Laboratory Utility Office Building to a Hazard Category 3 nuclear facility (see 5/22/15 weekly). LANL is now referring to the future facility as the Nuclear Laboratory/Office Building (NLOB). LANL included in the submittal an applicability matrix for DOE Order 420.1C, *Facility Safety*. NNSA management has yet to decide on moving forward with the NLOB.

Area G–Conduct of Operations: The newly assigned Senior Supervisory Watch (see 6/12/15 weekly) recently completed a review of Area G standing orders, abnormal operating procedures, and emergency procedures. He identified a number of opportunities for improvement that will help streamline the large number of currently open standing orders and bolster operator response to emergency and abnormal conditions.

Safety Basis: LANL safety basis personnel have completed their review of new information related to assignment of damage ratios for pipe overpack containers in various safety bases (see 7/3/15 weekly). As a result, LANL management declared Potential Inadequacies of the Safety Analysis for the Plutonium Facility, Area G, the RANT Shipping Facility and the Waste Characterization Reduction and Repackaging Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 31, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 31, 2015

DNFSB Staff Activity: Deputy Technical Director R.E. Tontodonato augmented the Site Representative office.

Emergency Management: This week, LANL hosted their annual HAZMAT Challenge. New for this year, LANL organizers added event stations in the Center for Emergency Planning and Analysis (CEPA) facility, in addition to stations at the Technical Area 49 training grounds. The CEPA is a large, high-bay facility that houses a system of movable walls supported by a wire grid structure beneath monitoring platforms. This arrangement allows organizers to replicate various facility environments for emergency response and protective force training. Organizers used the CEPA for stations associated with responses to scenarios involving radiological materials, hazardous chemicals, and biological agents. Notably, organizers designed the stations to minimize simulation and fully utilize actual response protective equipment, self-contained breathing apparatus, and detection gear. Challenge participants included two teams from Los Alamos County, the auxiliary LANL team, the city of Santa Fe, Sandia National Laboratories, the National Guard, and several other entities from around the region.

Waste Characterization Reduction Repackaging Facility: On Thursday, LANL resubmitted to the NNSA Field Office the annual update to the safety basis. The new submission corrects issues with the October 2014 submittal regarding the hazards associated with nitrate salts and other oxidizers.

Weapons Engineering Tritium Facility (WETF)–Restart Activities: On Monday, a contractor readiness assessment (CRA) team commenced their review of WETF operations. The team is evaluating WETF readiness to commence gas transfer operations in order to maintain facility safety/operability and to disposition legacy nuclear material-at-risk. This CRA is a reperformance of a CRA conducted last September that determined facility performance was insufficient to ensure gas transfer and associated operations could be safely and compliantly performed (see 9/19/2014 weekly). This week, the CRA team observed facility personnel simulating gas transfer operations, conducted interviews and performed document reviews. The assessment is scheduled to conclude next week.

WETF–Safety Systems: On Tuesday, during surveillances WETF personnel observed degraded performance associated with two safety systems requiring entry into their associated technical safety requirement (TSR) action statements. In the first instance, a fire riser pressure gauge was oscillating above and below the TSR required limit, with the average of the oscillation below the limit. Operators took appropriate actions and stationed a fire watch. During investigation into the cause of the oscillations, WETF personnel noted that the three-way gauge isolation valve was incorrectly installed. Maintenance personnel replaced the gauge and the valve and satisfactorily retested the system on Thursday. In the second instance, operators observed a tritium monitor indicating higher than expected tritium levels that failed a subsequent performance test. Again, operators took appropriate actions and later replaced the tritium monitor and retested it satisfactorily.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 7, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending August 7, 2015

DNFSB Staff Activity: R.K. Verhaagen attended training on safety basis development and review at DNFSB Headquarters.

Weapons Engineering Tritium Facility (WETF)–Restart Activities: On Friday, the contractor readiness assessment (CRA) team out-briefed the results of their assessment of tritium gas transfer operations. The team identified 12 findings, noted “dramatic” improvement in facility operations, and concluded that all 17 review objectives were met. The team concluded that the facility was ready to safely operate, subject to satisfactory closure of all pre-start findings. Notable findings included:

- A non-conservative discrepancy between the procedure and the associated engineering calculation related to the volume of a tank and its associated manifold piping
- Procedural execution issues important to Conduct of Operations compliance
- A significant fraction of wet pipe sprinkler maintenance has been deferred or cancelled in the past eight months
- Implementation of issues management and corrective actions do not meet contractor assurance system and quality assurance requirements
- Gaps in the implementation of software quality assurance call into question the readiness of safety software to support restart of operations

The federal readiness assessment is currently projected to start September 28, 2015.

WETF–Emergency Management: On Tuesday, WETF personnel conducted an emergency exercise for the CRA team to observe. The scenario involved an operator performing leak checks who falls from an elevated location, tears a glove creating a low-level tritium release, and sustains a broken arm. Exercise participants and CRA team members noted generally positive views compared to past performance and attributed this improvement to the benefits from the approximately dozen training drills conducted this year. However, based on observation of operations center response and comments from the participants, the CRA team noted that management should place additional emphasis on streamlining the communications process in order to prioritize the exchange of safe approach information from the operations center to the responding units from the fire department. The CRA team could not find a specific requirement related to this concern in DOE Directives or national consensus standards, but nonetheless emphasized the importance of ensuring timely emergency response.

Plutonium Infrastructure Strategy: This week, facility management increased the material-at-risk limit for the Radiological Laboratory Utility Office Building (RLUOB) from 8.4 to 38.6 g of plutonium-239 equivalent. The change in limits was facilitated by implementation of the new limits for a radiological facility using the NNSA Supplemental Directive Guidance 1027, *Guidance on using Release Fractions and Modern Dosimetric Information Consistently with DOE-STD-1027, Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports, Change Notice No 1*, May 2014. This increase represents an important step towards establishing a capability and capacity for analytical chemistry activities necessary to terminate operations in the aging Chemistry and Metallurgy Research building.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 14, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 14, 2015

Transuranic Waste Management: Senior managers from the NNSA and EM Field Offices, NNSA and EM Headquarters, the Carlsbad Field Office, and LANL conducted a day and a half workshop on transuranic waste management issues. The overarching objective of the workshop was to achieve alignment amongst these parties in the midst of an extremely complex situation that includes establishing the EM bridge contract, resolving numerous safety basis issues, treating the remediated nitrate salt wastes, and the inability of the Waste Isolation Pilot Plant (WIPP) to receive wastes. Of likely interest to the Board, LANL analysts currently forecast the potential for transuranic waste accumulation to reach the site's total estimated storage capacity, including Area G, TA-55 and the yet to be completed Transuranic Waste Facility, in approximately fiscal year 2017. The key drivers for this forecast are WIPP availability and safety basis limits for Area G. The vast majority of waste generation stems from key risk reduction activities at the Plutonium Facility and the Chemistry and Metallurgy Research (CMR) building. These activities include residue processing and vault cleanout activities under the Material Recycle and Recovery program, legacy equipment and materials cleanout for plutonium-238 operations, Confinement Vessel Disposition operations, and removal of legacy gloveboxes and equipment required to implement the Plutonium Infrastructure Strategy and cease operations at CMR.

Area G–Nitrate Salts: On Thursday, Area G personnel executed the NNSA Field Office direction to doublepack the four pipe overpack containers holding remediated nitrate salt wastes into standard waste boxes (see 7/24/15 weekly). These containers were remediated with absorbent polymer material rather than wheat-based cat litter. Area G personnel were able to perform this directed action using the relief granted from the Technical Safety Requirements to allow certain portions of the facility to temporarily return to OPERATIONS mode.

Plutonium Facility–Restart Activities: A federal readiness assessment team out-briefed the results of this week's review of the Isotope Fuels Impact Tester. This is the third in a series of readiness assessments necessary to resume all operations in the Plutonium Facility. The team found that all objectives were met, identified no pre-start and three post-start findings, and recommended IFIT operations should be allowed to restart. The post-start findings involved issues with the lack of a formalized operational drill program, obstructed sprinkler heads, and cognizant system engineer training. Of note, the team commended the operational excellence with which operators and their immediate management displayed.

Plutonium Facility–Seismic Safety: On Monday, following direction from NNSA Headquarters, the NNSA Field Office transmitted to LANL a letter identifying necessary actions to address a report developed by the Plutonium Facility Seismic Expert Panel (see 11/7/2014 weekly). One identified action includes the intent to establish a joint NNSA and LANL working group to develop a Request for Proposal to procure a final state-of-the-art analysis to evaluate whether the Plutonium Facility meets seismic performance requirements. Additionally, the NNSA Field Office directed LANL to perform a cost benefit analysis of suggested testing and facility upgrades, and to submit within 90 days a plan to address the remaining issues identified in the panel's report.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 21, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 21, 2015

DNFSB Staff Activity: J.W. Plaue was out of the office this week to attend training on root cause analysis and incident investigation.

Area G–Safety Basis: Senior managers from EM headquarters and the EM and NNSA field offices met with LANL personnel this week to discuss the proposed path forward with necessary safety basis changes to allow limited transuranic (TRU) waste receipts and a return to OPERATIONS mode in Area G. Currently all waste receipts are on hold due to exceedance of composite source term (CST) material-at-risk (MAR) limits (see 5/8/15 weekly). LANL has developed a draft Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) that will lower overall facility MAR limits and replace the CST limit with new limits on combustible waste. Additionally, LANL performed a new accident analysis for the 17 design basis accidents affected by the CST issues, which is included as an appendix to the ESS/JCO. A team comprised of EM and NNSA safety basis experts is reviewing the ESS/JCO and expect to complete their review in approximately two weeks.

Area G–Operations: This week, Area G operations personnel transitioned the facility from WARM STANDBY to OPERATIONS mode to permit various sampling activities to be performed on seven drums containing cemented inorganic wastes known to contain liquid. This is the second in a series of activities directed by the Field Office (see 7/24/15 weekly) to improve the safety posture of Area G while the facility is in WARM STANDBY mode due to the CST issue.

Plutonium Facility–Safety Basis: On Monday, the Field Office manager signed the safety evaluation report approving LANL’s submittal of a revision to the 2014 Plutonium Facility documented safety analysis. Of significance, this revision allows storage of TRU waste containers on designated pads located outside of the facility. Use of these waste storage pads will increase TRU waste storage capacity necessary for ongoing Plutonium Facility operations. This is important as TRU waste storage within the facility is nearing technical safety requirement MAR limits and disposal to Area G is curtailed.

The field office manager also recently approved the closure of an ESS for ammonium nitrate in the plutonium facility ventilation system (see 7/9/10 weekly). The approval letter notes that improvements made to door seals and glovebox exhaust systems, as well as rerouting of ventilation ductwork, has adequately segregated the source of the ammonium nitrate from the ventilation system.

Confinement Vessel Disposition Project: Chemistry and Metallurgy Research (CMR) building operators have completed cleaning out the second of ten confinement vessels stored at TA-55 that have been slated for disposition. The third vessel will not be transported from TA-55 to CMR for cleanout until necessary safety basis changes are implemented and the TRU waste generated from cleanout of the previous two vessels can be shipped out of the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 28, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 28, 2015

DNFSB Staff Activity: J.L. Meszaros observed LANL's independent assessment per DOE-STD-1158 of the nuclear criticality safety program at the Plutonium Facility. On Tuesday, a staff team lead by C. Berg and M.W. Dunlevy conducted a teleconference with NNSA Field Office, EM Field Office, and LANL personnel to discuss a range of safety basis topics associated with the remediated nitrate salt wastes and Area G.

Plutonium Facility–Restart Activities: On Thursday, machinists utilized the recently authorized T-Base II lathe to make a few cutting passes on a plutonium part sufficient to exercise the procedure, including the management of turnings. In accordance with the approved startup plan, a Senior Supervisory Watch and an independent group leader provided management oversight of the activity.

RANT Shipping Facility: In a letter to LANL management dated August 26, 2015, the NNSA Field Office noted numerous and significant deficiencies with the 2015 annual update to safety basis, which is currently in the form of a Basis for Interim Operations (BIO). However, the Field Office acknowledged that the BIO was sufficient to support continued operations under COLD STANDBY. The Field Office further directed that the facility remain in that mode until: (1) the previously identified seismic vulnerabilities are resolved (see 1/30/15 weekly) and (2) the facility implements an approved DOE-STD-3009 compliant Documented Safety Analysis consistent with its enduring facility status. The Field Office did not specify a version of DOE-STD-3009.

Weapons Engineering Tritium Facility–Safety Basis: On Monday, LANL submitted to the NNSA Field Office an Evaluation of the Safety of the Situation (ESS) addressing the Potential Inadequacy of the Safety Analysis declared for the discovery of safety significant oxygen monitor system (OMS) modules plugged into the incorrect power source (see 7/17/15 weekly). In the ESS, LANL noted that workers switched the power source for the modules to the required uninterruptable power supply and satisfactorily completed the appropriate surveillances to verify operability. As such, LANL suggested that no additional operational restrictions are necessary to place the facility in a safe condition and requested approval of the ESS without any required actions.

On Wednesday, LANL submitted to the NNSA Field Office a revision to the ESS for the potential for increased probability of OMS failure (see 11/9/13 weekly). With the submittal of this revision, LANL is requesting to reduce the frequency of OMS calibration surveillances from monthly to quarterly. Accompanying the ESS is a calculation that uses sixteen months of recorded calibration data to demonstrate that sensor lifetime is at least three months.

Emergency Management: On Thursday, LANL personnel conducted a second fact-finding associated with the lapse of Emergency Responder Radiological Training (ERRT) for members of the Los Alamos County Fire Department (LACFD). About two weeks ago, while responding to an external audit, LANL personnel discovered that the ERRT for more than a hundred LACFD personnel had expired around March 2015. LACFD personnel are in the process of completing the training. LANL personnel uncovered several weaknesses in the processes used to monitor and convey training status to LAFD and are examining the extent of condition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 4, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 4, 2015

DNFSB Staff Activity: R.K. Verhaagen attended hazard analysis training at DNFSB Headquarters.

Plutonium Facility–Nuclear Criticality Safety: On Thursday, LANL's independent assessment team outbriefed the results of their review of the nuclear criticality safety program and its implementation at the Plutonium Facility. The 15-member team conducted their review using DOE-STD-1158 and included observation of seven fissionable material evolutions and three relevant meetings. Overall, the team noted improvements in the formalization of criticality safety on the floor, worker adherence to procedure, and the relationship between operations staff and criticality staff. As outbriefed, the team identified three noteworthy practices, nine findings, and 22 observations. Findings and observations of note include: (1) some employees involved with operations using fissile material were not familiar with the criticality safety policy; (2) out of service equipment still connected to active systems are not evaluated to determine frequency for review; (3) procedures do not adequately implement all requirements of the institutional directive on conduct of operations; (4) there is not a clear and consistent understanding of the training requirements for a person in charge; and (5) the review process for the fire department's pre-incident plan does not ensure review by criticality safety personnel.

Safety Basis: On Thursday, LANL safety basis management submitted to the NNSA Field Office for approval three Evaluation of the Safety of the Situation (ESS) documents related to the use of damage ratios (DR) for pipe overpack containers (POC) at the Plutonium Facility, Area G, and the RANT Shipping Facility (see 7/24/15 weekly). For a POC in a fire event, the existing technical basis for a DR relies on four fire tests performed in 1997. This basis is questionable because all four POCs tested used filter types that are no longer used and the POCs did not contain combustible waste material, which might produce pyrolysis gases under fire conditions. As such, there is no relevant fire test data for the actual containers in their current manner of use at LANL until further tests or analyses are completed. For Area G and RANT, the ESSs note that no safety concerns exist given the state of operations and safety basis implementation. For the Plutonium Facility, the ESS proposes use of a DR of 0.1 for transuranic waste storage in the basement and the outdoor waste storage pads. For the latter, a new limit on the size and position of a refueling vehicle associated with operations adjacent to one of the waste pads will also be included. The ESS cites as the basis for using a DR of 0.1 the puncture by a forklift tine, which is the most conservative insult to the POC covered in DOE-STD-5506. The ESS proposes a DR of 1.0 for the first floor of the Plutonium Facility.

Emergency Management: This week, members of the Los Alamos County Fire Department completed their practical exercise for refresher training on glovebox firefighting (see 11/21/14 weekly). The training included approach, assessment, and mitigation of fires involving pyrophoric material such as plutonium. During the practical, small teams of firefighters talk through some actions with the trainers and demonstrate other actions such as applying manual extinguishment agent in a glovebox and using a Type D fire extinguisher through a glovebox glove. During the practical, firefighters do not use breathing apparatus in order to facilitate communications with the trainers. Additionally, the trainers are actively coordinating with Plutonium Facility management to ensure that the corrective actions associated with extinguishment agent in that facility are reflected in this training.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 11, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 11, 2015

DNFSB Staff Activity: C.T. Beaty was onsite to support data gathering on various emergency management and conduct of operations topics at the Plutonium Facility and Area G.

Plutonium Facility–Emergency Management: On Monday, facility personnel conducted an emergency exercise involving the response to a postulated fire in a glovebox. Notably, this was the first fire-type scenario exercised in the facility since at least 2008, as evidenced by published after action reports. The scenario was a limited fire involving ordinary combustibles without injury or contamination to personnel. In some aspects, the exercise involved improved realism such as the workers using the dropbox fire alarm and the Los Alamos Country Fire Department (LAFD) firefighters deploying a hose within the facility. Other important aspects of the response remain artificial such as LAFD assets pre-staging and arriving to the facility via a security bubble and firefighters not utilizing breathing apparatus. In particular, it is unclear when LAFD has drilled or exercised within this facility while using breathing apparatus to improve their understanding of limitations given the facility size and security protocols. Overall, exercise participants noted improvements in communications and commended the first line supervisor for recognizing the ability to isolate electrical power from the impacted glovebox.

Radioactive Liquid Waste Treatment Facility: During the past several months, low-level waste construction project personnel have experienced a number of unexpected encounters and near misses with buried utilities and piping highlighting the challenges of ongoing construction within an operating legacy facility environment. Most recently, personnel encountered four radioactive liquid waste transfer lines at a depth of about 3 ft below grade when they were expecting them to be around 13 ft. The construction crew leader's action to pause mechanical excavation upon the uncovering of a sand layer likely prevented breach of these lines. Subsequent to this incident and discussions with the Site Representatives, NNSA Field Office personnel questioned facility management on: (1) the adequacy of the piece of warped plywood protecting the exposed lines from construction hazards; (2) why personnel had expectations on the depth of the piping that were inconsistent with available drawings, (3) whether analysis existed to demonstrate the buried lines could support loads from heavy construction equipment; and (4) whether actions could be taken to better protect radioactive materials immediately adjacent to the primary thoroughfare for construction equipment contained within a large number of low-level waste containers and a piece of in-service filtration equipment.

Chemistry and Metallurgy Research (CMR) Building–Facility Evaluation: On Wednesday, an assessment team briefed the results of their Facility Evaluation of CMR. Facility Evaluations are one of LANL management's tools used to ensure continuous improvement of operations. Recently, a renewed emphasis has been placed on performing and improving Facility Evaluations across the site. The assessment team performed work observations, interviews, and document reviews to evaluate the level of performance and compliance implementation of various functional areas within CMR. The team identified a number of meaningful findings in the functional areas of Management Systems, Conduct of Engineering, Conduct of Operations, Safety Basis, and Criticality Safety.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 18, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending September 18, 2015

DNFSB Staff Activity: T.L. Hunt observed the contractor's readiness assessment of the Pit Flowsheet activities. J.E. Deplitch observed the emergency exercise described below. On Thursday, staff members A.K. Gwal, P.J. Foster, and B.K. Caleca conducted a teleconference with LANL personnel to discuss questions on the electrical systems at the Plutonium Facility.

Emergency Management: On Wednesday, personnel in the Emergency Operations Center (EOC) conducted an exercise simulating the response to an earthquake. The scenario included the collapse and subsequent fire of a wing at the Chemistry and Metallurgy Research (CMR) Building, hazardous material releases from two other facilities, and numerous impediments to local infrastructure and immediate response assets. Personnel from the DOE Office of Enterprise Assessments evaluated this exercise and briefed the NNSA Field Office on the issues they identified.

Transuranic Waste Management: Last Friday, the NNSA Field Office directed the LANL contractor to revise the *Master Plan for Enduring Waste Management*. The Field Office noted that many of the key assumptions in the 2012 version of the plan had significantly changed and that a higher level of assurance in waste management planning is needed to support transition of responsibility of Area G to EM. The Field Office also emphasized that final treatment of the remediated nitrate salt wastes warrants LANL's highest priority and provided a substantial list of elements to be addressed in the plan, which they requested by October 15, 2015.

On Tuesday and Wednesday, senior NNSA and EM Headquarters personnel toured the transuranic waste generating and management facilities and held an all-day workshop with personnel from both Field Offices and LANL as a follow on from the prior workshop (see 8/14/15 weekly). Notably, EM Headquarters personnel emphasized the need to work systematically and expeditiously through the myriad of safety basis issues present at Area G prior to considering receipt of newly generated wastes. For example, approved Evaluations of the Safety of the Situation do not exist for either the composite source term issue declared on April 29, 2015, or the new information formally provided by the NNSA Field Office regarding accidents for the remediated nitrate salts on June 25, 2015. As a result, NNSA has yet to formally accept the risks associated with these conditions.

Transuranic Waste Facility (TWF)–Safety Basis: On Thursday, the NNSA Field Office transmitted to LANL a direction letter regarding the submittal of the TWF 90% Documented Safety Analysis (DSA) and Technical Safety Requirements (TSR). In the letter, the Field Office identified numerous major changes to the DSA and TSR that are necessary to ensure timely review and approval of future submittals. Field Office comments included classification of safety significant support systems, improper screening of certain worker hazards as standard industrial hazards, and initial conditions as design features.

Confinement Vessel Disposition Project: On Tuesday, LANL personnel transported from TA-55 to CMR the third of ten confinement vessels slated for disposition. The second vessel remains within the enclosure in CMR awaiting NNSA Field Office approval of submitted safety basis changes necessary to complete final processing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 25, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending September 25, 2015

DNFSB Staff Activity: On Monday, D.K. Andersen, M.R. Bradisse, P.J. Foster, E.M. Gibson, R.L. Jackson, and M.T. Wright held a teleconference with Transuranic Waste Facility project personnel to discuss design codes and standards for the waste storage buildings.

Federal Oversight: One year ago, the Secretary of Energy requested a plan to transition responsibility for legacy environmental cleanup work at LANL from NNSA to the Office of Environmental Management. Recently, a number of significant milestones for that plan occurred. Last week, NNSA and EM approved a formal memorandum of understanding governing the relationship between the two field offices. Under this arrangement, the NNSA Field Office will maintain safety basis approval and startup authority until the EM Field Office can achieve appropriate staffing. However, EM will have participation and concurrence on all applicable safety basis approvals. On Monday, the permanent manager of the new EM Field Office, Douglas Hintze, reported for duty. On Wednesday, EM and the LANL contractor signed a cost-plus-award-fee contract for EM work scope to cover a bridging period until such time that EM can procure a new contractor. Notably, the bridge contract includes a milestone to complete treatment of the inappropriately remediated nitrate salt wastes by September 29, 2017.

The NNSA Field Office recently improved staffing levels with the return of the Deputy Manager, and arrival of a new Deputy Assistant Manager for Operations, two new Facility Representatives, and a Safety Basis Analyst. Additionally, permanent selections recently started in their roles as the Assistant Manager for National Security Missions and the Assistant Manager for Safeguards and Security.

Plutonium Facility–Restart Activities: This week, three Plutonium Facility resumption milestones were achieved, including:

- The contractor readiness assessment team completed their review of Pit Flowsheet operations and concluded that upon satisfactory resolution of identified pre-start findings LANL has adequately demonstrated operations can safely proceed in this area. Five preliminary findings provided at the team's outbrief were focused on areas of operations, quality assurance, and worker safety.
- The NNSA Field Office Manager approved LANL's corrective action plan for the Isotope Fuels Impact Tester (IFIT) federal readiness assessment and authorized the startup of IFIT operations.
- The NNSA Field Office Manager approved LANL's corrective action plan for the Balance of Machining (BOM) federal readiness assessment and authorized the startup of BOM operations.

Performance Management: On Wednesday, the Laboratory Director and the NNSA Field Office Manager signed LANL's Fiscal Year 2016 Strategic Performance Evaluation and Management Plan (PEMP). The PEMP is the mechanism that establishes performance evaluation criteria upon which the laboratory contractor's earned award fee is determined. The PEMP identifies performance category goals to be evaluated that include: Manage the Nuclear Weapons Mission; Reduce Nuclear Security Threats; DOE and Strategic Partnership Project Mission Objectives; Science, Technology, and Engineering; Operations and Infrastructure; and Leadership.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 2, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 2, 2015

DNFSB Staff Activity: C. T. Beaty was on site to observe the emergency exercises discussed below. On Wednesday, a staff team conducted a teleconference to discuss safety basis questions with personnel from the Transuranic Waste Facility project. On Thursday, a staff team conducted a teleconference with personnel from LANL and the NNSA and EM Field Offices to discuss the status of safety basis development activities for the storage and final treatment of the inappropriately remediated nitrate salt wastes.

Federal Oversight: On Friday, the Assistant Secretary for Environmental Management visited LANL for tours and discussions on the status of the transuranic waste management system.

Emergency Management: LANL personnel conducted annual emergency exercises at the Chemistry and Metallurgy Research (CMR) Building and the TA-48 Radiochemistry Facility. The exercise at CMR involved an acetylene tank explosion that killed a worker, injured a second worker, and damaged the facility, but did not release any radioactive materials. In accordance with their procedures, this event drove full evacuation of the facility, including the operations center and facility incident command. Evaluators preliminarily determined that all exercise objectives were met, but noted more than a dozen issues for corrective action. For example, radiological control technicians identified the need for an external supply of respirators and other response equipment. The scenario at TA-48 involved the spill of hydrochloric acid, which drove the need for a shelter-in-place action in area buildings. Participants experienced difficulties receiving the shelter-in-place notification resulting in the subsequent inability to take appropriate protective action for a release of a hazardous substance. The site representatives note that this result is concerning given the proximity of TA-48 to several hazard sources that could drive a shelter-in-place.

Area G–Safety Basis: On Monday, Area G personnel conducted a fact-finding after they determined that material-at-risk values for certain types of nitrate salt wastes may be underreported by a factor of as much as 10. Personnel determined that the historical data from the Plutonium Facility relied on safeguards values that did not accurately reflect the content of americium-241. Area G personnel are assessing the implications for the safety basis and are reviewing the extent of condition for other waste streams that may have elevated americium content.

Plutonium Facility–Seismic Safety: In a progress report issued on Wednesday, LANL management reported full completion of all milestones for the project execution strategy in fiscal year 2015, including the completion of wrapping one more girder than planned for a total of seven.

Weapons Engineering Tritium Facility (WETF)–Risk Reduction: WETF programmatic personnel recently reported on reductions of material-at-risk inventory within the facility. In particular, completion of readiness activities associated with UC-609 shipping container operations enabled facility personnel to transfer a significant quantity of tritium out of the facility (see 6/19/15 weekly). This week, a federal readiness assessment team began their review of facility operations. Successful completion of this readiness assessment is critical to additional reduction of legacy material-at-risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 9, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 9, 2015

Weapons Engineering Tritium Facility (WETF)–Restart Activities: On Tuesday, the federal readiness assessment team briefed the results of their assessment of tritium gas transfer operations. The team noted that all review objectives were met and identified three findings related to quality assurance and radiation protection. The team concluded that subject to satisfactory closure of all pre-start findings the facility is ready to operate safely. Additionally, the team commended WETF personnel for: (1) their exceptional rigor and formality in conduct of operations, (2) a comprehensive and well-implemented drill and exercise program, and (3) using lessons learned from Plutonium Facility readiness activities to strengthen preparation. The success with the readiness assessment is a significant milestone as gas transfer operations have not occurred since 2010 and restart of this activity is essential to reducing risk through the disposition of legacy tritium materials.

Plutonium Facility–Safety Systems: In accordance with guidance from the Secretary of Energy, the Acting NNSA Deputy Administrator for Defense Programs recently requested an Analysis of Alternatives (AoA) for planned upgrades to the Plutonium Facility. In particular, this AoA will focus on Phase III of the TA-55 Reinvestment Project (see 6/5/15 weekly) consisting of the following sub-projects: (1) fire alarm system replacement, (2) upgrading the active confinement ventilation system to safety class, and (3) separating non-seismically qualified structures from the safety class fire water supply loop. Of note, these upgrades are highlighted in LANL’s Project Execution Strategy to further reduce consequences from the Plutonium Facility resulting from seismically induced events. Results of the analysis are due no later than February 26, 2016.

Plutonium Facility–Safety Basis: Last Wednesday, Plutonium Facility management declared complete phase 2 of the implementation plan for the 2014 safety basis, revision 0.4. This step eliminated two Evaluations of the Safety of the Situation and one Temporary Modification, bringing the facility closer toward the goal of a consolidated and up-to-date safety basis. Facility management plans to complete phase 3 of the implementation plan by December 16, 2015.

Area G–Fire Protection: On Monday, operators entered their abnormal operating procedure for a discovery of an airborne, liquid, and/or solid material spill after receiving reports of water emanating from an underground firewater supply main. Fire suppression systems are not credited at Area G, but nonetheless provide an essential element of defense-in-depth. At the discretion of the shift operations manager, a fire watch was established and fire protection management notified. Fire protection subsequently informed the fire department of the impairment enabling them to consider adjusting response plans accordingly. Workers completed the repair on Wednesday

Safety Basis: Last Wednesday, LANL management transmitted to the NNSA Field Office a proposed protocol to perform atmospheric dispersion for use in safety analyses at the nuclear facilities. The protocol consolidates several improvements including updated meteorological data, recalculation of facility-specific values for deposition velocity and surface roughness, and evaluation of canyon effects. LANL requested Field Office review and concurrence prior to executing a schedule to implement the new protocol.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 16, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 16, 2015

DNFSB Staff Activity: M. W. Dunlevy was on site to perform familiarization activities, including facility walkdowns and meetings with senior Field Office and LANL management, as he assumes duties as the Board's staff cognizant engineer for LANL.

Area G–Safety Basis: On Thursday, LANL submitted to the NNSA Field Office for review and approval, a temporary modification to the Area G technical safety requirements (TSR). This temporary modification was developed to allow certain activities to proceed while the facility is in WARM STANDBY mode due to exceeding composite source term material-at-risk limits (see 5/8/15 weekly). The proposed activities are in direct support of improving the safety posture in Area G while LANL personnel resolve multiple outstanding potential inadequacies of the safety analysis conditions and other issues related to remediated nitrate salt wastes, composite source term, and uncertainties in actual material-at-risk values. Proposed activities include: (1) sampling and non-destructive assay of the unremediated nitrate salts currently stored in the Dome 231 Permacon; (2) performing real-time radiography and sampling drums containing cemented inorganic wastes; and (3) doublepacking transuranic waste containers found to exceed 80 Pu-239 equivalent curies. Of note, this temporary modification will more formally implement the relief from the TSRs provided by the Field Office in July of this year (see 7/24/15 weekly).

Plutonium Facility–Conduct of Operations: Facility personnel identified an incorrect criticality safety posting (CSP) was being used to move a waste drum through multiple fissile material operations. During a fact finding of the event, operators noted that at some point during transfer of the drum between activities the correct CSP was misplaced. Operators then completed the activity using a different CSP that was printed out, readily accessible, and had a title similar to the activity being performed without properly verifying it was the correct CSP. Issues identified during the fact finding were noted to be very similar to those that resulted in a similar event earlier this year (see 5/22/15 weekly). Facility management identified the need to develop corrective actions that will improve the process for ensuring operators verify the correct CSP is used when performing fissile material operations. Additionally, corrective actions taken in response to the previous event will be re-examined.

Plutonium Facility–Restart Activities: On Thursday, LANL submitted the Pit Flow Sheet contractor readiness assessment causal analysis and corrective action plan report to the NNSA Field Office. The Pit Flow Sheet federal readiness assessment team was on site this week to conduct a pre-visit for their assessment scheduled to commence November 9, 2015.

RANT Shipping Facility–Safety Basis: On Thursday, NNSA Field Office and LANL personnel conducted a video teleconference with the Board to provide a periodic update on the status of open issues identified with the RANT Shipping Facility safety basis communicated to the NNSA Administrator in a Board letter dated December 9, 2014. The site personnel briefed the Board on planned seismic upgrades to the facility and committed to develop a new compliant safety basis that incorporates the facility modifications and resolves the Board's concerns. The facility remains in COLD STANDBY mode until such time as the new safety basis can be approved and implemented.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 23, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 23, 2015

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office manager signed a Safety Evaluation Report (SER) approving the Plutonium Facility’s 2015 Documented Safety Analysis (DSA) and Technical Safety Requirements (TSR). The SER also approved revisions to the currently implemented 2011 DSA and TSRs. Some of the more significant changes were made to: (1) evaluate unmanned aircraft system use, (2) update a specific administrative control for intentional confinement penetrations, (3) evaluate a new outdoor above-ground fuel tank for a diesel fire pump, and (4) update the TSRs for storage of certain plutonium-238 heat sources.

Waste Characterization Reduction and Repackaging Facility (WCRRF): The NNSA Field Office approved LANL’s submittal of the Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis (PISA) declared for degradation of the facility roof resulting from flooding (see 7/17/15 weekly). WCRRF structural integrity is credited in the safety basis as a safety significant design feature to provide a confinement barrier. Facility personnel declared the structural integrity to be inoperable when damage to the roof was discovered. In the ESS, LANL states that the facility will remain in COLD STANDBY mode until the roof can be repaired.

Nuclear Criticality Safety: LANL management recently transmitted a number of documents to the NNSA Field Office aimed at improving the Nuclear Criticality Safety Program (NCSP) and its implementation site-wide. These documents include:

- The final report of an independent assessment of the NCSP and its implementation at the Plutonium Facility performed in accordance with DOE-STD-1158-2010, *Self-Assessment Standard for DOE Contractor Criticality Safety Programs* (see 9/4/15 weekly). Notable conclusions from the assessment included: (1) improved formalization of criticality safety program implementation, (2) improved coordination between operations and criticality safety personnel, (3) identification of some necessary improvements to procedure development, and (4) criticality resources for Plutonium Facility restart are consuming resources from other LANL facilities.
- An independent assessment of 179 previously closed NCSP corrective action items to determine the effectiveness of closure actions taken. Three closed items were determined to require additional actions and were reopened: (1) ensure application of upper subcritical limits are supported by the criticality safety evaluation’s validation report, (2) evaluate facility specific criticality directives for compliance with the site-wide directive, and (3) address emergency response deficiencies identified during an extent of condition review.
- An assessment of NCSP metrics for the third quarter of fiscal year 2015. The recently revamped Nuclear Criticality Safety Committee met this week to discuss the findings and to identify potential improvements actions.

Weapons Engineering Tritium Facility–Safety Basis: The NNSA Field Office approved LANL’s request to close the ESS and associated PISA declared when a safety significant oxygen monitoring appliance was discovered to be connected to the wrong power supply (see 7/17/15 weekly). The correct power source has been restored to the appliance and the oxygen monitoring system has since been declared operable.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 30, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.K. Verhaagen and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending October 30, 2015

The Site Representatives were at DNFSB Headquarters. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 6, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 6, 2015

DNFSB Staff Activity: C. Berg attended meetings of the Tritium Focus Group and walked down the Dome 375 Permacon used to store the inappropriately remediated nitrate salt wastes.

Plutonium Facility–Nuclear Material Management: On Monday, the six sigma improvement team issued their report on streamlining selection and use of containers for the storage of nuclear materials inside gloveboxes (see 7/3/2015 weekly). Plutonium Facility management initiated this effort following a technical safety requirement violation; however, the Site Representatives note that the scope aligned well with a number of topics discussed in the Board’s Technical Report 39, *Opportunities for Risk Reduction at the Los Alamos National Laboratory Plutonium Facility through the Minimization of Material-At-Risk*. Overall, the team identified a dozen recommendations, including: (1) creating a software filter to ensure only those containers that meet facility requirements are displayed to operators on the LANMAS database interface; (2) investing in additional SAVY containers to ensure availability; (3) investigating changes to bag-out bags that would enable overpacking containers in the next larger size rather than skipping a size; (4) developing a qualification standard covering containers; (5) simplifying credited heights for various containers in the safety basis; and (6) developing a requirements document to support a potential new in-glovebox container with cost and usability benefits. Facility management is currently determining a path forward on these recommendations.

Area G–Safety Basis: Last month, NNSA Headquarters approved LANL’s request to expand the restricted airspace zone above the laboratory by roughly 20 percent. One of the benefits of this expansion is to include airspace above Area G. According to existing approved safety analysis, an aircraft crash at Area G is one of the accident scenarios at LANL with mitigated consequences that exceed the DOE Evaluation Guideline of 25 rem. LANL analysts believe that approval of this expansion will lower the chance of an aircraft crash and in combination with other measures under consideration would result in a crash scenario no longer being credible as determined by DOE-STD-3014, *Accident Analysis for Aircraft Crash into Hazardous Facilities*. NNSA is currently working a request for the expansion approval with the Federal Aviation Administration.

Plutonium Infrastructure Strategy: On Monday, LANL transmitted revision 2 of the Safety Design Strategy for the PF-4 Equipment Installation (PEI) subproject. The PEI subproject impacts 17 gloveboxes that will house analytical chemistry and materials characterization equipment. Thirteen of these gloveboxes are existing installed equipment that will be repurposed as part of the subproject. Eight of the repurposed gloveboxes do not meet the existing safety basis requirement for Performance Category 2 seismic criteria. LANL’s submittal includes safety and nuclear criticality safety analyses indicating that the benefit of upgrading these glovebox stands is minimal (~2 mrem offsite per stand) and is outweighed by the cost and schedule impacts to the project. LANL therefore concluded that the existing safety controls for each glovebox were adequate and committed to reflect this information in a page change to the safety basis prior to submittal of the Critical Decision 2/3 design packages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 13, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 13, 2015

DNFSB Staff Activity: T. L. Hunt observed activities of the federal readiness assessment (FRA) underway for Pit Flowsheet activities at the Plutonium Facility.

Plutonium Facility–Restart Activities: On Monday, the FRA team commenced fieldwork for their assessment of Pit Flowsheet activities, which consists of 17 detailed operating procedures, supplemented by about 30 specific process instructions. These documents govern the general functional areas of welding, assembly, inspection, and evaluation. In addition to a large number of interviews, FRA team members observed six operational evolutions covering downdraft room operations, autoclave operations, assembly gas operations, weighing, dye penetrant testing, and a material move.

Plutonium Facility–Nuclear Criticality Safety: On Thursday, Plutonium Facility personnel conducted a fact-finding after operators declared a potential process deviation when a container listed on the printed inventory for a floor location was not actually present. Participants noted that the operators responded appropriately to the situation. Their subsequent review indicated that operators had moved the missing item into a new location on October 21, 2015, and that the revised printout was generated one minute after the transfer initiated. The timing of the printout is important since the LANMAS database indicates that an item being moved remains in its sending location, but is flagged with an “in transit” designation until it is received and logged into its destination. In addition to the time needed to physically move the item, operators require at least 10 minutes to complete a complicated login and LANMAS transaction process. As a corrective action, management decided to issue a lessons-learned and remind operators of their allowance to make ink-based changes in these types of situations. One of the participating group leaders also indicated that a preferable solution would be to change the software used to generate the printouts to indicate the “in-transit” status. He is separately working on a proposal to modernize the LANMAS login process, streamline the user interface specific to Plutonium Facility needs, and acquire additional terminals.

Transuranic Waste Facility (TWF): Given projections indicating that transuranic waste generation will exceed storage capacity at the Plutonium Facility sometime in early 2017, LANL management has initiated an effort to accelerate the transition to operations for the new TWF project. Their current accelerated schedule predicts final commissioning in January 2016, approval of the safety basis in February 2016, and ensuing readiness activities culminating in the start of a federal operational readiness review in September 2016. The Site Representatives note that the TWF provides about another year of storage capacity and that the majority of waste is generated through important risk reduction activities. Additional capacity will be necessary if LANL shipments to the Waste Isolation Pilot Plant do not resume in that time frame.

Area G–Safety Basis: Upon additional consideration, NNSA Headquarters has paused their effort to seek Federal Aviation Administration approval to expand the restricted airspace zone above the laboratory to include the space above Area G (see 11/6/15 weekly). If the option of expanding the restricted airspace is not pursued, LANL personnel will need to explore other measures to prevent or mitigate the consequences of this accident, such as footprint reduction, which is currently under evaluation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 20, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 20, 2015

DNFSB Staff Activity: M.W. Dunlevy conducted site familiarization activities and observed the transuranic waste workshop and Area G safety basis presentation discussed below.

Transuranic Waste Management: On Tuesday, personnel from LANL, NNSA, and EM conducted a workshop focused on management of the enduring waste stream. The workshop, which was truncated by a snow delay, included discussions on the overall waste forecast, efforts to accelerate operations at the Transuranic Waste Facility (TWF), and prioritization of anticipated permit changes. LANL analysts continue to forecast a number of pinch points between waste generation and available waste storage capacity. As reported last week, the acceleration of the transition to operations for the TWF can provide important additional capacity to the system (11/13/15 weekly). During the workshop, participants highlighted that maximum benefits from the accelerated TWF schedule are reliant on permit actions. The Site Representatives note that the alignment and coordination these workshops are stimulating is essential, particularly given the need for a functioning waste system to enable key risk reduction activities at the nuclear facilities.

Area G–Safety Basis: On Thursday, LANL management presented to NNSA and EM personnel an overview of a draft revision to the Evaluation of the Safety of the Situation (ESS) for the storage of remediated nitrate salt (RNS) wastes. LANL undertook the revision to address the NNSA Field Office direction concerning the profusion of New Information pertinent to the continued safe storage of the RNS waste (see 6/26/15 weekly). Of most significance, the New Information indicated that the value of the respirable release fraction (ARF_xRF) associated with RNS waste could be more than two orders of magnitude larger than the value used in the existing safety basis. LANL proposed a qualitative approach to factoring in an increased ARF_xRF for the purposes of analyzing potential accident consequences and evaluating the efficacy of controls to protect the public. The Site Representatives note that this approach contrasts to an EM decision to utilize a specific new value for the ARF_xRF in safety basis analysis at the Waste Isolation Pilot Plant. NNSA and EM personnel provided feedback on a number of areas including bolstering the conduct of engineering and maintenance of credited controls, improving the technical bases behind key control set points, and strengthening actions in the technical safety requirements. LANL personnel are working to incorporate this feedback prior to formal submission of the ESS.

Plutonium Facility–Restart Activities: On Wednesday, the federal readiness assessment team briefed the results of their review of Pit Flowsheet activities (see 11/20/2015 weekly). The team identified one pre-start and one post-start finding, both related to criticality safety. The team concluded that subject to satisfactory resolution of the findings the Pit Flowsheet activities are ready to safely resume. Also this week, operators successfully bisected and disassembled another pit with the robotic lathe associated with Advanced Recovery and Integrated Extraction System since receiving NNSA Field Office startup authorization on September 25, 2015. A management observation team performed oversight of this activity in accordance with the approved restart plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 27, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 27, 2015

Weapons Engineering Tritium Facility (WETF)–Restart Activities: Recently, LANL management submitted to the NNSA Field Office for review and approval a corrective action closure package supporting the recent federal readiness assessment (see 10/9/2015 weekly). LANL’s request addressed the two pre-start findings relating to software quality assurance and radiation protection and their proposed schedule for completing the actions necessary to close the post-start finding related to quality assurance non-conformance reporting. As the Startup Approval Authority, the NNSA Field Office Manager’s approval of this request will enable facility personnel to complete facility restart. Following resumption of authorized activities, WETF personnel plan to transfer gas out of the Tritium Gas Handling System in preparation for a maintenance outage necessary to make system upgrades to allow future gas processing for risk reduction activities. WETF personnel are also planning to conduct function testing of gas transfer systems when restarted.

Plutonium Facility–Criticality Safety: Last Friday, LANL transmitted a request to the NNSA Field Office to extend the deadline for directed safety basis changes. The NNSA Field Office direction came in a letter approving a previous request to extend the Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) concerning the potential for nuclear criticality due to firewater intrusion (see 5/15/15 weekly). LANL noted in the current request for extension that the Nuclear Criticality Safety Program Upgrades Project Plan, which is a prerequisite to making the safety basis changes, is still in revision to address necessary deficiencies. LANL committed to submit the necessary safety basis changes and the project plan by December 24, 2015. The ESS/JCO will be closed following approval and implementation of the safety basis changes.

Transuranic Liquid Waste (TLW) Treatment Facility Project: Last month, LANL management transmitted to the NNSA Field Office for approval the Preliminary Safety Design Report (PSDR). The TLW Treatment Facility will be a Hazard Category 3 nuclear facility with a proposed radiological material-at-risk limit of 55 americium-241 equivalent curies. From a risk perspective, the PSDR estimates Level C radiological consequences for the public and facility workers for a fire that vaporizes the entire facility inventory, which the PSDR deems as physically impossible but informative from a bounding standpoint. The PSDR defines Level C radiological consequences as lost work time without disability for the worker and < 5 rem Total Effective Dose for the public. The PSDR proposes 23 engineered controls with all but the safety significant chemical shields classified as defense-in-depth. The PSDR further proposes four Specific Administrative Controls that provide a limit on radiological material-at-risk limit, a limit on fissile material inventory, a fissile material transfer protocol, and a bulk chemical delivery control. For the code of record, the PSDR indicates that despite the availability of newer versions, the project’s design will adhere to DOE Order 420.1B, *Facility Safety*. LANL’s transmittal letter notes that they will provide the results of a separate review requested by the NNSA Field Office of the hazards associated with a natural gas line in proximity to the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 4, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 4, 2015

DNFSB Staff Activity: M.R. Bradisse was on site to observe the nuclear criticality safety program (NCSP) assessment discussed below. B.K. Caleca and C.J. March were on site to perform a review of Plutonium Facility fire suppression upgrades, to walkdown systems supporting the permacon in Area G storing the inappropriately remediated nitrate salts, and to observe wildland fuel reduction activities utilizing the LANL masticator in the vicinity of Area G. All three staff members conducted a walkdown of the Transuranic Waste Facility (TWF) construction site.

Weapons Engineering Tritium Facility (WETF)–Restart Activities: On Thursday, the NNSA Field Office Manager approved LANL’s submittal of the corrective action plan and prestart finding closure package supporting the recent WETF federal readiness assessment (see 11/27/15 weekly). In the approval letter, the NNSA Field Office Manager acknowledged the prestart findings have been verified closed and authorized restart of WETF gas transfer operations.

Transuranic Waste Facility–Safety Basis: On Monday, LANL submitted to the NNSA Field Office for review and approval a revision of the TWF 90% Documented Safety Analysis (DSA) and Technical Safety Requirements. This revision was submitted to address NNSA Field Office comments and directed actions for a previous submittal (see 9/18/15 weekly). In the revision, LANL noted that all directed actions had been addressed with the exception of one relating to initial conditions assumed for building dimensions and site layout in the aircraft crash analysis. LANL indicated in the submittal that the directed action will be incorporated into the 100% DSA submittal when as-built measurements become available.

Area G–Safety Basis: LANL recently submitted for review and approval a revision to the Evaluation of the Safety of the Situation (ESS) for the storage of remediated nitrate salt wastes. This most recent submittal incorporated comments received from NNSA and EM during a presentation of a draft version of the ESS (see 11/20/2015). On Thursday, NNSA, EM, and DOE Office of Environment, Health, Safety and Security headquarters personnel conducted a video teleconference with EM and NNSA Field Office personnel to discuss the strategy for moving forward with review and approval of the ESS.

Plutonium Facility–Criticality Safety: On Thursday, a team of criticality safety experts from NNSA briefed the results of their focused assessment of the NCSP at the Plutonium Facility. This assessment was primarily conducted to address a recommendation from the federal readiness assessment team for the balance of machining operations to conduct an independent federal assessment of facility implementation of the NCSP (see 7/3/15 weekly). The assessment was conducted using criteria from DOE-STD-1158-2010 scoped to include Supervisory Responsibilities, Operating Procedures, and Materials Control. The team identified seven findings relating to material labeling, material movement processes and procedures, criticality safety infraction corrective action effectiveness, and a nuclear material exemption process that inappropriately excludes certain items from the NCSP. Of note, the finding relating to exempt items was identified as requiring resolution prior to proceeding with the next scheduled federal readiness assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 11, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 11, 2015

Weapons Engineering Tritium Facility (WETF)–Operations: This week, WETF personnel commenced gas transfer operations following last week’s authorization to restart. This significant milestone represents the first time these operations have occurred in nearly eight years. WETF management implemented additional measures to ensure safe operations including the requirement for an assigned manager to observe and approve performance and the need to conduct a hot wash after each evolution to ensure lessons learned are carried forward. Operators demonstrated proper, deliberate, and complete performance of procedures, with particular emphasis on confirmation of expected system responses and a willingness to stop. This week’s activities included: (1) the consolidation of gas that had been resident in tanks within the tritium gas handling system for numerous years into a low pressure receiver, (2) sampling the contents of two low pressure receivers for material control and accountability purposes, and (3) removal of the low pressure receivers from the system. Facility personnel will continue to perform gas transfer operations until all gas has been removed from the tritium gas handling system. Following removal of all gas from the tritium gas handling system, WETF will be placed into a maintenance mode to facilitate necessary system modifications and upgrades that will allow processing and removal of legacy gas and a return to function testing operations.

Plutonium Facility–Seismic Safety: LANL management recently submitted to the NNSA Field Office an updated status on actions to address a report developed by the Plutonium Facility Seismic Expert Panel (see 8/14/15 weekly). LANL identified that actions are being taken to address both required and prudent actions identified by the Seismic Expert Panel. Additionally, LANL noted that the plan to address actions directed by the NNSA Field Office was not submitted by November 5, 2015 as requested, but will rather be submitted with the annual Plutonium Facility Project Execution Strategy no later than December 24, 2015.

Emergency Management: Earlier this month, the NNSA Field Office issued their review of LANL’s self-assessment of the Emergency Management Program. Rather than conduct independent federal assessments, the Field Office partnered with LANL assessors to shadow selected program element reviews believing that this approach benefits both sides and ensures timely feedback. The Field Office noted the positive practice that LANL continues to evaluate all 15-program elements utilizing the DOE evaluation guidance. Overall, the Field Office found that nearly all of the assessments were thorough, objective, and effective in identifying deficiencies. Notably, the Field Office indicated that the review of Training and Drills was excellent and very self-critical. That review concluded, “A sustainable, comprehensive, and coordinated training and drills program has not been fully implemented as required per DOE Order 151.1C.”

Plutonium Facility–Criticality Safety: On Wednesday, LANL management requested an extension of the Evaluation of the Safety of the Situation /Justification for Continued Operations (ESS/JCO) covering unclear criticality safety evaluations for two vault rooms within the facility. The ESS/JCO, which originated in 2012 and was previously extended twice, currently expires on January 9, 2016, or when a compliant evaluation is completed and implemented, whichever occurs first. LANL requested an extension to June 30, 2016, in order to facilitate continued priority on restart activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 18, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 18, 2015

DNFSB Staff Activity: R. L. Jackson was onsite to plan oversight activities associated with Plutonium Infrastructure Strategy. Accordingly, he met with key project staff and walked down the Plutonium Facility, the Chemistry and Metallurgy Research (CMR) building, and the Radiological Laboratory Utility Office Building (RLUOB).

Plutonium Infrastructure Strategy: Late last month, the Deputy Secretary of Energy approved a restructuring of the subprojects covered under the CMR Replacement project. There are now four subprojects: (1) RLUOB Equipment Installation, Phase 2; (2) Plutonium Facility Equipment Installation, Phase 1; (3) Plutonium Facility Equipment Installation, Phase 2; and (4) Re-categorizing the RLUOB to Hazard Category 3 with a material-at-risk limit of 400 g plutonium-239 equivalent. The first two subprojects enable LANL to cease programmatic activities in the CMR by 2019, while the latter two subprojects primarily support the increased capacity required for larger pit manufacturing rates. The memo requests an updated project execution plan within 90 days and indicates approval authority will remain with the DOE Deputy Secretary for subprojects 2–4 and with the NNSA Administrator for subproject 1.

In a separate action, the DOE Deputy Secretary also approved the mission need Critical Decision (CD)-0 for the Plutonium Modular Approach project. This project addresses life extension needs for the existing Plutonium Facility in support of Department of Defense requirements and Congressional Direction. The CD-0 schedule range for project completion is December 2025 to December 2027.

Transuranic Waste Management–Restart Activities: On Thursday, LANL transmitted to the NNSA Field Office for review and approval an amendment to the quarterly site-wide startup notification report (SNR). LANL amended the SNR primarily to request a scope change to the approved readiness assessment for treatment of remediated nitrate salt waste drums. In a previous approval letter, the NNSA Field Office directed LANL to conduct a federal readiness assessment for this activity. This recent amendment proposes combining the treatment of both remediated and unremediated nitrate salt waste drums into one startup activity and to perform only a contractor readiness assessment.

Plutonium Facility–Restart Activities: On Thursday, the Associate Director for Nuclear and High Hazard Operations submitted to the NNSA Field Office a request for Startup Authorization Authority approval to commence Pit Flow Sheet (PFS) operations in the Plutonium Facility. The request also included the PFS federal readiness assessment corrective action plan for approval and the PFS federal readiness assessment pre-start closure package for adequacy verification. If approved, the PFS activity will be the fourth operation Plutonium Facility personnel have successfully resumed through the formal readiness process this calendar year. Four additional operations are scheduled to go through the formal readiness process next calendar year. Successful resumption of these activities will represent a complete restart of the Plutonium Facility operations paused by the Laboratory Director in June 2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 25, 2015

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.K. Verhaagen and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending December 25, 2015

The Year on a Page: The Site Representatives' summary of the key happenings of 2015:

- Activities at Area G remain largely curtailed due to several unresolved inadequacies in the safety basis. Foremost of these issues, LANL personnel are working to accelerate final "render-safe" treatment of the inappropriately remediated nitrate salt wastes after EM and NNSA personnel raised questions on the adequacy of the controls for the continued safe storage of these materials.
- The Weapons Engineering Tritium Facility (WETF) performed gas transfer activities for the first time in nearly 8 years. Additionally, facility personnel completed a number of risk reduction activities and repackaged several tritium containers that were approaching their pressure limits.
- Plutonium Facility (PF-4) personnel successfully restarted four activity groupings. While these operations were of a low level of complexity, facility personnel have demonstrated an ability to prepare adequately the necessary people, procedures, and equipment. The balance of PF-4 operations, including significantly more complicated activities, will undergo restart in 2016.
- LANL's ability to process and store transuranic waste remains significantly impaired because of safety basis issues at Area G and the closure of the Waste Isolation Pilot Plant. This situation is hindering risk reduction activities at PF-4, the Chemistry and Metallurgy Research building, and WETF. To mitigate the situation, LANL management initiated transuranic waste storage on the outdoor pads at PF-4 and accelerated the schedule to commence operations at the new Transuranic Waste Facility.
- The NNSA Field Office filled several key positions, but continues to experience difficulty maintaining adequate staffing levels. The EM Field Office stood up operations and established a bridge contract for environmental cleanup activities.
- PF-4 personnel continued execution of important upgrades to the building's seismic safety posture. Notably, they placed reinforcing wraps on 7 of 27 roof girders with additional wraps in progress. They also upgraded the stands for three gloveboxes housing pyrochemical furnace equipment.
- Confinement Vessel Disposition project personnel finalized cleanout of the first sphere and completed most of the steps for a second sphere. The project's goal of completing three spheres was impeded by issues associated with the safety basis and transuranic waste storage.
- NNSA and EM raised questions on the performance of pipe overpack containers in fire scenarios at Area G resulting in complex-wide actions and experimental testing to improve the technical basis for crediting these containers in a safety basis.
- Staffing levels for the Nuclear Criticality Safety and Safety Basis divisions continue to hamper resolution of longstanding safety issues across the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 1, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 1, 2016

The Los Alamos National Laboratory was closed this week. This report is filed for continuity purposes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 8, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 8, 2016

Area G–Nitrate Salts: On Wednesday and Thursday, Area G management hosted a peer review team consisting of personnel from other National Laboratories to assess the state of knowledge and the path forward for the render-safe treatment of the inappropriately remediated nitrate salt (RNS) wastes. Personnel from DOE Environmental Management also observed the review, which covered the development of RNS surrogates, results of full drum surrogate testing, the proposed treatment process, environmental regulatory compliance issues, and safety basis strategy development.

Chemistry and Metallurgy Research (CMR) Building–Safety Basis: On December 21, 2015, LANL management transmitted a safety basis temporary modification to the NNSA Field Office for approval. The temporary modification supports a project to receive and store a package containing americium-241. LANL eventually intends to process the material to recover the isotope for beneficial use. The americium-241 dates back to 1979 and may include aqueous solutions and ion exchange resin; conditions that could result in the generation of hydrogen gas and other reactive species. The temporary modification proposes crediting an 85-gallon drum overpack as a new control for this activity, along with controls from the existing safety basis including the fire suppression system, combustible loading limits, material-at-risk limits for the loading dock, the emergency preparedness program, and the radiation protection program.

Plutonium Facility–Seismic Safety: On December 23, 2015, LANL submitted to the NNSA Field Office for review the fiscal year 2016 seismic project execution strategy for the Plutonium Facility. The updated strategy includes the estimated cost ranges, general scope, high level schedule, and potential funding sources for facility upgrades and maintenance activities. LANL identifies the following work scope for fiscal year 2016:

- Improve the shear capacity of the interior roof girders
- Improve anchorage of safety significant ductwork
- Complete modification of the sewer vent in the Bleed-off system to prevent the formation of ammonium nitrate on the ventilation system HEPA filters
- Seismic qualification for numerous replacement and spare components for safety systems
- Manage seismic expert panel activities and support NNSA alternative analysis as requested
- Conduct an engineering study to determine the work scope necessary to qualify the active confinement ventilation system to Performance Category 3 for seismic events

Plutonium Facility–Restart Activities: On December 22, 2015, the NNSA Field Office Manager approved LANL's corrective action plan and causal analysis for the Pit Flowsheet federal readiness assessment. The manager's approval letter noted that LANL's previously submitted objective evidence resolving a pre-start finding and manageable open item are verified closed and authorized restart of Pit Flowsheet operations. On December 29, 2015, the NNSA Field Office Manager approved LANL's Plan of Action for the contractor readiness assessment (CRA) for Muffle Furnace, Plutonium Casting, and Advanced Recovery and Integrated Extraction System operations. The CRA is currently scheduled to commence on February 1, 2016.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 15, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 15, 2016

DNFSB Staff Activity: P.J. Foster, M.R. Bradisse, and M.T. Wright walked-down the Transuranic Waste Facility project construction site and conducted a review of the revised 90 percent documented safety analysis. M.W. Dunlevy and D.J. Brown supported the site representative office. On Monday, B.K. Caleca, D.K. Andersen, and T.J. Dwyer held a teleconference with personnel from the NNSA Field Office, NNSA Headquarters, and LANL to discuss the status of various seismic safety analyses and improvements planned for the Plutonium Facility.

Chemistry and Metallurgy Research (CMR) Building–Safety Basis: On January 13, 2016, the NNSA Field Office approved without conditions the safety basis temporary modification supporting the receipt and storage of a package containing americium-241 (see 1/8/2016 weekly). Separately, CMR personnel completed their implementation verification review of safety basis changes needed to support the Confinement Vessel Disposition project and expect to commence cleanout activities of the third sphere next week.

Plutonium Facility–Seismic Safety: This week, NNSA Headquarters approved the charter for a joint working group to develop a request for proposal for conducting a dynamic, non-linear seismic evaluation of the Plutonium Facility (see 8/14/2015 weekly). NNSA elected to pursue a non-linear analysis instead of completing the second phase of NNSA's alternate seismic analysis consistent with the recommendations of the Seismic Expert Panel documented in a report dated March 31, 2015. The charter establishes a working group consisting of three NNSA personnel and two LANL engineers. According to the charter's notional timeline, the group expects to develop an initial draft of the request for proposal by June 2016 and submit a final proposal to NNSA by September 2016. The timeframe for executing structural modifications identified by the non-linear analysis will depend on durations associated with NNSA's process to procure the request for proposal, selection of modeling approaches and parameters, completion of the computationally intensive modeling, review of the results, and the design work and funding for any necessary modifications.

Weapons Engineering Tritium Facility (WETF)–Operations: On Wednesday, WETF management declared a technical safety requirement (TSR) violation when they discovered that they could not execute a limiting condition of operation (LCO) action statement. At a critique of the event, WETF personnel identified equipment failures and inappropriate operator implementation of the TSRs as the causes of the violation. In December, while conducting a surveillance on the oxygen monitoring system (OMS), operators damaged an OMS housing wire in the tritium waste treatment system (TWTS) sample loop number two. Operators placed sample loop number one in service to maintain operability of the TWTS. Subsequently, operators discovered the pressure in sample loop number one was below specifications and placed it out of service and also placed the low pressure receiver (LPR) for the TWTS in WARM STANDBY MODE as required by the TSRs. Following two weeks without an operable OMS, operators entered the LCO action statement to perform a daily nitrogen purge of the LPR as required by the TSRs. On Tuesday, operators opened a work package to replace the damaged OMS housing. The following morning, operators recognized that the lockout for the work package prevented the ability to purge the LPR, but incorrectly determined that the LCO action statement did not apply while maintenance was being performed. Following questioning by the NNSA Facility Representative, facility management agreed that the action statement should have been completed and declared the TSR violation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 29, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 29, 2016

The Site Representatives were at DNFSB Headquarters all week to support an in-depth review of the state of nuclear safety at LANL.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 12, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 12, 2016

DNFSB Staff Activity: On Tuesday, a staff team conducted a teleconference with personnel from the NNSA Field Office and LANL to discuss the safety basis supporting the receipt and storage of americium-241 materials into the Chemistry and Metallurgy Research building.

Plutonium Facility–Safety Basis: On Wednesday, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis associated with the use of cast iron and malleable iron fittings in the fire suppression system. The issue is that the seismic modeling used to qualify the system assumes pipe connections use ductile steel materials rather than cast iron, which may be installed in the facility. As a result, the basis for the system’s seismic qualification is in question. The Board’s staff identified this issue during a review in December 2015 after first raising questions about this assumption in 2012.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Facility Upgrades: On Wednesday, LANL submitted to the NNSA Field Office for review and approval a revision to the WCRRF Technical Safety Requirements. The LANL submittal identified select design features that will need to be placed out of service in order to accommodate facility repairs and modifications necessary to resume waste processing activities. These repairs and upgrades include:

- Maintaining the vehicle barrier cabling system and resetting the barriers where gravel has been pushed under the barriers
- Repairing damage to the ceiling and roof structure caused by rainwater damage (see 7/17/15 weekly)
- Replacing roll-up access doors that provide a containment function and have become difficult to operate
- Making multiple repairs and upgrades to the Waste Characterization Glovebox used for waste remediation and repackaging activities

LANL’s request for revision notes that the vehicle access system gates need to be temporarily removed to allow access for trucked-in equipment and other materials necessary for the upgrades and repairs. LANL’s submittal also indicates that the facility is currently in COLD STANDBY mode and will remain so for the duration of these activities.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: Last Wednesday, LANL submitted to the NNSA Field Office for review and approval a request to remove safety basis classification of the WETF Halon fire suppression system as safety significant. The currently implemented safety basis credits the Halon system with preventing an operations center fire from propagating to adjacent facility process areas. LANL’s request notes that the existing wet pipe sprinkler system in the operations center is adequate to perform this function alone. Last Friday, LANL submitted to the NNSA Field Office for review and approval an extension to the Evaluation of the Safety of the Situation (ESS) for the potential for increased probability of Oxygen Monitoring System failure (see 8/28/15 weekly). LANL’s request notes that the extension to the ESS will need to be in effect until the 2015 annual update to the safety basis has been approved and implemented.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 19, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 19, 2016

DNFSB Activity: Board Chair Connery and Board Member Hamilton, accompanied by staff members M.W. Dunlevy and J.A. Pasko visited the lab for familiarization. The visit included walk-downs of the primary defense nuclear facilities and introductions with key federal and laboratory management.

DNFSB Staff Activity: On Tuesday, staff members T.J. Dwyer and A.H. Hadjian conducted a teleconference with personnel from the NNSA and LANL to discuss the status and planned path forward for conducting a dynamic, non-linear seismic evaluation of the Plutonium Facility (see 1/15/2016 weekly) as well as ongoing facility upgrades.

Plutonium Facility–Safety Basis: Last Friday, LANL submitted to the NNSA Field Office for review and approval, a request for either closure or extension of the safety basis addendum for exceedance of seismic performance goals (see 2/1/2013 weekly). The current approved and implemented addendum is scheduled to expire on March 1, 2016. LANL notes in the request that all actions directed by NNSA in the Safety Evaluation Report approving the addendum have been completed and documented in other correspondence with the exception of planned Plutonium Facility structural upgrades. LANL submits that once these upgrades are made the Plutonium Facility will meet its required seismic performance goals. LANL's request cites a report developed by the Plutonium Facility Seismic Expert Panel (see 8/14/15 weekly) that made similar conclusions. These upgrades are currently scheduled to be completed by the end of fiscal year 2017.

Plutonium Facility–Restart Activities: Last Friday, the Contractor Readiness Assessment (CRA) team completed their review of the Muffle Furnace, Plutonium Casting, and Advanced Recovery and Integrated Extraction System operations. The CRA team identified three pre-start findings that included (1) inconsistent implementation of criticality safety requirements and steps that could not be performed as written in the procedures used, (2) failure of a criticality safety evaluation document to identify potential upset conditions, and (3) inconsistent and incomplete implementation of site requirements for procedure development. The team also identified two post-start findings relating to conduct of operations and technical safety requirement implementation. Overall the team concluded that subject to satisfactory resolution of the pre-start findings, LANL has demonstrated its readiness for equipment, procedures, and personnel to support these operations.

NNSA Field Office–Staffing Plan: On Thursday, the NNSA Field Office facility representative team supervisor submitted the fiscal year 2016 facility representative staffing plan to the Field Office Manager for review and approval. The plan identified the need for 14 full time facility representatives. This number is down from the identified need of 16 facility representatives in the fiscal year 2015 plan due to the transfer of oversight of waste management operations to the newly established EM Field Office. Currently the NNSA Field Office has six qualified facility representatives assigned in the field with two additional facility representatives in training.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 26, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 26, 2016

Chemistry and Metallurgy Research Building–Confinement Vessel Disposition (CVD)

Project: CVD project personnel recommenced cleanout operations following the implementation of necessary safety basis changes identified during previous operations and the removal of material-at-risk generated from the cleanout of the first two vessels. Ten vessels are slated for disposition. This week, CVD operators completed final assay of the second completed vessel. Additionally, operators performed the initial receipt assay and moved the third vessel into the enclosure in preparation for its cleanout. CVD personnel are on track to complete disposition of all ten vessels before the end of calendar year 2019.

Area G–Remediated Nitrate Salts: This week, the senior integrated project team hosted an Engineering Options Treatment Science Advisory Panel. The panel’s chartered function is to provide a diversity of thought with respect to the technical and operational aspects of the treatment plans for the inappropriately remediated nitrate salt wastes. In particular, this included an evaluation of potential facilities and portable capabilities to be used for the treatment process. The panel’s membership consisted of experts from Vanderbilt University, Lawrence Livermore National Laboratory, Idaho National Laboratory, Savannah River National Laboratory, Carlsbad Field Office, and several other parent contractor companies. They expect to deliver their report within 30 days.

Transuranic Waste Management: Earlier this month, LANL management transmitted an *Enduring Mission Waste Management Plan* to the NNSA Field Office, as previously requested (see 9/18/16 weekly). The plan provides LANL’s strategy to safely, compliantly, and efficiently manage all forms of wastes at the laboratory. Notable points in the plan related to transuranic (TRU) waste include the following:

- The volume of the current TRU waste inventory at Area G is equivalent to approximately 17,900 55-gallon drums. Ultimate disposition of this waste to the Waste Isolation Pilot Plant (WIPP) will require 270 and 730 shipments for the aboveground and the belowground inventories, respectively.
- LANL forecasts the generation of approximately 6,950 drum equivalents of new waste during fiscal years 2015 through 2021, resulting in 315 shipments to WIPP. For this newly generated waste, the Materials Recycle and Recovery program generates the most waste by volume and the plutonium-238 program generates the most by radioactivity. Both of these programs largely support risk reduction activities within the Plutonium Facility.
- The resumption date for shipments from LANL to WIPP is unknown, as well as the number of shipments that LANL will be allocated. Further, the schedules for completion of seismic upgrades and safety basis revisions for the RANT Shipping Facility are currently unknown.
- Other key unknowns for planning purposes include the future rates for drum remediation and certification activities and the date on which retrieval and processing of belowground waste will commence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 4, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 4, 2016

DNFSB Staff Activity: On Thursday, staff members C. Berg, D.J. Brown, R.T. Davis, M.W. Dunlevy, R.C. Eul, N.M. George, and J.A. Pasko conducted a teleconference with personnel from each of the Los Alamos Field Offices and LANL. The discussion covered the path forward and associated technical bases for planned near-term actions associated with LANL's strategy to improve the safety posture of the inappropriately remediated nitrate salt (RNS) wastes through enhancing vent capacity and other measures (see 2/5/16 weekly).

Area G–Emergency Management: On Thursday, Area G personnel conducted their second drill as part of their nascent program for emergency and operational drills. The tabletop style drill included a crew of waste operators and radiological control technicians that will be involved with the near-term installation of additional vent capacity for the RNS wastes. The scenarios covered responses to a radiological continuous air monitor alarm, as well as a medical emergency. The drill coordinators are using experience from successful efforts at the Plutonium Facility to develop the program at Area G. They have established two standing drill times each week and plan to increase the complexity and reduce the artificiality associated with upcoming drills. For example, next week's drills will require the use of full personal protective equipment, including powered air purifying respirators.

Emergency Management: LANL training personnel are in the process of completing evolutions of the practical component for Emergency Radiological Responder Training that covers firefighters from the Los Alamos County Fire Department. The practical consists of three modules: (1) contaminated patient handling, (2) doffing protective equipment simulated to be potentially contaminated, and (3) use of one type of radiation monitoring equipment. The training is thorough and conducted in a stop-action style intended for immediate feedback for both participating and observing firefighters. Use of simulation includes an approximately 60 pound mannequin and intentional lack of respiratory protection for the patient handling module to facilitate verbalization of actions. The Site Representatives note that LANL and NNSA Field Office personnel frequently point to this practical evaluation as the basis for simulating performance of these response steps during evaluated exercises.

Plutonium Facility–Safety Basis: On Tuesday, the NNSA Field Office Manager approved LANL's request for closure of the safety basis addendum for exceedance of seismic performance goals (see 2/19/16 weekly). The approval letter suggests that the Plutonium Facility meets established seismic performance goals and cites this as the basis for closure approval. The letter also notes that ongoing roof girder upgrades will further improve facility seismic performance.

Plutonium Facility–Nuclear Criticality Safety: Last Friday, LANL transmitted to the NNSA Field Office a Nuclear Criticality Safety Program Improvement Plan. This plan was submitted as required by the NNSA Field Office in an approval letter extending the Evaluation of the Safety of the Situation/Justification for Continued Operations regarding the potential for criticality due to firewater flooding (see 6/6/2014 weekly). The plan identifies intended actions to rebuild a robust Nuclear Criticality Safety Program that enables continued safe and efficient operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 11, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 11, 2016

DNFSB Activity: On Monday and Tuesday, Board Member Sullivan visited LANL for walk-downs of the Weapons Engineering Tritium Facility, Plutonium Facility, Chemistry and Metallurgy Research building, and Area G. He also attempted to observe an emergency drill at Area G; however, Emergency Management personnel cancelled the drill after Fire Protection Division personnel needed to support the planned scenario did not arrive because they had not been scheduled to participate.

Area G–Emergency Management: On Wednesday, Area G personnel conducted their first learning team event. Area G management called for the learning event after a slower than desired response to a transuranic waste drum of questionable integrity (i.e., potential breached drum) that occurred last week. Participants in the learning team discussed several items of interest. For example, an abnormal operating procedure guides the operations center response to this condition; however, written guidance for other key responders, such as industrial hygiene and radiological control technicians (RCT), is limited and largely reliant on training and on-the-job experience. A large number of the RCTs are new to Area G, exacerbating this problem. The Site Representatives also note that specific RCT practices vary extensively across the laboratory. For example, participants discussed that after the RCT detected radioactive contamination on the operator who had first observed the questionable drum, both individuals walked to another dome to utilize a different contamination monitor without attempting to fix or otherwise isolate the suspect contamination. While the contamination ultimately was determined to be radon, practices at other LANL facilities would necessitate some type of additional control prior to moving an individual with suspect contamination. Notably, Area G personnel identified two additional drums of questionable integrity this week. Response to these events was improved, in part resulting from actions taken to ensure industrial hygiene equipment is now checked daily for adequate electrical charge and given the necessary single point calibration check.

Area G–Safety Basis: Last week, LANL submitted to the NNSA Field Office a request for extension of the Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis (PISA) declared for a single drum fuel pool fire (see 3/13/15 weekly). On Wednesday, the NNSA Field Office approved a LANL request for extension of revision 3 of the ESS for the transuranic waste drums containing inappropriately remediated nitrate salts (RNS) PISA (see 3/27/15 weekly). Both of these ESSs also serve as Justification for Continued Operations and were set to exceed their twelve-month approval deadline.

On Monday, LANL submitted to the NNSA Field Office for review and approval revision 5 of the ESS for the transuranic waste drums containing RNS. While LANL previously submitted revision 4, the NNSA Field Office neither approved nor rejected it. Revision 5 allows for installation of increased venting capacity and pressure relief directly on the drums. The ESS will be implemented in two phases. The first phase will allow lid removal from the standard waste boxes currently housing the RNS drums. The second phase will allow installation of the additional venting and pressure relief devices. LANL is proposing this action because test data has demonstrated that preventing the RNS drums from over-pressurization significantly reduces the chance for a self-initiated thermal runaway reaction.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 18, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 18, 2016

Area G–Safety Basis: On Thursday, the NNSA Field Office recommended to the NNSA Cognizant Secretarial Officer partial approval of revision 5 of the Evaluation of the Safety of the Situation (ESS) for the inappropriately remediated nitrate salt (RNS) wastes. The approval for this revision is phased with this action authorizing LANL personnel to remove the lids from the standard waste boxes. The second phase will authorize installation of an additional vent and pressure relief device. In accordance with revision 5, controls for lid removal include: gas sampling; visual inspections; container temperature monitoring; prohibition on container movement; and Permacon temperature control. The installation step includes additional controls for non-sparking and non-conductive tooling. The post-installation control set includes: the new venting and pressure relief manifold; the Permacon fire suppression, ventilation, and cooling systems; response to continuous air monitors; visual inspection; prohibition on container movement; container spacing; and implementation of Conduct of Maintenance and Engineering. The ESS notes that revision 6 will include controls for wildland fire induced accidents and will be submitted within 30 days of approval of revision 5. Notably, this recommendation by the NNSA Field Office represents the first federal approval of a safety basis covering the RNS wastes following the new information that emerged in the March 2015 Accident Investigation Report indicating a substantially higher potential release hazard associated with these wastes.

Area G–Emergency Management: This week, Area G personnel conducted two discussion-based (Type I) drills. On Thursday, Area G management approved standing orders for operations center responses to continuous air monitor alarms and personnel contamination events. Management directed the development of the standing orders in response to an observation from a January drill indicating that written instructions did not exist for all conditions that require a response by operations center staff. In parallel, management has directed a review of all abnormal, alarm, and emergency procedures, including procedures that were retired.

Plutonium Facility–Criticality Safety: On Monday, LANL submitted to the NNSA Field Office a corrective action plan for the assessment of implementation of the Plutonium Facility criticality safety program (see 12/4/15 weekly). An independent federal team performed this assessment in two phases primarily in response to a recommendation by the Balance of Machining federal readiness assessment team following their review (see 7/3/15 weekly). The team recommended this assessment be completed prior to commencing the Actinide Recovery and Integrated Extraction System (ARIES), Furnace, and Casting contractor readiness assessment completed in February of this year. LANL identified five findings from the assessment that need to be addressed prior to commencing the ARIES, Furnace, and Casting federal readiness assessment scheduled for April of this year. LANL is tracking these findings in its Performance Feedback and Improvement Tracking System and the Plutonium Facility Nuclear Criticality Safety Board is managing closure of these corrective actions to support the upcoming federal readiness assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 25, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 25, 2016

DNFSB Activity: On Tuesday, the Board conducted a public hearing regarding the hazards posed to the public and workers by the management of transuranic waste at Area G. On Wednesday, Board Member Santos, accompanied by staff members M.W. Dunlevy and N.F. Khalil, walked-down the Plutonium Facility and the Dome 375 Permacon at Area G.

Area G–Safety Basis: On Tuesday, the NNSA and EM Field Offices transmitted approval to LANL management of phase 1 of revision 5 for the Evaluation of the Safety of the Situation (ESS) concerning the inappropriately remediated nitrate salts (RNS) wastes (see 3/18/16 weekly). The approval included four actions directed by NNSA Headquarters: (1) submission within 1 week of a resource-loaded schedule for installation of the pressure relief devices; (2) completion of a progress briefing by April 15th on wildland fire mitigation activities; (3) commencing April 18th, the NNSA Field Office is to conduct weekly briefings on the status of phase 2 activities until they are completed; and (4) concurrent with submission of revision 6 of the ESS, the NNSA Field Office is to submit a strategy for resolving all of the outstanding Potential Inadequacies of the Safety Analysis for Area G. On Friday, LANL personnel completed their Implementation Verification Review of the phase 1 controls and plan to commence a Management Assessment next week to confirm readiness to remove the lids from the standard waste boxes containing the RNS wastes.

Area G–Emergency Management: In the past two weeks, Area G and LANL wildland fire management personnel have taken dramatic actions to improve the protection of the Dome 375 Permacon from potential wildland fire insults. These actions include: (1) significantly expanding the zone of reduced shrubbery on the south side of the Permacon; (2) improving an existing fire break; (3) developing a new fire break; and (4) developing a new fire response plan that utilizes the fire breaks and an area for retardant application to minimize the potential for the postulated worst case fire impact to the Permacon. Area G personnel are also in the process of procuring specialized reflective fire blankets for additional protection of the RNS wastes. These actions come as conditions in northern New Mexico become increasingly favorable for wildland fire. In fact, on Tuesday a wind-driven brush fire burned about 30 acres near Pojoaque, a town approximately 15 miles northeast of Area G.

On Monday, LANL Emergency Management personnel issued an addendum to the Emergency Planning Hazards Analysis for the RNS wastes. The addendum incorporates specific information on the hazard posed by the RNS waste including use of the respirable release fraction identified for the RNS wastes by the DOE-EM Carlsbad Field Office (see 11/20/15 weekly). Issuance of this addendum addresses a significant issue identified in the Board’s letter dated January 7, 2016.

Area G–Engineering: Earlier this month, Area G personnel completed commissioning of the new supplemental chiller for the Dome 375 Permacon (see 7/10/15 weekly). They expect to issue operating procedures in April 2016.

Plutonium Infrastructure Strategy: On Thursday, LANL personnel completed placement of a second foundation for the new uninterruptible power supply (UPS) building. A difficult cold joint encountered during placement of the original foundation required complete rework. The new UPS building will be a seismic performance category 3 structure that could be used in support of the incremental upgrades necessary for an eventual performance category 3 active confinement system for the Plutonium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 1, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 1, 2016

DNFSB Staff Activity: C.T. Beaty observed the annual emergency exercise at the Plutonium Facility, observed an emergency drill at Area G, and conducted discussions with operators and emergency management personnel. She conducted these activities in preparation for an upcoming review of emergency preparedness and response.

Area G–Operations: On Monday, Area G personnel completed their corrective actions for a finding identified during the previous week’s Implementation Verification Review of the phase 1 controls for revision 5 of the Evaluation of the Safety of the Situation (ESS) concerning the inappropriately remediated nitrate salt (RNS) wastes (see 3/25/16 weekly). The finding concerned the level of knowledge of the operations center personnel regarding the procedures and processes in place that implemented the ESS. On Wednesday, following completion of the corrective actions, Area G management commenced a Management Assessment of the readiness of Area G personnel to perform phase 1 operations. In this phase, operators will remove the lids from the standard waste boxes housing the RNS waste. A Management Assessment is a tool for LANL managers to systematically observe work and evaluate performance of management systems, but is not directly tied to the LANL readiness program. The Management Assessment included interviews with key personnel, a demonstration of the operational evolution, and a discussion-type emergency drill.

Area G–RNS Wastes: On Tuesday, LANL management issued a resource-loaded schedule for completing phase 2 of ESS revision 5, pertaining to the installation of pressure relief devices and higher capacity venting for the RNS wastes contained in 48 waste drums. The schedule indicates completion of this effort by May 13, 2016. This schedule assumes that they receive NNSA and EM approval of phase 2 by April 11, 2016. In addition to the pressure relief devices, phase 2 will result in several additional controls including a formal Specific Administrative Control for response to a continuous air monitor and implementation of elements of Conduct of Engineering and Maintenance for the ventilation and fire suppression systems. LANL management intends to submit the plan for the balance of the RNS waste contained in 12 pipe overpack containers as part of ESS revision 6, which is due by April 22, 2016.

On Wednesday, most of Area G, including the Dome 375 Permacon that houses the RNS wastes, experienced a planned electrical power outage lasting about 5 hours. The outage occurred to replace a power pole that experienced wind damage on Tuesday. Notably, provisions do not currently exist for backup electrical power to many of the systems contributing to safety at the Permacon, such as the ventilation system, the air coolers, and the supplemental chiller. Area G management continues to explore options to address this situation.

Plutonium Facility–Emergency Management: On Wednesday, Plutonium Facility personnel conducted their annual Emergency Planning Hazards Analysis exercise. This year’s scenario involved a postulated release of chlorine gas on the exterior of the facility, which injured two workers and drove shelter-in-place actions for a large area. At the critique, evaluators preliminarily identified about 18 significant issues, many largely associated with shelter-in-place related difficulties.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 8, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 8, 2016

DNFSB Staff Activity: M. R. Bradisse and D. L. Burnfield observed the federal readiness assessment for the Furnace, Casting, and Advanced Recovery and Integrated Extraction System activities in the Plutonium Facility. The Site Representatives attended briefings at DNFSB Headquarters. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 15, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 15, 2016

DNFSB Staff Activity: C.T. Beaty, J.E. Deplitch, A.M. Hutain, and C.J. March were on site to conduct a review of the LANL emergency management program. Their review included discussions with LANL, NNSA Field Office, and Los Alamos County Fire Department personnel, observation of an exercise at the Emergency Operations Center, and walk-downs of the Plutonium Facility, Area G, and the Weapons Engineering Tritium Facility. T.L. Hunt conducted a supplemental review of the operational drill programs and abnormal response procedures at the same three facilities.

Area G—Inappropriately Remediated Nitrate Salts (RNS): Last week, following successful completion of a Management Assessment (see 4/1/2016 weekly), Area G operations personnel commenced activities to remove the lids from the standard waste boxes containing the RNS waste. Operators are performing this activity as part of the implementation of phase 1 of revision 5 of the Evaluation of the Safety of the Situation (ESS) for safe storage of the RNS waste (see 3/25/2016 weekly). To date, operators have removed 12 of the 46 lids planned for this phase. Removal actions have proceeded well—no contamination or degraded conditions have been encountered and unexpectedly no bolts have required drilling for removal. Area G personnel continue to prepare for the phase 2 pressure relief device installation effort and hope to commence the associated Management Self-Assessment late next week.

Plutonium Facility—Safety Basis: Last Thursday, the NNSA Field Office approved revision 1.1 of the facility's 2015 safety basis. The revision adds scope for a new activity, clarifies the ability to create confinement penetrations within the facility, closes two previous conditions of approval, and incorporates three outstanding ESSs associated with criticality safety, nonconforming heat-source plutonium clads, and the condition of the stand for the Isotope Fuels Impact Tester. Additionally, the revision deleted or modified previously identified vulnerabilities for some existing safety systems including the ventilation system, uninterruptable power supply, and the diesel fire pumps.

Plutonium Facility—Restart Activities: On Tuesday, the Federal Readiness Assessment (FRA) team delivered the final report of their assessment of Plutonium Facility readiness to restart Furnace, Casting, and Advanced Recovery and Integrated Extraction System (ARIES) operations. The FRA team identified two pre-start findings relating to criticality safety controls that included: 1) some operations did not have documentation demonstrating certain dimensional requirements identified in a criticality safety evaluation were being met, and 2) an approved item list in one procedure contained items that did not meet current criticality safety requirements. The FRA team also identified two post-start findings relating to emergency/operational drill programs and criticality safety. Of note, the assessment report stated that in general, the FRA team was impressed with the actions taken by Plutonium Facility management, staff, and operators to demonstrate readiness. The team recommended that upon correction of the two pre-start findings and development of a corrective action plan for the post-start findings Plutonium Facility personnel be authorized to restart these operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 22, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 22, 2016

Area G–Inappropriately Remediated Nitrate Salts (RNS): This week, Area G operators continued removal of the lids from the standard waste boxes containing the RNS waste as part of implementing phase 1 of revision 5 of the Evaluation of the Safety of the Situation (ESS). To-date, they have removed 35 of the 46 lids planned for this phase. Removal actions continue to proceed well—no contamination or degraded conditions have been encountered and relatively few bolts (10 of 1470) have required drilling.

Area G personnel continue to prepare for the phase 2 pressure relief device installation effort. This week's preparations included procedure refinement, which they conducted in accordance with the best practice of involving the work crews, persons in charge, industrial hygiene, radiation safety, and the Deputy Associate Director. Based on the progress toward approval of the phase 2 safety basis, they estimate starting the associated Management Self-Assessment next week.

Area G–Safety Basis: Several key safety basis transactions occurred on Thursday.

- The NNSA Field Office approved phase 2 of revision 5 of the ESS for the RNS waste and forwarded it on to the NNSA Cognizant Secretarial Officer for approval, given the potential for mitigated consequences to exceed the DOE Evaluation Guideline. Noting the need for additional review, the Field Office did not act on the revised aircraft crash analysis for the RNS included in this ESS.
- LANL management transmitted to the NNSA Field Office for approval revision 6 of the ESS for the RNS. Revision 6 provides the results of a postulated worst-case wildland fire model coupled to a heat transfer model in order to determine peak temperature insults to the RNS waste. The peak temperature was determined to be 32 °C, which is below the 40 °C threshold of concern established from LANL's research. Notwithstanding this result, LANL proposed a formal wildland fire management control, including the use of fire retardant, fuel mitigation, and fire blankets. Revision 6 also proposes moving forward with the installation of the pressure relief devices for the RNS waste contained within the pipe overpack containers.
- LANL management transmitted the project execution plan for the safety basis changes necessary for the final treatment of the RNS waste. The plan outlines 14 new work activities to be included among the safety basis documents for Area G, onsite transportation, and the Waste Characterization, Reduction, and Repackaging facility. The planned submittal of the first two documents is June 16, 2016, and the latter document is July, 20, 2016.
- LANL management committed to submit by May 13, 2016, a new ESS to cover all of the other open Potential Inadequacies of the Safety Analysis (PISA) at Area G with the exception of the pipe overpack, which is contingent on ongoing testing at Sandia National Laboratories.

Plutonium Facility–Safety Basis: Last Friday, LANL management submitted to the NNSA Field Office for review and approval an ESS to address the PISA associated with the use of cast iron and malleable iron fittings in the fire suppression system (see 2/12/16 weekly). The ESS indicates the fire suppression system may not meet its required performance category 2 seismic criteria and additional testing is required. LANL has implemented additional material-at-risk limits as a compensatory measure until the results of the analysis are complete.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 29, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 29, 2016

Area G—Inappropriately Remediated Nitrate Salts (RNS): This week, Area G operators completed removal of the lids from the standard waste boxes containing the RNS waste as part of implementing phase 1 of revision 5 of the Evaluation of the Safety of the Situation (ESS). Of the 46 boxes covered in phase 1, 39 have had their lids removed. The seven remaining boxes will undergo an integrated process for lid removal and pressure relief device installation as part of phase 2.

On Tuesday, LANL management received approval from NNSA and DOE-EM on phase 2 of revision 5 of the ESS. As part of the approval, the NNSA Cognizant Secretarial Officer noted that the installation of the pressure relief devices will significantly reduce the likelihood of a self-initiated thermal runaway; however, he concluded that the risks associated with the RNS wastes will not be completely eliminated due to the absence of additional conclusive statements from LANL. As a result, he emphasized the importance of all the planned controls and compensatory measures. Additionally, he noted the March loss of electrical power event (see 4/1/16 weekly) and requested weekly status reports on LANL's ongoing effort to ensure the availability of backup power. Given Tuesday's approval, Area G personnel will commence their Management Self-Assessment for phase 2 on Monday. Full implementation of the balance of the controls will follow completion of phase 2.

Safety Basis: On Wednesday, LANL management declared a Potential Inadequacy of the Safety Analysis (PISA) at Area G and the Plutonium Facility regarding certain sealed sources used for a piece of transuranic waste assay equipment known as the High Efficiency Neutron Counter (HENC). These sources, which the Carlsbad Field Office has specified for use throughout the complex, consist of highly dispersible contents—actinide oxides mixed in a diatomaceous earth matrix—welded into steel containers that are fire rated to survive a 400 °C insult. Preliminary results of fire modeling for one of the HENC units currently at Area G and planned for use at the new Transuranic Waste Facility indicates that fire temperatures could exceed 1000 °C due to significant quantities of plywood and plastic used in its construction. LANL analysts' initial review concluded that at this temperature the sources could be expected to undergo a pressurized release as opposed to the ordinary thermal insult currently reflected in the safety analysis. This change results in an increase in the amount of radioactive material released by a factor of nearly 1200. Management at both facilities conducted fact-findings and initiated operational restrictions that mainly involve storing the sources in fire-rated safes, ensuring operations with the sources are continuously attended, and excluding nearby use of fuels. Concerns with the respirable release fraction associated with these sources first originated in a Board letter dated June 11, 2012.

Plutonium Facility—Nuclear Materials Management: Plutonium Facility personnel recently conducted a bimonthly inventory as part of their nuclear materials control and accountability (MC&A) program. During these inventories, personnel perform a visual inspection on nearly all of the containers of nuclear material in the facility outside of the vault. The inventory is performed twice—first by the operations group as a pre-inventory check and then a second time by MC&A personnel. The Site Representatives note that these inventories represent an ideal opportunity for personnel to identify and record the container type for each item. Currently a large fraction of the container types are unspecified in the nuclear material management database, as noted in DNFSB Tech-39.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 6, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 6, 2016

Area G–Inappropriately Remediated Nitrate Salts (RNS): This week, Area G personnel conducted their Management Self-Assessment (MSA) for pressure relief device installation as part of implementation of phase 2 of revision 5 of the Evaluation of the Safety of the Situation (ESS). The MSA team observed work evolutions covering assembly of the pressure relief device and its installation on a simulated RNS waste drum, reviewed documents, and conducted interviews. The team also observed an evaluated emergency drill (Type III) that involved work crew and operations center response to the discovery of a pressurized bag in a simulated RNS drum during pressure relief device installation. The team expects to brief their results on Monday and installation activities should commence soon thereafter following closure of any pre-start issues. While this represents important progress on improving the safe storage of the RNS waste, much remains to be done to complete implementation of revision 5 of the ESS. Additionally, the NNSA Field Office has yet to review and approve revision 6 of the ESS (which covers the wildland fire threat), and the EM Field Office has yet to produce a project plan for the RNS final treatment effort.

Area G–Operations: On Wednesday, Area G personnel responded to two abnormal events that occurred during the planned window for the evaluated drill. The events were the discovery of two drums labeled as radioactive and missing their bungs and a third drum labeled as empty that spilled unknown solid materials. In both cases, responders found no industrial hygiene or radiological issues. The operations center staff responded well and was likely aided by their pre-drill posture. As such, the operations center was manned above typical levels and had informed the workforce to suspend normal calls and in-person queries. Area G management expects to conduct a fact-finding next week on these events.

Plutonium Facility–Restart Activity: Plutonium Facility personnel commenced their MSA for pyrochemistry operations, which includes metal chlorination, multiple-cycle/direct oxide reduction, metal coalescence, chloride melt preparation, salt distillation, and molten salt extraction. The current schedule anticipates the commencement of the contractor readiness assessment in July, which is currently paced by completion of revised criticality safety evaluations expected in June. LANL management recently briefed NNSA Headquarters on a proposal to remove the aqueous processing activities from the formal restart project. If this change is approved, the project hopes to be complete by the end of the fiscal year. Following completion, management has indicated the intent to reprioritize criticality safety and conduct of operations resources across the balance of the facility that did not undergo formal readiness.

The NNSA Field Office chartered a Line Management Review Team to shadow this pyrochemistry MSA and follow-on Contractor Readiness Assessment. The team is comprised of NNSA headquarters and Field Office personnel and is tasked with evaluating the robustness of LANL's readiness process. The team has been directed to develop a summary report documenting their conclusions and to make a recommendation to the Startup Authorization Authority on LANL's readiness to proceed with the Federal Readiness Assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 13, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 13, 2016

DNFSB Staff Activity: R.V. Kazban and R.L Jackson observed a multi-day external independent review on phase 2 of the equipment installation project for the Radiological Laboratory Utility Office Building. They also walked down portions of the Chemistry and Metallurgy Research Building and the Plutonium Facility. On Thursday, B. K. Caleca, T.J. Dwyer, and A.H. Hadjian observed a meeting of the Seismic Expert Panel to discuss the path forward for additional analysis and testing in support of the Plutonium Facility.

Area G–Inappropriately Remediated Nitrate Salts (RNS): This week, the Management Self-Assessment (MSA) team briefed the results of their review on the readiness to conduct phase 2 of revision 5 of the Evaluation of the Safety of the Situation for the RNS waste. The team identified six pre-start and six post-start issues. The pre-start issues involved conduct of engineering concerns regarding the design and testing for the pressure relief devices, disposal of oily rags, procedure issues, and several concerns with radiological protection and industrial hygiene practices. Notable post-start issues included inaccurate and incomplete information in emergency response documents (run sheets and pre-incident plans) and conduct of maintenance concerns regarding the fire suppression system. Area G management is actively working closure of corrective actions and expects to commence pressure relief device assembly and installation activities next week.

Safety Basis: LANL safety basis analysts determined that the Potential Inadequacy of the Safety Analyses declared at Area G and the Plutonium Facility regarding the potential for pressurized releases from certain sealed sources represented a positive unreviewed safety question (see 4/29/16 weekly).

Weapons Engineering Tritium Facility (WETF)–Safety Basis: On Tuesday, the NNSA Field Office manager signed the Safety Evaluation Report (SER) approving LANL’s submittal of the 2015 Documented Safety Analysis and Technical Safety Requirements for WETF. Once implemented, this safety basis will supersede the existing safety basis, which consists of a 2012 SER and a 2013 SER addendum. Of significance, this safety basis reduces the material-at-risk (MAR) allowed in the facility to 60 percent of the current limit. As a result of this MAR reduction, the consequences of the worst case postulated accident scenario are reduced below the DOE evaluation guideline from 26 rem to 16 rem total effective dose. The SER notes that the reduction in MAR was taken in response to vulnerabilities identified with numerous safety significant systems and their inability to survive a Performance Category 2 seismic event as required. Although this updated safety basis is a needed improvement to the WETF operating posture, the SER notes that the safety basis is still baselined to a 2002 submittal and legacy issues still exist that will require a complete rewrite of the safety basis to resolve.

Confinement Vessel Disposition (CVD) Project: This week, CVD project personnel removed the third processed vessel from the enclosure. In the coming weeks, project personnel will relocate the three processed vessels from the Wing 9 high bay to the yard in order to support receipt of a fourth vessel for processing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 20, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 20, 2016

DNFSB Staff Activity: M.W. Dunlevy and R.C. Eul met with LANL Quality Performance Assurance Group personnel to discuss the current status of LANL's Contractor Assurance System (CAS) as well as improvement initiatives underway to revitalize the CAS program.

Area G–Inappropriately Remediated Nitrate Salts: This week, following closure of corrective actions for the Management Self-Assessment pre-start findings, Area G personnel commenced pressure relief device assembly and installation (see 5/13/16 weekly). As of Thursday, operators had installed seven pressure relief devices and expect to install six to eight devices per day going forward. If operators maintain this pace, all pressure relief devices required by phase 2 of revision 5 of the Evaluation of the Safety of the Situation (ESS) could be installed by the end of next week.

Workers paused operations while preparing to install the first pressure relief device when thermocouples monitoring drum temperature erroneously indicated a rising temperature in both the drum being prepared and a nearby drum. Operators exited the Dome 375 Permacon upon receiving the indication of the rising drum temperatures. At a fact finding of the event, Area G managers determined the most likely cause of the erroneous readings was the operators moving one thermocouple wireless transmitter and laying a procedure on the other in preparation for pressure relief installation. Area G operators do not credit the thermocouples with providing reliable temperature indications; an infrared thermometer is used locally to determine drum temperature prior to performing work. Area G engineering personnel are currently working to commission the thermocouple system. For corrective actions, the Facility Operations Director developed a written direction to operations center personnel on how to manage the thermocouple readings during future operations and directed operators not to use adjacent drums/standard waste boxes as work stands.

Area G–Safety Basis: Last Friday, LANL submitted to the NNSA Field Office for review and approval, an ESS for three Potential Inadequacies of the Safety Analysis (PISA) for transuranic waste inventory discrepancies in Area G. These PISAs affect material-at-risk (MAR) quantity and form assumptions used in the safety basis, and have remained unresolved for many months. The ESS identifies a number of more stringent MAR limits as compensatory measures to ensure Area G remains in a safe condition. NNSA Field Office approval of the ESS will allow Area G to return to OPERATIONS MODE, and as such will serve as a Justification for Continued Operations as well.

Plutonium Facility–Restart Activities: On Wednesday, the NNSA Field Office manager approved LANL's corrective action plan for the Muffle Furnace, Casting, and Advanced Recovery and Integrated Extraction System (FCA) Federal Readiness Assessment (FRA). Additionally, the NNSA Field Office manager verified the FRA pre-start findings were closed and authorized Plutonium Facility personnel to restart FCA operations. Also on Wednesday, LANL transmitted to the NNSA Field Office for review and approval, a Plan of Action for the Contractor Readiness Assessment for Plutonium Pyrochemical Operations. Of note, the Plutonium Pyrochemical Operations are the final planned activities of the Plutonium Facility resumption project following the LANL Director's decision to pause Plutonium Facility operations in June 2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 27, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 27, 2016

DNFSB Staff Activity: P. J. Foster observed the independent construction project review for the new Transuranic Waste Facility (TWF) project.

Area G–Inappropriately Remediated Nitrate Salts (RNS): There were several notable accomplishments:

- On Thursday, Area G operators completed installation of the pressure relief devices on all of the 55-gallon drums containing RNS wastes. Installation of high capacity filter vents should proceed next week.
- LANL has staged sufficient fire blankets to protect all of the RNS waste in the event of an encroaching wildland fire.
- Last week, the senior integrated project team leads issued the overall project execution plan for the *Nitrate Salt Safing and Treatment Project*. This represents a key document in the path toward eliminating the hazard associated with the RNS waste.

TWF Project: On Tuesday, the LANL contracting officer requested NNSA Field Office approval to proceed with an alternate approach to completing the safety basis for the project utilizing DOE-STD-3009 instead of proceeding with the controls identified in the preliminary safety basis developed using DOE-STD-1189. In particular, LANL management believes controls associated with the passive physical characteristics of the site, the fire suppression system and its supporting systems, and controls associated with standard industrial hazards exceed the requirements of the contract. While these systems have already been designed and installed per their current safety classifications, LANL provided a rough order of magnitude estimate of the lifecycle savings associated with their alternate approach of about \$50M to \$120M. During this week's construction project review, LANL managers also emphasized that existing project schedule commitments were in jeopardy should their alternative approach be denied. LANL requested a response by June 3, 2016. The Site Representatives note that this relatively simple storage facility is consuming significant NNSA and LANL senior management attention.

Plutonium Facility–Work Control: On Tuesday, an empty safe estimated to weigh several thousand pounds tipped into a glovebox while being moved for seismic anchoring. No injuries occurred and no release of contamination was detected despite the fact that the safe impacted the glovebox on a glove port. During the fact finding, workers indicated that they utilized two transport skates instead of the four specified in the work package. Management is developing a recovery plan to upright the safe, inspect the glovebox line for damage, and assess the lift plan development process.

Weapons Engineering Tritium Facility (WETF)–Programmatic Operations: On Thursday, WETF personnel successfully completed a programmatic function test of a tritium gas transfer system research and development unit. This significant milestone marks the first time WETF operators have conducted a function test since July 2011.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 3, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 3, 2016

Weapons Engineering Tritium Facility (WETF)–Operations: On Tuesday, an operator was performing a surveillance on the tritium monitoring system when he operated an incorrect switch on the back of a tritium monitor. After determining the incorrect switch was functioned, the operator inappropriately repositioned the switch without stopping and informing management as required. This action also activated the facility evacuation alarm and all personnel evacuated to the facility control room. The same sequence of events occurred in December 2015 (see 1/30/2016 weekly). In the previous event, WETF management determined that the appropriate corrective action was to label the switches. In the current event, the switches were labeled; however, operators indicated that the labels cannot be visualized while performing the work because of the constrained visual access to the back of the panel. WETF management is evaluating more effective means of ensuring operators can easily assure they are positioning the required switch. The Site Representatives note that in the recent instance, the operators executed the associated alarm response procedure until they could verify that there was not a release of tritium into the facility—an improvement from the December 2015 event response. WETF management also convened a hot-wash to discuss this response. Participants noted that due to recent network security issues, there is currently limited means of external monitoring facility alarms and indications (e.g., from the Facility Incident Command).

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Friday, Area G operators completed installation of the high capacity filter vents onto the RNS waste drums. This action is the final physical modification of the RNS waste drums required to meet the safe storage requirements identified in the currently implemented revision 5 of the Evaluation of the Safety of the Situation. NNSA and EM personnel continue to review revision 6, which covers the path forward for the pipe overpack containers with RNS waste, the wildland fire threat, and the aircraft crash scenario for Dome 375.

Area G–Emergency Management: LANL Fire Protection personnel recently worked with the Los Alamos County Fire Department (LAFD) to correct the post-start finding related to pre-incident planning for the RNS waste (see 5/13/16 weekly). LAFD recently revised the pre-incident plan for Dome 375 to correct 20 of the 21 identified issues including: providing an accurate description of the dome’s current function, contents, and associated hazard (i.e., storage of RNS waste); updating after-hours and other contact information; and correcting information on available exits, floor slopes, and detection equipment. Of note, this revision did not include an update on strategies for response to events associated with the unique hazards of the RNS wastes. As such, there continues to be no documented guidance on tactics responders should use for emergencies involving these materials. NNSA Field Office personnel are currently engaging with LAFD to rectify this situation.

Emergency Management: Late last month, LANL management issued the after-action reports from the 2nd quarter exercise of the Emergency Operations Center and the chlorine release exercise at the Plutonium Facility (see 4/1/16 weekly). For the former, they determined that all objectives were met with six opportunities for improvement, including the need to formalize a process for collapsing protective actions and protective action recommendations based on actual field data. For the latter, they identified two findings regarding exercise simulation and facility command not developing incident objectives. There were also seven opportunities for improvement, two notably associated with personnel ignoring and/or confusion with direction to shelter-in-place.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 10, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 10, 2016

DNFSB Staff Activity: R. C. Eul observed the training on causal analysis and corrective action development discussed below. On Thursday, B. K. Caleca, M. W. Dunlevy, and T. J. Dwyer conducted a teleconference with personnel from the NNSA Field Office and LANL to follow-up on actions from last month's working group meeting on additional seismic analysis for the Plutonium Facility.

Federal Oversight: A team of experienced personnel from across the DOE complex conducted an Organizational Health Assessment of the NNSA Field Office. The team's objective, executed primarily through interviews, was to identify challenges to enhancing organizational effectiveness for a nuclear safety environment, including follow-up on a number of recent employee concerns raised regarding the manner used for resolution of divergent views on issues.

Continuous Improvement: On Tuesday and Wednesday afternoon, Quality and Performance Assurance (QPA) personnel conducted training on techniques for causal analysis and corrective action development. The training supports a key initiative under LANL's Performance Assurance Improvement Plan and was the second instance of a substantially reinvigorated version of the course that until recently had been dormant for several years. The course was well attended with personnel from a diverse set of roles across the laboratory. QPA management also intends to supplement the training with recurring workshops to sustain analyst development.

Plutonium Facility–Safety Basis: Last Friday, LANL management transmitted to the NNSA Field Office for approval the 2016 annual update to the documented safety analysis (DSA) and technical safety requirements (TSR). This submittal joins a large number of documents supporting the facility's safety basis, which currently consists of portions of DSA and TSR documents from 2015, 2014, and 2011, plus five Evaluation of the Safety of the Situation documents, two temporary modifications to the safety basis, and a different revision of the 2015 DSA and TSR awaiting implementation. Plutonium Facility management utilizes a 26-page TSR implementation matrix to facilitate configuration management of this challenging situation.

The approach to consolidate most of these documents relies on a different version of the 2014 DSA and TSR that contains a modern hazards analysis, but that remains under comment resolution with the NNSA Field Office. Once the comments are resolved, LANL safety basis analysts will then need to update this DSA and TSR to reflect the various changes that have occurred since it was originally drafted and then resubmit for NNSA approval. There is no formal schedule associated with this process, but considering additional time for implementation, safety basis personnel estimate that the facility is optimistically another year or two from achieving a consolidated, modern DSA and TSR.

Area G–Inappropriately Remediated Nitrate Salts (RNS): LANL, NNSA, and EM personnel continue to debate alternative approaches to the safety basis strategy formally submitted by LANL in April to support final treatment of the RNS wastes (see 4/22/16 weekly). The prolonged debate continues despite the fact that the first two revised safety basis documents for onsite transportation and the Waste Characterization, Reduction, and Repackaging Facility are due next week according to the project plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 17, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 17, 2016

Transuranic Waste Facility (TWF) Project: Last Friday, the NNSA Field Office Manager approved LANL's request for relief from previous directed actions in order to allow for a revised hazards and accident analysis (see 5/27/16 weekly). LANL management believes this approach has the potential to derive a revised control set, including the possibility of no longer crediting the fire suppression system. As part of the approval, the NNSA Field Office also requested a strategy to accomplish submission and approval of the revised approach in the 100 % Documented Safety Analysis by the end of this August.

Plutonium Facility–Emergency Management: On Wednesday, Plutonium Facility personnel conducted their annual nuclear criticality exercise. This year's scenario examined the response to a pulsing slurry system, one heavily exposed individual with radiation sickness, and one non-viable individual that remained at the scene of the accident. Initial feedback from players and controllers indicated problems with the annunciation of alarms in several buildings, inattentiveness of workers to a fellow injured worker, some workers not properly responding to the alarm, and exercise control issues associated with the dose readings used to simulate the event.

Plutonium Facility–Seismic Safety: On Thursday, LANL management transmitted to the NNSA Field Office a revision to the Evaluation of the Safety of the Situation (ESS) regarding potential non-conservatism in the seismic capacity of the fire suppression system. This ESS covers one of the primary concerns articulated in the Board's letter dated May 12, 2016. The ESS revision addresses comments from the NNSA Field Office on the April submission (see 4/22/16 weekly). The conclusion of the revised ESS remains the same—that the material-at-risk limits and other controls in place provide reasonable assurance of adequate protection without crediting the fire suppression system for post-seismic fires.

Area G–Emergency Management: On Tuesday, Area G management conducted a fact-finding regarding the responses for two separate instances where operators identified bulging low-level waste containers. In both cases, LANL HAZMAT crews determined that the drums were empty and did not contain radioactive or chemical contaminants. The fact-finding revealed concerns with the quality of data contained in the Waste Characterization and Tracking System (WCATS). For example, WCATS did not contain the genealogy for one of the drums and did not identify the other as previously bulged due to freezing as indicated by a hand-written note on the drum. The fact-finding also identified a concern regarding ensuring that contact information is appropriately logged for individuals during the process of granting unescorted access to the facility. This was revealed after a painter working alone had a delayed exit because his pager was not registered to receive evacuation instructions. Lastly, the fact-finding identified the need to heighten awareness of unexpected conditions for waste containers, including those containing low-level waste. Management is developing corrective actions for each of these concerns.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Monday, LANL management proposed to NNSA and EM management a revised strategy for the safety basis changes needed to support final treatment of the RNS waste (see 6/10/16 weekly). For each of the three facilities, they are now proposing safety basis attachments with integrated Technical Safety Requirements documents. This approach is consistent with DOE-STD-3009 and DOE-STD-1104 and will include application of the process for *Existing Facilities with Mitigated Offsite Consequence Estimates over the Evaluation Guideline*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 24, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 24, 2016

DNFSB Staff Activity: D. M. Gutowski participated in Site Representative Office activities to compare and contrast practices with the Hanford Site. On Tuesday, M. R. Bradisse, B. K. Caleca and P. J. Foster conducted a teleconference with the Transuranic Waste Facility project personnel to discuss commercial grade dedication processes used for a seismically-actuated electrical shutoff switch.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: WETF management entered their New Information process for two separate issues. First, during a fact-finding associated with a failed weekly surveillance on the Oxygen Monitoring System (OMS) for the Load-out glovebox, they discovered that the “fail” light condition is not indicated remotely in the operations center nor via local indication. As a consequence, this inoperable condition is only detectable when personnel physically open the door to the OMS module, which had previously only been performed as part of the weekly surveillance. The safety basis credits local indication as Safety Significant. As an interim corrective action, WETF management has added visual inspection of the modules to the daily rounds. The second New Information issue concerns the potential for the tritium beta decay to induce radiolysis in tritiated water stored in a type of container known as the AL-M1. Personnel from the Savannah River Site raised this question during observation of WETF activities with AL-M1s.

Emergency Management: On Monday, Emergency Operations Center (EOC) personnel conducted their quarterly exercise. The scenario involved a seismic event with a tritium release at WETF, concurrent high explosive operations at the Dual Axis Hydrodynamic Test Facility, and minor damage and elk-related injuries elsewhere across the site. At the hotwash, players generally noted positive performance.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office approved LANL’s request to further extend the Evaluation of the Safety of the Situation/Justification for Continued Operations (ESS/JCO) governing nuclear criticality safety for two rooms in the facility vault. The new expiration date is January 5, 2017. The Field Office last granted a six month extension in January 2016 for this ESS/JCO that originated in 2012 (see 1/22/16 weekly). The Field Office approval letter notes that additional time is needed to complete the criticality safety evaluation documents, resolve comments, and implement the documents once approved.

Plutonium Facility–Safety Basis: Last Thursday, operations personnel declared a process deviation after observing plutonium oxide in taped slip-lid containers in quantities that required a water-resistant container per the criticality safety posting. NNSA Field Office management expressed disappointment, as this operation had recently successfully completed a federal readiness assessment.

Plutonium Facility–Operations: Workers righted the multi-thousand pound safe that tipped into a glovebox line last month (see 5/27/16 weekly). The glovebox will remain out of service until a modification can be made to restore confinement capability to the damaged gloveport.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 1, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 1, 2016

DNFSB Staff Activity: On Tuesday, DNFSB staff members conducted a teleconference with LANL and NNSA Field Office personnel to discuss revisions to the addendum to the Area G Emergency Planning Hazard Assessment (EPHA) associated with emergency response for accidents involving the inappropriately remediated nitrate salt waste. On Thursday, DNFSB staff members conducted another teleconference with LANL and NNSA Field Office personnel to discuss dispersion modeling protocol with emphasis on its application for the safety basis at the Transuranic Waste Facility.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Tuesday, Area G personnel secured power to the Dome 375 Permacon in order to safely conduct a replacement activity on a lightning protection system component. In addition, personnel used this opportunity to obtain images of the inside of the electrical cabinets to support design of a proposed backup electrical power supply. The outage lasted about two hours and was conducted during the cooler morning temperatures to accommodate securing the Permacon ventilation system. Despite these conditions, the Permacon temperature rapidly increased from about 58 to 73° F, nearly putting the facility into the associated action statement for the Limiting Condition for Operations. The Site Representatives note that this experience underscores the need to expeditiously install a backup power capability. LANL and EM Field Office personnel are currently working through the contractual arrangements needed to support moving forward with such capability.

Area G–Emergency Management: On Wednesday, Area G personnel conducted their annual EPHA exercise. This year’s scenario examined the response to an exothermic chemical reaction involving a drum of RNS waste, as indicated by a fire alarm and the simulated detection of radioactivity by the electronic continuous air monitor (eCAM) placed adjacent to the ventilation system exhaust. The activation and response of the eCAM was a novel aspect of the scenario, particularly since these units do not provide indication of release locally or at the Area G operations center and are managed by a separate entity at LANL. As an aside, Area G management is pursuing installation of new continuous air monitors that will improve direct notification. In addition to Area G personnel, exercise participants included the Emergency Operations division, LANL Hazardous Materials and Field Monitoring Teams, and the Los Alamos County Fire Department. Area G management noted several areas for improvement to be captured in the after action report. The Site Representatives note that the response was governed by the existing EPHA. Once approved and implemented, the revised EPHA addendum discussed on Tuesday would increase protective action distances for this scenario by a factor of about four.

Area G–Safety Basis: After receiving comments from NNSA and EM reviewers, LANL management determined that they will revise and resubmit a new version of revision 6 of the Evaluation of the Safety of the Situation for the RNS wastes. Revision 6 provides analysis and controls related to the potential threat from a wildland fire and establishes the path forward for the RNS contained in pipe overpack containers. While these containers do not yet have pressure relief devices installed, LANL personnel believe the design of the containers make them less susceptible to thermal runaway reactions. Separately, NNSA Field Office personnel concluded that they agree with the revised safety basis strategy for final treatment of the RNS waste (see 6/17/16 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 8, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 8, 2016

DNFSB Staff Activity: On Wednesday and Thursday, Deputy Technical Director R.E. Tontodonato observed the activities of the Site Representatives. Observations included discussions with senior LANL management, attending the Plutonium Facility fact-findings described below, and walk-downs of multiple defense nuclear facilities.

Plutonium Facility–Criticality Safety: On Wednesday, Plutonium Facility personnel recognized that they had mistakenly moved a container of plutonium oxide into a glovebox with a criticality safety evaluation that allowed only metal. Following discovery of this error, operators declared a process deviation, paused operations, isolated the area and made appropriate notifications as required. During a fact-finding for the event, management noted that a recent process deviation (see 6/24/26 weekly) had occurred using the same general nuclear material movement procedure that was used during this operation. In response to this earlier event, management initiated a causal analysis to include evaluation of the general move procedure and its contribution to the event. For the more recent process deviation, management will evaluate the results of the causal analysis against the findings from this event in an attempt to identify systemic issues with material movement operations. Additionally, management is seeking opportunities to improve the pre-job brief process to place more emphasis on criticality safety.

Plutonium Facility–Operations: On Wednesday, Plutonium Facility personnel conducted a fact-finding after the NNSA Facility Representatives identified several items in a glovebox that appeared potentially melted and charred. The items were located in a glovebox that is associated with the bench-scale recovery line, an aqueous operation that uses several multi-liter open top vessels to purify heat-source plutonium (i.e., material enriched in plutonium-238). Personnel presented pictures of several degraded items including a plastic graduated cylinder, a ground fault interrupt electrical cord, a pipettor, and a slip-lid container full of acid-soaked cellulosic rags. Operations personnel described two recent spills—one that occurred during processing of plutonium-238 rich solution and one that occurred as part of moving acid reagent. The consensus of the LANL personnel at the critique was that the degradation was caused by the harsh environmental conditions resulting from the spills of nitric and hydrofluoric acids, along with the high alpha radiation from the plutonium-238. The notable corrective actions are to have a fire protection engineer walk-down the glovebox and have the waste management coordinator review the acceptability of cellulosic rags soaked with a plutonium-238 containing nitric acid solution. The Site Representatives note that issues with similar rags contributed to the August 5, 2003, radioactive material uptake event that was subject to a DOE Type B Accident Investigation.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Tuesday, Area G management declared implemented revision 5 of the Evaluation of the Safety of the Situation (ESS) for the RNS waste. Last Thursday, they also issued a standing order to implement compensatory actions, directed actions, and conditions of approval that are not embodied by existing procedures. Notably, this standing order includes a provision to ensure the defensible space with respect to vegetation is maintained around the Dome 375 Permacon, as required by ESS revision 6 (which was previously submitted, but is now under additional revision). The defensible space control is one of two key input assumptions used in the wildland fire model to demonstrate temperatures do not threaten the RNS wastes. The other control, additional combustible loading limits within the dome, is not yet implemented pending further study.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 15, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 15, 2016

DNFSB Staff Activity: On Thursday, M.W. Dunlevy, R.L. Jackson, and R.V. Kazban conducted a teleconference with LANL and NNSA Field Office personnel to discuss the safety design strategy for the Plutonium Facility Equipment Installation Phase 1 subproject.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Thursday, LANL, EM, and NNSA personnel held the first of a series of in-process reviews of safety basis documents needed to support RNS treatment. The goal of these reviews is to foster timely feedback from the various federal review personnel in support of achieving expeditious treatment—development and approval of safety basis documents is nearing the critical path for treatment. This first review meeting focused on the Area G safety basis changes necessary to move the RNS waste drums from the Dome 375 Permacon to the vehicle that will be used to transport the drums to the Waste Characterization Reduction and Repackaging Facility (WCRRF) for processing. Of interest, LANL and NNSA Field Office personnel presented an alternative approach that pursues defending certain RNS accidents as beyond extremely unlikely. The review team agreed to consider the viability of this approach next week. The Site Representatives note that additional technical justification for making this assertion will likely be needed. In particular, the NNSA Cognizant Secretarial Officer acknowledged in the most recent safety basis approval letter that installation of pressure relief devices will significantly reduce the likelihood of a self-initiated thermal runaway; however, he ultimately concluded that the risks associated with the RNS wastes will not be completely eliminated (see 4/29/16 weekly). Additional in-process reviews are planned for the coming weeks to discuss safety basis changes for Area G, onsite transportation and WCRRF. LANL personnel indicated they remain on target for document submittal by August 15, 2016. DOE personnel expect to take an additional two weeks to review and approve the documents.

Plutonium Facility–Criticality Safety: On Wednesday, Plutonium Facility management issued a shift order change to improve performance during nuclear material movements within the facility. Management issued this change as a temporary corrective action for recent criticality safety process deviations that occurred during two separate material moves (see 7/8/16 and 6/24/16 weeklies). The change incorporates two newly developed tools to aid operators, including a material move planning tool and a nuclear criticality safety verification checklist. In addition to directing operators to use these tools for material move planning, the shift order change requires the first line manager to be informed prior to material movements being performed. These changes are in addition to an earlier standing order to utilize the material move procedure as Use Every Time. Facility personnel are currently revising this material movement procedure to more permanently implement these temporary corrective actions, as well as to address issues that were identified by a causal analysis of these process deviations.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: This week, facility personnel completed an Implementation Verification Review for the most recently approved revision of the WETF Documented Safety Analysis and Technical Safety Requirements. Of significance, this safety basis revision reduces the material-at-risk allowed in the facility to 60 percent of the current limit and reduces the consequences of the worst case postulated accident scenario to below the DOE Evaluation Guideline (see 5/13/16 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 22, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 22, 2016

DNFSB Staff Activity: M.W. Dunlevy was on site to support Site Representative activities including observation of the commencement of the Contractor Readiness Assessment for Plutonium Pyrochemical Operations, meetings with senior NNSA Field Office management, and a walkdown of the Plutonium Facility and associated technical area. On Friday, C.T. Beaty, T.L. Hunt, and A.M. Hutain conducted a teleconference with LANL and NNSA Field Office personnel to summarize their observations made during an onsite review of the LANL emergency management program (see 4/15/16 weekly).

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Wednesday, LANL management presented to the NNSA Field Office the safety basis review team’s final decision for the planned safety basis approach to support RNS treatment. The safety basis review team has determined that the alternate approach to pursue defending certain RNS accidents as beyond extremely unlikely that was proposed during last week’s in process review would be abandoned (see 7/15/16 weekly). Instead, the team will continue with the original plan to develop the necessary safety basis attachments with integrated Technical Safety Requirements documents that will include application of the DOE-STD-3009 and DOE-STD-1104 process for *Existing Facilities with Mitigated Offsite Consequence Estimates over the Evaluation Guideline* (see 6/17/16 weekly). The safety basis review team expects to meet again next week to finalize the details of the Area G safety basis changes and to start focusing on the details necessary to support a revision to the Waste Characterization, Reduction, and Repackaging Facility safety basis to complete treatment of the RNS into an acceptable form for disposal.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: Last Friday, the Implementation Verification Review team for the most recently approved revision of the WETF Documented Safety Analysis and Technical Safety Requirements presented the results of their review to WETF management (see 7/15/16 weekly). The team identified one finding with a new Surveillance Requirement to conduct a visual inspection of the wet pipe sprinkler system. The surveillance requires the distance between the bottom of sprinkler heads and stored equipment or material to be greater than 18 inches. The review team identified instances where this requirement was not met. The team concluded that once this finding is adequately addressed WETF personnel have demonstrated implementation of the safety basis change.

Plutonium Facility–Restart Activities: On Wednesday, Plutonium Facility personnel commenced the Contractor Readiness Assessment for Plutonium Pyrochemical Operations. This week, review team members performed document reviews, observed metal chlorination and chlorine gas delivery system calibration activities, and conducted interviews with facility personnel performing and supporting this activity. The review team is scheduled to continue with similar activities throughout next week and expect to have the review and a draft of the final report completed by next Friday. Plutonium Pyrochemical Operations are the final planned activities of the Plutonium Facility resumption project following the LANL Director’s decision to pause operations in June 2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 29, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending July 29, 2016

DNFSB Staff Activity: On Thursday, R.L. Jackson, conducted a teleconference with LANL and NNSA Field Office personnel to out-brief observations from the review of the safety design strategy for the Plutonium Facility Equipment Installation Phase 1 subproject.

Emergency Management: This week, LANL personnel hosted the annual HazMat Challenge for various regional hazardous materials responders, including the Los Alamos County Fire Department. In addition to some new scenarios, LANL personnel leveraged the institutional drill program processes to improve the training value of the event. In particular, the LANL organizers significantly increased the duration for each scenario to achieve a more realistic response and provided each team with a detailed written evaluation.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Monday, LANL received approval from the New Mexico Environment Department on the permit modification needed to support treatment of the RNS waste. Despite this achievement, approval of the safety basis documents continues to pace the treatment schedule. At this week's in-process review, LANL managers indicated that they remain on track to submit the documents by the middle of August. However, NNSA reviewers continue to finalize their review plan and attempt to deconflict several competing priorities to support the approval need date reflected in the project schedule.

Plutonium Facility–Operations: On Tuesday, Plutonium Facility management convened a second fact-finding to review the degraded items found in a plutonium-238 glovebox (see 7/8/16 weekly). After an improved attempt to construct a timeline, LANL personnel reaffirmed their prior conclusion that the degradation was the result of radiolytic and acid attack. Specifically, the operators present during a spill of a plutonium-238 rich, high molar nitric acid solution, stated that they tossed the cellulosic rags used to soak up the spill into the adjacent dropbox. As a result, they believe that the rags likely came into contact with the items that became degraded. Corrective actions include an effort to review spill response procedures, continued review of waste acceptability, and review of prior corrective actions from the 2003 Type B and 1994 Type C accident investigations. The Site Representatives note that the latter accident involved two instances where cellulosic wipes (i.e., cheesecloth) used in plutonium-238 operations ignited. In addition, recent LANL testing in support of RNS treatment indicated that cellulosic wipes that have contacted nitrate solutions possess the ignitability characteristic (D001).

Plutonium Facility–Criticality Safety: On Monday, Plutonium Facility management declared a criticality safety process deviation when inaccuracies in criticality safety postings for two outdoor transuranic waste storage pads were identified. These inaccuracies included: (1) misspellings, some technical in nature, (2) the second page of a two page posting was missing, (3) two revisions of the same posting were posted in the same area, and (4) the actual postings on the storage pad were not maintained in the facility document management system. During a fact-finding of the event, facility personnel identified a number of issues with the processes used to ensure configuration management during implementation of procedural revisions that include criticality safety postings. Management intends to develop a lessons learned that emphasizes the approved process to implement procedure revisions. Additionally, operators will develop a process to ensure the technical accuracy of postings and to frequently evaluate outdoor postings to verify their physical integrity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 5, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.K. Verhaagen and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending August 5, 2016

DNFSB Staff Activity: On Thursday, B.K. Caleca, M.W. Dunlevy, T.J. Dwyer, and A.H. Hadjian conducted a teleconference with NNSA and LANL contractor personnel to discuss planning for the request for proposals covering additional seismic analyses and testing for the Plutonium Facility.

Area G–Inappropriately Remediated Nitrate Salts (RNS): Updates on a few key actions:

- The NNSA Field Office review and approval of the Evaluation of the Safety of the Situation (ESS) concerning transuranic waste inventory discrepancies continues. There currently is no schedule for the review of this document, which was submitted on May 13, 2016 (see 5/20/16 weekly).
- LANL continues to develop the submittal package for revision 6.1 of the ESS concerning the RNS waste. In mid-June, the NNSA Field Office informally discontinued review of revision 6.0 after there was consensus that several changes were needed. Approval and implementation of revision 6.1 is needed to disposition the wildland fire and aircraft crash scenarios, as well as authorize installation of the pressure relief devices on the pipe overpack containers holding RNS waste.
- LANL engineering personnel continue to finalize the design and cost estimate for a backup electrical power capability to the Dome 375 Permacon. NNSA personnel became concerned about the lack of backup power following a loss of power event this spring (see 4/1/16 weekly).
- Area G safety basis personnel provided NNSA and EM personnel with high quality drafts of the safety basis documents for Area G and the Waste Characterization Reduction and Repackaging Facility (WCCRF). They hope this approach will facilitate timely federal review and approval.
- Area G personnel have established a high fidelity mockup of the WCRRF glovebox and are using it to prove out procedures for the mixing and blending operations needed for RNS treatment.

Plutonium Facility–Restart Activities: Last Friday, the Contractor Readiness Assessment (CRA) team completed their review of Plutonium Pyrochemical Operations (see 7/22/2016 weekly). The CRA team identified two pre-start findings: (1) inadequate hazard assessment and abatement for the Chlorine Gas Delivery System and (2) ineffective implementation of criticality controls into operating procedures to ensure criticality safety limits are protected in a sustainable manner. The team also identified one post-start finding related to deficiencies with facility Contractor Assurance and Issues Management systems and questioned whether these systems were adequate to support future resumption efforts and ensure sustainment of ongoing operations. Overall the team concluded that subject to satisfactory resolution of the pre-start findings, LANL has demonstrated its readiness for equipment, procedures, and personnel to safely support Plutonium Pyrochemical Operations. Of note, the Line Management Review Team chartered by the NNSA Field Office to shadow this review (see 5/6/2016 weekly) is developing a summary report documenting their conclusions and recommendations on LANL's readiness to proceed with the Federal Readiness Assessment.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: On Thursday, WETF personnel completed corrective actions from the Implementation Verification Review of the most recently approved revision of the WETF Documented Safety Analysis and Technical Safety Requirements. The Facility Operations Director declared the new safety basis implemented which marks a significant milestone by lowering facility material-at-risk limits to a level that reduces the consequences of the worst case postulated accident scenario to below the DOE Evaluation Guideline.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 12, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 12, 2016

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Thursday, LANL management transmitted to the NNSA Field Office revision 6.1 of the Evaluation of the Safety of the Situation (ESS) concerning the safe storage of the RNS waste. Revision 6.1 includes refinements to the wildland fire calculation that considers the heat contribution from burning the as-found combustibles within Dome 375. This and other refinements derived from peer review, result in a new maximum credible waste temperature of 35 °C—an increase from the prior calculation, but still below the 40 °C threshold of concern. Revision 6.1 also includes new technical references to support installation of pressure relief devices on the 8 remaining pipe overpacks containing RNS waste and a reference to support no additional action prior to final treatment of the 4 pipe overpack containers with WasteLock waste. The project schedule anticipates federal approval of revision 6.1 by September 7, 2016, with relief device installation to be completed a week later.

Notably, revision 6.1 does not incorporate the NNSA Cognizant Secretarial Officer's view expressed in the approval letter for ESS revision 5 that the pressure relief devices do not completely eliminate the risk of a self-initiated thermal runaway reaction (see 4/29/16 weekly). Notwithstanding this fact, the NNSA Field Office intends to submit revision 6.1 to DOE Headquarters for approval and also expects forthcoming safety basis attachments for RNS treatment to acknowledge this fact and adhere to the process for mitigated accident consequences that exceed the evaluation guideline.

On Tuesday, the EM Field Office issued contracting direction to LANL to begin work on the procurement and installation of backup electrical power for the Dome 375 Permacon. The current project schedule anticipates this capability to be ready by October 3, 2016.

Emergency Management: On Thursday, the NNSA Field Office rescinded direction from 2009 concerning the need for federal approval of certain emergency management related documents. Specifically, the direction restores federal review and approval prior to implementing Emergency Plans, Emergency Planning Zones, Emergency Readiness Assurance Plans, Emergency Planning Hazard Analyses, and site exercise packages, as required by DOE Order 151.1C, *Comprehensive Emergency Management System*.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office approved the ESS regarding certain sealed sources used for the High Efficiency Neutron Counter at Technical Area-55 (see 4/29/16 weekly). LANL submitted this ESS on July 8, 2016, following a declaration of a Potential Inadequacy of the Safety Analysis on April 27, 2016. In the approval letter, the NNSA Field Office determined the ESS is acceptable due to the relatively low risk associated with these sources and an additional compensatory measures that requires the sources be containerized when not in use and outside of their normal fire-rated storage safes. The approval letter concluded that based on this information, removing the initial operational restrictions of storing the sources in fire-rated safes, ensuring operations with the sources are continuously attended, and excluding nearby use of fuels is also acceptable. The related ESS for Area G remains under review by NNSA Field Office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 19, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaué
SUBJECT: Los Alamos Report for Week Ending August 19, 2016

Plutonium Facility–Issue Recurrence: The recent spill of about 100 mL of solution containing an estimated 10 g of plutonium-238 in 9.8 M nitric acid and hydrofluoric acid (see 7/8/16 and 7/29/16 weeklies) brought to light the practice of using cellulosic materials (i.e., cheesecloth) as an absorbent for acid spills despite strong evidence indicating that this can create a chemically unstable material. In 1994, LANL requested an emergency permit from the New Mexico Environmental Department to allow treatment of plutonium-impregnated nitrated cheesecloth to remove hazardous waste characteristics of ignitability and reactivity. Additionally, the Plutonium Facility has been the subject of two formal accident investigations concerning this material, including two instances in 1994 of the material self-igniting due to the presence of plutonium-238. A 2006 memo documenting corrective actions from the 2003 Type B accident notes this material is considered a potential fire hazard, as does current institutional LANL guidance for spill response. Other sites (e.g., Savannah River Site) have long prohibited the use of cellulosic material for acid applications. From about 2009 to 2015, LANL procedures for plutonium-238 glovebox cleanup acknowledged this hazard, emphasized minimizing use of cheesecloth, and provided operators with explicit instruction for rinsing, handling, and stabilization of cheesecloth through pyrolysis.

On Thursday, Plutonium Facility management responded to a request from the NNSA Field Office for information regarding the safety and waste management implications of the continued use of cheesecloth. LANL management maintains that these materials are covered by the safety basis and represent an acceptable waste form. Further, they assert that reporting is unnecessary under a DOE data call (OE-2: 2015-1) which focused on the addition of organic absorbents to “nitrate-bearing” transuranic waste streams because cellulose cannot be chemically nitrated solely by nitric and hydrofluoric acids. The Site Representatives note that LANL’s own experiments indicate that the organic cat litter that caused the Waste Isolation Pilot Plant radiological release event did not require the waste to be chemically nitrated, but was nitrate-bearing and therefore represented an ignitable material and an unsuitable waste form. Plutonium Facility management has temporarily suspended the use of cheesecloth for acid spills while they develop a paper to address the chemistry of this application.

Plutonium Facility–Infrastructure: Last week, LANL management provided the NNSA Field Office with a proposal for a revised execution strategy for Phase C of the TA-55 Reinvestment Project II. In order to accommodate cost overruns, the strategy proposes to defer scope on several elements. NNSA is currently reviewing the proposal, which includes:

- The Criticality Alarm System will be completed under its current reduced scope.
- The Uninterruptible Power Supply building will be completed with the exception of the batteries, automated transfer switch, and cable connection to the Plutonium Facility.
- The remaining Plutonium Facility exhaust stack work will be suspended.

Transuranic Waste Facility Project: Last week, the NNSA Field Office approved permanent equivalencies to several National Fire Protection Association code requirements for this newly constructed facility. The equivalency covers a missing drain valve, an undersized pipeline on the pump test header, an undersized pump test flow meter, and an insufficient flush rate for the pump suction pipeline. The approval letter concludes that no adverse reliability concerns are posed by LANL’s proposed equivalencies for these conditions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 26, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 26, 2016

DNFSB Staff Activity: Board Member Hamilton, accompanied by staff members C.T. Beaty and M.W. Dunlevy, observed the annual full-scale exercise discussed below.

Emergency Management: LANL personnel conducted their annual full-scale exercise. This year's exercise spanned three days and involved a force-on-force security event at the Plutonium Facility that resulted in the simulated breach of confinement and release of radioactive material. Players included the full Emergency Response Organization, the LANL protective force, the Federal Bureau of Investigation, the Los Alamos Medical Center, the Los Alamos County Fire Department, and several other entities from the county. The player hotwash and controller critique are scheduled for next week.

Plutonium Facility–Infrastructure: On Tuesday, Plutonium Facility operators placed the facility into Mode 2–Standby after the 14 day limit in the Technical Safety Requirements (TSR) had elapsed to restore operability to one of the diesel firewater pumps. Maintenance personnel are currently working with the equipment vendor to resolve issues with head gaskets. Per the TSR, they have 50 days to restore operability while in Mode 2—if not, the TSR action statements require the containerization of all material-at-risk. The TSR defines containerization as a metal container for solids and a glass or plastic closed top container for liquids—there are no further specifications on the fire resistance of the containers even though the facility has credited fire-resistant container types. While it is unlikely to be needed in this instance, the Site Representatives note that the facility has not previously demonstrated the ability to containerize all material-at-risk and question whether this action statement is executable. Area G and the Weapons Engineering Tritium Facility have encountered similar issues with their TSRs. Other current equipment and infrastructure issues include:

- Both emergency diesel electric generators are out of service since February 2015 and May 2016. The safety basis does not credit these electric generators.
- One of the instrument air compressors has been out of service since April 2015. Instrument air is a safety significant support system for the ventilation system. The facility is currently running on an alternate compressor.
- Questions on the fittings for fire suppression system challenge its ability to meet its safety significant performance criteria to remain operable following a performance category 2 seismic event.

Safety Basis: The NNSA Field Office recently approved two Evaluations of the Safety of the Situation (ESS) associated with damage ratios (DR) for pipe overpack containers (POC) at the Plutonium Facility and Area G. LANL submitted these ESSs in September of 2015 (see 9/4/15 weekly). In the approval letters, the NNSA Field Office notes that insufficient technical information exists to justify any DR value other than one under thermal insults, but allows the continued use of non-zero DRs until ongoing POC thermal testing has been completed. Of note, LANL only currently uses a DR other than one for the Plutonium Facility.

Confinement Vessel Disposition Project: Last week, project personnel received the fifth vessel for processing. They commenced processing this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 2, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 2, 2016

DNFSB Staff Activity: D.J. Brown observed federal readiness activities for Plutonium Pyrochemistry Operations on Monday through Wednesday. C.T. Beaty observed the player hotwash and evaluator critique from last week's full-scale exercise on Monday and Tuesday.

Plutonium Facility–Issue Recurrence: On Thursday, Plutonium Facility management issued an extent-of-condition review on the use of cheesecloth with nitric acid and plutonium-238 (see 8/19/16 weekly). They elected to issue the extent-of-condition review in lieu of a technical white paper defending the practice due to the number of internal peer review comments received on the draft white paper and more importantly, a recognition conveyed in the transmittal email that they should not have generated these materials and do not intend to generate them in the future. The review utilized the Waste Compliance and Tracking database and identified that of the 2513 waste containers generated since 2010, 174 may contain cheesecloth and plutonium-238. Of these, 84 were generated as a result of aqueous scrap recovery operations that use nitric acid, but none mention the word spill in the comments section of the records. They did identify two containers with plutonium-239 and comments indicating the presence of these materials and the word spill. The memo indicates that this validates the usefulness of the comments field. However, the Site Representatives note the waste visual inspection procedure does not provide operators details on what should be populated in the comments field. The cheesecloth from the June spill remains in three pipe overpack containers not yet declared as waste, and is expected to be reintroduced into a glovebox for treatment.

Federal Oversight: On Wednesday, the leader of the team that conducted an Organizational Health Assessment of the NNSA Field Office briefed the results of the review at a field office all hands meeting (see 6/10/2016 weekly). The team's objective, executed primarily through interviews, was to identify challenges to enhancing organizational effectiveness for a nuclear safety environment, including follow-up on a number of recent employee concerns raised regarding the manner used for resolution of divergent views on issues. The team identified opportunities for improvement in four general areas including leadership, learning, establishing a respectful environment, and improving the differing professional opinion (DPO) process. The NNSA Field Office Manager briefed corrective actions taken or planned that most notably included: (1) establishing a senior review board to resolve divergent views on safety basis issues; (2) revising the field office procedure on the DPO process; (3) conducting inclusion training and making improvements to the Employee Concerns Program; (4) conducting 360 reviews for the leadership team; and (5) having NNSA headquarters concur on future safety basis approvals.

Confinement Vessel Disposition (CVD) Project: On Tuesday, CVD operators paused work when they noticed a tear in the bag being used to provide confinement while removing a vessel port cover. Operators responded by covering the tear with their gloves until they could tape the tear closed. During a fact finding of the event, LANL personnel discussed whether the appropriate actions were taken because a tear in the bag could represent a potential criticality safety process deviation which would require operators to immediately move away competing with the priority to take action to maintain confinement. Management concluded that the appropriate actions were taken and noted that the procedures governing the operation could more clearly identify the desired response in the event this occurs in the future.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 9, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.K. Verhaagen and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending September 9, 2016

Plutonium Facility–Restart Activities: On Wednesday, the federal readiness assessment team out-briefed the results of their review of the plutonium pyrochemistry operations. The team identified one pre-start finding related to the procedural control on steps used to place a sparging tube above a plutonium metal melt that were insufficiently rigorous to consider it an unlikely upset, as opposed to an expected off normal event in the criticality safety evaluation. The team also identified one post-start finding related to the need to verify the operability of wax coated fire sprinkler heads in accordance with National Fire Protection Association standards. During the out-brief, the team leader praised several LANL and NNSA Field Office readiness practices, opined that they were best in the complex, and announced that these practices are to be adopted for the restart of the Waste Isolation Pilot Plant.

Following successful closure of the corrective actions, LANL will have completed the revised scope of the formal restart project, restoring basic functionality to the facility's manufacturing and surveillance missions. An additional 18 readiness activities are planned for the next two years, including some new activities and some that were de-scoped from the formal restart project such as the aqueous chloride and nitrate operations.

Federal Oversight: This week, Mr. Ted Wyka, the current Director of the Office of Safety Management for DOE-EM, commenced an eight month detail to help improve safety management and culture issues affecting the work environment within the NNSA Field Office. Mr. Wyka's presence fulfills one of the corrective actions from the Organization Health Assessment (see 9/2/16 weekly) to seek improvement advice from a senior executive from outside the NNSA chain of command.

Area G–Safety Basis: Last week, Area G management declared a Potential Inadequacy of the Safety Analysis (PISA) after preliminary calculations indicated a possibility that several Flanged Tritium Waste Containers may be pressurized with an explosive mixture of hydrogen isotopes and oxygen. The gas buildup is suspected from the radiolysis of tritiated water sorbed to zeolite beds that were loaded above their recommended limit. Some of these containers also have integrity concerns related to potential corrosion issues and non-conformances related to over-torqueing of improper closure bolt types. Management has prohibited all access to the containers.

Weapons Engineering Tritium Facility (WETF)–Emergency Management: On Wednesday, WETF personnel conducted their annual emergency exercise. This year's scenario involved a malevolent act by a disgruntled employee that resulted in the release of tritium gas. Participants noted an inconsistency between the actions taken by facility personnel to ensure the safety of local personnel and the formal protective actions that the Emergency Manager declared via a simulated mass notification. Participants also discussed several issues with the integration of response by the protective force and postulated response by Los Alamos Police Department (LAPD). While LAPD did not play in the exercise, participants noted that LAPD officers do not receive the familiarity and the hazard awareness training that is provided to members of the Los Alamos Fire Department. As a result, the participants expressed concerns that the police procedures and response actions may not appropriately account for the unique hazards at certain LANL facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 16, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 16, 2016

DNFSB Staff Activity: On Thursday, B.K. Caleca, M.W. Dunlevy, T.J. Dwyer, and A.H. Hadjian conducted a video teleconference with NNSA and LANL contractor personnel to discuss details of planned seismic analyses and testing for the Plutonium Facility. Going forward, NNSA and LANL personnel intend to conduct monthly meetings with the Board's staff to present their plans for and progress on developing the request for proposal for the alternate seismic analysis of the Plutonium Facility.

Confinement Vessel Disposition (CVD) Project: On Monday, CVD operators paused work when they noticed a tear in the glovebox glove being used by one of the workers. The workers were in the process of attaching the sphere to the workstation when the tear in the glove was observed. With direction of the radiological controls technician, workers covered the glove tear with tape and continued working to place the sphere/workstation into a safe configuration. Upon exiting the gloves, contamination was detected on both inner protective gloves of the worker. After additional inspection, workers identified tears in both glovebox gloves. During a fact finding of the event, LANL personnel discussed whether the appropriate actions were taken to continue work with a known glove tear. The Site Representatives note that this is the second time in two weeks (see 9/2/16 weekly) that operators have had to make decisions balancing the risk between the safety of the sphere configuration and the required response to a breach of the confinement boundary.

Plutonium Facility–Infrastructure: On Tuesday, Plutonium Facility operators placed the facility into Mode 1–Operations following repairs and successful post maintenance testing of the previously out of service diesel firewater pump (see 8/26/2016 weekly). On Wednesday, facility operators had to enter a Limiting Condition for Operations when the tank level indicator for the other pump house malfunctioned. Facility personnel restored the level indicator to service prior to the 12 hour Completion Time that would have required them to suspend molten plutonium operations.

Area G–Safety Basis: On Tuesday, Area G safety basis personnel determined that the Potential Inadequacy of the Safety Analysis for several Flanged Tritium Waste Containers potentially pressurized with an explosive mixture of hydrogen isotopes and oxygen (see 9/9/16 weekly) represents a positive Unreviewed Safety Question. Management continues to prohibit all access to the containers while an Evaluation of the Safety of the Situation is being developed.

Area G–Inappropriately Remediated Nitrate Salts (RNS): Last week, LANL submitted to the NNSA Field Office an approved Contractor Readiness Assessment (CRA) Plan of Action for de-nesting, refrigerating, and loading RNS waste drums onto a transportation vehicle for shipment to the Waste Characterization, Reduction and Repackaging Facility (WCRRF) for treatment. This follows the NNSA Field Office Manager's approval of an amendment to LANL's Quarter 4 Fiscal Year 2016 Startup Notification Report authorizing a Federal Readiness Assessment for RNS treatment activities at WCRRF and directing a CRA for the Area G RNS activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 23, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 23, 2016

DNFSB Staff Activity: On Wednesday, P.J. Migliorini, J.A. Pasko, and T.J. Dwyer, conducted a teleconference with EM, NNSA, and LANL personnel to discuss issues identified by the Board's staff during a review of the safety basis documents discussed below to support treatment of the inappropriately remediated nitrate salt (RNS) waste being stored in Area G.

RNS–Safety Basis: This week, personnel from EM and NNSA headquarters, EM and NNSA Field Offices, and LANL safety basis met for four full days to finalize necessary safety basis changes for final treatment of the RNS waste currently store in Area G. The safety basis review team worked on changes to documents including the Documented Safety Analysis and Technical Safety Requirements for Area G and the Waste Characterization, Reduction and Repackaging Facility (WCRRF), as well as a temporary safety basis modification for the LANL Transportation Safety Document. LANL personnel require these safety basis changes to allow de-nesting, refrigerating, and loading RNS waste drums onto a transportation vehicle for shipment to WCRRF, and to perform final treatment. Next week, senior management from EM and NNSA headquarters will be on site to review these documents with a goal of concurring on a Safety Evaluation Report and recommending approval to the NNSA Cognizant Secretarial Officer for Safety.

Federal Oversight: On Tuesday, the NNSA Field Office Manager transmitted an Improvement Action Plan for the Organizational Health Assessment conducted in June 2016 (see 9/2/2016 weekly) to field office personnel for their information. In the correspondence transmitting the plan, the manager emphasized the goals of inclusion and transparency, in particular as they apply to developing safety basis documents. The manager has also started providing weekly notes to the field office staff in an effort to improve communications and to highlight a few thoughts for consideration and discussion. The manager indicated that the first several notes will focus on safety culture and will highlight attributes from DOE's guide on Integrated Safety Management emphasizing Leadership, Employee/Worker Engagement, and Organizational Learning.

Plutonium Facility–Restart Activities: On Thursday, The NNSA Field Office Manager approved the pyrochemical process operations Federal Readiness Assessment Corrective Action Plan and the associated pre-start objective evidence file, and authorized restart of pyrochemical operations.

Plutonium Facility–Infrastructure: On Tuesday, facility operators entered a Technical Safety Requirement Limiting Condition for Operation when a diesel firewater pump shut down on overspeed during performance of a weekly Surveillance Requirement. Facility personnel have 14 days from the time of failure to return the diesel to service before they are required to place the facility into Mode 2–Standby. This is the same diesel firewater pump that operators recently repaired and returned to service after experiencing a series of mechanical issues including previous problems with the diesel overspeed (see 8/26/2016 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 30, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending September 30, 2016

DNFSB Staff Activity: P.J. Migliorini was on site this week for an indoctrination visit as he assumes the role of the Board's Cognizant Engineer for DOE-EM activities at LANL.

Inappropriately Remediated Nitrate Salt (RNS)–Safety Basis: This week, senior management from EM and NNSA headquarters, as well as participants from DOE's Offices of Nuclear Safety and Enterprise Assessments met on site to convene a Senior Review Board (SRB) for the safety basis changes needed for final treatment of the RNS waste (see 9/23/16 weekly). SRB members included the NNSA Cognizant Secretarial Officer (CSO) for Safety, NNSA's Central Technical Authority, EM and NNSA's Chiefs for Nuclear Safety, EM's Deputy Assistant Secretary for Safety, Security, and Quality Assurance, and both EM and NNSA Field Office Managers. The SRB identified and discussed their technical issues with the Safety Evaluation Report (SER) developed to approve the safety basis changes, and presented these issues to the Safety Basis Review Team to resolve. Over the course of the three day meeting, this process resulted in the development of a SER that all members of the SRB agreed provided an adequate safety basis for treating the RNS waste. The NNSA CSO is expected to give final approval of the SER next week.

Weapons Engineering Tritium Facility (WETF)–Lessons Learned: On Thursday, WETF operations and program personnel convened a learning team to study an event that occurred during a gas transfer operation resulting in an inadvertent transfer of tritium into the Tritium Waste Treatment System. LANL uses learning teams as a Human Performance Improvement tool to improve processes, to plan work, and to learn from events. In this case, the learning team met to identify process improvements that could help prevent a similar incident in the future. The learning team identified potential process improvements that included procedural changes, equipment configuration modifications, and mentoring opportunities.

Plutonium Infrastructure Strategy: On Wednesday, the NNSA Field Office Manager approved a revision to the Safety Design Strategy (SDS) for the PF-4 Equipment Installation (PEI) subproject. The PEI subproject involves 17 gloveboxes that will house analytical chemistry and materials characterization equipment. Thirteen of these gloveboxes are existing installed equipment that will be repurposed as part of the subproject. In a previous revision of the SDS, LANL identified that eight of the repurposed gloveboxes did not meet the existing safety basis requirement for Performance Category (PC)-2 seismic criteria (see 11/6/15 weekly). In this newest revision, LANL references an engineering evaluation of the seismic qualification of these glovebox stands to conclude that these gloveboxes can meet their required PC-2 seismic criteria with a high degree of confidence because of redundancies in the seismic load path. In the approval letter, the NNSA Field Office Manager also agreed with LANL's proposed strategy to submit a safety basis page change to delete the requirement that all new glovebox stands meet PC-3 seismic criteria.

Plutonium Facility–Infrastructure: On Wednesday, Plutonium Facility personnel returned the diesel firewater pump to service (see 8/23/16 weekly) and exited the associated Limiting Condition for Operation following repair and retest.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 7, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 7, 2016

Plutonium Facility–Operations: This week, operators retrieved from pipe overpack containers the cheesecloth used to cleanup a spill of plutonium-238 in a nitric acid solution (see 8/19/16). The material is now stored in SAVY containers awaiting measurements to resolve an inventory discrepancy and pending development of the overall disposition. On Monday, facility management entered the New Information process to examine whether the hazard posed by cheesecloth and nitric acid is adequately covered in the safety basis. Previously, in response to NNSA Field Office questions, LANL management asserted the adequacy of the safety basis.

Plutonium Infrastructure Strategy: On Tuesday, the NNSA Field Office informed LANL management that it was premature to approve the safety design strategy for the upgrade of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility. They based their decision on funding and outstanding National Environmental Protection Act actions.

Chemistry and Metallurgy Research Building–Safety Basis: On Wednesday, facility management declared a Potential Inadequacy of the Safety Analysis after non-destructive assay measurements indicated the presence of about 550 g of Pu-239 equivalent holdup in Wing 7. This quantity exceeded the 200 g assumed in the safety basis. As an immediate action, management has reduced the allowed limit to account for this additional material-at-risk.

Emergency Management: On Wednesday, LANL issued the after action report from the August full-scale exercise (see 8/26/16 weekly). They identified that 2 of the 152 total objectives were not met. The unmet objectives involved the failure of incident command to develop and implement an action plan and the inability of the Los Alamos Medical Center to prepare for a surge of contaminated patients. There were no findings associated with these unmet objectives; however, there were 27 opportunities for improvement. Notable improvement actions involve: avoiding patching into real-world public safety radio traffic; the need to implement a formalized approach to the hotwash; several items with improving shelter-in-place actions; unfamiliarity of facility command personnel with the use of the radio system; and lack of protective actions for security personnel.

Environmental Waste Facility Operations–Facility Evaluation: On Thursday, a team briefed the results of their Facility Assessment. The team consisted of 24 personnel from outside of the Environmental Waste Facility Operations organization. The team performed the assessment in August, and focused on compliance with applicable Safety Management Programs and selected Occupational, Safety and Health elements for operations at Area G and the Waste Characterization, Reduction, and Repackaging Facility (WCRRF). The Associate Director for Nuclear and High Hazard Operations, with the assistance of the Quality and Performance Assurance Group, recently instituted the Facility Evaluation process as a mechanism for LANL to self-assess facility performance. The team identified a number of findings and opportunities for improvement, primarily in the areas of Conduct of Engineering, Conduct of Maintenance, Criticality Safety, Fire Protection, Quality Assurance, and Radiation Protection. Area G and WCRRF will use these results to help prepare for the upcoming readiness assessments on treatment of the inappropriately remediated nitrate salt waste currently stored in Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 14, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 14, 2016

DNFSB Staff Activity: P.J. Foster observed discussions between LANL and the NNSA Field Office on the final resolution of comments regarding the safety basis for the Transuranic Waste Facility.

Emergency Management: Subsequent to receiving comments from the NNSA Field Office, LANL management rescinded the after action report for the full-scale exercise (see 10/7/16 weekly). Separately, the NNSA Field Office and LANL management are negotiating implementation of DOE Order 151.1D, *Comprehensive Emergency Management System*. This revision reflects many of the improvements made under the Board's Recommendation 2014-1, *Emergency Preparedness and Response*.

Inappropriately Remediated Nitrate Salts (RNS)–Safety Basis: On Friday, the EM Field Office transmitted to LANL the Safety Evaluation Report (SER) approving the safety basis documents needed to support final treatment of the RNS waste into an acceptable waste form. The documents encompass activities at Area G, onsite transportation, and the Waste Characterization, Reduction, and Repackaging Facility. The SER includes five conditions of approval and four directed changes associated with establishing temporary road closures during transfer operations, several corrections to the documents, and the need to implement revision 6.1 of the Evaluation of the Safety of the Situation (ESS) concerning the safe storage of the RNS waste. The NNSA Field Office continues to review revision 6.1 of the ESS which is required to support treatment as it covers denesting and pressure relief device installation on the 8 pipe overpacks containing RNS waste, as well as finalizes the wildland fire analysis and associated controls.

Plutonium Facility–Nuclear Material Management: Material management personnel recently realized progress with respect to implementing some of the opportunities identified in DNFSB/Tech-39. In response to a recent timely order, programmatic operations personnel have been documenting the type of outer container in the LANMAS material accountability system for all material-at-risk (MAR) stored outside of gloveboxes on the first floor of the facility (i.e., floor locations and safes). As of this past Tuesday, they have identified all but 5 of the 247 previous unspecified containers. As a result of this information and ongoing repackaging efforts, material management personnel estimate a nearly 21 percent relative reduction in MAR against the fiscal year 2016 baseline after accounting for damage ratios for certified containers. Material management personnel are also monitoring risk reduction using the methodology specified in DOE Manual 441.1-1, *Nuclear Material Packaging*, and currently estimate a nearly 55 percent relative reduction in risk against the fiscal year 2016 baseline.

Safety Basis: DOE Standard 3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analyses*, was issued in November 2014. The NNSA Field Office and LANL management incorporated this standard into the contract as part of modification 359, which was jointly approved on August 11, 2016.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 21, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: R.K. Verhaagen and J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending October 21, 2016

The Site Representatives were at DNFSB Headquarters. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 28, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 28, 2016

DNFSB Staff Activity: On Monday, a staff team conducted a teleconference with NNSA Field Office and LANL personnel to discuss questions regarding the safety basis for the Transuranic Waste Facility.

Emergency Management: On Tuesday, LANL management reissued their after action report for the full-scale exercise (see 10/14/16 weekly). The revised report identified that 10 of 152 objectives were not met, resulting in four findings and 25 opportunities for improvement. The findings involve: non-functioning telephones at the Joint Information Center; an inappropriate radio patch that interfered with real world public safety; lack of familiarity on the part of LANL radiological control technicians of the layout and process for contaminated patient handling at the Los Alamos Medical Center; and poor implementation of an exercise freeze. The report captures the fact that a unified command was never effectively established as an opportunity for improvement and notes that it would have resulted in a finding; however, the event jurisdiction fell under the Federal Bureau of Investigation and LANL does not issue findings against external entities.

Area G–Safety Basis: LANL recently submitted to the NNSA Field Office for review and approval an Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis (PISA) concerning newly identified explosive hazards on several Flanged Tritium Waste Containers (see 9/9/16 weekly). The ESS references a calculation that demonstrates the currently established 50 foot standoff distance is adequate to ensure safety of the workers. The ESS also identifies safety significant Specific Administrative Controls for fire protection and container management to reduce the likelihood of a container deflagration from anticipated to extremely unlikely. LANL concludes that temporary storage in this configuration is safe and have established a team of experts to develop a path forward for disposition of this material.

Plutonium Facility–Safety Basis: Last week, safety basis personnel concluded that the concern regarding hazards associated with cellulosic material (i.e., cheesecloth) contacted with nitric acid and plutonium-238 did not constitute a PISA (see 10/7/16 weekly). Their assessment relies on a white paper produced by the waste management group at the Plutonium Facility. The white paper largely focuses on nitrating cellulose in chemically simple systems, though it does acknowledge that ignitable or reactive material could be produced and recommends further testing. The safety basis assessment also points to two hazard scenarios in the approved safety basis that involve nitric acid and cheesecloth. The Site Representatives note that the white paper fails to consider the operational history of accidents involving cheesecloth and nitric acid at LANL, and more broadly in the nuclear industry, and also note that both hazard scenarios occur inside the building, whereas the extent-of-condition indicates there may be 174 waste containers of potential concern that may not all be indoors.

Inappropriately Remediated Nitrate Salts (RNS): Last week, LANL submitted to the NNSA Field Office for review and approval a Plan of Action (POA) for a Contractor Readiness Assessment (CRA) for the restart of the Waste Characterization, Reduction, and Repackaging Facility to safely treat the RNS waste currently stored in Area G. The CRA is planned to commence in early January 2017. LANL notes in the POA that the CRA will be followed by a Federal Readiness Assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 4, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 4, 2016

DNFSB Staff Activity: B.K. Caleca, M.W. Dunlevy, N.M. George, P.J. Migliorini, A.R. Powers, and C.P. Scheider were onsite to conduct an initial scoping review of the Plutonium Facility safety basis and for site familiarization. Activities included walkdowns of Technical Area-55, the Plutonium Facility, Area G, and the Chemistry and Metallurgy Research (CMR) Building, as well as holding discussions with LANL safety basis personnel. B.K. Caleca participated in a Plutonium Facility seismic discussion with NNSA and LANL personnel and observed seismic trenching activities in Technical Area-16.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Operations: Last week, LANL submitted to the NNSA Field Office for review and approval a request to transfer a drum containing transuranic (TRU) waste from WCRRF, which is currently in COLD STANDBY, to CMR for temporary storage. Operations personnel created this waste drum when cleaning out the waste characterization glovebox that will be used in the treatment of the inappropriately remediated nitrate salts (RNS) currently stored in Area G. WCRRF personnel did not anticipate the possibility that this activity would generate TRU waste which is prohibited by the Technical Safety Requirements when the facility is in COLD STANDBY. Complicating this matter, WCRRF management notes that transition to WARM STANDBY cannot be achieved in a timely manner due to a lack of qualified operations personnel and the current operability status of facility equipment. In the request letter, LANL states that the presence of the drum is impacting the ability to conduct readiness activities necessary to startup the RNS treatment campaign.

Plutonium Facility Infrastructure: On Monday, the NNSA Administrator approved Critical Decision (CD)-2/3, *Performance Baseline and Start of Construction*, for the Radiological Laboratory Utility Office Building (RLUOB) Equipment Installation Phase 2 (REI-2) and Plutonium Facility Equipment Installation Phase 1 (PEI-1). These subprojects of the CMR Replacement project (see 12/18/15 weekly) are needed to move the remaining analytical chemistry and material characterization activities out of CMR. The CD-2/3 approval letter identifies the scope of the subprojects to include outfitting or repurposing 10,000 square feet of laboratory space in RLUOB and 2,800 square feet of space in the Plutonium Facility. Additionally, the letter indicates these projects are scheduled to receive approval for CD-4, *Start of Operations*, in early calendar year 2022.

Transuranic Waste Facility (TWF)–Safety Basis: On Wednesday, the NNSA Field Office convened a Senior Review Board (SRB) to evaluate the draft Safety Evaluation Report (SER) for approval of the TWF Documented Safety Analysis. The SRB was comprised of senior leaders from NNSA's Field Office and headquarters, including NNSA's Cognizant Secretarial Officer for Safety and Deputy Associate Administrator for Safety. In addition to reviewing the SER, the SRB heard a number of minority opinions from members of the Safety Basis Review Team. The SRB identified a number of issues the Safety Basis Review Team will have to resolve prior to SER approval.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 11, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 11, 2016

Weapons Engineering Tritium Facility (WETF)–Safety Basis: Last Thursday, WETF management declared a Potential Inadequacy of the Safety Analysis (PISA) when they determined that three Flanged Tritium Waste Containers stored within the facility are potentially pressurized with an explosive mixture of hydrogen isotopes and oxygen. WETF personnel recognized this potential issue following the declaration of a PISA for a similar situation with waste containers from WETF stored at Area G (see 9/9/16 weekly). WETF management has limited access to the portion of the facility containing these waste drums to ensure the facility is in a safe configuration while the Unreviewed Safety Question is being determined.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Operations: On Tuesday, the NNSA Field Office approved LANL’s request to transfer a drum containing transuranic waste from WCRRF, while in COLD STANDBY, to the Chemistry and Metallurgy Research Building for temporary storage (see 11/4/16 weekly). On Wednesday, LANL personnel transferred the drum.

Also on Tuesday, the NNSA Field Office manager approved LANL’s Plan of Action for a Contractor Readiness Assessment for the restart of WCRRF to safely treat the inappropriately remediated nitrate salt (RNS) waste currently stored in Area G (see 10/28/16 weekly).

WCRRF and AREA G–Safety Basis: Last week, LANL issued final reports for Implementation Verification Reviews (IVR) of WCRRF and Area G safety basis changes needed for final treatment of the RNS waste. The IVR team noted that the conditions of approval (COA) and directed changes in the approving Safety Evaluation Report (see 10/14/16 weekly) have been implemented but cannot be finalized until approval of COA responses have been received from both the EM and NNSA Field Offices. The IVR team identified necessary administrative issues that must be resolved and concluded that once these changes are made the revised safety bases are adequately implemented.

Transuranic Waste Management: On Wednesday, personnel from the Sandia National Laboratories, NNSA Field Office, EM Headquarters, and LANL met to discuss the status and path forward for testing on pipe overpack containers (POC). LANL and NNSA senior management have become increasingly concerned regarding the safety basis uncertainty with POCs. Currently, the existing inventory of filled POCs at LANL is on the order of 600. Additionally, LANL management has accepted the risk of continuing to use POCs for packaging of combustible transuranic waste because of the reduction in waste container volume afforded by their use. The risk stems from the fact that the safety basis for the Waste Isolation Pilot Plant (WIPP) currently prohibits POCs with combustibles. As a result, either these POCs will need to be repackaged or EM and NNSA will need to complete adequate testing of POCs in fuel pool fire conditions—a credible accident at WIPP. This uncertainty has also prompted the NNSA Field Office into considering a prohibition of POCs in the new Transuranic Waste Storage facility, which had originally envisioned reliance on POCs to increase the material-at-risk. Overall, LANL personnel intend to review what capabilities they could apply to the testing program and the group agreed to reconvene in early December.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 18, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 18, 2016

DNFSB Activity: Board Member Santos was on site to observe the Board's staff review of LANL's software quality assurance (SQA) program discussed below. Board Member Santos walked down the high fidelity mockup of the Waste Characterization Reduction and Repackaging Facility (WCRRF) glovebox that LANL is using to prepare operators and procedures for the mixing and blending activities needed for inappropriately remediated nitrate salt (RNS) waste treatment. Mr. Santos also met with the NNSA Field Office Manager and Deputy Manager.

DNFSB Staff Activity: R.C. Eul was onsite and W.S. Horton called in remotely to conduct a review of LANL's SQA program. The team evaluated the program's compliance with DOE SQA directives as well as the implementation of the program through a sampling of safety software being used at LANL defense nuclear facilities.

Weapons Engineering Tritium Facility (WETF)–Safety Basis: On Thursday, WETF personnel determined that the Potential Inadequacy of the Safety Analysis declared for three flanged tritium waste containers (FTWCS) stored within WETF (see 11/11/16 weekly) represents a positive Unreviewed Safety Question. WETF safety basis personnel identified that the facility hazards analysis does not consider scenarios to evaluate the generation of flammable hydrogen-oxygen mixtures in tritium containment vessels. WETF management cite the robust construction of the FTWCS, the way the FTWCS were loaded, and the ability to prevent any ignition sources as justification for the current safe storage of these items. WETF safety basis personnel are now developing an Evaluation of the Safety of the Situation (ESS) to submit to the NNSA Field Office for review and approval.

WCRRF–Safety Basis: On Thursday, LANL submitted to the NNSA Field Office for review a notification and supporting documentation for closure of the ESS for the July 2015 WCRRF roof leak (see 7/17/15 weekly). LANL informed the NNSA Field Office that the repairs to the roof have been completed and the building structural integrity has been restored and declared operable.

Transuranic Waste Facility (TWF)–Safety Basis: This week, the NNSA Field Office reconvened the Senior Review Board (SRB) to evaluate a revised Safety Evaluation Report (SER) for the TWF safety basis (see 11/4/16 weekly). The SRB went line-by-line through the draft SER and heard minority opinions from the Safety Basis Review Team. The SRB continues to deliberate and are expected to make a presentation of their proposal for the path forward to NNSA's Cognizant Secretarial Officer for Safety next Monday.

Area G–RNS Waste: On Thursday, LANL submitted to the NNSA Field Office for review and approval a request to remove and replace a lid on one of the 55 gallon drums in Area G containing RNS waste that has stripped filter hole threads. LANL notes in the request that this will also require removal and replacement of the pressure relief device with supplemental filtration that is currently installed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 25, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending November 25, 2016

Plutonium Facility–Infrastructure: Last month, the NNSA’s Office of Recapitalization approved the analysis of alternatives for phase III of the TA-55 Reinvestment Project (TRP III). The decision endorsed moving forward with a full fire alarm system replacement with the addition of a second alarm panel for the non-nuclear facilities. This action solidifies the fact that TRP III will not include an upgrade to a safety class active confinement ventilation system or support separation of the non-nuclear facilities from the firewater loop. Both of these sub-projects are identified in the TA-55 Project Execution Strategy as required to help further reduce the mitigated offsite consequences from seismically-induced events. Both sub-projects are also identified in the approved safety basis as planned improvements, as well as listed as compensatory measures associated with acknowledged vulnerabilities in the existing safety systems. The path forward for these sub-projects is currently unclear.

Earlier this month, LANL personnel hosted a multi-day deep dive focused on conveying the laboratory’s infrastructure needs for the NNSA Office of Safety, Infrastructure and Operations. With respect to the Plutonium Facility, the presentations highlight needs associated with the failing wet vacuum material handling system, several safety and compliance projects to ensure the operability of safety systems, ventilation and confinement system upgrades, fire wall repairs, firewater loop component replacements, vault rack upgrades, and revitalization of the trolley system. Many of these identified needs have an uncertain path forward.

Area G–Inappropriately Remediated Nitrate Salts (RNS): On Tuesday, the NNSA Cognizant Secretarial Officer unconditionally approved the safety evaluation report for revision 6.1 of the Evaluation of the Safety of the Situation (ESS) concerning the storage of the RNS wastes. This version includes some corrections to revision 6 (see 8/12/16 weekly) originally submitted on April 21, 2016, and primarily provides analysis and controls for the wildland fire scenario and installation of pressure relief devices on the remaining RNS contained in pipe overpacks.

The Site Representatives note that the lengthy development and approval cycle for revision 6.1 demonstrates the need for LANL to adjust their safety basis processes to ensure that safety controls identified as necessary during the development of an ESS are implemented as soon as they are determined to be necessary. In this case, revision 6.1 identified four new safety controls. In the absence of Area G management’s proactive intervention earlier this summer, the controls identified as needed would not have been implemented until the coming weeks—well past their intended use for prime wildfire season.

Transuranic Waste Facility (TWF)–Safety Basis: On Monday, NNSA personnel completed the last of several days of meetings for their Senior Review Board to reach their conclusions on the final safety basis for this new facility. The safety evaluation report is expected next week. This approval, as well as the revision 6.1 discussed above, is expected to free up NNSA Field Office safety basis personnel to address other pressing documents waiting on approval, including the revised attachments for RNS treatment (submitted 10/21/16), the ESS for Flanged Tritium Waste Containers (submitted 10/13/16), and the ESS for waste inventory discrepancies (submitted 5/13/16).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 2, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 2, 2016

DNFSB Staff Activity: On Wednesday, D.K. Andersen and B.K. Caleca participated in the fortnightly teleconference with LANL and NNSA regarding seismic analysis and testing for the Plutonium Facility. On Thursday, M.W. Dunlevy, P.J. Foster, P.J. Migliorini, and S. Sircar conducted a teleconference regarding atmospheric dispersion, including an emphasis on the application in the safety basis for Transuranic Waste Facility, with LANL and NNSA Field Office personnel.

Inappropriately Remediated Nitrate Salt (RNS) Waste Treatment–Startup Activities: On Tuesday, the management self-assessment (MSA) team conducted an in-brief for their review of readiness of the RNS waste processing campaign, including the restart of the Waste Characterization Reduction and Repackaging Facility (WCRRF). The MSA team will conduct document reviews, personnel interviews, facility walk-downs, and observe performance demonstrations and emergency response. The team will observe activities in Area G and WCRRF to include: denesting an RNS drum from its standard waste box; drum movements in the Dome 375 Permacon, refrigerator, and WCRRF; loading and unloading the designated transport vehicle; and process operations using surrogate material.

Area G–Safety Basis: On Wednesday, LANL transmitted to the NNSA Field Office for approval, a request for Area G to receive and store waste drums related to RNS treatment activities. LANL requires this approval because of the material-at-risk restrictions that are currently implemented by the Evaluation of the Safety of the Situation for material-at-risk discrepancies. LANL identified the following waste as candidates for this request: (1) transuranic and/or low level waste generated from cleanout of the WCRRF glovebox prior to processing RNS waste; (2) low level waste containers currently staged in the WCRRF transportainers; (3) the transuranic waste drum currently stored in the Chemistry and Metallurgy Research (CMR) building that originated from WCRRF (see 11/4/16 weekly); and (4) any drums identified in (1) or (2) that may be sent to CMR for temporary storage while the request is pending approval.

RANT Shipping Facility: On Tuesday, sub-contractors commenced geotechnical investigation activities needed to inform the design for the seismic structural upgrade. LANL currently anticipates completion of the design in March 2017.

Contractor Assurance System: Last week, the LANL Director signed and transmitted the annual contractor assurance letter to the NNSA Field Office and LANS LLC Board of Governors. The letter documents LANL's verification that the CAS is compliant with contractual requirements and laboratory policies. The letter notes continued progress against the multi-year Performance Assurance Improvement Plan with this year's focus on strengthening the issues management process. Other notable achievements include: re-establishing the Institution Management Review Board; revision of the CAS description document; completion of four Facility Evaluations; a re-boot of the causal analyst program; and newly developed institutional metrics linked to the LANL Director's critical issues list.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 9, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 9, 2016

DNFSB Staff Activity: On Wednesday, staff members T.J. Dwyer, M.W. Dunlevy, and P.J. Migliorini met with NNSA and LANL personnel at DNFSB Headquarters to discuss progress made with respect to DNFSB/Tech 39, *Opportunities for Risk Reduction at the LANL Plutonium Facility through the Minimization of Material-at-Risk*.

Transuranic Waste Facility (TWF) Project: On Tuesday, the NNSA Field Office Manager approved the final safety basis for the project. The approval included directed changes to: (1) temporarily reduce the material-at-risk limit by 15 % and (2) revise the basis for a technical safety requirement associated with drum banding. Additionally, the approval included conditions to: (1) submit a revised safety basis that classifies the fire suppression system as safety significant, including the minimum necessary and sufficient support systems (directed change #1 would then expire) and (2) prohibit the receipt of pipe overpack containers (POC) until the safety basis is re-evaluated to consider the results of the ongoing fire testing (see 11/11/16 weekly). Notably, several of the safety basis review team members did not recommend approval. Furthermore, the NNSA Cognizant Secretarial Officer, who concurred on the documents, also placed a condition of approval to require full implementation of the safety significant fire suppression no later than February 28, 2018.

LANL anticipates the start of operations in late spring 2017. The Site Representatives note that the current prohibition of POCs and limitations contained in the permit from the New Mexico Environment Department mean that TWF can only receive about 100 of approximately 700 waste containers currently stored at the Plutonium Facility. Moreover, NNSA management has accepted the programmatic and safety risks of continuing to pack combustible waste in POCs with the expectation that fire testing will eventually support the acceptance of these packages into the Waste Isolation Pilot Plant.

Plutonium Infrastructure Strategy: On Monday, the LANL Director sent the NNSA Administrator a letter outlining a potential slip in the commitment to cease programmatic operations in the Chemistry and Metallurgy Research (CMR) building from 2019 to 2021. LANL cites the source of the schedule risk as funding alignment issues and the delay in the CD-2/3 approval and with the equipment installation subprojects (see 11/4/16 weekly). Notwithstanding this potential delay, the Director noted past and continued risk reduction activities at CMR.

Emergency Management: On Monday, the NNSA Field Office Manager approved LANL's revised after action report for the full-scale exercise (see 10/28/16 weekly). The approval letter included seven observations, the most significant of which included the failure to establish an effective incident command and to ensure responding personnel were not in the radioactive plume without proper protective equipment.

Waste Characterization Reduction and Repackaging Facility (WCRRF)–Emergency Management: On Wednesday, WCRRF personnel conducted their annual emergency exercise. This year's scenario involved a thermal runaway of an inappropriately remediated nitrate salt waste drum and an unconscious worker who sustained injuries while trying to move away from the drum. Of significance, emergency responders were slow to respond to the injured individual who remained unconscious in the radioactive plume and cold weather for more than an hour and a half.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 16, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 16, 2016

DNFSB Staff Activity: J.W. Plaue conducted oversight activities at the Lawrence Livermore National Laboratory. On Wednesday, B.K. Caleca, M.W. Dunlevy, and T.J. Dwyer participated in the monthly video teleconference with NNSA and LANL contractor personnel to discuss details of planned seismic analyses and testing for the Plutonium Facility. On Thursday, a staff team conducted a teleconference with NNSA, EM, and LANL personnel to discuss staff questions regarding the hazards associated with the cheesecloth used to clean up a spill of plutonium-238 in a nitric acid solution (see 10/28/16 weekly).

Radioactive Liquid Waste Treatment Facility–Emergency Management: Earlier this month, LANL issued the after action report for the annual exercise held on October 26, 2016. This year's scenario involved the simulated spill of 200 gallons of sodium hydroxide during a transfer from a delivery truck that splashed and chemically burned the involved worker. The report notes that 42 of 45 objectives were met with the remainder not applicable. Seven opportunities for improvement were identified, including the following of note: (1) a recommendation to use a real tanker truck, since the simulation of the presence of a tanker truck and associated spill confused some players and complicated injects; (2) an employee who was monitoring the transfer was not assisted or evacuated from the 25 meter isolation zone and the facility procedures were not specific enough to clarify the correct action for this situation; (3) only one person in the facility command knew how to use the video monitor system; and (4) communication challenges existed between two operations centers, facility command, and incident command all in geographically distinct locations.

Safety Basis–Flanged Tritium Waste Containers (FTWC): LANL management recently stood up an integrated project team to develop a path forward to disposition all 12 of the FTWCs currently stored at Area G and the Weapons Engineering Tritium Facility. Calculations indicate that eight of these containers may be pressurized with a potentially explosive headspace mixture of oxygen and hydrogen isotopes. The team is in the early stages of options analysis and is considering such decisions as in-situ versus alternate locations for processing; mechanical versus dynamic approaches to relieving the pressure; and disposal at Area G or offsite facilities. In parallel, they are also investigating the feasibility from a regulatory perspective of direct disposal for some of the containers. The team has set mid-summer 2017 as their target for completion to avoid the additional complications once the new contractor takes over Area G in October 2017.

Inappropriately Remediated Nitrate Salt (RNS) Waste Treatment–Startup Activities: On Wednesday, the Management Self-Assessment team briefed the results of their review of readiness for the RNS waste processing campaign (see 10/28/16 weekly), including the restart of the Waste Characterization Reduction and Repackaging Facility (WCRRF). The team identified eighteen pre-start findings relating to WCRRF restart, the most significant of which related to emergency management, conduct of engineering, and conduct of training. Facility management intends to resolve these pre-start findings in time to support a Contractor Readiness Assessment currently scheduled for January 2017.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 22, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 23, 2016

Weapons Engineering Tritium Facility (WETF)–Flanged Tritium Waste Containers (FTWC): Last Friday, LANL submitted to the NNSA Field Office for review and approval an Evaluation of the Safety of the Situation (ESS) for the Potential Inadequacy of the Safety Analysis declared for three FTWCs stored within WETF that may be pressurized with a potentially explosive headspace mixture of oxygen and hydrogen isotopes (see 11/17/16 weekly). The ESS concludes that the current situation is safe based upon the immediate actions taken to provide increased management oversight, strict operational control over the area containing the FTWCs, and a prohibition on moving or venting the FTWCs. WETF safety basis personnel contend in the ESS that with these controls in place it is extremely unlikely that any electrical, mechanical, or thermal ignition source could ignite the potentially explosive mixture.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Safety Basis: Last week, the EM Field Office transmitted to LANL a letter approving four proposed changes to the Area G and Waste Characterization Reduction and Repackaging Facility (WCRRF) safety bases as well as LANL’s Transportation Safety Document. LANL submitted these changes to meet the Conditions of Approval identified in the Safety Evaluation Report approving the safety basis documents needed to support final treatment of the RNS waste into an acceptable waste form (see 10/14/16 weekly).

Area G–RNS: Last week, the Area G facility operations director declared revision 6.1 of the ESS for safe storage of RNS waste implemented (see 11/25/16 weekly). Following this declaration, operators completed lid removal from the remaining standard waste boxes containing RNS waste in pipe overpack containers and installed pressure relief devices with supplemental filtration onto the 55 gallon drums housing the pipe components. This action represents the final activity necessary to implement all of the controls specified in the ESS.

Plutonium Facility–Safety Basis: On Monday, LANL submitted to the NNSA Field Office a request to further extend the ESS/Justification for Continued Operations (JCO) governing nuclear criticality safety for two rooms in the facility vault (see 6/24/16 weekly). LANL originally submitted this ESS/JCO in December 2012, but limited criticality safety resources and prioritization of these resources on Plutonium Facility resumption activities has resulted in delays in completing and receiving approval of the criticality safety evaluations needed to close this ESS/JCO.

Plutonium Facility–Readiness Activities: On Wednesday, a management self-assessment (MSA) team conducted an in-brief for their upcoming review of aqueous chloride processing in the Plutonium Facility. The MSA for aqueous chloride operations is the first readiness activity scheduled to be performed following the completion of the formal restart project of Plutonium Facility operations accomplished earlier this year (see 9/9/16 weekly). The MSA team will conduct their review in two phases. Phase 1 will focus on document reviews and will commence January 9, 2017. Phase 2 will involve field activities and is scheduled to begin on January 19, 2017.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 30, 2016

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 30, 2016

The Year on a Page: The Site Representatives' summary of the key developments of 2016:

- LANL completed key actions necessary to minimize the risk associated with the inappropriately remediated nitrate salt wastes (RNS). The most prominent of these actions include: implementation of new controls identified in the Evaluation of the Safety of the Situation (ESS) to prevent or mitigate consequences from a wildland fire and thermal runaway event; completion of the safety basis changes necessary to support the final treatment of the RNS wastes into an acceptable waste form; and preparation for upcoming readiness reviews to conduct final treatment activities. LANL managers believe they remain on schedule to complete the treatment prior to the next peak wildland fire season.
- Transuranic waste operations at Area G remain largely curtailed pending resolution of eight Potential Inadequacies of the Safety Analysis (PISA). Resolution of several of these PISAs has languished for many months due to competing priorities for LANL and NNSA Field Office safety basis personnel.
- Plutonium Facility personnel completed the revised scope of the restart project. Notably, several process deviations occurred in resumed operations prompting management to significantly change the material move procedure. The next significant readiness review is scheduled to occur in April 2017 for the aqueous chloride and americium oxide operations.
- Plutonium Facility personnel accomplished significant progress addressing DNFSB/Tech-39 concerns, including reducing material-at-risk on the first floor located outside of gloveboxes by 127 kg by relocation to more robust storage locations and improved utilization of certified containers.
- NNSA's decisions on the scope for Phase III of the TA-55 Reinvestment Project translated into the loss of line item funding for Plutonium Facility to upgrade the active confinement ventilation system to safety class and eliminate non-seismically qualified loads from the safety class fire water loop. These sub-projects were key elements of NNSA's previous strategy to mitigate the consequences of a post seismic fire to well below the DOE Evaluation Guideline. The situation is further exacerbated by the recently acknowledged seismic fragility issues with the fire suppression system, as well as LANL's planned reliance on executing these line items to counter system aging, vulnerability, and obsolescence issues.
- The Plutonium Infrastructure Strategy moved forward with approval of Critical Decision 2/3 for the equipment installation sub-projects and conduct of the analysis of alternatives for the Plutonium Modules. Notwithstanding this progress, delays and resource issues with the subproject approval will likely prolong programmatic operations in the Chemistry and Metallurgy Research Building.
- LANL declared PISAs associated with the potential for explosive mixture of oxygen and hydrogen isotopes in the headspace of Flanged Tritium Waste Containers. In the coming months, the NNSA Field Office is expected to complete review and approval of the ESSs for this condition and LANL is expected to develop a process and associated safety basis to disposition these containers.
- Weapons Engineering Tritium Facility personnel completed programmatic function tests for the first time since July 2011. They have also nearly completed a maintenance outage to make system modifications and resolve pressure safety concerns. The modifications are necessary to support risk reduction activities associated with the removal of bulk tritium gas.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 6, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 6, 2017

Plutonium Facility Infrastructure: Last month, LANL management transmitted to the NNSA Field Office for information the fiscal year 2017 TA-55 Project Execution Strategy (PES). Planned work for this year includes: a number of continued seismic structural activities; completion of walk-downs for the firewater pump houses; completion of the preliminary evaluation of the cast iron fittings issue for the fire suppression system; installation of concrete pads for a future diesel generator to support the electric firewater pumps; continuation of the development of an execution strategy for glovebox fire suppression systems; and identification of equipment and components needed to support a potential Performance Category 3 ventilation system. Notable out-year activities include: determination of a path forward to remediate seismic interaction issues (2 over 1), particularly with the fire suppression system; completion of seismic evaluations for safety significant systems, structures, and components in order to complete the project to identify the totality of seismic vulnerabilities that began in 2008; modifications to achieve 2-hour fire barrier status for certain walls; removal of non-seismic loads from the safety class firewater loop; and an active confinement ventilation system.

Confinement Vessel Disposition (CVD) Project: CVD project personnel continue with cleanout operations of the fifth sphere, despite the recent loss of several operators. The fifth sphere contains substantially more debris than prior spheres with more than 40 drums worth removed to-date.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Emergency Management: On Thursday, the NNSA Field Office Manager approved an addendum to LANL’s Emergency Planning Hazards Assessment (EPA) for RNS waste storage and treatment. The addendum supplements the existing EPAs for Area G, the Waste Characterization, Reduction, and Repackaging Facility, and onsite transportation. LANL submitted the addendum to update the EPAs to be consistent with the safety basis changes made for RNS treatment and to address the identified increase in hazard presented by the RNS following the February 2014 drum breach at the Waste Isolation Pilot Plant.

Federal Oversight–2016 Performance Evaluation Report: On Tuesday, NNSA posted its 2016 Performance Evaluation Report for LANL. In the Operations and Infrastructure goal, NNSA acknowledged that LANL exceeded expectations for operational resumption activities at the Weapons Engineering Tritium Facility and the Plutonium Facility. NNSA identified a number of areas under this goal where LANL did not meet expectations that included: (1) necessary improvements to the criticality safety program are not proceeding at an acceptable pace; (2) although improving, the contractor assurance system continues to have significant deficiencies, and (3) weaknesses in the emergency management program continue to be identified by both internal and external reviews.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 13, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 13, 2017

DNFSB Staff Activity: Z.S. Beauvais, C. Berg, and J.D. Anderson were on site to attend the kick-off meeting for the W76 Nuclear Explosives Safety Study. They also conducted walk-downs of the Plutonium Facility and Weapons Engineering Tritium Facility, and observed an emergency drill at the Waste Characterization, Reduction, and Repackaging Facility (WCRRF).

Inappropriately Remediated Nitrate Salt (RNS) Waste–Emergency Management: LANL management has taken action to strengthen emergency management following a less than adequate performance during an emergency exercise that resulted in a pre-start finding from the management self-assessment for WCRRF readiness (see 12/9/16 weekly). For example, this week WCRRF personnel conducted three type 2 (instructional) emergency drills involving limited participation from the Los Alamos Fire Department and the LANL Emergency Operations organization. They plan to conduct additional operational and emergency drills, including a type 3 (evaluated) drill next week to assess the adequacy of preparations to commence the contract readiness assessment, currently scheduled for January 30, 2017. Additional actions include detailing several emergency management specialists to help prepare the facilities for the RNS treatment campaign and beginning to introduce the concept of “critical steps” into the drill evaluation objectives.

WCRRF Operations: On Tuesday, WCRRF personnel took the facility into WARM Standby mode for the first time in nearly three years. This action allowed operations personnel to complete cleanout of the waste characterization glovebox, removal and shipment of the associated transuranic waste, and installation of the equipment needed for the RNS treatment campaign.

Federal Oversight: On Monday, the NNSA Field Office issued a revision to its Differing Professional Opinion procedure. The Field Office issued this revision as a corrective action for the Organizational Health Assessment conducted earlier this year (see 9/2/16 weekly).

On Tuesday, the staff of the Chief of Defense Nuclear Safety commenced its review of the NNSA Field Office. The review is expected to run through March 2017 and will include review of 14 functional areas including, criticality safety, safety culture, emergency management, issues management, readiness, and oversight processes.

Transuranic Waste Facility (TWF) Project: On Monday, LANL management transmitted to the NNSA Field Office for information the TWF safety basis implementation plan. The scope of the plan includes all safety controls with the exception of those associated with the deferred project scope involving the waste characterization trailers. A formal schedule for completing the trailer scope is not yet available, but the trailers are needed to certify the waste for offsite disposition and current regulatory permit requirements dictate that waste containers can reside at TWF for no more than one year. The implementation plan states completion in March 2017.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 20, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 20, 2017

Plutonium Facility–Safety Basis: On Tuesday, LANL safety basis personnel opened a New Information (NI) screening regarding the use of cellulosic wipes (i.e., cheesecloth) in aqueous process operations. A similar NI was closed in late October (see 10/28/16 weekly). Developments since that time include the issuance of a memorandum stating that the white paper referenced in the NI closure documentation represented the issuing body’s philosophy and as such, formal resolution of peer review comments was not performed. Additionally, as briefed to the NNSA Field Office on Wednesday, LANL management recognized that the previous NI contained information from the approved safety basis that did not reflect current operational practices. Specifically, the safety basis states that cheesecloth used in aqueous processing operations for plutonium-238 would be rinsed and pyrolyzed in preparation for waste disposal. In reality, the pyrolysis unit operated briefly in the 2007 timeframe, but was suspended after disposition issues arose with the resulting homogenous waste form (see 9/21/07 weekly) and a simplified direct-discard process became viable. Similarly, the instruction to operations personnel to rinse cheesecloth had been removed from the applicable procedures.

LANL management indicated they were pursuing several actions to complete the NI processing including additional testing, calculations, and regulatory permit research. Per LANL’s procedure, they have 15 calendar days to complete processing of the NI to determine whether a Potential Inadequacy of the Safety Analysis exists; however, the procedure allows for additional time without NNSA Field Office approval.

Plutonium Facility–Emergency Management: On Wednesday, Plutonium Facility personnel conducted their annual emergency exercise. This year’s scenario involved a postulated spill of nitric acid from a delivery vehicle whose driver had a stroke. Determination that the spill from the truck was limited to about 50 gallons, allowed responders to significantly reduce the isolation zone from the bounding distance of 764 meters facilitating a simpler response.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Emergency Management: On Thursday, RNS treatment personnel conducted a type 3 (evaluated) drill at the Waste Characterization Reduction and Repackaging Facility. The scenario involved a thermal runaway of an RNS drum inside the facility with an injured worker in need of extraction. RNS, LANL Emergency Managers, and Los Alamos Fire Department personnel have recently spent considerable effort touring the facility, planning responses, integrating the new video monitoring capability, and training consistent terminology. These efforts resulted in a response that was improved from the performance during the recent annual exercise (see 12/9/16 weekly).

Weapons Engineering Tritium Facility (WETF)–Safety Basis: On Friday, LANL submitted to the NNSA Field Office for validation a revision of the WETF Technical Safety Requirements (TSR). LANL submitted the change to address three directed actions the NNSA Field Office Manager provided in a letter approving the initial TSR submission. The directed actions included: (1) revise the Specific Administrative Control (SAC) for containerization, (2) provide page changes to the TSRs reflecting the SAC revision to the NNSA Field Office for validation, and (3) incorporate changes from a previously approved version of the safety basis into the 2017 annual update.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 27, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending January 27, 2017

Area G–Safety Basis: Last Friday, LANL submitted to the NNSA Field Office for review and approval a safety basis strategy and implementation plan for resolution of three outstanding Potential Inadequacies of the Safety Analysis for material-at-risk (MAR) inventory discrepancies in Area G (see 5/20/16 weekly). LANL’s strategy includes the need for the NNSA Field Office to approve the related Evaluation of the Safety of the Situation (ESS) submitted in May 2016. Following approval, Area G operators will implement stricter MAR limits and will relocate approximately 500 waste containers to meet array spacing requirements for the aircraft crash analysis for all of Area G. LANL indicates that a revised safety basis incorporating the ESS will be submitted in April 2017 to fully resolve the issues.

On Thursday, the NNSA Field Office Manager approved LANL’s request for Area G to receive and store waste drums related to inappropriately remediated nitrate salt (RNS) waste treatment activities (see 12/2/16 weekly). In the approval letter, the NNSA Field Office Manager notes that care was taken to ensure this effort does not conflict with the pending safety basis approvals for MAR discrepancy issues discussed above.

Unremediated Nitrate Salt (UNS) Waste–Safety Basis Strategy: Also last Friday, LANL submitted to the NNSA Field Office for review and approval a treatment plan and safety basis strategy for the 29 UNS waste containers currently stored in Area G. LANL’s proposed treatment activities include non-destructive assay and physical inspection of the UNS containers in Area G, transport from Area G to the Waste Characterization, Reduction, and Repackaging Facility (WCRRF), and final treatment at WCRRF to eliminate the waste’s ignitability characteristics. LANL’s proposed safety basis strategy includes the need to conduct a process hazard analysis on the activities in Area G to determine if safety basis changes will be necessary, and the submittal of a temporary modification to the WCRRF safety basis to support treatment activities. The safety basis strategy indicates that all necessary safety basis changes will be submitted to the NNSA Field Office for review and approval by April 2017. Of note, LANL’s submittal indicates that discussions with the NNSA and EM Field Offices concluded treatment of RNS and UNS wastes remain the top risk reduction priorities at Area G and WCRRF.

Emergency Management–Federal Oversight: On Monday, the NNSA Field Office published a fiscal year 2016 self-assessment of its emergency management program. The assessment was performed by the NNSA Field Office emergency management program manager and included the following subjects in its scope: (1) hazards surveys and hazards assessments, (2) program administration, (3) training, drills and exercises, (4) readiness assurance, (5) emergency response, and (6) offsite interfaces. The assessment report identifies three findings including: (1) oversight of the wildland fire management plan is inadequate, (2) the NNSA Field Office is not approving and submitting hazards surveys, emergency planning hazards analyses, nor emergency planning zones in a timely manner, and (3) mutual aid agreements between the NNSA Field Office and tribal authorities pertaining to emergency response do not exist. The emergency management program manager has entered the identified findings and observations in the NNSA Field Office issues management system for resolution.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 3, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 3, 2017

DNFSB Staff Activity: On Thursday, a staff team lead by R.C. Eul provided to LANL and NNSA Field Office personnel their closeout observations regarding their review of software quality assurance.

Federal Oversight: On Thursday, the NNSA Field Office Manager announced several staff rotations intended to improve organizational health. Additional forthcoming actions include commencing daily standup meetings for the operations group and developing a joint prioritization matrix for safety basis actions.

Plutonium Facility–Safety Basis: On Thursday, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis (PISA) for the use of cellulosic wipes (i.e., cheesecloth) in contact with heat source plutonium (HS-Pu). This determination closes out the New Information screening initiated last month (see 1/20/17 weekly). Management’s rationale for declaring the PISA stems from preliminary analysis that indicates a bounding threshold of around 200 °C for initiating combustion of cheesecloth that has come in contact with nitric acid. Additional conservative thermal modeling indicates that quantities of HS-Pu in excess of 10 g and in certain packaging configurations has the potential to challenge the 200 °C threshold. Their preliminary review of the waste inventory revealed five pipe overpack containers impacted by this information—one of these containers is located on the outdoor waste storage pad. Management’s initial compensatory actions include: (1) conducting the in-service inspection on the outdoor container to ensure no indications of a prior thermal event with emphasis on the state of the filter, (2) returning the outdoor container to the Plutonium Facility confinement structure, (3) issuing a prohibition on waste containers with greater than 10 g HS-Pu and cheesecloth, and (4) providing this information to management at Area G and the Waste Isolation Pilot Plant for their consideration.

Weapons Engineering Tritium Facility (WETF)–Readiness: On Monday, the NNSA Field Office Manager approved LANL management’s request to revise the level of readiness review required to load, package, and ship hydride transport vessels (HTV). Previously, the NNSA Field Office had approved a proposal to conduct a Federal Readiness Assessment (RA) to startup these operations. In the revised request, LANL proposed to forego the Federal RA and to initiate HTV operations under a revised and more rigorous startup plan that will extend management oversight. LANL’s request notes that WETF personnel successfully completed a Federal RA in October 2015 that evaluated gas transfer operations similar to those needed to load, package, and ship the HTVs. Of note, startup of HTV operations will enable WETF personnel to process and ship bulk tritium gas from the facility that represents a large fraction of the material-at-risk and has no programmatic use.

Waste Characterization Reduction and Repackaging Facility–Readiness Activities: Last Friday, the Associate Director for Nuclear and High Hazard Operations approved a request to proceed with the Contractor RA for processing of waste drums containing the inappropriately remediated nitrate salt waste currently stored in Area G. On Monday, the Contractor RA team held their in-brief and commenced their review which is scheduled to conclude next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 10, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 10, 2017

DNFSB Staff Activity: P.J. Migliorini and M.W. Dunlevy were on site this week augmenting the site representative office. Their activities including walking down the safety systems and waste storage areas at the Plutonium Facility and observing the drill at the Waste Characterization, Reduction, and Repackaging Facility (WCRRF) for the Contractor Readiness Assessment (CRA) discussed below.

Plutonium Facility–Infrastructure: Last Wednesday, during conduct of a weekly Surveillance Requirement, operators observed the diesel firewater pump fail to come up to speed after starting. Facility operations personnel had entered the appropriate Limiting Condition for Operations prior to commencing the surveillance, which allows 14 days to restore the pump to service prior to having to change the facility operations to Mode 2–Standby. Maintenance personnel identified the cause of the failure to be bad bearings on the auxiliary drive that powers the fuel injector and water pumps. Facility personnel received the necessary parts and expect to complete repairs before the 14 days have expired. This is the same diesel firewater pump that operators repaired and returned to service after experiencing a series of mechanical issues last year (see 9/23/16 weekly). On a related note, on Wednesday construction workers placed concrete for one of the pads to be used for the future installation of a diesel power generator. Facility personnel plan to install a diesel power generator at each pump house in order to provide an additional power supply to the electric firewater pumps.

Area G–Safety Basis: Last Friday, Area G management entered the New Information process regarding the potential fire hazard of cellulose waste material containing greater than 10 g of plutonium-238. This action was taken in response to the Potential Inadequacy of the Safety Analysis declared at the Plutonium Facility (see 2/3/17 weekly). LANL’s review of the inventory indicates that there are currently three 55-gallon drums stored at Area G with records indicating the presence of cheesecloth and greater than 10 g of plutonium-238. All three of these drums are overpacked in Standard Waste Boxes.

WCRRF–Readiness Activities: On Friday, the CRA team out-briefed the results of their review of the personnel, equipment, and procedures needed to process the waste drums containing the inappropriately remediated nitrate salt waste. The CRA team identified five pre-starts and no post-start findings. The pre-starts dealt with the need to strengthen the startup plan, improve field validation of operating procedures, resolve two training issues, and deploy the production version of the Waste Characterization and Tracking System database.

WCRRF–Emergency Management: On Tuesday, WCRRF personnel conducted an emergency drill for the CRA team. Drill participation included personnel from the LANL Emergency Management, the LANL Hazardous Materials Team, and the Los Alamos Fire Department. The scenario involved a thermal runaway of an inappropriately remediated nitrate salt waste drum with a worker experiencing a concurrent incapacitating medical condition. The scenario was similar to drills conducted last month (see 1/12/17 weekly). Players and controllers identified several areas for improvement, particularly with respect to contamination control and drill conduct. Fire department personnel noted a significantly improved ability to respond and make timely rescue entry after receiving additional radiation safety information to supplement their pre-incident plans from facility personnel. Area G and Transuranic Waste Facility personnel are in the process of developing similar supplemental information for their facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 17, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 17, 2017

Transuranic Waste Management: Earlier this month, LANL issued the 2017 update to their *Enduring Mission Waste Management Plan* (see 2/26/16 weekly). The plan indicates that LANL expects to be prepared to resume shipments to the Waste Isolation Pilot Plant by September 2017. Accomplishment of this goal will require LANL personnel to complete several waste compliance reviews, as well as complete the formal readiness review process for the startup of a new nuclear operation to support the loading and shipping function. Given the status of necessary structural repairs and a required rewrite of the safety basis for the RANT Shipping Facility, shipping activities will likely need to utilize mobile loading units at either Area G or the Technical Area 55 yard.

Area G–Safety Basis: On Friday, the NNSA Field Office approved the safety basis annual update submitted last August. The update, which took the form of a letter, fulfills the regulatory requirement for an annual update contained in 10 CFR 830. However, the update does not resolve the multiple Potential Inadequacies of the Safety Analysis that have been open for many months.

Nuclear Criticality Safety: In addition to the Department of Energy’s annual report on nuclear criticality safety metrics submitted to the Board on February 1, 2017, LANL produces its own program performance metrics. LANL’s most recent report, for the period through the end of January 2017, ranked the program as “Needs Improvement,” which is defined as on a positive trajectory but only improving minimally through time towards a stable and compliant status. The report notes that no new infractions occurred in January and that the Institutional Nuclear Criticality Safety Committee completed four field observations. It also highlights concerns with procedures and postings created by the program operations staff requiring rework, as well as noting that although deemed to be safe by NNSA, three quarters of the open infractions have existed without resolution for longer than a year. The report notes total permanent analyst staffing at 19 with 10 fully qualified, including one senior qualified. These staffing levels remain well short of the need—a recent management self-assessment team identified the need for an additional 17 personnel to meet routine mission requirements.

Plutonium Facility–Infrastructure: On Tuesday, Plutonium Facility personnel entered Mode 2–Standby when maintenance personnel were unable to repair the diesel firewater pump within the applicable Technical Safety Requirement Limiting Condition for Operation completion time (see 2/10/17 weekly). On Thursday, facility personnel successfully completed repairs and post maintenance testing of the pump and returned the facility to Mode 1–Operations.

Transuranic Liquid Waste (TLW) Treatment Facility Project–Safety Basis: On Thursday, LANL submitted to the NNSA Field Office for review and approval, the Preliminary Documented Safety Analysis (PDSA) for the TLW Treatment Facility. The TLW Treatment Facility is a Hazard Category 3 facility that will replace the portion of the existing Radioactive Liquid Waste Treatment Facility dedicated to TLW treatment. The submittal letter notes that all directed actions from the Preliminary Safety Validation Report, as well as the NNSA Field Office comments on the 80% PDSA have been addressed. Further, the submittal notes that the NNSA Field Office and LANL have agreed that the PDSA is subject to a 60 working day Safety Evaluation Report approval cycle.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 24, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending February 24, 2017

Area G–Safety Basis: Last Thursday, Area G management declared a Potential Inadequacy of the Safety Analysis (PISA) concerning a weakness in the waste acceptance criteria for transuranic waste containing greater than 10 g of plutonium-238 and cellulosic wipes originating from the aqueous scrap recovery line in the Plutonium Facility. This action stemmed from the extent of condition review following the declaration of a similar PISA at the Plutonium Facility (see 2/3/17 weekly). At the fact finding, Area G personnel explained their logic that the existing safety basis adequately covered the three impacted containers currently stored at the facility and that no additional controls are necessary. However, they noted that the waste acceptance criteria would not have prevented receipt of containers that could have exceeded certain safety basis assumptions and therefore determined a need to place an additional restriction in the criteria. Interestingly, the onsite transportation safety basis already restricts transport of packages containing greater than 10 g of plutonium-238—the affected containers at Area G were the subject of a previous violation of the Technical Safety Requirements. There are also a number of additional containers in excess of this limit currently stored at the Plutonium Facility that may require remediation prior to onsite shipping.

Plutonium Facility–Safety Basis: Last Friday, the NNSA Field Office Manager approved the 2016 safety basis annual update letter submitted in May 2016. Notably, the NNSA Field Office Manager directed the LANL contractor to develop a plan to resolve all outstanding conditions of approval, directed changes, directed actions, and safety basis comments. The objective of this plan is to capture resolution of these items into a consolidated safety basis by August 3, 2017.

Chemistry and Metallurgy Research Building–Safety Basis: On Wednesday, the NNSA Field Office Manager unconditionally approved the Evaluation of the Safety of the Situation (ESS) for the PISA concerning nuclear material holdup quantities that may exceed the values assumed in the safety basis (see 10/7/16 weekly).

Area G–Safety Basis: Last Friday, the NNSA Field Office Manager approved the ESS for the flanged tritium waste containers (FTWCs) stored in Area G that may be pressurized with a potentially explosive headspace mixture of oxygen and hydrogen isotopes (see 10/28/2016 weekly). In the approval letter, the NNSA Field Office Manager concludes the FTWCs are currently in a safe configuration and requests LANL submit the final disposition plan and schedule for approval by the end of April.

Plutonium Facility–Readiness Activities: Last Friday, the management self-assessment team issued the report from their review of aqueous chloride processing and americium production capability in the Plutonium Facility (see 12/23/2016 weekly). The team determined that thirteen of the fourteen core requirements were met—the criticality safety core requirement was judged as not met. The team concluded that subject to closure of the 5 identified pre-start findings, Plutonium Facility personnel have adequately demonstrated readiness to move on to the Contractor Readiness Assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 3, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 3, 2017

Area G–Readiness Activities: On Tuesday, a Contractor Readiness Assessment (CRA) team completed their review of the Area G portion of the inappropriately remediated nitrate salt (RNS) waste processing campaign. The scope of the CRA included de-nesting the RNS waste drums from their standard waste boxes, transporting the drums to the refrigeration unit attached to the Dome 375 Permacon, and loading the drums onto a vehicle for transport to the Waste Characterization, Reduction and Repackaging Facility. During their outbrief, the team identified seven pre-start findings in the areas of radiological controls, hoisting and rigging, procedures, confined space entry, and engineering documentation. The team concluded that upon successful resolution of these pre-start issues, Area G personnel were ready to commence RNS operations.

Plutonium Facility–Infrastructure: On Wednesday, LANL personnel briefed the NNSA Field Office on the status of the Potential Inadequacy of the Safety Analysis declared for the seismic performance of cast iron and malleable iron fittings in the fire suppression system (see 4/22/16 weekly). Plutonium Facility personnel informed the field office that the sub-contractor has completed the necessary testing, modeling, and calculations and results indicate that the fire suppression system meets seismic performance category level 2, as currently specified in the safety basis. Facility personnel also indicated that in order to improve the fire suppression system's performance to safety class for seismic events as previously planned, additional modeling and analysis would have to be performed to identify necessary upgrades to meet performance category level 3.

Plutonium Facility–Conduct of Operations and Nuclear Criticality Safety: On Wednesday, a division leader conducting a walk-around identified an issue with two containers that exceeded the location's aggregate limit for soluble plutonium compounds. The limit is a temporary provision included in the safety basis stemming from the Evaluation of the Safety of the Situation associated with firewater ingress into gloveboxes. The specific limit requires operators to use approved water resistant containers for aggregate quantities in excess of 500 g of plutonium metal turnings, plutonium metal fines, plutonium metal pieces weighing less than 5 g, compounds, or dry residues. In this case, the operators incorrectly interpreted the requirement and believed they were in compliance since they had split the material—which was the dried residue of a dissolution run that had been dormant for more than 3 years—into two containers each with less than 500 g. As part of the response to the process deviation, facility management directed the over-packing of one of the items into a water resistant container. Two of the corrective actions discussed at the fact-finding involve reviewing the language of the limit for operator friendliness and emphasizing the limit in upcoming continuing training.

We note this event underscores the need to establish gloveboxes with compliant nuclear criticality safety limits that allow work with greater than 500 g of compounds. In particular, the facility has nearly 1500 items totaling about 365 kg of nuclear material that is impacted by this limit. Much of this material is categorized as No Defined Use and will require some amount of handling prior to disposition. Currently, development of an appropriate nuclear criticality safety evaluation is scheduled for completion in the first quarter of fiscal year 2018 due to higher priority actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 10, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 10, 2017

DNFSB Activity: Chairman Sullivan and Vice Chairman Hamilton visited the laboratory on Monday through Wednesday. They walked down wings 5, 7, and 9 at the Chemistry and Metallurgy Research Building; rooms in each of the processing areas, the basement, the vault, and some of the outdoor areas at the Plutonium Facility; the Weapons Engineering Tritium Facility; and observed federal readiness assessment (FRA) activities at the Waste Characterization, Reduction, and Repackaging Facility (WCRRF). In addition, they held discussions with the NNSA Field Office Manager and the LANL Deputy Director.

WCRRF–Readiness Activities: On Monday, the FRA team commenced their review of the WCRRF facility and personnel to safely accomplish the treatment of the inappropriately remediated nitrate salt wastes. The team, which is composed of DOE Environmental Management personnel, conducted interviews and observed demonstrations of the waste receipt process and the drum bag-on and bag-off process. For the latter, the team noted stellar command and control practices by the operations crew. On Thursday, operations personnel were preparing to commence an evolution to demonstrate the glovebox-based treatment process when an unplanned loss of electrical power occurred. Facility personnel responded appropriately and have begun troubleshooting the issue. At this point, the impact on the FRA schedule is unknown.

Area G–Safety Basis: On Thursday, the NNSA Field Office Manager unconditionally approved the Evaluation of the Safety of the Situation (ESS) that LANL submitted on May 13, 2016, related to discrepancies in the transuranic waste inventory (see 5/20/16 weekly). This ESS addressed three open Potential Inadequacy of the Safety Analyses—the first of which was declared on December 3, 2014, subsequent to questions raised by the Board’s staff (see 12/5/14 weekly). The primary issue addressed by the ESS were errors in the assumed composition of the waste and its related dispersal properties in a fire. The ESS corrected these errors based on a comprehensive review of the as-found waste inventory, which resulted in changes in consequences for 14 postulated accident scenarios and changes in the details associated with 16 Specific Administrative Controls. The changes in controls primarily involve inventory limits and spacing distances associated with each of the various processes and storage areas with the overall aboveground transuranic waste inventory reduced from 57k to 39k plutonium-239 equivalent curies. Notably, implementation of this ESS is expected to eliminate the postulated aircraft crash accident that results in public consequence in excess of the DOE Evaluation Guideline. LANL previously proposed a 90 day implementation schedule, subject to additional refinement, needed to implement this ESS, primarily due to the need to move about 500 waste containers.

Unremediated Nitrate Salt (UNS) Waste–Safety Basis Strategy: Last Friday, the NNSA Field Office Manager transmitted a letter concurring with LANL’s proposed safety basis strategy and treatment plan for the 29 UNS waste containers currently stored in Area G (see 1/27/17 weekly). In the concurrence letter, the manager also approved LANL’s request to commence preliminary activities necessary to support the UNS treatment campaign.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 17, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 17, 2017

DNFSB Staff Activity: On Wednesday and Thursday, a staff team participated in teleconferences with LANL and NNSA personnel, and members of a seismic expert panel to discuss the details of planned seismic analyses and testing for the Plutonium Facility. Also on Thursday, P.J. Migliorini participated in a teleconference with NNSA, EM and LANL personnel to discuss the current status of the Potential Inadequacy of the Safety Analysis for the flanged tritium waste containers in Area G that may be pressurized with a potentially explosive headspace mixture of oxygen and hydrogen isotopes.

Chemistry and Metallurgy Research (CMR) Building–Safety Basis: The NNSA Field Office Manager recently approved LANL’s submittal of the 2016 annual update to the CMR safety basis. This annual update incorporates a temporary modification that was implemented to support cleanout of the confinement vessels currently stored in Technical Area 55. Additionally, this update closes the only open Evaluation of the Safety of the Situation in the safety basis that was developed for a glovebox found to be inappropriately excluded from the Technical Safety Requirements.

On Thursday, LANL submitted a safety basis temporary modification to the NNSA Field Office for review and approval. The temporary modification revises a previous safety basis change for receipt and storage of a package containing americium-241 (see 1/8/16 weekly). LANL proposes a two phased approach to ensure continued safe storage and ultimate recovery of the isotope for beneficial use. In this temporary modification, LANL identifies Phase 1 activities to include venting and sampling of the existing outer containers holding the material, as well as unpacking and repacking the seven inner containers into individual new outer containers. LANL will perform non-destructive assay and radiography of the inner containers to better characterize their contents and then develop a Phase 2 plan to open the inner containers to recover their contents.

Waste Characterization, Reduction, and Repackaging Facility–Readiness Activities: The Federal Readiness Assessment team continues to evaluate facility and personnel readiness to safely accomplish the treatment of the inappropriately remediated nitrate salt wastes (see 3/10/17 weekly). The team is extending their assessment activities into next week due to last week’s unplanned loss of power and glovebox discrepancies identified by facility personnel this week.

Federal Oversight: On Friday, the review team for the Chief of Defense Nuclear Safety briefed the results of their biennial review of the NNSA Field Office. The 25 member team had been performing aspects of their review since early January (see 1/7/17 weekly). The team identified numerous issues, including four high-level management concerns that cross-cut multiple functional areas. These management concerns cover areas associated with oversight procedures, issues management, staffing, and nuclear safety. Of note, many of the issues overlap with previously identified problems that already have corrective actions underway (e.g., last summer’s organizational health assessment).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 24, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 24, 2017

Federal Oversight: On Tuesday, the NNSA Field Office Manager signed out the annual work force and technical staffing plan. Overall, the plan identifies the need for increased staffing.

Support to Pantex: Weapons response personnel recently commenced a series of experiments to address questions concerning the potential for safety impacts to nuclear explosives operations if a Pantex technician were to fall toward an assembly while carrying various pieces of tooling. The test reports are expected in about a month.

Waste Characterization, Reduction, and Repackaging Facility–Readiness Activities: Last Saturday, the Federal Readiness Assessment team briefed the results of their review. As briefed, the team found that all 23 functional area objectives were met; however, they identified 15 pre-start and 6 post-start findings. Pre-start findings of interest include: questionable ability to notify nearby workers of emergency conditions; maintenance work control documents that include broad provisions to adjust task sequence; and procedural and radiological posting deficiencies. Notably, the assessment team leader complimented the treatment team’s embracement of safety culture and commitment to disciplined operations, while noting them to be among the best that he has seen in the Department of Energy.

Emergency Management–Federal Oversight: The NNSA Field Office Manager recently transmitted to LANL the fiscal year 2017 emergency management program element assessment plan. The plan identifies five program elements to be assessed independently by the field office emergency management program manager including: (1) technical planning basis; (2) emergency exercise; (3) training and drills; (4) emergency public information; and (5) program administration. This action is intended to ensure the field office meets the requirement to conduct independent assessments of all 15 emergency program elements every 3 years, consistent with DOE Order 151.1C, *Comprehensive Emergency Management System*.

Plutonium Facility–Safety Basis: Last Friday, LANL management transmitted to the NNSA Field Office for approval the Evaluation of the Safety of the Situation (ESS) regarding concerns associated with the use of cheesecloth in plutonium-238 operations, specifically the lack of rinsing these materials as stated in the approved safety basis (see 2/3/17 weekly). The ESS summarizes recent LANL thermal studies on temperatures produced in pipe overpack containers with varying quantities of plutonium-238. These results justify the 10 g limit established as part of the initial operational restrictions. Accordingly, the ESS proposes to codify this limit as a Specific Administrative Control to minimize the likelihood of fires associated with cheesecloth and plutonium-238. The reduced loading limit also translates into low potential radiological consequences.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 31, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending March 31, 2017

Inappropriately Remediated Nitrate Salts (RNS) Wastes–Startup Activities: Last Friday, the Associate Director for Nuclear and High Hazard Operations (ADNHHO) approved startup of the RNS denesting and cold-safing activity in Area G. On Thursday, Area G personnel successfully commenced this activity with the removal of the first two RNS drums from their standard waste boxes and subsequent placement into the freezer unit. Area G personnel hope to load eight additional containers into the freezer in the coming week while corrective actions are completed and verified in advance of the startup of treatment activities in the Waste Characterization, Reduction, and Repackaging Facility (WCRRF).

WCRRF–Safety Basis: After contemplating feedback from the federal readiness assessment team, facility personnel decided to pursue authorization to use an electric forklift to unload the RNS containers from the transportation vehicle. Accordingly, on Wednesday they transmitted for approval to the NNSA Field Office a temporary modification to the safety basis. The modification enumerates eight benefits of using an electric forklift as compared to the currently authorized electric drum stacker, including reduction on the amount of manhandling required of the RNS drums, improved operator proficiency and efficiency, and the avoidance of the awkwardness of two people handling a drum at a slight angle with up to a 2000 lbs combined load. To address the potential hazard posed by the electric forklift, the modification proposes four new Specific Administrative Controls regarding forklift inspection prior to use and allowed locations for the electric forklift.

Confinement Vessel Disposition (CVD) Project: On Thursday, CVD personnel completed cleanup and closure of the fifth vessel. This vessel differed from the previous vessels in that it contained impact mitigation material resulting in the generation of 73 transuranic waste drums—a substantially greater number than the previous vessels. The remaining four vessels also contain various impact mitigation materials. CVD personnel expect to receive the sixth vessel in mid-April.

Plutonium Facility–Infrastructure: On Tuesday, facility operations personnel were performing the weekly surveillance on the west pump house diesel firewater pump when they observed elevated temperatures and the release of smoke and steam from the packing gland. They had replaced the gland the previous week after discovery of an unsatisfactory drip rate. At the fact-finding, they were unable to conclusively determine the cause of the failure. However, they discussed the need to re-instate past practices of pre-soaking the gland material prior to installation and allowing additional post-installation soak time prior to operating the pump. The manufacturer does not specify the need for either of these steps. Personnel replaced the packing and successfully returned the pump to service on Wednesday.

Conduct of Operations: On Wednesday, the ADNHHO briefed the NNSA Field Office on a planned initiative to institute a bi-monthly operational performance forum. The forum is designed to bring senior leadership from LANL and the NNSA Field Office together to discuss performance improvement initiatives, as well as selected operational events and associated follow-up actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 7, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 7, 2017

We were at DNFSB Headquarters this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 14, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 14, 2017

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Safety Basis:

Last Thursday, the NNSA Field Office Manager, with concurrence from NNSA and DOE-EM Headquarters personnel, unconditionally approved the safety basis change related to the use of an electric forklift for handling of the inappropriately remediated nitrate salt (RNS) waste drums (see 3/31/17 weekly).

WCRRF–Engineering: Last Wednesday, the facility experienced its second momentary loss of electrical power in a month. The previous loss of power occurred as personnel were preparing to commence a performance demonstration as part of the federal readiness assessment (see 3/10/17 weekly). In both cases, the response of facility personnel was appropriate; however, the electrical distribution systems did not respond as intended. In the first instance, the uninterruptible power supply (UPS) did not function properly. In the second instance, the UPS functioned but the automatic transfer switch indicated several potential anomalies. Given the high priority associated with commencing the RNS treatment campaign, LANL senior management has engaged in this situation and placed several additional institutional resources on the problem. They are also pursuing vendor support and installation of additional monitoring devices to augment their typical troubleshooting activities.

Area G–Safety Basis: On Wednesday, the NNSA Field Office returned comments to LANL management pertaining to the technical inadequacy of the Evaluation of the Safety of the Situation (ESS) concerning the Flanged Tritium Waste Containers (FTWCs) with potentially explosive headspace mixtures of oxygen and hydrogen isotopes (see 10/28/16 weekly). The NNSA Field Office identified deficiencies that included: an incorrect energy threshold for ignition that potentially challenges the need to further consider hazards from wind-driven vibrations; inadequate technical bases supporting the exclusion zone distance of 50 feet for protection from projectiles; and insufficient bases to exclude the potential for deflagration to detonation transition.

On Thursday, LANL submitted to the NNSA Field Office for review a set of proposed milestones for high-level actions to be taken to mitigate the hazard posed by the Area G FTWCs. In the proposal, LANL notes that a process hazard analysis will be completed by May 5, 2017, that will determine whether the FTWCs will be safely stored in place or remediated for offsite disposition. LANL indicates that if the offsite disposition path is followed an adequate control set will have to be developed and an updated ESS will have to be approved, and estimates remediation could be completed by September 2018.

Plutonium Facility–Safety Basis: As directed by the NNSA Field Office Manager, LANL submitted a plan and schedule for resolving by August 3, 2017, all outstanding conditions of approval, directed changes, directed actions, Field Office comments and open ESSs that affect the Plutonium Facility safety basis (see 2/24/17 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 21, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 21, 2017

DNFSB Staff Activity: J. B. Weathers observed the Generator Site Technical Review (GSTR). The GSTR is one of several actions that LANL will need to complete in order to resume shipping transuranic waste to the Waste Isolation Pilot Plan. R. Wu and P. J. Migliorini augmented oversight and observed portions of the contractor readiness assessment (CRA) discussed below.

Plutonium Facility–Readiness Activities: On Tuesday, the CRA team commenced their review of aqueous chloride and americium production activities. The planned two week review will cover the restart of aqueous chloride operations including size reduction, dissolution, solvent extraction, and anion exchange, as well as new start activities including americium precipitation, calcination, and packaging and handling.

Plutonium Facility–Fire Event: On Wednesday morning, three operators encountered a pyrophoric materials fire associated with a black powder that they had minutes earlier emptied in a plastic bag from a number of unlabeled legacy containers as part of a facility-wide housekeeping day. Upon discovery, an operator attempted to place the bag into a metal container when the bag conflagrated, causing minor burns to several fingers. He then pushed the cart containing this material to the front of the room away from the glovebox line and smothered the fire using an appropriate handheld extinguisher. The operators called 911, exited the room, and made additional notifications in accordance with procedure. After some thought, programmatic personnel determined the material likely to be lanthanum nickel hydride, which they believed had been used as a hydrogen storage bed for activities roughly 20 years ago. Following this determination, personnel from the LANL Hazardous Materials team were able to stabilize the material without further incident. There was no radioactive release or contamination involved in this fire. At the associated fact-finding, facility and emergency response personnel discussed issues including: protocol for the need to receive permission from the New Mexico Environment Department prior to stabilizing the material; uncertainty on roles and responsibilities and nomenclature regarding incident command; the need to clearly define the scope of approved housekeeping activities; and declared the need for another corner-to-corner inventory for legacy items.

Waste Characterization Remediation and Repackaging Facility–Engineering: On Tuesday, facility personnel held a second fact-finding to discuss the results of troubleshooting activities associated with the recent loss of power events (see 4/14/17 weekly). They discussed completed actions to perform thermography, examine and replace breakers, test cabling, and receive vendor support for the automatic transfer switch (ATS). Based on feedback from the vendor and review of the ATS data log, they concluded that tolerances for certain parameters on the incoming power were overly restrictive. As a result, minor fluctuations would cause the ATS to switch from line to neutral, but return to line prior to engagement of the diesel causing a brief loss of power. Engineers were able to replicate this scenario and have since properly adjusted the parameters. Facility personnel also installed and will be reviewing data from additional power monitors up and downstream of the ATS.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 28, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending April 28, 2017

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Readiness:

LANL continues to make progress toward startup of WCRRF to enable processing of the inappropriately remediated nitrate salt (RNS) wastes currently stored in Area G. On Thursday, the Associate Director for Nuclear and High Hazard Operations (ADNHHO) submitted to the Startup Authorization Authority for review and approval a request to commence WCRRF operations in a two-phased approach. Included in the request was the causal analysis and final corrective action plan for the WCRRF federal readiness assessment (FRA), as well as the objective evidence files for the closure of FRA pre-start findings. The ADNHHO request notes that one pre-start finding remains open—the process for treating the RNS waste has not been approved by the National TRU Program and Environmental Management Headquarters as required. The ADNHHO proposes phase 1 of the WCRRF startup would allow processing of surrogate materials in the Waste Characterization Glovebox with the facility in OPERATIONS MODE. Phase 2 of the startup would allow receipt of the RNS waste from Area G and would allow processing of the waste following approval of the treatment process.

WCRRF–Electrical Distribution System (EDS): LANL engineering personnel have identified additional issues with the WCRRF EDS following the adjustments made to the automatic transfer switch last week (see 4/24/17 weekly). Most recently, the WCRRF operations center, which is in an adjacent building to the main processing area, lost power unexpectedly. Notable loads that were lost include the waste management tracking database and the video monitors installed in WCRRF to observe RNS treatment activities. Engineering personnel conducted troubleshooting that revealed the transformer feeding the operations center building was not bonded, the building’s power panel had a loose connection on the main neutral, and the breaker for one phase of the main feed was not making proper contact. These issues were all addressed and the system returned to service. Of note, the automatic transfer switch data loggers indicated discrepancies with the phase feeding the operations center building that had occurred prior to the repairs being made. Engineering personnel will continue to monitor the data loggers into next week to see if the repairs have successfully eliminated the anomalies prior to completing the system operability determination.

Plutonium Facility–Infrastructure: On Tuesday, facility personnel were performing the weekly surveillance on the west pump house diesel firewater pump when the diesel unexpectedly shut down. Operations personnel entered the appropriate Technical Safety Requirement Limiting Condition for Operations and have commenced troubleshooting activities.

Transuranic Waste Facility (TWF)–Readiness Activities: Last Friday, a management self-assessment team briefed the results of their assessment of TWF readiness to begin operations. During the brief, the team identified 24 pre-start and 9 post-start findings as well as 5 noteworthy practices. The team also commended the workers’ professionalism and willingness to pause or stop work when the unexpected occurs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 5, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 5, 2017

Waste Characterization Reduction and Repackaging Facility–Restart: Last Friday, the NNSA Field Office approved the corrective actions from the federal readiness assessment regarding the treatment of the inappropriately remediated nitrate salt (RNS) waste. Additionally, they granted LANL management permission to commence a phased startup of treatment activities. The approval letter notes that one pre-start finding associated with Department of Energy approval of the treatment procedure remains outstanding. As such, LANL is authorized to perform phase 1 of the startup plan involving the treatment of surrogate wastes. LANL must notify NNSA and EM managers prior to phase 2 activities with the actual RNS wastes. On Tuesday, program personnel commenced processing of the first container of surrogate waste. They plan to process at least two additional containers of surrogate next week.

Area G–Emergency Management: On Thursday, Area G personnel conducted an instructional emergency drill against their procedure for potential wildland fire impacts to the RNS waste containers currently stored in the Dome 375 Permacon. The procedure directs actions related to the Permacon ventilation system and the installation of fire blankets on the RNS containers. Separately, Area G personnel recently completed turnover for the backup electric diesel generator for the Permacon.

Plutonium Facility–Readiness Activities: Last Friday, the contractor readiness assessment team briefed the results of their review of aqueous chloride and americium production activities. The team identified two pre-start findings on training associated with the response to a process deviation and operations center actions during criticality alarm testing. Additionally, there are three self-identified pre-start findings regarding the calibration of tanks and the need to consider the caustic waste liquid discharge from the chloride processes as part of the technical basis for criticality safety at the Radioactive Liquid Waste Treatment Facility.

On Tuesday, the NNSA Field Office responded to a request from LANL management to re-evaluate the readiness activities associated with startup of the new electrorefining line and the startup of a new mobile loading activity for offsite shipment of transuranic waste. In both cases, the field office overruled LANL's proposal for performing only management self-assessments and determined that appropriately scoped federal readiness assessments were warranted.

Plutonium Facility–Infrastructure: Last Friday, facility management accepted for operation the new Criticality Alarm System, one of the sub-projects associated with Phase II of the TA-55 Reinvestment Project. Project personnel expect to complete some additional modifications to the previous system in order to retain the capability for remote area radiation monitoring. On Tuesday, the west safety class diesel firewater pump failed its weekly surveillance test when it tripped offline and did not restart. A similar problem occurred with this same pump last week. They are currently troubleshooting and plan to hold a fact-finding on the situation next week. On Wednesday, an engineer photographing penetrations in the safety class confinement structure observed rays of sunlight coming through one of the penetrations. It is unlikely that the engineer would have noticed this breach except for the particularly dark location of this penetration. Facility staff responded appropriately and repaired the condition in the afternoon.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 12, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 12, 2017

Fire Protection: Two small fires occurred at the laboratory this week—one at the Los Alamos Neutron Science Center and the other at the Sigma Complex. In both instances, lab employees extinguished the fire; however, notification to the fire department was delayed in the first instance and did not occur in the second. In particular, the fire at Sigma Complex involved an activity with depleted uranium metal turnings performed under an integrated work control document that provided workers with an allowance to avoid calling the fire department if they were able to extinguish the fire using graphite powder or machining coolant. In response to these events, fire protection personnel are reinforcing the need to contact the fire department as part of training and procedures.

Emergency Management: On Thursday, LANL personnel conducted their annual full-scale emergency exercise. This year's scenario involved a simulated spill of chromic acid with a concurrent fire at the Sigma Complex that resulted in chemical burns to two individuals and smoke inhalation to an additional six. In an attempt to reduce simulation, fire department responders utilized breathing apparatus and transported mannequins as victims. At the hotwash, several participants highlighted the benefits from recent training, tabletops, and drills. Additionally, NNSA Field Office performed an independent evaluation of the exercise utilizing additional experts from the NNSA Office of Emergency Operations and the Carlsbad Field Office.

Waste Characterization Reduction and Repackaging Facility–Restart: On Monday, while preparing equipment to treat the second container of surrogate waste, operators observed a potential crack in the waistband associated with the drum lifting fixture on the waste characterization glovebox. As a result, operators entered the limiting condition of operation for this credited equipment. On Thursday, operators executed a work package to replace the waistband thereby restoring the operability of the drum lifting fixture. They continue to troubleshoot a separate issue with the limit switch for the lift.

The EM and NNSA Field Offices have implemented a federal oversight plan for LANL's processing of the remediated nitrate salt waste drums. The plan ensures continuous federal coverage for the processing of two surrogate and the first ten remediated nitrate salt waste drums.

Plutonium Facility–Safety Basis: On Wednesday, LANL submitted to the NNSA Field Office for approval, an update to the plan and schedule for resolving all outstanding conditions of approval, directed changes, directed actions, Field Office comments and open evaluations of the safety of the situation that affect the Plutonium Facility safety basis (see 4/14/17 weekly). LANL submitted the update to provide specific dates for closure of outstanding items. LANL's update also proposes to submit for approval no later than August 31, 2017, a project plan for incorporating into the safety basis the most recent site meteorological data and an updated strategy for fire and leak path factor modeling.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 19, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 19, 2017

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: This week, after more than three years of investigation and testing, process and safety basis development, and readiness activities, LANL workers successfully treated the first RNS waste drum to remove its ignitability characteristics. Last Friday, the EM Deputy Assistant Secretary for Safety, Security, and Quality Assurance approved a request from the EM Field Office Manager to close the last two judgements of need from the LANL corrective action plan for the February 2014 radiological release event at the Waste Isolation Pilot Plant. On Wednesday, LANL personnel transferred three RNS containers from the refrigerator in the Dome 375 Permacon to the refrigerator at the Waste Characterization Reduction and Repackaging Facility (WCRRF). On Thursday, WCRRF operators successfully treated the contents of one RNS drum, and on Friday they removed from the glovebox used for treatment one drum of treated RNS, one drum of debris, and the empty parent drum that originally contained the RNS waste. LANL personnel will leverage some lessons learned during the processing of this first drum to gain efficiencies and improve the treatment procedures. WCRRF personnel are scheduled to commence treatment of the second RNS drum next Monday. LANL’s current schedule predicts completion of the RNS campaign in early August.

WCRRF–Safety Basis: On Tuesday, LANL submitted to the NNSA Field Office for review and approval, a revision to the WCRRF Basis for Interim Operation and Technical Safety Requirements to support processing the 29 unremediated nitrate salt (UNS) waste containers currently stored in Area G. LANL plans to commence treatment of the UNS waste immediately following the RNS campaign with a goal of completing all remediation before Area G contract turnover scheduled for the end of this fiscal year.

Transuranic Liquid Waste (TLW) Treatment Facility Project: On Thursday, the NNSA Field Office approved LANL’s submittal of a revised Safety Design Strategy for the TLW treatment facility. In the approval letter, NNSA directed LANL to: 1) design and construct the TLW active confinement ventilation system using the American Society of Mechanical Engineers Code on Nuclear Air and Gas Treatment, and 2) perform a cost benefit analysis between using the most current version of DOE Standard 3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analyses*, and its predecessor version issued in 1994 which is currently in the code of record. Of note, the NNSA Field Office and LANL management incorporated the 2014 version of the standard into the contract as part of modification 359, which was jointly approved on August 11, 2016.

Plutonium Facility–Confinement: On Thursday, an NNSA Facility Representative identified two conduits penetrating the facilities confinement boundary to be loose. Facility personnel entered the appropriate Limiting Condition for Operations (LCO) and subsequently sealed the penetrations. Also on Thursday, facility personnel identified a broken hinge pin on a facility confinement door latch to be broken. Facility personnel again entered the appropriate LCO and have commenced repair work.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 26, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending May 26, 2017

DNFSB Staff Activity: D.K. Andersen, M.W. Dunlevy, R.L. Jackson, and P.J. Migliorini were at the laboratory this week to review the status of several efforts associated with the Plutonium Infrastructure Strategy. M.W. Dunlevy and P.J. Migliorini also observed treatment activities associated with the inappropriately remediated nitrate salt (RNS) wastes and walked down three radiological facilities.

RNS–Treatment Activities: Waste Characterization Reduction and Repackaging Facility (WCRRF) personnel successfully treated a second RNS container this week. However, they encountered several challenges and issues that prolonged the treatment of this drum, including:

- Substantial debris that was expected based on radiography of the container, but at times became challenging for operators to manage in the limited space of the glovebox
- Difficulty macerating cellulosic wipes in the blender because they were too dry, which is a pre-requisite to ensure effective mixing with zeolite as part of the treatment process—resolution of this issue necessitated a procedure change to pre-soak the wipes
- An unexpected large area cloth wipe that required the use of the manual cloth treatment section of the procedure
- Poor control of the pedigreed zeolite feed material that resulted in the need to retreat some material
- Several procedural issues, including instances where workers paused, as well as one instance when Department of Energy Headquarters oversight prompted the proper response

Following completion of the container on Friday, management conducted a lessons-learned discussion with the workers. Also this week, workers at WCRRF received two additional RNS containers and returned three daughter transuranic waste containers back to Area G.

Plutonium Facility–Infrastructure: On Monday, Plutonium Facility personnel held a fact-finding to discuss last week’s discovery of two degraded confinement penetrations (see 5/19/17 weekly). This was the second instance of degraded confinement penetrations discovered this month (see 5/5/17 weekly). The confinement structure is a safety class system that is relied upon to mitigate the release of radioactive material to the environment. The safety basis notes that the penetrations are to be air and watertight with an associated performance criterion to be sealed with a through-penetration assembly that is appropriately pedigreed with a 2-hour fire rating. Fact-finding participants viewed images and video of the degraded penetrations that revealed one conduit had about an inch of horizontal travel and both had about 60 degrees of spin. Workers noted that the condition was discovered when an NNSA Facility Representative incidentally handled the conduit on a walk-down focused on an unrelated matter. Of note, in all three instances, the penetrations would have likely passed the required visual in-service inspection. In response to this apparent weakness, facility management is evaluating whether a sampling of other penetrations is warranted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 2, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 2, 2017

DNFSB Staff Activity: On Wednesday, B.K. Caleca, M.W. Dunlevy, P.J. Foster, P.J. Migliorini, and J. Parham conducted a teleconference with Transuranic Waste Facility project personnel to discuss the results of their review of the commercial grade dedication process for the Seismic Power Cutoff System.

Area G–Emergency Management: On Wednesday, Area G personnel conducted their annual emergency exercise. This year’s scenario involved the collision of a truck with a forklift resulting in four breached transuranic waste drums and two injured workers. Participants included Area G personnel, the LANL Emergency Management and Response organizations, and the Los Alamos County Fire Department. Evaluators will hold their critique next Monday.

Emergency Management: On Wednesday, two post-doctoral researchers at the TA-48 Radiochemistry facility observed flames from the depleted uranium metal turnings that they were cleaning with nitric acid in a fume hood. The researchers choose not to fight the fire, closed the hood sash, pulled the fire alarm, and contacted 911. The Los Alamos County Fire Department, LANL emergency management, and the LANL hazardous materials team responded. No radioactive contamination, injuries, or damage beyond the containment tray in the fume hood occurred. Facility, program, and emergency response personnel held a fact-finding on Thursday to discuss the response. Of relevance to the broader emergency management program at the laboratory, several individuals indicated that they did not receive a mass notification message to stay clear of TA-48 because the notification is based on office location and some TA-48 users have their offices in other locations. No corrective action was assigned for this point. Facility personnel discussed challenges using their accountability process during the lunch hour and proposed to review the process and conduct a future accountability drill. Management also concluded that the fire did not meet Department of Energy reporting criteria for a fire and instead reported the event as a management concern.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office Manager conditionally approved a temporary modification to the safety basis associated with the mobile loading of transuranic waste containers. This new activity provides the capability for Plutonium Facility personnel to directly load transuranic waste containers for offsite shipment to the Waste Isolation Pilot Plant—similar to the RANT Shipping Facility. The condition of approval prohibits assembly of payloads that include pipe overpack containers until such time that the accidents involving these containers are re-evaluated using the results of the ongoing testing efforts. The approval letter also stipulated that the temporary modification expires in two years and directs LANL to include the contents of the temporary modification in the next annual update of the safety basis.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: Waste Characterization, Reduction, and Repackaging Facility workers successfully treated two RNS drums. On Thursday, they received two additional RNS drums and returned three daughter transuranic waste drums to Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 9, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 9, 2017

DNFSB Activity: On Tuesday, Board Member Santos discussed the state of emergency preparedness and response with managers from the NNSA Field Office, LANL, and the Los Alamos County Fire Department. On Wednesday, Board Members Sullivan, Hamilton, Connery, and Santos received a briefing at the laboratory concerning the nuclear material inventory in the Plutonium Facility. That evening, they conducted a public hearing in Santa Fe regarding the safety posture of the Plutonium Facility.

DNFSB Staff Activity: Hanford Resident Inspector D.M. Gutowski observed the federal readiness assessment discussed below. M.W. Dunlevy was on site to support the Board visit and to observe the readiness assessment.

Transuranic Waste Facility (TWF)–Startup Activities: On Monday, a contractor operational readiness review team commenced their assessment of the TWF to commence nuclear operations. The review is scheduled to be completed next week and is to include performance demonstrations, various interviews, and an emergency exercise.

Plutonium Facility–Safety Basis: Late last month, LANL submitted to the NNSA Field Office for review and approval the 2017 annual update to the safety basis. In addition to this document, the safety basis document list currently indicates that the facility is operating under three versions of the Documented Safety Analysis and two versions of the Technical Safety Requirements.

Plutonium Facility–Readiness Activities: NNSA conducted a federal readiness assessment for the restart of aqueous chloride operations and the new start of americium oxide production capabilities (see 4/21/17 weekly). The review team concluded that the contractor is ready to begin these operations following completion of corrective actions for one prestart finding. The finding involves a lack of documentation to protect accident analysis assumptions in the safety basis associated with the mass of americium-241 used in this operation.

Federal Oversight: Last Wednesday, the DOE-EM Deputy Assistant Secretary for Safety, Security, and Quality Assurance approved a memorandum delegating specific safety authority approvals to the EM Field Office Manager. In the approval letter, the Deputy Assistant Secretary notes that because the EM Field Office is not yet fully staffed compensatory measures are necessary to ensure adequate subject matter expertise is used to support execution of the delegated safety authorities.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: This week, Waste Characterization, Reduction, and Repackaging Facility personnel successfully treated two more RNS waste drums for a total of six drums treated to date. They also received two additional RNS drums and returned 15 daughter transuranic waste drums to Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 16, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 16, 2017

Transuranic Waste Facility (TWF)–Emergency Management: On Tuesday, TWF personnel conducted their annual emergency exercise. The scenario involved a pool fuel fire from the transportation vehicle that engulfed a load of 16 transuranic waste drums. Notably, this was the third exercise that involved a new rigorous and comprehensive approach to the player hot-wash and evaluator critique. For the latter, evaluators met for more than three hours to develop a common understanding of the timeline for significant events and discuss issues and best practices for each of the response elements. A sampling of the issues they self-identified include: workers in the yard mustered in a location downwind of the fire; fire department assets also approached from downwind; there is not a fire hydrant in proximity to the south entrance; the fire department’s map lacked indication of hydrants; the need to include more subject matter experts in the exercise design and evaluation process; and the need to exercise, instead of simulate, the deployment of additional radiological control technicians (RCT) from other facilities. Fire department personnel also noted the benefits of the realism achieved by using an actual truck and smoke generator over past simulations.

Conduct of Engineering: On Tuesday, LANL management informed the NNSA Field Office that they intend to discontinue by the end of the month the practice of conducting vital safety system assessments for passive safety systems. They note that there is no requirement for this practice and assert that the ongoing system health reporting and in-service surveillance processes remain robust and effective.

Plutonium Facility–Infrastructure: Facility engineers recently completed their evaluation of the need to further examine a sampling of penetrations in the safety class confinement. They determined that six penetrations will be examined by August 11, 2017. This is a corrective action in response to earlier discoveries of three penetrations with degraded seals that would have otherwise passed the visual inspection criteria (see 5/26/17 weekly).

Plutonium Facility–Readiness Activities: During the past eight days, facility personnel have performed a series of assessments to determine readiness to perform mobile loading of TRUPACT II waste containers. Startup of this activity will allow operators to load transuranic waste from the high-efficiency neutron counter pad at Technical Area-55 and ship the waste directly to the Waste Isolation Pilot Plant (WIPP). The ability to ship transuranic waste directly to WIPP is essential while the RANT Shipping Facility is non-operational due to ongoing seismic and safety basis upgrades. On Friday, a contractor readiness assessment team out-briefed the results of their review and identified one pre-start finding concerning missing elements and inaccuracies with the critical lift plan, which is identified in the safety basis as a Specific Administrative Control.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: This week, Waste Characterization, Reduction, and Repackaging Facility (WCRFF) personnel successfully treated two more RNS waste drums, including the sibling of the drum involved in the radiological release event at the WIPP, for a total of eight drums treated to-date. Processing activities have taken more than a single day for each of the eight drums. Subsequently, WCRFF management recently modified their implementation practices for the stationary fire watch, which is required when a parent drum remains in process during off-hours. The new process relies on the fire watch using a camera system supplemented with hourly facility entries and, if needed, assisted by an RCT on call within two hours.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 23, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 23, 2017

DNFSB Staff Activity: On Thursday, M.W. Dunlevy and P.J. Migliorini conducted a teleconference with staff from the NNSA Field Office to discuss questions related to the safety basis provisions for the storage and mobile loading of transuranic waste at TA-55 outdoor pads.

Transuranic Waste Facility–Startup Activities: Last Friday, the 13 member contractor operational readiness review team out-briefed the results of their assessment. They identified five pre-start findings associated with: (1) procedural control of hand placement during a loading evolution; (2) premature declaration of readiness in the functional areas of operations, procedures, and radiation protection; (3) lack of formality in execution with in-service inspections; (4) lack of adequate procedural field validation; and (5) improper radiological controls coverage during evolutions and the emergency exercise. The post-start finding involved issues with preventive maintenance evaluation and implementation. Overall, the team concluded that 15 of 17 primary objectives were met and that the issues with procedures and operator performance can be corrected through proper use of existing LANL programs.

Plutonium Facility–Infrastructure: On Tuesday, NNSA Field Office personnel in-briefed their assessment of the safety-class firewater pumps. The purpose of the review is to assess the adverse trend of numerous outages with the pumps and the associated risk to the reliability of the safety-class control. They expect to issue a report in August 2017.

Plutonium Facility–Criticality Safety: Last Friday, nuclear criticality safety personnel, including some newer staff members, were walking-down a room with a safe containing nuclear material to assess concerns regarding housekeeping when they observed a piece of shielding affixed to one side of the safe. They were unable to find evidence that this condition had been evaluated, as required by the posting, and declared a process deviation. At the fact-finding, personnel determined that the as-found configuration, including consideration of the current nuclear material contents, was safe and that they would add the shielding issue to the other two infraction issues associated with this safe's out-of-service condition. They also noted that the shielding had not been detected on the last two annual walk-downs and decided to further evaluate the need for an extent of condition review and a change to the walk-down checklist.

Area G–Safety Basis: On Monday, the NNSA Field Office issued direction to LANL regarding the need for an additional compensatory measure associated with the safe storage of the Flanged Tritium Waste Containers with potentially pressurized and flammable headspaces. The new compensatory measure requires LANL personnel to utilize appropriate protective equipment should there be a need to enter the 50 foot exclusion zone during emergency conditions. The Field Office observed the need for this control after a LANL worker approached the shed without any protective equipment in order to close a door that had opened.

On Thursday, the NNSA Field Office denied approval of the Evaluation of the Safety of the Situation (ESS) submitted on July 8, 2016, regarding the Potential Inadequacy of the Safety Analysis associated with the behavior of certain sealed sources in fire events (see 4/29/16 weekly). They requested that the laboratory resubmit the ESS within 120 days to improve the rigor and quality of the fire analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 30, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending June 30, 2017

DNFSB Staff Activity: M.R. Bradisse, R.C. Eul, N.M. George, J. McKamy, and P.J. Migliorini were at the laboratory this week to review the effectiveness of actions taken to improve nuclear criticality safety and conduct of operations at the Plutonium Facility.

Emergency Management: Last Thursday, LANL issued the after-action report for this year's full-scale exercise (see 5/12/17 weekly). This is the first such report issued after strengthening the evaluation process to achieve an improved level of self-criticism. Evaluators determined that 10 out of 126 applicable objectives were unmet, including 8 findings. Findings of note include: the Emergency Manager incorrectly selected the Emergency Action Level (EAL) based on indicators from the facility—the report further notes that the EALs are confusing and difficult to navigate; Protective Action Recommendations for the public were not issued in accordance with the EAL; Occupational Medicine staff failed to implement measures to manage potential contamination; and the site-wide mass notification system was not effectively implemented and failed to provide accurate information to building occupants. The report also identified 14 opportunities for improvement and a further 27 observations. Items of note from these categories include: the need to strengthen the use of WebEOC® and the associated display of information for situational awareness in the Emergency Operations Center (EOC); the incident command post was initially setup within the isolation zone due to communications challenges; plume modeling responders departed for the EOC prior to receiving safe route information, since they suspected that they would otherwise get caught in a shelter-in-place; and facility management lacked familiarity with the EALs.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: During the past two weeks, Waste Characterization, Reduction, and Repackaging Facility workers successfully treated three RNS drums for a total of eleven treated since the campaign started on May 18, 2017. Recent challenges included ventilation system failures, continuous air monitor alarms subsequently determined to be false, and unanticipated items discovered in the waste.

Weapons Engineering Tritium Facility (WETF)–Flanged Tritium Waste Containers (FTWC): Last Thursday, the NNSA Field Office Manager approved LANL's Evaluation of the Safety of the Situation (ESS) for three FTWCs stored within WETF that may be pressurized with a potentially explosive headspace mixture of oxygen and hydrogen isotopes (see 12/22/16 weekly). In the approval letter, the NNSA Field Office Manager directs WETF management to revise a standing order that implements the current operational restrictions to include prohibition of intentional movement or venting of the FTWCs until further notice from the NNSA Field Office. The approval letter directs WETF management to implement the statement regarding no intentional movement or venting of the FTWCS through a Specific Administrative Control in the WETF Technical Safety Requirements. The NNSA Field Office Manager also directed LANL to submit a plan to update the safety basis to support FTWC remediation and to address additional ESS review comments by late August.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 7, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 7, 2017

Federal Oversight: This week, the NNSA Field Office initiated a special assessment team to oversee and evaluate LANL's causal analysis and corrective actions associated with the recent incidents involving the inappropriate air cargo shipping of plutonium. The team will also perform a meta-analysis of other recent incidents with similar contributing causes and evaluate the plans to resume offsite shipment of hazardous and radioactive cargos.

Last Friday, the EM Field Office Manager assumed authority for safety basis approval and startup authorization for work associated with Area G and the Nuclear Environmental Sites.

Plutonium Facility–Seismic Safety: On Wednesday, NNSA Field Office and LANL personnel briefed the NNSA Associate Administrator for Safety, Infrastructure, and Operations, on the status of plans to procure a nonlinear dynamic analysis of the facility structure and a separate, but related effort, to test the performance of column capitals. The Associate Administrator approved moving forward with both procurements. The preliminary high-level schedule indicates that completion of both efforts will necessitate approximately two years.

Area G–Safety Basis: Last Friday, LANL submitted to the EM Field Office for review, a proposed safety basis strategy to support transuranic waste shipments from other LANL facilities to Area G. The strategy identifies the need to cancel the operating restrictions on transuranic waste receipt put in place following an inadequacy in the safety analysis regarding material-at-risk inventory discrepancies (see 5/20/16 weekly), as well as a need to increase allowable material-at-risk limits. The LANL strategy proposes to first revise the evaluation of the safety of the situation put in place for the material at-risk-discrepancies to allow transuranic waste receipt, and then to revise the current safety basis to increase material-at-risk limits. LANL notes in the strategy that these changes are necessary to support mission needs, in particular to alleviate waste storage issues at the Plutonium Facility.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: Waste Characterization, Reduction, and Repackaging Facility (WCRRF) workers successfully treated the 12th RNS drum. They also received two additional RNS containers from Area G. Last week, Area G personnel denested four containers of unremediated nitrate salts (UNS) to evaluate drum integrity. They encountered drum degradation and determined that the poly drum liners will likely need to be pulled and placed into new drums prior to shipment to the WCRRF.

Last Friday, LANL management informed the EM Field Office that they would not meet the current contractual milestones for processing of RNS and the UNS wastes of June 30 and September 30, 2017, respectively. Their current working schedule, which was adjusted using efficiency data from the completed portion of the campaign, now projects respective completions of December 22, 2017, and April 10, 2018. WCRRF management is actively engaging workers for feedback on additional efficiency opportunities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 14, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 14, 2017

DNFSB Activity: On Thursday, NNSA Headquarters and Field Office personnel briefed the Board Members on the results and path forward associated with the 2017 review performed in accordance with NNSA Supplemental Directive 226.1-1A, *Headquarters Biennial Review of Nuclear Safety Performance* (see 3/17/17 weekly).

Plutonium Facility–Housekeeping: On Wednesday, management completed their extent of condition review stemming from the fire associated with unlabeled pyrophoric legacy materials (see 4/21/17 weekly). As a result, they determined that there was a need for eight additional multi-item actions to remedy the identified issues. Examples of the identified issues include items that were unlabeled, missing barcodes, otherwise lacking acceptable knowledge, or located in inaccessible spaces. Management’s plan is to complete the actions by the end of August 2017.

Area G–Flanged Tritium Waste Containers (FTWC): On Tuesday, two maintenance workers crossed a barrier intended to restrict access to a 50-foot exclusion zone around the FTWCs with potentially explosive headspace mixtures of oxygen and hydrogen isotopes (see 10/28/16 weekly). The exclusion zone was established as a safety significant Specific Administrative Control in the Evaluation of the Safety of the Situation to protect workers from a potential explosion accident. In addition to a roped barrier with signs indicating restricted access, the exclusion zone is implemented through a standing order.

During a fact-finding of the event, the worker with access to Area G who was acting as the escort admitted to mistakenly crossing the boundary, not recognizing it as an exclusion area. Management identified the escorting worker had not been trained on and had not read the standing order. Additional issues identified during the fact finding included: (1) the hazard identification and control worksheet included in the work package was not updated when the exclusion zone was established; (2) the badge reading system at Area G is not capable of tracking the training requirements necessary for access; (3) the plan of the day did not indicate the maintenance was going to be performed in this particular location; and (4) operations center personnel did not ascertain the intended location of the maintenance when the workers checked in prior to commencing their work. Facility management is taking immediate actions that include installing a more robust barrier around the exclusion zone and ensuring all personnel with access to Area G are personally briefed on the exclusion zone. LANL personnel are also conducting a causal analysis of the event, as well as an extent of condition review.

Transuranic Waste Facility (TWF): On Thursday, NNSA Field Office personnel briefed NNSA Headquarters on the path forward regarding the malfunctioning seismic power cutoff system. The system is a safety class control intended to isolate electrical power to the waste storage building upon detection of a seismic event. TWF personnel encountered issues with this new system’s internal fault-checking functions, as well as oversensitivity to severe weather and have proposed an 18 month plan to develop a retrofit. In the interim, they are proposing a new surveillance requirement to compensate for the impaired functionality. On Friday, the NNSA Field Office approved this proposal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 21, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 21, 2017

Plutonium Facility–Transuranic (TRU) Waste Operations: On Thursday, a Federal Readiness Assessment team briefed the results of their review of Plutonium Facility readiness to perform mobile loading of TRUPACT II waste containers for offsite shipment to the Waste Isolation Pilot Plant. The team concluded that operators adequately demonstrated their ability to start this new activity and identified one post-start finding relating to the Plutonium Facility’s Unreviewed Safety Question process. Last Friday, the NNSA Field Office Manager approved a temporary modification to the Plutonium Facility safety basis that rescinds previous direction excluding pipe overpack containers from the mobile loading activity (see 6/2/17 weekly). The approval letter notes that allowing POCs in mobile loading activities is essential to ongoing Plutonium Facility material-at-risk reduction efforts.

Transuranic Waste Facility (TWF): On Thursday, LANL transmitted to the NNSA Field Office for review and approval, an execution plan for a redesign of the malfunctioning TWF seismic power cutoff system (see 7/14/17 weekly). LANL’s plan details the scope and schedule to complete the redesign in 18 months to ensure the system meets its performance criteria and design requirements.

Chemistry and Metallurgy Research (CMR) Building–Emergency Management: On Thursday, CMR personnel conducted their annual emergency exercise. This year’s scenario included an explosion and a brief fire in the facility ventilation system ducting that seriously injured a maintenance worker. Participation included CMR personnel, the LANL Emergency Management and Response Organizations, and the Los Alamos County Fire Department. Evaluators will hold their critique next Monday.

Plutonium Facility–Infrastructure: Last Tuesday, the east safety class diesel firewater pump failed its weekly surveillance test when it did not continue running after startup. Maintenance personnel completed troubleshooting that revealed a faulty relay in the starting circuitry. On Wednesday, the diesel was repaired, successfully retested, and placed back in service. On Thursday, LANL submitted to the NNSA Field Office for review and approval, a request for extension of the Evaluation of the Safety of the Situation (ESS) for the potential non-conservatism in the seismic capacity of the fire suppression system (see 6/17/16 weekly). LANL’s request notes that the current ESS expires on August 3, 2017, and engineering personnel require additional time to evaluate potential interaction issues with non-seismically qualified equipment and the fire suppression system to support revision of the ESS.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: Waste Characterization, Reduction, and Repackaging Facility workers successfully treated the 17th RNS drum. On Wednesday, a worker discovered the safety-significant drum lift was missing a hinge pin clip. Operations personnel entered the appropriate Limiting Condition for Operations while maintenance personnel replaced the clip and returned the drum lift to service.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 28, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: R.K. Verhaagen and J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending July 28, 2017

DNFSB Staff Activity: On Thursday, B.K. Caleca, Y. Li, P.J. Migliorini, and L. Schleicher conducted a teleconference with LANL personnel to review the design for the seismic retrofit of the RANT Shipping Facility. The team also discussed the risk associated with proceeding with the retrofit prior to revising the safety basis to better understand the overall seismic control strategy.

Plutonium Facility–Infrastructure: On Tuesday, the west diesel firewater pump failed its weekly surveillance due to an issue with packing. Operations staff entered the appropriate limiting condition for operations, initiated troubleshooting, and returned the pump to service on Friday. Last week's firewater pump issue concerned the east diesel firewater pump (see 7/21/17 weekly).

Recently, facility staff received and placed the new diesel electric generators intended to support the electric firewater pumps at each pump house. Once installation is complete and associated safety basis changes are approved and implemented, the electric firewater pumps will eliminate dependency on the diesel pumps that have proven problematic in recent years. Unfortunately, placement of the east generator was hindered by an alignment problem between cast-in-place bolts and the anchor points on the base of the generator. Engineering personnel believe that the bolts shifted after the concrete was placed and was not caught because a confirmation measurement was not performed. Engineering is now developing a solution to ensure the attachment meets the required safety class, performance category 3 functions.

Transuranic Waste Facility (TWF): On Thursday, the NNSA Field Office approved and forwarded to NNSA Headquarters for final approval LANL's requested changes to a previously approved exemption request regarding the safety class seismic switches. The original 2013 exemption request against requirements in DOE Order 420.1B, *Facility Safety*, specified a certain separation distance between the switch enclosures and a prohibition on combustible materials between the enclosures that the TWF project did not meet with the as-built configuration. Additionally, the original request relied on the project installing safety significant fire suppression in the utility buildings; however, the fire suppression system is not currently scheduled to achieve this status until February 28, 2018, with the potential that the facility will commence nuclear operations prior to that date.

On Thursday, LANL management transmitted to the NNSA Field Office their closure package from the Contractor Operational Readiness Review (see 6/23/17 weekly). The causal analysis codes identified included: adequate means not provided to assure quality procedures; resources not provided to assure adequate training; management expectations not well-defined, understood, or enforced; written communication content incomplete; and management monitoring of activities did not identify the problems. The Federal Operational Readiness Review is scheduled to commence on Monday.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: Waste Characterization, Reduction, and Repackaging Facility workers successfully treated the 20th RNS drum, including the first pipe overpack container. On Thursday, operators paused work when they noticed a tear in the containment bag between the glovebox and a debris drum. Radiological control technicians located and cleaned up small amounts of contamination in the vicinity of the debris drum.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 4, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending August 4, 2017

DNFSB Staff Activity: D.J. Brown observed the Federal Operational Readiness Review (FORR) for the Transuranic Waste Facility (TWF) project discussed below.

TWF–Readiness: On Monday, the FORR team commenced their review of the facility’s equipment, personnel, and procedures to start nuclear operations. The review is scheduled to complete next Wednesday and entails numerous interviews and observations of work evolutions, including emergency and operational drills. Notably, the FORR team requested demonstrations using sets of four weighted drums, which represents the anticipated work conditions. Previously, TWF workers had used no more than two empty drums for practice and evaluation purposes.

Completion of the FORR, including any subsequent corrective actions, is the last formal hurdle for this new project since its inception in 2006. Once the TWF is operational, the facility will represent a significant improvement to the safety posture of stored transuranic waste as compared to Area G and the outdoor pads at the Plutonium Facility. However, the project has had a history of deviations from DOE requirements and expectations that have impaired the facility’s ability to support key risk reduction efforts across the laboratory and suggests there are lessons to be learned. For example, the original mission need statement identified required capabilities that included waste storage, certification, container repackaging, and TRUPACT II shipping operations. The latter two capabilities were eliminated from the project scope with a strategy to rely on existing facilities. The project has also deferred the scope to install the certification capability meaning that the TWF will temporarily be unable to fully enable shipments to the Waste Isolation Pilot Plant. From a safety systems perspective, the new safety class seismic switches do not function as intended, including inadvertent actuations from severe weather, and require execution of an 18 month plan for replacement. The project also requires changes to a previously approved exemption after the as-constructed seismic switch enclosures did not comply with the conditions of exemption. The fire suppression system will begin operation as defense-in-depth and achieve its required safety significant status by the end of February 2018. The approved fire hazards analysis lists 13 open issues, deficiencies, and recommendations, in addition to the 11 that have been remedied. NNSA has imposed compensatory measures for these conditions; however, the overall safety basis and environmental permit is such that only about a third of the accumulated transuranic waste container inventory at the Plutonium Facility is currently eligible for receipt at the TWF. Additionally, as startup nears, the project has not obtained most of the critical spares needed for the suite of credited safety systems.

Plutonium Facility–Infrastructure: Earlier this week, issues with a motor controller for a fan necessitated multiple unplanned entries into the limiting condition for operations associated with the required pressure regime for the ventilation system. Maintenance personnel resolved the issue on Tuesday night.

Emergency Management: This week, a four person team commenced a Parent Organization Functional Management Review of emergency management. The team’s scope includes review of independent and external assessments, including the Board’s draft recommendation, as well as program improvement initiatives.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 11, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending August 11, 2017

DNFSB Staff Activity: Y. Li and L. Schleicher met with LANL personnel to discuss the process for the forthcoming update to the probabilistic seismic hazards analysis, which is expected to refine, and possibly lower, the earthquake hazard for the laboratory's nuclear facilities. They also walked-down sites for paleoseismic trenching, as well as several previously studied hoodoos that will provide inputs for the seismic update.

Plutonium Facility–Startups: On Monday, the NNSA Field Office authorized the startup of aqueous chloride and americium production operations (see 6/9/17 weekly). Operations personnel plan to execute their startup plan in the coming months and complete a production milestone of americium-241 oxide for the DOE Office of Science. The line will then undergo an outage during the winter to replace a glovebox spool piece that is thought to be degraded and the source of a previous radiological uptake by a worker several years ago. The spool piece is currently taped and monitored to support interim operations. Also on Monday, the NNSA Field Office authorized startup of the mobile loading operations for TRUPACT II containers (see 7/21/17 weekly). LANL anticipates a limited shipping campaign of transuranic waste to the Waste Isolation Pilot Plant in September 2017.

Transuranic Waste Facility (TWF)–Readiness: On Wednesday, the Federal Operational Readiness Review (FORR) team completed their review. They complimented the TWF operators on their professionalism and concluded that TWF was ready to commence limited nuclear operations following closure of the pre-start findings. However, the FORR team also provided three recommendations based on the inability of TWF personnel to effectively complete several key work evolutions. The recommendations are to: modify the startup plan to limit daily throughput (likely to four drums) and require DOE approval for release of startup phases, as well as the senior supervisory watch; prohibit stacking of drums until further verification of readiness; and prohibit facility startup until further verification of readiness to adequately overpack a waste container with compromised integrity. For the latter case, the safety basis requires that a container must be overpacked within seven days after discovering damage to its integrity. The facility does not currently have a process to accomplish such overpacking in a non-emergency condition.

In addition to the recommendations, the FORR team identified five pre-start findings concerning: (1) the NNSA Field Office lacks an oversight plan for TWF startup; (2) the primary container handling procedure is inadequate; (3) the abnormal response procedure doesn't address key conditions and appropriate responses; (4) the startup plan is inadequate to ensure deliberate escalation to normal operations; and (5) procedures that manage abnormal conditions lack detailed corrective actions to achieve a safe and stable state. The team identified six post-start findings involving: (1) noncompliant fire barrier penetrations seals; (2) ineffective controls for nitrogen asphyxiation hazards; (3) inadequate commercial grade dedication; (4) lack of climate controlled storage for spare parts; (5) issues with the technical safety requirements; and (6) insufficient minimum staffing.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: Waste Characterization, Reduction, and Repackaging Facility workers have successfully treated 24 of the RNS containers, including the container with the highest radiological inventory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 18, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending August 18, 2017

DNFSB Staff Activity: M.R. Bradisse, R.C. Eul, and N.M. George observed conduct of operations and nuclear criticality practices at the Plutonium Facility. They also observed the criticality exercise discussed below. On Friday, R.K Verhaagen completed his service with the DNFSB.

Chemistry and Metallurgy Research (CMR) Building–Safety Basis: Last Friday, LANL transmitted to the NNSA Field Office for approval a revision to a temporary safety basis associated with the storage and processing of americium-241 materials received from an off-site location in February 2016. This revision supports removing the 55 gallon drum from its overpack and subsequent installation of a drum vent. Once a definitive path forward for the americium is determined, CMR personnel will need a further safety basis revision to support opening the inner containers and processing the materials.

Transuranic Waste Management: On Thursday, the NNSA Field Office authorized startup of the mobile loading operations for TRUPACT II containers at the Plutonium Facility (see 7/21/17 weekly). LANL anticipates completing the associated safety basis implementation actions in September 2017, but will need to complete several other hurdles, including the Generator Site Technical Review (see 4/21/17 weekly), in order to commence shipping of transuranic waste containers to the Waste Isolation Pilot Plant. LANL's latest waste accumulation forecast indicates that operation of the new Transuranic Waste Facility (TWF) is required by May 2018. This projection assumes that Plutonium Facility personnel are able to ship 14 large volume, low material-at-risk containers to Area G. The EM Field Office is currently reviewing the necessary safety basis changes to receive these containers (see 7/7/17 weekly). Without the relief afforded by shipping the large containers, the Plutonium Facility will reach storage capacity in approximately November 2017. TWF project personnel are currently planning to complete the actions required to commence limited nuclear operations in September 2017.

Plutonium Facility–Safety Basis: Earlier this month, LANL transmitted to the NNSA Field Office for approval a revision to the 2014 safety basis that addresses previous comments and conditions of approval. The 2014 version of the safety basis represents a substantial overhaul as compared to the currently implemented versions and is intended to eventually become the controlling safety basis, once approved and implemented. The NNSA Field Office is developing their review plan.

Plutonium Facility–Emergency Management: On Thursday, Plutonium Facility personnel conducted their annual nuclear criticality exercise. This year's scenario featured a simulated inadvertent criticality involving an over-batched aqueous solution system coincident with an inoperable ventilation system. Additionally, two workers were exposed with one non-viable and the other requiring rescue. Evaluators and controllers will conduct their exercise critique next week.

Weapons Engineering Tritium Facility (WETF): On Thursday, the NNSA Field Office rescinded a previous condition of approval from 2013 that prohibited the receipt of new material-at-risk into the facility. WETF management recently requested this change in order to support the facility's gas transfer stewardship mission. The material-at-risk limit remains 240 g of tritium.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 25, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending August 25, 2017

Management: On Wednesday, the LANL Director announced that Scott Gibbs will serve as the Deputy Director for Mission Assurance, beginning September 5th. The role of this newly created position is to provide strategic and tactical support in the areas of contract assurance and risk management.

Plutonium Facility–Safety Basis: Subsequent to questions raised by the NNSA Facility Representatives, facility management declared a violation of the technical safety requirements (TSR) after determining the annual in-service inspection of pipe overpack containers (POCs) had been performed on a statistical sample rather than the complete inventory as required. At the fact-finding, the cognizant system engineer for containers acknowledged an error in executing the surveillance procedure and noted opportunities to eliminate future confusion. In particular, the surveillance, which covers multiple types of fire-rated containers that are credited in the safety basis to provide reduced damage ratios, permits statistical sampling for all containers except POCs and DOE-STD-3013s. Management is determining a path forward to restore TSR compliance for the approximately 700 POCs at the facility, as well as the associated implications for continuing to use a damage ratio for purposes of complying with TSR limits on material-at-risk. Additionally, attendees discussed an apparent conflict between the TSR surveillance criteria for the visual examination and language within DOE-STD-5506 that mandates use of the criteria in the payload integrity checklist for the waste acceptance criteria for the Waste Isolation Pilot Plant when reduced container damage ratios are utilized. On this point, management decided to enter the New Information process.

Plutonium Facility–Conduct of Operations: On Monday, an operator declared a potential process deviation after questioning a nuclear criticality safety posting on a glovebox slated for decontamination and demolition. Attendees at the fact-finding determined that the approved process for changing postings had not been followed.

Transuranic Liquid Waste (TLW) Project: On Wednesday, the NNSA Field Office provided LANL management with direction regarding the preliminary documented safety analysis. The direction included: revise the hazard evaluation to reflect sodium hydroxide as a standard industrial hazard; revise the hazard analysis to reflect the potential for spray leaks of acidic liquid waste; and affirm the designation of defense-in-depth for the piping system and chemical shields.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: On Tuesday, treatment activities were paused after an operator's coveralls snagged and snapped a pressure gauge assembly on a fire suppression system riser rendering the system inoperable. At the fact-finding, attendees noted appropriate responses and requested an evaluation to determine whether the assembly could be better protected, as it is located in a space-constrained location that is frequently trafficked. Maintenance personnel repaired the system on Wednesday, but noted unexpected corrosion on the broken assembly. As a result, the cognizant system engineer is investigating the need for additional intrusive inspections of the fire suppression system. On Friday, Waste Characterization, Reduction, and Repackaging Facility workers expected to complete treatment of the 30th RNS container—marking the halfway point of the campaign.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 1, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending September 1, 2017

DNFSB Staff Activity: B.K. Caleca, M.W. Dunlevy, T.J. Dwyer, D.M. Gutowski, A.R. Powers, and M.T. Wright conducted a review of the safety posture of the Plutonium Facility, including the compensatory measures and plans to remedy identified deficiencies associated with the safety systems.

Plutonium Facility–Conduct of Operations: On Tuesday, facility personnel conducted a fact-finding associated with a criticality safety event that occurred in the casting room on August 18, 2017. As discussed by attendees, the casting crew did not utilize a required use-every-time attachment to the material move procedure. As a result, the crew moved a shell into a location that already contained plutonium metal, violating the posted limit set, which allows for either metal or shells. The crew discovered this violation on August 21 while moving the shell to another location. Following discovery, the crew conducted two additional nuclear material movements that they felt were necessary for product quality and security, rather than declare a potential process deviation as required by procedure and training. They then contacted programmatic operations management for a post-job review. Notably, this casting operation had recently completed a federal readiness review and is one of the few operations where the crew that underwent readiness has not experienced personnel turnover. Additionally, this was the first shell cast in the facility in about four years and the second time that a restarted operation encountered conduct of operations issues related to the criticality safety of material movements shortly after resuming nuclear work (see 7/8/16 weekly).

On Wednesday, Plutonium Facility management briefed the NNSA Field Office on immediate actions taken, which include: conducting a formal causal analysis; pausing all casting operations; disqualifying the involved workers; requiring group leader authorization for all future moves in the casting room; mandating all group leaders observe at least three material movements; temporarily requiring a hard copy of the material move checklists for all moves; and studying longer-term improvements to the material movement process.

Plutonium Facility–Radiological Control: On Tuesday afternoon, the operations center restricted access to and suspended movement of all personnel within the facility for about two hours after radiological control technicians (RCT) found contamination on the personal protective clothing of several workers. In total, RCTs identified contamination on 11 workers associated with a job removing a limited volume chilled water supply—one worker with 1.3 k dpm alpha contamination on his knuckle and the rest with contamination on their protective clothing, mainly booties, at levels ranging from 2–10 k dpm alpha. Surveys in the affected rooms found no indications of airborne contamination; however, they revealed multiple contaminated locations, including two discarded booties found with 100 k dpm alpha. Attendees at the fact-finding identified issues with the congested and space constrained location of the job, which was adjacent to the main room exit and the hand and foot monitors. They surmised that small drops of liquid from the system, which had been previously sampled and found to be below detection levels, were actually contaminated (or became contaminated during the course of the job) and the liquid spread beyond the room as a result of the job. Management identified corrective actions associated with evaluating: the methodology for sampling liquid systems to be breached; the approach for relaxing radiological controls when breaching systems; and the design of hot job exclusion area boundaries.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 8, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending September 8, 2017

DNFSB Staff Activity: D.J. Brown, M.W. Dunlevy, and P.J. Foster held two teleconferences with NNSA Field Office personnel to discuss questions regarding the state of readiness and the technical safety requirements for the Transuranic Waste Facility.

Plutonium Facility–Safety Basis: On Thursday, the cognizant system engineer completed the required in-service inspections for the pipe overpack containers, restoring compliance with the technical safety requirements (see 8/25/17 weekly). As part of their new information process, safety basis personnel are still analyzing the potential impacts of the differences in visual examination criteria between those used to implement the existing technical safety requirements and those required by DOE-STD-5506-2007 to justify use of a reduced damage ratio.

RANT Shipping Facility: On Thursday, the NNSA Field Office approved the letter that LANL submitted on April 20, 2017, in lieu of the annual update to the safety basis. The approval reiterated that the safety basis was sufficient for operations permitted in COLD STANDBY mode, but further operations would require approval of a new safety basis developed in accordance with DOE-STD-3009-2014. Separately, LANL engineering staff recently completed a seismic retrofit design to ensure the structure will meet performance category 2 seismic criteria. Safety basis personnel have begun preliminary analyses to ensure this level of seismic performance will be adequate to support the future safety control strategy.

Area G–Safety Basis: Late last month, the EM Field Office approved a revision to the Evaluation of the Safety of the Situation concerning transuranic waste inventory discrepancies, formerly known as the composite source term issue (see 7/7/17 weekly). The approved analysis indicates the postulated accidents with the highest consequences are a large combustible fire and lightning strikes to multiple waste containers with mitigated consequences to the public of about 19 and 12 rem, respectively. Implementation of this revision will eliminate the aircraft crash accident through a reduced frequency argument, as well as support resumption of normal operations at Area G. Implementation is currently scheduled for later this month, and will be closely followed by receipt of oversized, low material-at-risk containers from the Plutonium Facility.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: On Wednesday, Waste Characterization, Reduction, and Repackaging Facility (WCRRF) management declared a violation of a Specific Administrative Control after receiving a report that a DOE-EM Headquarters overseer witnessed a lapse in required fire watch coverage during shift turnover. Specifically on Tuesday morning, the overseer noted that the required hourly entry was performed after the grace period and witnessed lapses in video monitoring, contrary to the procedure for a condition with an RNS container present outside of the refrigerator. Fact-finding attendees discussed contributing causes and corrective actions related to strengthening procedural guidance for transitions, improving conduct of operations training for the pool of laborers performing the fire watch function, and issuing a vest to the fire watch assigned to monitor the video. As of Friday, WCRRF workers were treating the 34th RNS container out of 60.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 15, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending September 15, 2017

DNFSB Staff Activity: D.J. Brown observed the follow-up demonstrations for the Federal Operational Readiness Review (FORR) at the Transuranic Waste Facility (TWF) discussed below.

Federal Oversight: On Thursday, the NNSA Field Office Manager, Kim Davis Lebak, announced her upcoming retirement from federal service. She will be succeeded by Steve Goodrum in October 2017.

Infrastructure: NNSA Headquarters personnel were at LANL this week to conduct the second deep dive associated with NNSA's Master Asset Plan. The deep dive attendees were provided presentations and tours associated with key laboratory infrastructure.

TWF–Readiness: On Monday and Tuesday, TWF operators demonstrated their ability to direct-load a simulated degraded transuranic waste drum into a standard waste box and stack three pallets of drums for a subset of the FORR team. The FORR team had previously identified that both of these activities required further federal assessment (see 8/11/2017 weekly). At their outbrief, the team again complimented the professionalism of the TWF operations personnel and noted that both tasks were successfully executed. However, they noted several opportunities to strengthen the applicable procedures and expressed concern regarding the margin for fork lift maneuvering during the stacking evolution. Project personnel designed the waste storage buildings with the intent to load them with two rows of drums on pallets, each row stacked three high. The spacing of these rows is such that the facility's current forklift has about 14 inches to maneuver into a position perpendicular to a row in order to stack a pallet. The FORR team expressed concern that this degree of margin was putting the operators in an unnecessarily difficult position and may necessitate alternate arrangements.

In parallel, TWF personnel continue to close corrective actions for the pre-start findings in support of receiving startup authorization before the end of the month. Currently, technicians are conducting a 100 percent inspection and repair of the safety class penetration fire seals, which is pacing progress. This action requires technicians to systematically work each building to catalog, relabel, inspect, and rework the penetrations as needed. When last reported, they found deficiencies requiring rework for 26 of 28 through-wall seals, including the use of incorrect materials and incomplete coverage.

Plutonium Facility–Safety Basis: On Monday, LANL management transmitted to the NNSA Field Office for information a project execution plan associated with updating key modeling used in the development of the safety basis. The plan responds to previous directed actions and aims to: (1) update the dispersion modeling using recent meteorological data; (2) revise the fire modeling using current combustible loading levels; (3) create a unified leak path factor analysis of an integrated model of the facility using MELCOR; and (4) examine the actual amounts of material-at-risk used to support programmatic operations to more accurately reflect the source-term in the accident analysis. Notably, the plan indicates uncertainty in funding and does not mention including consideration of co-located worker consequences.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 22, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D.M. Gutowski
SUBJECT: Los Alamos Report for Week Ending September 22, 2017

DNFSB Staff Activity. D. Gutowski was onsite providing resident inspector coverage.

Plutonium Facility–Safety Basis. Last week, safety basis personnel finalized their new information process analysis concerning adequacy of the visual examination criteria used during in-service inspections for the pipe overpack containers (see 8/25/2017 weekly). They concluded that the situation did not constitute a potential inadequacy of the safety analysis. Their rationale included the fact that DOE Directives do not require in-service inspections for credited design features and therefore there could be no requirement to implement criteria in DOE-STD-5506.

Plutonium Facility–Readiness. A contractor readiness assessment (RA) team commenced their review of the electrorefining process. During demonstration of breaking press operations, fragments of a surrogate material ring bypassed the shield around the press. There was no damage to the glovebox. Facility personnel are evaluating how to prevent future occurrences. The RA is expected to finish next week and will be followed by a Federal RA.

Plutonium Facility–Criticality Safety. Two detectors for the criticality accident alarm system in the basement failed the quarterly TSR surveillances test. Facility personnel entered the appropriate Limiting Condition for Operation and launched a fact-finding meeting where they discussed that the surveillance test is likely to show failures in areas with higher background radiation. The detectors passed a revised test and have been returned to service.

During a fissile material operation review, LANL personnel discovered that uranyl nitrate hexahydrate material from TA-18 did not have a current technical basis for criticality safety controls. They restricted access to the location, determined that the material was safe and stable from a criticality perspective, and are developing a recovery plan.

Area G–Safety Basis. LANL completed implementation of the revised Evaluation of the Safety of the Situation for material-at-risk discrepancies (see 9/8/2017 weekly).

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: As of Friday, Waste Characterization, Reduction, and Repackaging Facility workers were treating the 40th RNS container out of 60.

Transuranic Liquid Waste (TLW) Facility Project. In a letter dated August 24, 2017, NNSA directed LANL management to suspend the TLW project by the end of September 2017 due to a number of factors associated with budget, schedule, and competing priorities. The TLW was to fulfill a mission need for an enduring capability to process aqueous waste from the Plutonium Facility. This capability is currently performed in the 1963 vintage Radioactive Liquid Waste Treatment Facility. As directed per the suspension letter, LANL delivered an updated version of the preliminary documented safety analysis to the NNSA Field Office last Friday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 29, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending September 29, 2017

Plutonium Facility–Conduct of Operations and Work Control: On Saturday, pipefitters released airborne radioactive material when they removed a plug from a service panel on the base of a glovebox. This was the same work crew and glovebox involved in the contamination event late last month (see 9/1/2017 weekly). At the fact-finding, attendees reviewed the scope of work which included replacing two elbows on the service panel with shorter versions. The pipefitters described difficulty in turning one of the elbows because of an interference from a plug and decided to remove the plug thereby releasing the contamination. They believed they had allowance to take such an action because the work document provided only vague constraints on “field routing.” The two pipefitters and supporting radiological control technician were wearing air purifying respirators and anti-contamination clothing, but exited the room when airborne radioactive contamination levels exceeded their safety thresholds. All three workers were contaminated on their protective clothing, including one with 100 k dpm alpha on the skin of the chest area, which was successfully decontaminated. Nasal smears were all determined to be negative and the workers were placed on special bioassay. Continuous air monitors indicated airborne levels as high as 4520 DAC-hours in the impacted room, as well as lower readings in the adjacent room and an area in the north corridor, which was also found to have areas of floor contamination. Fact-finding attendees discussed concerns and corrective actions associated with: establishing a common understanding of field routing; ensuring adequate on-call support during off-hours; and worker perceptions of increased programmatic pressure for project work.

Plutonium Facility–Safety Basis: Earlier this month, LANL management submitted to the NNSA Field Office a revision to the Evaluation of the Safety of the Situation (ESS) addressing the seismic interaction concerns for the fire suppression system (FSS). The initial ESS focused on questions regarding the seismic performance of cast iron fittings raised in the Board’s letter dated May 12, 2016. The Board’s letter also noted that LANL engineering personnel had documented concerns in 2010 with the potential for adverse seismic interactions (so-called 2 over 1 concerns) where unqualified equipment may fall or otherwise impact portions of the credited FSS. The revised ESS formally addresses this interaction issue and identifies 17 specific areas of concern within the facility, one global concern in the filter plenums, and a coupling issue present in both of the firewater pump houses. The ESS proposes maintaining the previously specified operational restrictions to reduce material-at-risk limits. The ESS further commits to implement corrective actions for the specific areas of concern through an annual revision to the TA-55 Project Execution Strategy.

Area G–Operations: On Tuesday, Area G personnel received the first shipment of newly generated transuranic waste since January 2014 when they accepted a number of oversized boxes from the Plutonium Facility. According to LANL’s projections, this shipment will extend the ability to continue accumulating waste at the Plutonium Facility’s outdoor storage pads until March 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 6, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending October 6, 2017

Federal Oversight: On Thursday, Steve Goodrum became the Manager of the NNSA Field Office.

Plutonium Facility–Operations: With the start of the fiscal year, the Associate Director for Plutonium Science and Manufacturing implemented a re-organization that melds personnel from the previous engineering and operations divisions into three new organizations associated with pit technologies, actinide processing, and strategic science and engineering. Consequently, the roles and responsibilities that were learned and assessed during the restart reviews have changed.

Plutonium Facility–Restart Activities: Last Thursday, the contractor readiness assessment team briefed the results of their review of the electrorefining process (see 9/22/2017 weekly). They identified two prestart issues: (1) the criticality safety evaluation document has not demonstrated that all credible abnormal conditions associated with the potential for fissile material overmass will remain sub-critical and (2) the hazards with the movement of materials and use of gloves in the primary staging glovebox, which is a unique carousel design, were not defined in the procedure and were not appropriately demonstrated or communicated during the operation. In response to the first finding, management has paused all pyrochemistry operations.

Transuranic Waste Facility (TWF): Last week, NNSA Headquarters approved the phased startup of nuclear operations and Critical Decision-4, *Project Completion*. This accomplishment comes after several weeks of intense efforts to complete and verify corrective actions. In particular, TWF and NNSA Field Office personnel expended efforts closing the fire penetration seal issues (see 9/15/2017 weekly), which ultimately required rework for 127 of 228 seals, including some that required additional rework. TWF personnel hope to receive their first shipment of waste containers next week. In the first phase of the approved startup plan, TWF personnel may receive no more than four waste containers at one time. Progression to the subsequent phases requires TWF management to assert, and NNSA Field Office to concur, that performance supports increased throughput. Other efforts to complete the functionality for the TWF continue with: the recent submittal of a safety basis revision that supports the use a 10 % damage ratio for pipe overpack containers stored in certain locations; installation of the characterization trailers; upgrades to the fire suppression system; redesign of the seismic-shutoff switches; and transition of the workforce to a new management reporting structure.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: On Thursday, Waste Characterization, Reduction, and Repackaging Facility (WCRRF) workers completed treatment of the 45th RNS container out of 60. With the recent progress, LANL management is now projecting completion of the RNS campaign in early November. Last Thursday, the NNSA Field Office unconditionally approved a revision to the WCRRF safety basis necessary to support the treatment of the unremediated nitrate salt (UNS) wastes. While WCRRF workers will utilize a similar treatment process for the UNS, these materials do not exhibit the reactivity hazards associated with the RNS. As such, the related controls on pressure and temperature will no longer be necessary.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 13, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending October 13, 2017

Plutonium Facility–Operations: This week, programmatic operators successfully produced their first batch of americium-241 oxide. The activity used the recently authorized aqueous chloride-based solvent extraction system and the separations process known as the Chloride Extraction and Actinide Recovery (CLEAR) line. This was the first time the CLEAR line operated and the first time that the solvent extraction process has operated since 2013. During the process, operators experienced intermittent problems with a vacuum pump and briefly paused to re-evaluate controls after they encountered higher than expected radiation levels during the precipitation process.

Transuranic Waste Facility (TWF): On Wednesday, TWF operators successfully received their first shipment of four transuranic waste drums. Workers appropriately paused and consulted management after they observed two discrepancies associated with labeling: (1) the word “EMPTY” along with an individual’s contact information hand written on the bottom of one drum and (2) an unexpected label indicating the presence of beryllium in a second container. Of note, waste handlers at the Plutonium Facility observed, but did not address, these discrepancies during their pre-shipment inspection.

Area G–Safety Basis: Last Friday, LANL management submitted to the EM Field Office for approval a revision the Evaluation of the Safety of the Situation (ESS) for the continued safe storage of the Flanged Tritium Waste Containers (FTWC) that have potentially explosive headspace mixtures of oxygen and hydrogen isotopes (see 2/24/2017 weekly). The ESS revision reflects additional analysis regarding accident initiators associated with container movement, lightning, external fire, and electrostatic discharge. In particular, the latter work establishes a technical basis to support resumption of regulatory inspections of the shed containing the FTWCs, as well as other nearby activities. Additionally, the ESS presents a new mechanical failure analysis of an exploding FTWC that indicates the lid bolts will elongate resulting in a venting event without the generation of a shrapnel hazard. Consequently, LANL has proposed changing the 50 foot exclusion area to a 15 foot isolation area with a new process to evaluate proposed work activities in the vicinity of the FTWCs.

Earlier this month, LANL management submitted to the EM Field Office for approval the annual safety basis update. Consistent with the previously submitted waste strategy (see 7/7/2017 weekly), the update proposes increasing the material-at-risk limits from 39k to 64k plutonium-239 equivalent curies (PE-Ci) total with 14.5k combustible PE-Ci. The increase is intended to provide contingency space for NNSA.

Area G–Restart Activities: Last week, the EM Field Office approved the checklist plan of action associated with the contractor readiness assessment planned to support the upcoming treatment campaign for the unremediated nitrate salt (UNS) wastes. The UNS campaign will require limited Sort, Segregate, Size Reduction, and Repackaging operations in the Dome 231 PermaCon to remove the UNS materials in their drum liners from their existing degraded containers and place them into new containers suitable for shipment to the Waste Characterization, Reduction, and Repackaging Facility. The plan of action specifies review of radiation protection program, the hoisting and rigging program, and worker level of knowledge, as the remainder of the core requirements were determined to be justifiably excluded. The planned three day assessment is targeted for the end of this month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 20, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending October 20, 2017

DNFSB Staff Activity: On Wednesday and Thursday, D.J. Brown observed the federal readiness assessment team's pre-visit for their upcoming review of plutonium electrorefining operations. J.W. Plaue attended briefings at DNFSB Headquarters. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 27, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending October 27, 2017

Plutonium Facility–Conduct of Operations: Last Thursday, Plutonium Facility management briefed the NNSA Field Office on the results of their causal analysis and associated corrective actions related to the August 17, 2017, overmass event in the casting room (see 9/1/17 weekly). The analysis concludes that the event occurred primarily due to several error precursors, lack of specific role and responsibility assignments, communications failures, and residual ambiguities in required documents. The report provides 15 recommended actions, including several associated with clarifying requirements. The corrective action plan commits to address these recommendations, as applicable, by January 12, 2018. Other corrective actions are grouped associated with improving performance accountability and communication, improving management oversight, developing and utilizing conduct of operations metrics, and enhancing conduct of training. Overall targeted completion dates range from November 6, 2017, to July 6, 2018. The NNSA Field Office is separately developing an enhanced oversight plan to ensure that their monitoring of these actions is focused and sustained.

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office approved a revision of the evaluation of the safety of the situation (ESS) concerning the presence of unrinsed cellulosic materials (i.e., cheesecloth) that may have contacted plutonium-238 and nitric acid. The revision addresses NNSA Field Office comments questioning the safety of the five containers currently residing at the facility that exceed the newly established limit of 10 g plutonium-238 (see 3/24/17 weekly). Approval of the revised ESS means that the operational restriction to ensure the five containers are stored within the facility’s confinement structure is no longer necessary.

Transuranic Waste Facility (TWF): Last Thursday, TWF management appropriately paused their planned second receipt of waste subsequent to questions from NNSA Field Office personnel regarding the implementation of the waste acceptance criteria. In particular, the safety basis assumes as an initial condition that all incoming waste complies with the current waste acceptance criteria for the Waste Isolation Pilot Plant. This initial condition is protected by a key element of a safety management program, contrary to the discussion clarifying the protection of initial conditions found in DOE-STD-3009-2014, and does not currently flow into an implementing procedure. Implementation is further challenged by the language of the key element, which refers to “hazardous constituents” rather than the specific properties that are relevant to the assumptions in the safety analysis (e.g., nuclear material content, flammable gas generation rates, incompatible materials, potential for energetic reactions, etc.). TWF personnel are currently working to define and incorporate verification of these properties into their waste receipt processes.

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: On Friday, Waste Characterization, Reduction, and Repackaging Facility workers completed treatment of the 55th RNS container out of 60. Area G personnel also executed their management self-assessment in preparation for the upcoming campaign to treat the unremediated nitrate salts (see 10/13/17 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 3, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending November 3, 2017

Inappropriately Remediated Nitrate Salt (RNS) Waste–Treatment Activities: On Friday, Waste Characterization, Reduction, and Repackaging Facility (WCRRF) personnel completed treatment of the 60th and final RNS container of the campaign. WCRRF personnel accomplished this significant milestone in a safe and deliberate manner, resulting in the elimination of a substantial hazard at the laboratory. Next week, Area G personnel plan to commence their contractor readiness assessment in support of the upcoming campaign to treat the unremediated nitrate salts.

Plutonium Facility–Conduct of Operations and Work Control: On Wednesday, Plutonium Facility management briefed NNSA Field Office personnel on the status of efforts to recover from the radiological contamination event that occurred on September 23, 2017 (see 9/29/17 weekly). The managers noted progress from the decontamination team in the affected rooms. Earlier this week, the adjacent room was released for access under restrictions that require the use of additional protective equipment and contamination surveys. They anticipate similar release of the primary room next week. Managers discussed corrective actions taken to ensure craft personnel have a consistent understanding of “field route,” as well as plans to enhance facility access training with information associated with the hazards of exposing new surfaces and accessing radiological systems. They further noted that this event had prompted the need to develop a larger standing team of personnel trained in decontamination and the acquisition of additional powered air purifying respirators. NNSA Field Office personnel questioned how corrective actions from the overmass event (see 10/27/17 weekly) had been integrated with these corrective actions from this event, as well as emphasized the need for management presence on the floor and consistency in training between operations and craft personnel.

Plutonium Facility–Startup Activities: On Wednesday, the NNSA Field Office approved the plan of action (POA) for the upcoming federal readiness assessment of electrorefining operations. Notably, the POA includes scope to evaluate the actions taken and planned to address issues identified in the contractor readiness assessment that did not rise to the level of a finding, as well as actions taken and planned to address the operational weaknesses identified during the overmass event in the casting room.

Safety Basis: On Thursday, the NNSA Field Office transmitted their close-out of comments related to the site-wide dispersion protocol. The direction maintains previous restrictions related to certain atmosphere phenomena, but allows LANL management to propose modifications on a case-by-case basis.

Weapons Engineering Tritium Facility: On Wednesday, LANL management transmitted to the NNSA Field Office for approval a safety basis addendum to support the removal of the Building 205 ventilation stack. The stack, which is 60 feet tall, has not been used in several years. The submittal addresses hazards associated with the use of a mobile crane and the associated lifting and maneuvering. The facility will continue using the Building 450 stack.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 10, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending November 10, 2017

Unremediated Nitrate Salt (UNS) Waste–Readiness Activities: On Thursday, the contractor readiness assessment (CRA) team completed their review of the UNS drum liner pulling activity at Area G. The activity involves opening and cutting away a portion of the 85 gallon drum overpack to access the inner 55 gallon drum, opening that drum, using a lifting fixture to remove the high density polyethylene liner containing the UNS waste, and placing the liner in a new 55 gallon drum. The CRA team conducted interviews, observed a demonstration of the activity, and observed an operational drill examining the response to a breach liner. During the outbrief, the CRA team noted that the operations team demonstrated elements of a strong safety culture and identified two pre-start findings associated with: (1) the critical lift plan and (2) problems regarding lighting and a ventilation fan in the Permacon.

Readiness: On Tuesday, the Joint Evaluation Team (JET) convened to determine the proposed readiness review levels for three upcoming activities. At the Plutonium Facility, the activities included the restart of a lathe associated with the Special Recovery Line and the startup of a two new gloveboxes containing coordinate measuring machines. The JET recommended management self-assessments for both activities on the basis that both were expansions of existing capabilities, since there are other lathes and measuring machines currently in operation. The expansion of capability argument has previously created debate at LANL regarding the definition of an existing capability (see 5/5/2017 weekly). The activity reviewed for the Weapons Engineering Tritium Facility involves the startup of a new process to vent the Flanged Tritium Waste Containers (FTWC) that may contain headspaces with potentially explosive mixtures of hydrogen isotopes and oxygen (see 12/16/2016 weekly). The safety basis modification to support the venting is still under development, but the process is expected to involve a critical lift to remove the FTWCs from their overpacks and installation of a custom-designed fixture to support manual venting. The JET recommended a CRA for this activity.

Emergency Management: Last week, the NNSA Field Office issued their assessment report on the technical planning basis element of LANL's emergency management program. The report notes that the overall program framework is adequate, but includes two findings concerning: (1) inadequate implementation of the chemical management program leading to inadequate identification of hazards for emergency planning and (2) Emergency Planning Hazards Analyses (EPHA) with inadequacies concerning the documentation of inputs and assumptions, sources of values used, or technical justification for input parameters. In the former case, the report cites several instances where Field Office personnel identified hazardous biological agents and chemicals within LANL facilities, including some in proximity to nuclear facilities, which were incorrectly excluded or missing from hazard surveys. In the latter case, the report provides examples of inconsistent and poorly justified atmospheric dispersion assumptions, incorrect indicators of an emergency events, and other inaccuracies in EPHAs. The Field Office requested a corrective action plan within 30 days.

Plutonium Facility–Infrastructure: In late September, craft personnel completed reinforcing the 27th roof girder with carbon-fiber. Engineering personnel subsequently decided to reinforce a 28th girder. Craft personnel expect to complete it before the end of the year. These actions strengthen the seismic safety posture of the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 17, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending November 17, 2017

DNFSB Activity: On Tuesday, Board Member Santos called a staff member at the EM Field Office to discuss questions related to the extent of condition for a fire protection issue described in the Board's letter regarding the Transuranic Waste Facility dated November 9, 2017.

DNFSB Staff Activity: On Thursday, A.R. Powers, P.J. Migliorini, and M.T. Wright held a teleconference with the NNSA Field Office to discuss observations from the first phase of the safety posture review of the Plutonium Facility.

Transuranic Waste Management: On Tuesday, Plutonium Facility waste management personnel successfully utilized the mobile loading unit to prepare a shipment of six drums of waste from the Offsite Source Recovery Program for transport to the Waste Isolation Pilot Plant (WIPP). This represents the first shipment from LANL since WIPP resumed waste receipt operations. Last week, LANL personnel had planned on shipping a larger number of drums that included some sent to TA-55 from Area G; however, that effort was challenged with issues concerning safeguards, procedures, and unfavorable weather conditions. In particular, weather restrictions related to temperature and wind speed significantly constrain the use of the mobile loading unit in LANL's climate.

Re-establishing a reliable transuranic waste shipping capability remains essential to risk reductions activities across LANL. For example, the limited availability of safety controls for the aboveground inventory means that disposition to WIPP is the primary risk-reduction method for Area G. Similarly, LANL's forecast indicates that waste generation at the Plutonium Facility will be dominated for about the next decade by the disposition of legacy residues and contaminated equipment. LANL personnel are currently analyzing options for restoring operations at the RANT Shipping Facility or establishing an alternative capability.

Unremediated Nitrate Salt (UNS) Waste Treatment-Readiness Activities: Last Thursday, the Waste Characterization, Reduction, and Repackaging Facility (WCRRF) entered COLD STANDBY mode after the last daughter drums from the remediated nitrate salt waste treatment campaign were shipped to Area G. The mode change facilitates an ongoing outage to complete a number of maintenance activities and prepare the facility for the UNS campaign. In particular, WCRRF personnel plan to remove the large refrigerator unit and change the flasks on the water delivery system for the processing glovebox. They currently plan to commence UNS liner-pull activities and treatment at the end of this month.

Weapons Engineering Tritium Facility: Last Thursday, the NNSA Field Office directed LANL management to provide for concurrence a plan to either replace the existing Halon fire suppression system in the operations center or submit an appropriate exemption/equivalency for the system. This action should solidify a path forward for the existing system, which was downgraded from safety significant in July 2016 and is nearing its end-of-life.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 24, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending November 24, 2017

Transuranic Waste Facility (TWF)–Safety Basis: Last Tuesday, TWF safety basis personnel entered the New Information process regarding an apparent inconsistency between language in the safety basis and an element of a safety management program associated with the waste acceptance criteria. Waste receipts remain on hold after TWF management paused work when NNSA Field Office personnel raised this question last month (see 10/27/2017 weekly).

Confinement Vessel Disposition (CVD) Project: On Monday, CVD personnel received the seventh vessel for processing at the Chemistry and Metallurgy Research building, following a recent series of waste container transfers to the Plutonium Facility to lower material-at-risk. The sixth vessel was completed in mid-September and had resulted in the creation of 69 transuranic waste drums. CVD personnel anticipate completion of the seventh vessel in June 2018 with the generation of an estimated 80 transuranic waste drums. Overall project completion, including an added tenth sphere with minimal material-at-risk, remains on track for December 2019.

Unremediated Nitrate Salt (UNS) Waste Treatment: On Tuesday, the Associate Director for Nuclear and High Hazard Operations, as startup authorization authority, approved commencement of UNS liner pull activities at Area G. Area G personnel expect to begin next week, pending DOE-EM Headquarters approval of the UNS treatment procedure, as required by the corrective action plan for the radiological release event at the Waste Isolation Pilot Plant.

Plutonium Facility–Radiation Protection: Last week, radiological control technicians (RCT) reported several contamination events in the facility. In all cases, either workers detected the contamination as part of routine monitoring or continuous air monitors (CAM) alarmed as designed. Additionally, there are no indications of radiological uptakes by the involved workers. The events included: (1) three closures of the north corridor resulting from a CAM alarm and RCT surveys indicating contamination of up to 4500 dpm. RCT management believes this contamination may have migrated from the room undergoing decontamination discussed below and have strengthened confinement practices; (2) a glovebox glove breach during repackaging activities of legacy nuclear materials, which was identified by the worker during self-monitoring. Glovebox safety personnel will review the location for latent sharps and recommended glove change periodicity; (3) a worker handling previously surveyed items, proactively self-monitored and discovered contamination on his glove. RCTs determined the contamination was from a particle, but were unable to otherwise find a source in the area; and (4) a worker detected skin contamination on their hand during self-monitoring, which RCTs successfully decontaminated and determined to be a particle.

Decontamination activities continue in the room affected by the errantly breached glovebox. Since management briefed the NNSA Field Office on progress (see 10/3/2017 weekly), six CAM alarms have been reported while the room was restricted. In the coming weeks, RCT management expects to release this room and its neighbor as contamination areas. As such, workers will be required to wear additional protective clothing and receive more extensive radiological exit surveys than is typical in the facility. RCT management proactively instituted this practice in a nearby room used for Pu-238 processing after a number of contamination events occurred during the last two months.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 1, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending December 1, 2017

DNFSB Staff Activity: R.P. Arnold and P.J. Migliorini augmented oversight activities, including walk-downs of the Plutonium Facility, Chemistry and Metallurgy Research building, Area G, and the Weapons Engineering Tritium Facility.

Management: On Tuesday, the leadership of Los Alamos National Security, LLC announced that Terry Wallace will succeed Charlie McMillan as LANL Director effective beginning January 1, 2018.

Transuranic Waste Facility (TWF)–Safety Basis: On Thursday, TWF management concluded their New Information (NI) process and determined that changes are required to both the safety basis and technical safety requirements at the next annual update; however, the situation did not constitute a potential inadequacy of the safety analysis. The NI concerned an apparent inconsistency between language in the safety basis and an element of a safety management program associated with the waste acceptance criteria (see 11/24/2017 weekly). The safety function of the control in question, which protects key initial conditions in the safety analysis, is to: “prevent energetic events and runaway reactions resulting from noncompliant TRU [transuranic] waste contents, such as oxidizers, time-sensitive materials, incompatible chemicals, and oxidizer fuel mixtures.” The NI justification asserts that this function can be effectively implemented via a records check to ensure wastes to be received do not possess the hazardous waste codes for ignitability, corrosivity, or reactivity. The NI further suggests that this check is adequate to ensure that incoming wastes are approvable against the chemical properties section of the waste acceptance criteria for the Waste Isolation Pilot Plant.

Unremediated Nitrate Salt (UNS) Waste Treatment: On Wednesday, Area G operators commenced their campaign to pull the liners from the UNS containers and repackage into new 55 gallon drums. By midday Friday, they had completed 5 of the 26. Personnel at the Waste Characterization, Reduction, and Repackaging Facility continue maintenance activities, including troubleshooting a HEPA filter, in preparation for the upcoming UNS treatment activities.

Plutonium Facility–Glovebox Safety: On Tuesday, the glovebox safety program manager and a team of independent operators walked-down the glovebox involved in a recent glove breach (see 11/24/2017 weekly) and discovered a potential latent sharp. The sharp is associated with a latching mechanism used to secure external shielding to certain nuclear material containers. The latch is in a location consistent with the typical hand positioning needed to move the container in a glovebox, as well as the breach location found on the glove. They plan to issue a lessons learned and ensure that the latches are protected with tape or other materials when used inside a glovebox.

Emergency Management: On Thursday, the NNSA Field Office approved the Emergency Readiness Assurance Plan for fiscal year 2018. Goals of particular interest include: development of an all-hazards emergency management plan; establishment of a comprehensive and standardized facility preparedness program; enhancement of worker awareness of protective actions; and continued maturation of the group to improve planning, training, drills and exercises, and readiness assurance.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 8, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue
SUBJECT: Los Alamos Report for Week Ending December 8, 2017

DNFSB Staff Activity: On Tuesday, M.R. Bradisse and N.M. George held onsite discussions with LANL and NNSA Field Office personnel regarding their ongoing review of the nuclear criticality safety program at the Plutonium Facility. On Wednesday, A.R. Powers and team held a teleconference with LANL and NNSA Field Office personnel to discuss observations from the first phase of their safety posture review of the Plutonium Facility.

Emergency Management: On Thursday, LANL personnel conducted a multi-facility exercise involving the Radioactive Liquid Waste Treatment Facility (RLWTF), the Waste Characterization, Reduction, and Repackaging Facility (WCRRF), and the Technical Area (TA)-35 complex. The scenario involved a simulated leak of a one pound lecture bottle of chlorine gas in a TA-35 laboratory hood. After correctly identifying the appropriate Emergency Action Level, LANL emergency management personnel ordered shelter-in-place protective actions for four different technical areas; however, only the workers in the TA-35, RLWTF, and WCRRF participated in the exercise. Emergency management personnel have scheduled their formal critique with exercise evaluators for next Monday. Of note, this exercise represents a shift in LANL's approach to meeting the requirements for annual exercises. The new approach combines facilities with the intent of reducing the overall number of exercises to enable increased complexity, improved planning, and more thorough evaluation.

Unremediated Nitrate Salt (UNS) Waste Treatment: Area G personnel successfully pulled and repackaged the liners from 11 of the 26 UNS containers by Thursday night. They plan to complete an additional two containers on Friday. On Monday, WCRRF personnel received UNS containers in anticipation of commencing treatment activities; however, they paused work subsequent to questions from the NNSA Field Office regarding a temporary modification that had been made to the confinement ventilation system. WCRRF engineering personnel approved a temporary modification to support the use of cargo tape to adequately seal the filter plenum access doors. They had discovered that the doors were not properly sealing during filter efficiency testing conducted the previous week. On Tuesday, WCRRF management also determined that they had failed to perform a required surveillance on the ventilation system, declared the system inoperable, entered the appropriate limiting condition for operation, and returned the UNS to Area G. WCRRF management initiated a series of learning teams to review these events and plans to resume UNS treatment once the plenum seals are replaced.

Plutonium Facility–Nuclear Criticality Safety: Last Friday, LANL management proposed closure of an Evaluation of the Safety of the Situation (ESS) that resolves longstanding issues with the nuclear criticality safety evaluations for vault rooms B and I. Closure comes after facility personnel implemented revised evaluations late last month. The issues with these rooms originated in 2007 after questions were raised regarding the reliance on, and supporting certification of, boron used as a neutron poison as part of shielding materials in these rooms (see 8/31/2007 weekly). LANL personnel completed new evaluations in 2012 that did not credit the presence of boron, but then discovered a separate evaluation on the interaction between drawer and floor storage locations that assumed the presence of boron resulting in the ESS (10/19/2012 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 15, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending December 15, 2017

DNFSB Staff Activity: D.J. Brown observed the federal readiness assessment (FRA) on the electrorefining operation (ER) discussed below.

Plutonium Facility–Readiness: This week, a FRA team conducted their review of the new ER line, which consists of six gloveboxes and their associated connecting trunk line. NNSA approved the mission need for this new line in 2001 in order to replace the existing line which was transferred in 1979 from a previous facility. The review included interviews, process demonstrations, and an operational drill. At their out-brief, the FRA team noted three pre-start findings associated with: (1) inadequate seismic and static loading analyses to support the proposed operation in the primary staging glovebox; (2) procedure issues; and (3) startup plan inadequacies with the validation of equipment operability and management oversight. They also identified two post-start findings concerning the conduct of operations sustainability plan and the fire hazard evaluation.

Federal Oversight: NNSA Field Office personnel continue development of their enhanced oversight plan of the operating culture in the Plutonium Facility. The plan is intended as a companion to LANL's conduct of operations sustainment/improvement plan stemming from the overmass event that occurred on August 17, 2017 (see 10/27/2017 weekly). Notable topics of discussion included: coping with recent staffing losses, balancing the oversight and partnering roles of the new NNSA governance model, handling activity-level oversight planning given weaknesses in the facility's plan of the day processes, and assessing the significance of the fact that the sustainment initiative does not specifically address facility operations or maintenance/craftwork. Field office management intends to approve the plan in the coming weeks.

Plutonium Facility–Conduct of Operations: Early last Thursday morning, facility operators received a low temperature alarm on a ventilation intake necessitating a shutdown of a portion of the ventilation system and the transition to Mode 2. The facility returned to normal operations around mid-morning. At the fact-finding, held this Wednesday, attendees discussed concerns and identified corrective actions with the failure to appropriately react to a previous low temperature alarm, independent verification of valve lineups, and a lack of formality with call-out work.

Transuranic Waste Facility (TWF): On Thursday, TWF operators successfully received their second four-drum shipment of waste containers from the Plutonium Facility. Operators appropriately paused when they observed that the expected radiological information tags had been removed from the containers, but were able to obtain copies and verify the necessary information. Based on the success, TWF management is considering requesting NNSA concurrence to move forward to an eight drum receipt in early 2018. Last week, Plutonium Facility program and facility operations management assumed responsibility for TWF.

Unremediated Nitrate Salt (UNS) Waste Treatment: On Thursday, Waste Characterization, Reduction, and Repackaging personnel restored the operability of the ventilation system and returned the facility to OPERATIONS mode after the successful repair of the filter housing gaskets (see 12/8/2017 weekly). They subsequently received a UNS container and commenced treatment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 22, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending December 22, 2017

DNFSB Staff Activity: On Tuesday, N.M. George, P.A. Meyer, P.J. Migliorini, A.R. Powers, and M. Randby held onsite discussions with LANL and NNSA Field Office personnel. The discussions involved questions concerning the statistical methodology and associated analyses supporting the leak path factor values used in the safety basis for the Plutonium Facility.

Fire Protection: Last Monday, the NNSA Field Office conditionally approved LANL's permanent equivalency request in order to resolve conflicts among fire protection requirements for gloveboxes and similar process enclosures. The request proposed utilizing a fire hazard evaluation (FHE) process to meet requirements and expectations contained the DOE-STD-1066, International Building Code, National Fire Protection Association, and American Glovebox Society standards for establishing fire protection requirements. The request also establishes inerting systems, when properly designed and alarmed, as an equivalent alternative to fire suppression systems. The conditions of approval include mandatory use of LANL's FHE procedure, required NNSA Field Office concurrence for gloveboxes that contain a heat source without either inerting or fire suppression, and quarterly updates on FHE progress. LANL managers are currently developing a schedule to complete FHEs for all of the gloveboxes in the Plutonium Facility. While some FHEs have been developed as part of readiness, many gloveboxes without inert atmospheres await completion of FHEs and associated installation of fire suppression systems, as to be determined by evaluation.

Unremediated Nitrate Salt (UNS) Waste Treatment: Last Friday, the Associate Director for Nuclear and High Hazard Operations, as the relevant startup authorization authority, notified the EM Field Office regarding her approval to proceed with processing one UNS container without further readiness review. This container requires a liner-pull activity at Area G, but had been excluded from the contractor readiness assessment because its inventory of radioactive material exceeds the Hazard Category 2 threshold. LANL personnel applied a correction factor based on the material's dispersion properties and were able to support a revised equivalent inventory. Specifically, the UNS material is considered non-combustible/dispersible in the safety basis. LANL personnel used estimates of the mass fraction of organic material derived from real-time radiography imagery to determine an updated combustible equivalent factor of 8 percent for the UNS.

RANT Shipping Facility: On Tuesday, LANL and NNSA Field Office personnel briefed NNSA Headquarters personnel on the status of preliminary safety basis analyses meant to examine the adequacy of the proposed seismic retrofit (see 9/8/2017 weekly). The retrofit design is intended to achieve performance category 2 seismic criteria; however, preliminary safety analyses indicate this level of performance may be insufficient under some postulated scenarios. As such, LANL personnel are evaluating alternatives to achieve an enduring transuranic waste loading capability that is weather resistant. In the interim, LANL will continue to rely on mobile loading (see 11/17/2017 weekly).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 29, 2017

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue

SUBJECT: Los Alamos Report for Week Ending December 29, 2017

The Year on a Page: A summary of the key developments of 2017.

- Area G and Waste Characterization, Reduction, and Repackaging Facility personnel successfully completed their campaign to treat the inappropriately remediated nitrate salt wastes thereby eliminating a significant hazard. They have also commenced the follow-on campaign to treat the unremediated nitrate salt wastes and are on track for completion before the end of the bridge contract with DOE-EM.
- The NNSA Field Office Manager and LANL Director both announced retirements in advance of the upcoming transition of the management and operations contract. Both organizations also initiated accompanying changes in personnel and reporting structures.
- The Transuranic Waste Facility achieved operational status as a new hazard category 2 nuclear facility and began execution of their startup plan with the receipt of two, four-drum shipments. Facility personnel continue efforts to replace the seismic switches, upgrade the fire suppression system, and convert the dry pipe system from nitrogen to air.
- Plutonium Facility personnel completed readiness activities for aqueous chloride processing and americium oxide production, mobile loading of transuranic waste, and electrorefining. The pace of startups continues next year with planned readiness assessments for the new high-voltage electron beam welder, uranium part decontamination, and aqueous nitrate processing.
- Plutonium Facility management issued a new plan to improve and sustain the conduct of operations in the facility after an overmass in the casting room and two significant radiological contamination events. The NNSA Field Office is developing a companion plan.
- Plutonium Facility personnel continued to improve the safety posture of the facility, notably completing the effort to wrap 27 roof girders with carbon fiber reinforcement and increasing by 350 since March 2015 the number of certified containers in use on the first floor to better protect nuclear material. They also continue to refine their understanding of the seismic fragility and interactions issues with fire suppression system raised in the Board's letter dated May 12, 2016.
- Weapons Engineering Tritium Facility (WETF) personnel successfully shipped four tritium items to the Savannah River Site and are nearing completion of the system upgrades necessary to begin risk reduction activities associated with the bulk removal of tritium gas.
- WETF and Area G personnel continue to improve their understanding of the safety of the situation associated with the Flanged Tritium Waste Containers. In August 2016, LANL personnel determined some of these containers may be pressurized with an explosive mixture of oxygen and hydrogen isotopes. They are finalizing the process to vent the containers currently located at WETF following completion of safety basis changes and readiness.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 5, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski

SUBJECT: Los Alamos Activity Report for Week Ending January 5, 2018

D. Gutowski started his assignment at LANL.

Federal Oversight. Last month, NNSA Headquarters approved an organizational change and realignment for the local field office. The key changes include: establishing a Deputy Manager for Technical Operations; retitling the existing Deputy Manager to Business, Security, and Missions; and splitting the previous office of the Assistant Manager (AM) for Operations into an AM for Field Operations and a new AM for Nuclear Safety, Engineering, and Readiness. In addition, each AM will be assigned a deputy. Overall, this action addresses span of control concerns and returns the field office to a structure similar to several years ago. Field office management has also prioritized working qualification and hiring processes for Facility Representatives after the loss of five personnel last year.

Plutonium Facility–Infrastructure. Last month, LANL management transmitted the fiscal year 2018 (FY18) update to the TA-55 Project Execution Strategy to the NNSA Field Office. Major accomplishments from FY17 included: completing the wrapping of roof girders; seismic qualification testing of critical spares for electrical and ventilation systems; and installation of concrete pads for new generators serving the electric firewater pumps. Planned work for this year includes: development of a prioritized list of gloveboxes to undergo fire hazard evaluations; complete installation of the diesel generators and transfer switches for the electric firewater pumps; and continuing seismic qualification testing of other critical spares. Notable out-year activities include: modifications to ensure certain walls meet their intended fire barrier functions by FY21; ventilation system modification by FY22; replacement of the fire alarm system by FY23; and removal of non-seismically qualified buildings from the fire water yard main by FY24.

Plutonium Facility–Work Control. On Wednesday, Plutonium Facility personnel held a post-job review for a radiological contamination event that occurred in mid-December. During replacement of filters for glovebox service lines, a routine job survey discovered contamination on one worker's gloves and then a continuous air monitor alarmed. The maintenance personnel who were wearing respirators placed the work in a safe condition and exited. Radiological control technicians found contamination on three of the workers' protective clothing. Post-job participants identified that the isolation process did not recognize that the potential for contamination in this filter (a negative service system) differed from those replaced previously without incident (positive service systems). As such, the work package did not identify appropriate controls. Facility management intends to issue a lessons learned.

Emergency Management. On Tuesday, the NNSA Field Office approved the implementation plan for DOE Order 151.1D, *Comprehensive Emergency Management* (see 10/14/2016 weekly). NNSA Headquarters revised this order in response to the recently closed Board Recommendation 2014-1, *Emergency Preparedness and Response*. LANL's plan indicates that most requirements will be implemented by the end of fiscal year 2019, though full implementation to include updated hazard surveys and technical basis documents is anticipated by the end of fiscal year 2021. The approval letter also notes the need for NNSA Headquarters to clarify the annual exercise requirements for Defense Nuclear Facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 12, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending January 12, 2018

Federal Oversight. On Wednesday, the NNSA Field Office Manager and Senior Technical Safety Advisor conducted the final qualification walk-through for the senior Facility Representative at the Plutonium Facility. They noted the candidate's exceptional performance. This action brings the total of fully qualified NNSA Facility Representatives up to two.

Plutonium Facility–Work Control. On Monday, Plutonium Facility personnel conducted a post-job review after craft workers heard an unusual whistling noise and identified unexpected breaches in the confinement for an existing glovebox undergoing refurbishment. The breaches were associated with improperly sealed penetrations; however, in this case, radioactive contamination did not migrate from the glovebox. Post-job personnel and facility management determined the need to develop a process to ensure confinement integrity is appropriately maintained and controlled as new gloveboxes and associated components are connected to existing contaminated systems. Management also directed the review of installation activities currently underway for the need to implement compensatory measures while the new confinement integrity process is developed.

Plutonium Facility–Safety Basis. LANL prepared a new Project Execution Plan describing the approach to consolidate legacy safety basis items for the Plutonium Facility into a single DOE-STD-3009-94 compliant Documented Safety Analysis and Technical Safety Requirements. This supersedes a previous plan (see 2/24/2017 weekly) that projected a consolidated safety basis in August 2017. The new plan projects submittal of a consolidated safety basis to the NNSA Field Office in August 2018 with approval in October 2018.

Transuranic Waste Facility (TWF). On Thursday, TWF personnel successfully completed their third receipt of four waste containers from the Plutonium Facility. TWF management had previously requested concurrence to proceed with an eight container receipt in accordance with the second phase of their startup plan; however, NNSA Headquarters denied concurrence based on concerns with oversight and corrective action related documentation.

RANT Shipping Facility. Last month, LANL completed an analysis of alternatives to ensure a long term capability for shipping transuranic waste offsite as the RANT facility remains in cold standby due to seismic concerns (see 12/19/2014 weekly). They analyzed five options including seismic upgrades to RANT, a replacement for RANT, a new covered loading structure, and accepting the risk of using RANT in its current condition. The alternatives analysis concluded that the best overall option was to accept RANT in its current condition. The NNSA Field Office is evaluating this recommendation.

Unremediated Nitrate Salt Waste Treatment. Last week, Area G personnel completed the remaining five drum liner pulls. Personnel at the Waste Characterization, Reduction, and Repackaging Facility completed the sixth out of twenty-seven drums this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 19, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending January 19, 2018

Federal Oversight. NNSA provided the LANL contractor with the fiscal year 2017 Performance Evaluation Report. The report notes successes in areas such as treatment of remediated nitrate salt waste, stockpile modernization, and restart of activities at the Plutonium Facility. Performance weaknesses included issues with procedure compliance, a negative trend in the source of reporting for criticality safety infractions, and a disconnect between causal analyses and corrective actions.

At the direction of NNSA Headquarters, the NNSA Field Office Manager, the Deputy Manager for Technical Operations, and the Assistant Manager for Mission Assurance and Infrastructure recently opened second offices in the LANL contractor's main administration building. The intent of the move is to improve partnering with the LANL contractor; however, field office management is mindful of the need to continue a strong presence with the federal staff in support of their oversight role.

Plutonium Facility–Equipment Deactivation. Last Wednesday, Plutonium Facility personnel attempted to transfer about 60 liters of a legacy nitric acid solution with a low plutonium concentration out of tanks in a glovebox slated for removal. This material was not drained and flushed following completion of programmatic activities in this room more than ten years ago. The transfer did not arrive at the receiving tank, and the majority of the material remains held-up in the transfer line. Facility personnel believe that the most likely problem was insufficient vacuum to lift the dense solution into the receiving tanks. This Thursday, they started evaluating options for recovery. Vacuum systems and water addition capability were removed from this area prior to the attempt at draining the solution making recovery more challenging. DOE guidance on deactivation and decommissioning processes notes that support and utility systems should remain in operating condition if they may be required during the disposition phase.

Transuranic Waste Facility–Safety Basis. Last month, LANL management submitted to the NNSA Field Office a project execution plan for the reclassification of the fire suppression system (FSS) to safety significant. The plan responds to a condition of approval that requires the submission of a safety basis change to support the reclassifying the FSS within six months of the start of operations. Additionally, the NNSA Cognizant Secretarial Officer caveated his previous approval with the intent to re-evaluate approval if the safety significant FSS was not fully implemented by February 28, 2018. The plan's schedule indicates a period of comment iteration with the NNSA Field Office beginning in February with approval projected for April 26 and subsequent implementation on July 26, 2018. On Thursday, the NNSA Field Office Manager approved the safety basis review plan for this submittal. Notably, the review plan includes the participation of three personnel from external NNSA entities. This safety basis submission has the potential to address many of the concerns communicated in the Board's letter dated November 9, 2017.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 26, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending January 26, 2018

Plutonium Facility–Conduct of Operations. Last week, Plutonium Facility personnel entered the appropriate limiting condition for operations after they were informed that they had potentially exceeded the material-at-risk limit for the radiography tunnel. Workers removed a non-credited tantalum can containing a non-certified heat-source plutonium component from a certified container. Once removed from the certified container, the material no longer benefited from the reduced damage ratio and they exceeded the material-at-risk limit for the area. Operators returned the can with the component to the certified container in about an hour after acknowledging the error. During the fact-finding, management noted that special attention should be paid to non-standard configurations. They also restricted radiography of non-standard configurations of heat-source plutonium.

Plutonium Facility–Nuclear Criticality Safety. On Tuesday, Plutonium Facility personnel conducted a fact-finding for a potential process deviation concerning a High Reactivity Unit (HRU). Criticality safety engineers use the HRU term for fissionable material items that are intended as part of a nuclear explosive, but do not meet the requirements of their defined term Pu in Pit. HRUs require specific authorization prior to movement and a unique item description code in the safeguards database. While planning a future work activity, workers noted the presence of a HRU that was incorrectly coded in the database and was not covered in the criticality safety posting. In this case, the posting was generated prior to the origin of the HRU term and the unit appears to have been missed during the initial HRU coding roll-out. Fact-finding participants determined the need to perform an extent of condition and strengthen training regarding HRUs.

Plutonium Facility–Equipment Deactivation. Plutonium Facility personnel are moving forward with plans to remove the solution that became stuck in a transfer line (see 1/19/2018 report). They are adjusting the valve lineup for the vacuum transfer system with the intent of providing more motive force to move the solution out of the transfer line. NNSA Field Office senior management walked-down the sending and receiving process rooms, as well as the transfer line with Plutonium Facility management. During the walk-down, NNSA Field Office personnel suggested the need for additional sampling of the solution. Subsequently, Plutonium Facility personnel plan to take samples to augment their characterization, which is based on process knowledge and sample data taken last summer. They plan on reattempting the vacuum transfer with a new valve lineup prior to receiving the new sample data.

Area G–Safety Basis. On Monday, the EM Field Office transmitted to LANL management comments related to the revised Evaluation of the Safety of the Situation (ESS) for the continued safe storage of the Flanged Tritium Waste Containers that have potentially explosive headspace mixtures of oxygen and hydrogen isotopes (see 10/13/2017 report). They requested a resubmittal of the ESS that address the comments at their earliest convenience.

Environmental Management. On Wednesday, the EM Field Office notified their new contractor, Newport News Nuclear BWXT-Los Alamos, to proceed with transition activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 2, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending February 2, 2018

DNFSB Staff Activity. Members of the Board's staff held a closeout teleconference with NNSA Field Office and LANL personnel to provide the staff's observations from their review of the leak path factor modeling used in the Plutonium Facility safety basis (see 12/22/2017 report).

Plutonium Facility–Equipment Deactivation. Plutonium Facility personnel were able to adjust the valve lineup to improve vacuum and complete the solution transfer that had been stuck in the line for more than two weeks. The exact volume transferred has not been determined due to uncertainty in the original volume and uncalibrated tanks on the receiving side. They plan to flush the line with water in the near future. Since water utilities were removed from the sending location, they plan to bring small bottles of water into the glovebox to supply flush water. The next step is to conduct a limited scope campaign to cement this solution along with other legacy solutions that have accumulated since the 2013 pause. They expect to conduct this campaign under a special allowance, since it will likely occur prior to completing formal restart.

Plutonium Facility–Conduct of Operations. On Monday, Plutonium Facility personnel conducted a fact-finding after a craft worker entered an airborne radioactivity area without filters installed in his powered air-purifying respirator (PAPR). While there were no indications of an uptake, fact-finding participants noted that the work crew would benefit from a checklist to ensure proper use of equipment rather than exclusively relying on their training. They also noted that this was the worker's first hot job and would have benefited from additional experience in less hazardous environments. The maintenance supervisor paused PAPR jobs until a learning team is completed.

Unremediated Nitrate Salt (UNS) Waste Treatment. On Monday evening, while leaving the facility for the day, a Waste Characterization, Reduction, and Repackaging Facility (WCRRF) operator alarmed the personal contamination monitor. The responding radiological control technicians identified alpha contamination on the skin of the operator's forearm at levels of about 17 k dpm. They commenced decontamination activities and worked with the operations center staff to transfer the individual to LANL's Occupational Medicine (OccMed) clinic, where he was successfully decontaminated and released without restrictions. At the fact-finding, operations center personnel noted difficulty reaching the after-hours on-call OccMed provider delaying the response. Ultimately, the operations center supervisor was able to reach an OccMed supervisor who was able to initiate preparations for their response. Fact-finding participants determined the need for a learning team to review the communications difficulty, which they currently believe was related to cell phone connectivity at the on-call provider's home. WCRRF personnel also subsequently determined that the contamination resulted from a breached glovebox glove. As of Thursday evening, WCRRF operators completed processing of 16 of 27 UNS containers.

Transuranic Waste Facility (TWF). TWF management received NNSA approval to proceed with phase 2 of their startup plan. Accordingly, they successfully received a shipment of eight containers during a roughly six hour evolution on Wednesday. TWF operators and management continue to refine their conduct of operations in order to ensure safe and efficient work accomplishment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 9, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski

SUBJECT: Los Alamos Activity Report for Week Ending February 9, 2018

Federal Oversight. On Tuesday, the NNSA Field Office issued their enhanced oversight plan and conduct of operations implementation plan for the Plutonium Facility (see 12/15/2017 report). The oversight plan includes use of field office personnel augmented by resources from the NNSA Office of the Deputy Associate Administrator for Safety to increase field oversight to assure the contractor's sustained operational compliance with their conduct of operations manual. The initial focus area is an assessment of implementation of controls and conduct of operations. The implementation plan specifies that federal oversight will be coordinated through one of the Facility Representatives and includes templates for expected deliverables from oversight personnel.

Fire Protection. On Monday, Sigma Complex workers removed a burr from a recently cut piece of depleted uranium metal to prevent injury; however, it sparked and ignited two rags wetted with acetone. They quickly placed the rags into a nearby plastic bucket used to collect chips and extinguished the fire with staged graphite, preventing further involvement of uranium materials. No injuries and no contamination resulted from the event. Notably, this was the same operation that experienced a small chip fire last year (see 5/12/2017 report) and corrective actions were completed, including an improved work control document that a fire protection engineer reviewed due to the anticipated frequency of fires involving pyrophoric materials. However, at a follow-up discussion requested by the NNSA Field Office, LANL personnel acknowledged the need to clarify expectations for reporting extinguished fires—in this case, the workers' supervisor contacted the emergency operations center, but the fire department was not dispatched to check the scene as intended.

Plutonium Facility–Risk Reduction Activities. LANL personnel briefed NNSA Headquarters managers on progress with the Materials Recovery and Recycle program. Achievements included processing 33 items from the vault, developing a tool to facilitate safer disposition of metallographic mounts, and processing of 26 liters of bottled solutions under a safe and stable campaign to eliminate a criticality infraction associated with the electrolytic decontamination system. They also reviewed options to support the future of the Special Recovery Line, which provides a unique capability for the weapons complex (see 3/21/2014 report).

Emergency Management. Last month, the NNSA Field Office established a formal watch bill for the federal officials that may be needed to support an emergency response. LANL emergency management personnel are still assessing the need for a formal watch bill.

Safety Basis. LANL safety basis personnel informed the NNSA field office that they intend to adjust the timing of annual updates for safety bases. Instead of submitting annual updates one year after the last submittal, they plan to submit them one year after the date of NNSA approval.

Weapons Engineering Tritium Facility (WETF). Last week, WETF safety basis personnel entered the New Information process due to a question as to whether clips on a seismic rack have a safety function to retain containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 16, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski

SUBJECT: Los Alamos Activity Report for Week Ending February 16, 2018

DNFSB Activity. NNSA Field Office senior staff reported that they held a phone discussion with Board Member Santos regarding restart of electrorefining operations in the Plutonium Facility.

Transuranic Waste Facility (TWF). On Monday, TWF managers briefed the NNSA Field Office on the number of containers available for shipment from the Plutonium Facility. TWF managers indicated there are currently 351 eligible standard 55-gallon drums after accounting for state regulatory restrictions and a prohibition on pipe overpack containers. In response to questions associated with compliance with the current waste acceptance criteria (WAC) for the Waste Isolation Pilot Plant (WIPP), which is required by an element of a safety management program, TWF managers expressed confidence that each of these containers would likely meet the new WAC; however, they indicated that none of the containers had completed the new elements of the WIPP WAC. The new elements of the WIPP WAC include the Generator Site Technical Review, the basis of knowledge review, and a chemical compatibility evaluation—all corrective actions to prevent recurrence of the energetic event that resulted in the WIPP radiological release event. This is important because the approved safety basis notes that the unmitigated consequences from a WIPP-like event, in the absence of new DOE direction, could be two to three orders of magnitude higher than currently analyzed. On Wednesday, TWF safety basis personnel entered their New Information process on this issue for a second time (see 12/1/2017 weekly).

Chemistry and Metallurgy Research Building. A contractor readiness assessment team completed their review of the drum venting and overpacking operation for the americium-241 materials previously received from an offsite commercial vendor (see 8/18/2017 weekly). At their outbrief, the team identified three pre-start findings associated with: (1) radiological dose tracking for a lifting sling; (2) subject matter expert review of the procedure changes; and (3) implementation of a safety basis control in the procedure. The team also raised significant concerns regarding procedural adequacy, conduct of operations, and resolution of previously identified issues. They linked these concerns to human performance error precursors and weaknesses in institutional programs.

Radioactive Laboratory Utility Office Building (RLUOB). The contractor submitted a revised Safety Design Strategy for upgrading RLUOB from a radiological facility to a hazard category-3 nuclear facility to the NNSA Field Office for review and approval (see 4/17/2015 weekly). The proposed strategy relies on a Specific Administrative Control to keep the material-at-risk inventory in the facility at a level that ensures offsite and collocated worker consequences are well below the threshold for additional controls. The strategy also includes engineered and administrative defense-in-depth controls including the fire protection system, ventilation system, and building structural design.

Plutonium Facility–Infrastructure. Plutonium Facility personnel started the tie-in of the new safety-significant Uninterruptable Power Supply. The NNSA Field Office approved a temporary safety basis modification that accommodates the interim configuration during the transition from the existing to the replacement system. This modification allows the system to be inoperable for a period of time during the final tie-in. Final connection activities are being performed while the facility is in standby mode.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 23, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending February 23, 2018

DNFSB Activity. Acting Chairman Hamilton and staff members Herrera and Migliorini visited the laboratory on Wednesday and Thursday. They received briefings on improvements to the emergency management program; safety posture and conduct of operations at the Plutonium Facility; and activities at the NNSA and EM Field Offices. They also walked-down multiple facilities, including the Plutonium Facility.

Safety Basis. On Thursday, the NNSA Field Office formally requested that the LANL contractor develop a strategy including milestones and the resources required to upgrade the safety bases to achieve compliance with DOE-STD-3009-2014 for the Plutonium Facility, Transuranic Waste Facility, RANT Shipping Facility, and Weapons Engineering Tritium Facility. This represents a positive step toward developing high quality safety bases and implementing previous contract requirements (see 10/14/2016 weekly) in advance of the upcoming change in LANL contractors.

Plutonium Facility–Restart Activities. On Thursday, the NNSA Field Office Manager approved startup authorization for electrorefining operations. His approval comes after a line management review team completed their assessment and briefed him on the adequacy of actions taken to resolve the pre-start findings and the actions planned for the post-start findings (see 12/15/2017 weekly).

Plutonium Facility–Infrastructure. During final tie-in of the new Uninterruptable Power Supply (UPS) last weekend (see 2/16/2018 weekly), one programmable logic controller and two communications links supporting the facility control system did not return to service following testing. Facility personnel entered the limiting condition for operation for the criticality alarm system due to inoperability of the UPS. They replaced the communications links and are using a redundant programmable logic controller. On Thursday, they successfully completed a two-hour load test and declared the new UPS to be operable.

Plutonium Facility–Radiological Safety. On Tuesday, a glovebox worker detected contamination on their personal protective gloves upon exiting the glovebox gloves. Radiological control technicians reported 73,000 dpm alpha contamination on the individual's finger. Decontamination efforts were successful and nasal smears were negative. At the fact-finding, participants noted the need to develop a tool to eliminate a potential latent sharp associated with a scouring pad.

Waste Characterization Reduction Repackaging Facility (WCRRF). Last week, workers observed water dripping from the glovebox bag off stub. A radiological control technician determined the water was contaminated and found contamination on the protective clothing of two glovebox workers. All personnel successfully cleared contamination monitors following doffing. As a corrective action, WCRRF management has eliminated water misting to control dust during bagging operations as it appears the water is collecting. This is consistent with practice at the Plutonium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 2, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski

SUBJECT: Los Alamos Activity Report for Week Ending March 2, 2018

Plutonium Facility–Safety Basis. On Wednesday, Plutonium Facility management declared a potential inadequacy of the safety analysis related to the unanalyzed storage of plutonium-238 feed materials in a basement safe. Programmatic personnel had stored about 80 units of this material in a safe for about two months beginning on March 15, 2017. Shortly after the units were removed, safety basis personnel raised a potential issue about the practice and initiated their safety basis change review process. As part of that review, they identified issues regarding thermal loading and the adequacy of the safety basis description, and entered their New Information process last Tuesday. At the fact-finding, participants raised questions regarding procedural coverage for material movements and unreviewed safety question screening for new equipment installations; confusion with the terms “staging” and “storage” between the safety basis and safeguards documents; and the availability of storage space for future shipments. Facility management has restricted storage of these materials in safes via the shift orders.

Plutonium Facility–Work Planning. On Wednesday, Plutonium Facility personnel held a fact-finding after a craft worker received a puncture wound while kneeling in a high contamination area. Participants noted appropriate response to the injury, which was found to have no detectable radioactivity. However, management noted the need to strengthen the processes used to protect against sharps hazards in high contamination areas. In particular, they noted that the sharps expert needs to observe the work area and the workers need to enhanced rigor for placing equipment and debris.

Emergency Management. On Wednesday, emergency management personnel conducted a quarterly exercise in Areas G and L of TA-54. The scenario involved an ammonia release from a container in Area L and worker injuries. During the formal critique, the evaluators noted opportunities for improvement with emergency notifications. Not all notifications to TA-54 personnel included details such as the location or nature of the release to support immediate protective actions. There were also instances where workers did not receive notifications from the multiple forms of communications in use. These are longstanding issues as noted in the Board’s letter dated October 11, 2017. The NNSA Field Office used four outside evaluators to observe this exercise as part of an assessment.

Transuranic Waste Facility (TWF). On Monday, TWF personnel held a post-job to review practices after a piece of scaffolding fell and damaged the insulation on the firewater tank. The tank wall was not damaged and facility personnel are working with the vendor to obtain a repair kit. The tank is currently credited as defense in depth, but the NNSA Field Office has directed the fire protection system to be upgraded to safety-significant. The scaffolding was supporting a job to replace the tank level switch, as the original is not properly rated for outdoor usage. Post-job personnel noted the need to ensure the appropriate number of craft personnel for the job.

Weapons Engineering Tritium Facility–Safety Basis. The NNSA Field Office approved the safety basis amendment to allow removal of an unused exhaust stack (see 11/3/2017 report). Removal eliminates the hazard of the stack falling onto the facility. The safety basis change includes a new specific administrative control for a critical lift plan to reduce the likelihood of the mobile crane from impacting the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 9, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski
SUBJECT: Los Alamos Activity Report for Week Ending March 9, 2018

Transuranic Waste Facility (TWF). On Wednesday, TWF management declared a potential inadequacy of the safety analysis (PISA) regarding the version of the waste acceptance criteria (WAC) for the Waste Isolation Pilot Plant (WIPP) used to implement the TWF safety basis. The TWF safety basis requires that all incoming waste meet the current version of the WIPP WAC. The WIPP WAC was last updated in July 2016 to include corrective actions from the radiological release event; however, LANL did not incorporate this revision until August 2017 and had not fully implemented it in the procedures used to package waste for TWF. During the fact-finding, participants noted that questions regarding the WAC were prevalent during the safety basis development phase of the project and re-emerged after the first waste receipt last October (see 10/27/17 report) leading to two entries into the New Information process (see 2/16/2018 report) prior to declaration of this PISA. Participants concluded that the current inventory of 28 drums is safe due to their belief in the rigor of existing waste management practices. TWF management suspended further waste receipts and structured a path forward to develop an Evaluation of the Safety of the Situation/Justification for Continued Operations that decouples the TWF safety basis from the WIPP WAC, but preserves the technical criteria necessary to ensure that energetic events and runaway reactions are appropriately prevented.

Plutonium Facility–Conduct of Operations. Programmatic operations personnel completed their first run of the new electrorefining line (see 2/23/2018 report). Their oversight team noted no conduct of operations issues, though the run was unsuccessful due to a crucible failure. On Friday, Plutonium Facility management issued their first monthly report on conduct of operations. The report summarizes adverse trends, highlights noteworthy practices, provides a conops culture scorecard, and lists focus areas for next month’s management observations.

Plutonium Facility–Criticality Safety. Last Thursday, a manager performing routine oversight questioned a work team regarding several samples that were placed within a hemishell. The Criticality Safety Posting for this operation prohibits staging of fissile material within hemishells. The team exited the room until criticality safety personnel concluded the configuration was safe and placed the box out of service. At the fact-finding, it became clear that this was another situation where facility personnel were caught in the error trap of the differing definitions of “staging” and “storage” (see 3/2/2018 weekly).

Waste Characterization Reduction and Repackaging Facility. Last week, facility personnel discovered contamination associated with degrading caulking on the underside of the glovebox. They concluded that while the caulk was a discrepant condition, it did not serve a confinement function, which was instead provided by a seal weld within the glovebox. Personnel performed a visual in-service inspection of this weld and concluded it was adequate. However, direct observation of this particular location is challenging and further hindered by residue that obscured the weld. Facility personnel have increased their radiological survey frequency of this location as an additional measure to verify confinement.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 16, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 16, 2018

Transuranic Waste Facility (TWF): On Wednesday, TWF management transmitted an evaluation of the safety of the situation (ESS) on the questions concerning the waste acceptance criteria (WAC) for the Waste Isolation Pilot Plant (WIPP) used to implement the TWF safety basis (see 3/9/2018 report). The ESS concludes that the current inventory of 28 drums is safe based on a review by subject matter experts. The ESS also proposes resuming operations under redefined language for the shipping and receiving safety management program. The proposed language notes that TWF can only receive transuranic waste that is generated by trained and qualified personnel and has an active waste stream profile that is included in an approved acceptable knowledge report. This language replaces previous language linked to the current WIPP WAC. The NNSA Field Office is currently reviewing the ESS.

Plutonium Facility–Process Improvement: Heat source plutonium operations generate liquid waste, which is accumulated in plastic carboys until it is processed. Currently, Plutonium Facility personnel use a rotary tool to size reduce these plastic containers in order to improve their packing efficiency in pipe overpack containers for disposal. On Wednesday, Plutonium Facility personnel demonstrated a new oscillating tool as part of an effort to reduce the potential for sharps injuries during this size reduction activity. They demonstrated that the oscillating tool was incapable of cutting the protective over gloves proposed for the activity. Longer term, management has notions to eliminate the use of the carboys by establishing a glovebox with the appropriate fixed vessels for the waste processing activity. Facility personnel are also establishing the means to more readily use standard waste boxes, which might provide a viable avenue for direct disposal of the carboys without size reduction.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office approved the second revision of the ESS for seismic interaction concerns with the fire suppression system (see 9/29/2017 report). The ESS will remain in place until August 31, 2019, which is the schedule associated with implementing a safety basis revision that includes the content of this ESS. To compensate for the seismic vulnerability, the ESS continues to include lower material-at-risk limits.

Plutonium Facility–Nuclear Criticality Safety: Last week, a restroom faucet malfunctioned, which overflowed into an area on the first floor near the aqueous processing rooms. A few gallons of water subsequently leaked into the basement in an area used to store transuranic waste drums. NNSA Field Office personnel are examining whether this result challenges assumptions related to spills of fissile solutions from the first floor and into the basement where large volume geometries are currently uncontrolled.

Waste Characterization Reduction and Repackaging Facility: On Tuesday, facility personnel completed processing the 27th and last unremediated nitrate salt drum. The next day, they processed two additional miscellaneous drums. The facility entered a maintenance outage ahead of the next planned mission to clean residues out of unremediated nitrate salt parent drums. On Wednesday, the NNSA Field office approved the safety basis revision supporting this mission.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 23, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 23, 2018

DNFSB Staff Activity: P. Foster was at Los Alamos for resident inspector training for a detail at another DOE site.

Area G–Safety Basis: Last week, a subcontractor to the EM Field Office submitted a draft safety basis for review and approval. This new Documented Safety Analysis (DSA) will eventually be given to the operating contractor to replace the existing Basis for Interim Operations reflecting the acknowledgement that operations are likely to continue for more than five years. The new DSA also represents the first safety basis at LANL developed in compliance with DOE-STD-3009-2014. Notably, the draft DSA includes several proposed engineered controls that are not currently credited in the existing safety basis, including storage structures, enclosures, ventilation systems, and fire suppression systems.

Nuclear Criticality Safety: On Wednesday, the division leader briefed the NNSA Field Office on ongoing program improvements. He indicated that since October 2016, the division staff has remedied deficient technical basis documents for 54 fissionable material operations, leaving 236 in the backlog with a goal to remedy 60 this fiscal year. He also noted that the division has reduced the number of infractions that have been open longer than a year to eight with a plan to resolve them by the end of the fiscal year. Of particular interest, he stated that staffing of criticality safety analysts is at an all-time high with 11 analysts fully qualified and 10 in qualification. He also noted better than expected progress establishing an analyst pipeline program with several universities and issuing standard criticality safety requirement evaluations that should expedite remedy of the technical basis document backlog.

Plutonium Facility–Conduct of Operations: Plutonium facility personnel moved a pit into a glovebox that is not authorized to contain that material form in the criticality safety posting. There was no other fissile material in the box. Introducing a disallowed item is an analyzed credible upset condition in the criticality safety evaluation for the box. Facility personnel have restricted access to the box and are developing a recovery plan and other corrective actions.

Plutonium Facility–Transuranic Waste Operations: On Tuesday, the NNSA Field Office approved a safety basis change that allows use of standard waste boxes as an acceptable waste container. Once fully implemented, this should provide program and maintenance workers with an alternative that minimizes the need for size reduction of contaminated equipment.

Chemistry and Metallurgy Research Building: An exit monitor discovered contamination on the fingers of a worker who had been performing decontamination and decommissioning activities. The worker was decontaminated, nasal smears had no detectable activity, and a bioassay will be performed. At the fact-finding meeting, participants noted that work continued as radiological surveys detected increasing levels of contamination which exceeded limits in the radiological work permit. Management suspended this job pending replanning and is developing lessons learned to reinforce the importance of checking the condition of personal protective equipment and staying within the bounds of one's radiological work permit.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 30, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 30, 2018

Plutonium Facility–Conduct of Operations: Last Friday, in response to recent process deviations (see 3/23/2018 and 3/9/2018 reports), the Pit Technologies Division management proactively paused all of their operations involving special nuclear materials. They developed a criteria and review approach document to assess all of their operations through plant walk-downs and discussions with fissile material handlers. The assessment evaluated three areas: compliance and usability of the criticality safety postings; worker engagement and understanding; and best practices and areas of improvement from the perspective of the “voice of the worker.” Notably, management required that personnel independent of specific operations participate in the assessment to ensure objective evaluation. Pit Technologies management completed their review on Wednesday and resumed the majority of their 93 fissile material operations on Thursday after receiving concurrence from the Responsible Associate Director. Seven operations remain restricted, including newly discovered potential process deviations concerning two operations with posting compliance issues and a third operation that needs to implement a new posting. The seven operations will be released individually once the issues are resolved. Additionally, management is developing a remediation process for the workers involved in last week’s inappropriate pit movement.

Plutonium Facility–Nuclear Criticality Safety: On Thursday, Plutonium Facility personnel conducted a fact-finding after nuclear criticality safety personnel noted that language in a criticality safety posting had drifted from the technical basis resulting in a potential process deviation. Specifically, the technical basis originally supported a limit of “dry Pu in a SNMC (special nuclear material container),” that had been changed via a level 2 memo to “Pu in waste;” however, the underlying assumptions on the presence of moderating materials for these defined terms are different. The affected locations are currently posted out-of-service and deemed safe. Management took an action to review other level 2 memos, as well as review the response to a potential process deviation for occasions when it is initiated away from the work location.

Federal Oversight: On Thursday, NNSA Field Office personnel conducted a walk-down of the Plutonium Facility as part of their enhanced oversight plan (see 2/9/2018 report). This walk-down focused on the accuracy of the plan of the day. An accurate plan of the day is necessary to ensure work activities are authorized, conflicting work is precluded, and supporting resources are available. An accurate plan of the day can also be a useful tool for laboratory management and NNSA oversight personnel to effectively plan work observations necessary to strengthen conduct of operations. During this walk-down, NNSA Field Office personnel observed instances of work being performed that was not on the plan of the day. They also noted that the operations center staff demonstrated an inconsistent level of awareness between ongoing programmatic, maintenance, and construction activities. They plan to discuss these observations with LANL management during their periodic enhanced oversight briefings.

Weapons Engineering Tritium Facility: Last week, one of the safety-significant room tritium monitors failed when water entered the system. The monitor has been replaced, and facility management is evaluating why water collected and overwhelmed a drier system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 6, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending April 6, 2018

The Resident Inspectors were at DNFSB headquarters this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 13, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 13, 2018

Confinement Vessel Disposition (CVD) Project: On Wednesday, CVD personnel discovered that daughter transuranic waste drums were being moved to a low dose area for non-destructive assay that was not covered in the criticality safety evaluation document. About 65 of these material moves occurred since February 2018. Facility management has a number of planned corrective actions including revising procedures to perform assays in an approved location and revising the criticality safety evaluation to include the new location.

Plutonium Facility–Work Control: A worker manipulated potentially energized 120 V wires without the required energized electrical work permit. Subsequent locking of the breaker was unsuccessful due to an ineffective locking device. Work continued with the breaker tagged, but not locked. At the fact-finding meeting held on Tuesday, participants noted that laboratory management had previously eliminated periodic retraining on lockout/tagout against the advice of subject matter experts. Lockout/tagout program personnel noted that they are revisiting their policy to address known worker confusion between hazardous energy isolation and system configuration control in advance of about two thirds of the program users requiring retraining by November 2018 per the current national consensus standard.

Plutonium Facility–Safety Basis: Last Friday, safety basis personnel provided the NNSA Field Office with an Evaluation of the Safety of the Situation (ESS) for storage of heat source plutonium in safes (see 3/2/2018 report). There are no additional compensatory measures, since the material was already removed. Analysis supporting storage in these safes was outside of the scope of this ESS so they remain an unauthorized storage location.

Safety Basis: Last week, LANL management responded to the NNSA Field Office with their tentative plan and schedule for achieving DOE-STD-3009-2014 compliant safety bases (see 2/23/2018 report). The proposal includes a submittal next month of a DOE-STD-3009-2014 compliant safety basis for the Radiological Laboratory Utility Office Building upgrade to a hazard category 3 nuclear facility. For the Plutonium Facility, the strategy is to: approve a unified safety basis by October 2018; update the unified version with new material-at-risk values, as well as new leak path factor and atmospheric dispersion modeling in October 2019; and ultimately submit a DOE-STD-3009-2014 compliant safety basis in October 2024. The other nuclear facilities are serially staggered between these time frames.

Federal Oversight: Last week, the NNSA Field Office requested that LANL management submit a plan by May 5, 2018, to develop a strategy that will accomplish integration of ongoing improvement initiatives to safely support required increases in pit production demands. The field office cites the need to integrate ongoing initiatives associated with safety basis unification, conduct of operations enhancements, nuclear criticality safety improvements, and transuranic waste system effectiveness with supporting infrastructure and safety management program efforts.

Transuranic Waste Facility: Last week, the NNSA Field Office conditionally approved with directed changes the ESS associated with the waste acceptance criteria issue (see 3/16/2018 report). The pertinent directed change requires the development of a Specific Administrative Control to protect the initial condition that runaway reactions or energetic events will not occur.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 20, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending April 20, 2018

Plutonium Facility–Safety Systems: On Tuesday, facility operations personnel entered the appropriate limiting condition for operation after a surveillance found the liquid level in an anion exchange column below the top of resin bed, which is an unsatisfactory condition. Program personnel promptly restored compliance with the addition of about a liter of weak nitric acid to the system. At the fact-finding, personnel were unable to determine an apparent cause for this changed condition. They reported that the last addition of solution occurred in January 2018 and recalled additions are typically made every three to four months; however, this information is not formally logged or trended. Management directed a confirmation of the valve alignment for the system. Notably, the NNSA Facility Representatives recently identified findings concerning system alignment checklists. In the case of the anion exchange system, a checklist exists for normal operations, but not for the inactive state that has existed for the past four years.

Plutonium Facility–Conduct of Operations: Last week, programmatic personnel opened a container from the early 1980's with database information indicating the presence of an unknown material based on the most recent measurement. They found an extra object in the container and requested a non-destructive assay that indicated the presence of plutonium. The workers confirmed that plutonium was not allowed in the glovebox and declared a potential process deviation. Fact-finding participants determined the need to use a glovebox with broader criticality safety limits for the handling of legacy items. The glovebox is posted out-of-service awaiting a recovery plan.

Transuranic Waste Facility (TWF): On Thursday, TWF personnel successfully received their sixth shipment, which consisted of eight waste containers. They executed the receipt using revision 10 of the procedure, which included changes to implement direction from the NNSA Field Office on the need for a new Specific Administrative Control to protect the initial condition that runaway reactions or energetic events will not occur (see 4/13/2018 report). The procedure implements this control with new steps requiring verification that the technical supervisor and waste facility management reviews are indicated as completed in the Waste Compliance and Tracking System. TWF personnel intend to seek approval to proceed with a 16 container receipt.

Waste Characterization Reduction and Repackaging Facility: Management decided not to pursue the planned campaign to clean residues out of unremediated nitrate salt parent drums given the limited time before the DOE Office of Environmental Management contract transition (see 3/16/2018 report). On Wednesday, workers began cleaning out the waste repackaging glovebox, removing campaign-specific equipment, and replacing glovebox filters to prepare the facility for dormancy. The parent drum campaign will be reprioritized as part of the legacy transuranic waste activities at Area G.

Emergency Management: On Monday, emergency response personnel responded to a bulging waste drum at the Sigma Facility. The drum primarily contained reactive metal powders, water, and machining oil; there was no radiological material. The response plan involved two robots, one of which used a new shearing tool to vent the drum at the bung. A smaller drum containing the same waste stream in Area L showed no visual evidence of bulging upon a follow-up visual examination.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 27, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 27, 2018

DNFSB Staff Activity: A.R. Powers supported the on-site office this week.

Federal Oversight: The NNSA Field Office Deputy Manager for Technical Operations recently reinforced expectations for field presence from his management and staff. The initiative is intended to drive participation in their enhanced oversight of conduct of operations in the Plutonium Facility, as well as increase overall operational awareness at the other nuclear facilities. Their goal for enhanced oversight is to execute each week: one proactive review by a subject matter expert, one review of a conduct of operations element by a Facility Representative, and one evaluation of the contractor's management observation program. They have begun tracking against these goals.

Plutonium Facility–Infrastructure: The engineering manager reported that current fiscal year efforts on the Project Execution Strategy are either on track or ahead of schedule (see 1/5/2018 report). A key deliverable for this fiscal year is the completion of seismic structural evaluations for four gloveboxes and development of an overall schedule for analysis of the remaining gloveboxes. Engineering personnel have completed three evaluations and are attempting to use a more efficient methodology for the fourth that will inform development of the overall schedule. This is important because currently more than 270 gloveboxes require seismic analysis.

Plutonium Facility–Conduct of Operations: On Wednesday, LANL management briefed the NNSA Field Office on the status of their conduct of operations improvement plan. They reported to be on schedule for most actions with several key training and mentoring initiatives coming due in the next few months. On Thursday, NNSA Field Office personnel met with LANL managers to discuss the results of their enhanced oversight effort for the month of April. On the positive side, they noted an excellent effort to collect worker identified issues as part of the pause of pit operations (see 3/30/2018 report). Among the weaknesses, they emphasized the need to strengthen processes and execution of the plan of the day to ensure work de-confliction and cognizance of operations. LANL managers noted that they have recently embarked on an effort to improve their scheduling and integration in an effort to increase productivity and this effort should have benefits for the plan of the day.

Waste Characterization Reduction and Repackaging Facility (WCRRF): WCRRF personnel completed the clean out and removal of programmatic equipment from the waste repackaging glovebox, shipped the resulting drums to Area G, and placed the facility into COLD STANDBY mode. Notably, WCRRF managers initiated a knowledge capture effort with key personnel ahead of the workforce dispersing as part of the pending transition to the new contractor for the EM Field Office. NNSA will retain ownership of WCRRF. They are currently working with LANL personnel to determine the future of the facility. While the facility has known deficiencies, it is the sole capability at LANL for repackaging transuranic waste with hazard category 2 amounts of nuclear materials.

Area G: N3B-Los Alamos, the new contractor for the EM Field Office, is poised to assume control of Area G operations on Monday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 4, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending May 4, 2018

DNFSB Staff Activity: Members of the Board's staff held a telephone call with NNSA Field Office personnel to discuss leak path factor calculations for the Plutonium Facility.

Plutonium Facility–Infrastructure: Two weeks ago, Plutonium Facility personnel entered a limiting condition for operations due to inoperability of the new uninterruptable power supply (UPS). The UPS was placed into maintenance bypass to correct a deficiency identified during commissioning. Personnel were unable to restore operability. Further work on the system during the past two weeks has restored the UPS function, but the replacement parts used to repair the system are not fully qualified. Facility personnel are expecting to receive fully qualified replacement parts next week. During a post-job review for this activity, personnel identified a number of issues with the conduct of the job and proposed corrective actions to resolve them including component labeling, availability of appropriate tools and parts, lockout/tagout performance, and adequacy of work documents.

Weapons Engineering Tritium Facility (WETF): WETF personnel loaded tritium onto a hydride transport vessel for the first time in approximately a decade. The evolution proceeded smoothly. This process is essential to allow deinventory of significant quantities of legacy tritium that are no longer needed for programmatic purposes. Last month, WETF personnel removed the unused exhaust stack without incident (see 3/2/2018 weekly).

RANT Shipping Facility–Safety Basis: On Wednesday, LANL management transmitted a safety basis strategy document to the NNSA Field Office for review and approval. The RANT facility has been in cold standby since 2014 due to safety basis inadequacies and seismic vulnerabilities. The strategy proposes using the facility without a seismic retrofit and proposes a revision to the existing safety basis that reduces material-at-risk such that mitigated consequences are less than 5 rem to the public and 100 rem to the collocated worker. The strategy indicates the likely resulting material-at-risk limits will support shipping of about 95 % of the existing transuranic waste inventory. Notably, the strategy proposes deferring an upgrade to a safety basis complaint with DOE-STD-3009-2014 until next year, contrary to the path forward NNSA briefed to the Board on February 23, 2017. The strategy indicates safety basis submission in June 2018 with approval anticipated the following month in order to support restart of RANT in calendar year 2018.

Area G: On Monday, N3B-Los Alamos assumed control of Area G operations. They have established minimum staffing and established interim procedures largely adopted from previous versions. They plan to implement their own newly developed processes and procedures within 90 days. Operations this week focused on establishing communication systems and personnel relocations.

Transuranic Waste Facility (TWF): On Thursday, the NNSA Field Office released TWF from their startup plan allowing them to transition to normal operations and forgo the phase three demonstration of 16 waste containers based on multiple successes with eight containers. The approval emphasizes the need to practice prior to stacking operations. The practice is intended to address the constrained maneuvering environment for the existing forklift that NNSA observed during readiness.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 11, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 11, 2018

DNFSB Staff Activity: A.M. Hutain observed the emergency exercise discussed below.

Emergency Management: On Thursday, laboratory personnel conducted their annual full-scale exercise. This year's scenario involved a simulated helicopter crash into the Weapons Engineering Tritium Facility that resulted in a fire and three injured and tritium-contaminated patients. Participating response elements included the facility command, Security and Emergency Operations assets, Protective Force, Los Alamos County Fire and Police Departments, the Federal Aviation Administration, and the Los Alamos Medical Center. Exercise players provided self-critical feedback during the hot washes and noted several recurring issues including: incomplete notifications to the workforce; confusion between shelter-in-place and stay put protective actions; difficulties with radio and mobile phone connectivity; delays in medical response to patients; workforce personnel disobeying road blocks; and a lack of understanding on the hazards and detection methods for tritium by some response elements. Exercise controllers will conduct formal critiques and develop an after action report in the coming weeks. A team of NNSA personnel also provided oversight assistance to the field office.

Safety Basis: Last month, the DOE Office of Enterprise Assessments issued their report on the development and maintenance of safety bases at LANL. The report notes that LANL has increased its safety basis staffing and has adequate procedures, training and qualification, and unreviewed safety question processes. However, the report notes inadequate implementation of the quality assurance processes needed to improve the quality of safety basis submittals and the lack of associated assessments and metrics that could help drive improvements in this area. The report also notes persistent differences between LANL and NNSA Field Office personnel on the interpretation of safety basis requirements, despite recent initiatives to improve alignment.

Plutonium Facility–Infrastructure: On Tuesday, LANL management submitted to the NNSA Field Office for approval the safety design strategy for the fire alarm system replacement as part Phase 3 of the TA-55 Reinvestment Project. The project is being executed in accordance with DOE-STD-1189-2016.

On Wednesday, the NNSA Field Office unconditionally approved a safety basis addendum needed to install a modern chlorine gas delivery system in support of pyrochemical programmatic operations. The new system uses larger capacity source bottles and supports higher pressure gas delivery to an additional glovebox.

Plutonium Facility–Conduct of Operations: Last week, an observant worker noted a waste drum that did not have a label indicating it had gone through the in-service inspection required by the Technical Safety Requirements. An extent of condition on every waste drum in the facility discovered a handful of additional drums with errors in labeling or paperwork related to in-service inspections. All of the discrepancies have been addressed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 18, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending May 18, 2018

Plutonium Facility–Safety Basis: On Wednesday, safety basis personnel entered their New Information (NI) process to examine questions raised last fall by the Board’s staff on the appropriateness of the respirable release fraction used in the accident analysis for seismic events (see 11/17/2017 report). The institutional NI procedure requires closure within 15 calendar days. DOE guidance for the contractor’s 10 CFR 830 obligation to declare a potential inadequacy of the safety analysis states “hours or days, but not weeks.”

Plutonium Facility–Infrastructure: Facility personnel repaired the uninterruptable power supply with qualified parts and exited the relevant limiting condition for operation (see 5/4/2018 report).

Plutonium Facility–Conduct of Operations: Last week, the Pit Technology division issued their report from their criticality safety days pause of operations in March (see 3/30/2018 report). The report noted excellent workforce engagement and lack of hesitance in raising issues and declaring process deviations. The report notes worker concerns including the need to: further simplify and strengthen the consistency of criticality safety postings across the facility; reduce administrative burdens to enable increased management floor presence; and address protracted temporary assignments for managers.

Plutonium Facility–Software Quality Assurance and Criticality Safety: On Monday, a management oversight team member identified that the total mass of nuclear material listed on the SLIP inventory posting for the glovebox was less than the actual amount in the glovebox. The work team declared a potential process deviation and responded appropriately. Criticality safety personnel determined the glovebox to be safe, as the actual material present was in compliance with the limits. Further investigation revealed that the inaccurate mass total had resulted from the presence in the location’s account of a negative plutonium value associated with a “non-physical parent lot,” which is a mathematical artifact used by the nuclear materials control and accountability system to account for measurement uncertainties. Fact-finding participants determined that the SLIP software did not properly account for this artifact and simply summed the values listed for the location resulting in a non-conservative and inaccurate total. Facility management has directed the use of more detailed inventory listings while corrective actions are pursued with the SLIP software.

Plutonium Facility–Conduct of Operations and Work Control: On Wednesday, a craft worker performing an exit survey discovered skin contamination on his hands. Follow-up surveys found contamination on the personal protective equipment of the other crew members. Radiological control personnel controlled the room, successfully doffed and decontaminated all impacted individuals, and performed follow-up surveys in the work area. The work crew had been installing clean piping underneath a glovebox. The most likely source of the contamination spread was from the breach of a contaminated system. The planned scope for the day did not include this higher hazard work to connect new piping to an existing vacuum system, similar to the significant contamination event this past fall (see 9/29/2017 report). Facility management paused all pipefitter work while corrective actions are executed.

Area G: Facility personnel performed a coached table-top emergency drill for training. The scenario was a lightning induced wildfire encroaching on the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 25, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending May 25, 2018

DNFSB Staff Activity: J. Parham was on site to walk-down the electrical distribution systems at the Plutonium Facility, as well as supporting institutional electrical facilities.

Plutonium Facility–Conduct of Operations: Early last week, workers placed a container of plutonium salts in a glovebox where the criticality safety posting only allowed plutonium oxide or metal. While reviewing procedural changes last Thursday, the first line manager observed that the location did not permit the salts and initiated the potential process deviation process. At the fact-finding held last Friday, the workers involved in the event stated that they believed the salts were allowed because they were not explicitly forbidden by the posting. Notably, operations in this particular laboratory room have recently undergone two federal readiness assessments, as well as the criticality safety days pause (see 5/18/2018 report). Management revoked fissile material handler certification for this work crew and is currently conducting oral boards prior to their reauthorization for work. Management is also broadly assessing fissile material handler training based on apparent weaknesses exposed by this and other recent conduct of operations events. Management and nuclear criticality safety personnel learned that storage of salts was occurring in this glovebox, even though the operation includes a specialized storage box that has allowance for storing salts. As a result, they initiated an effort to map process flows across all glovebox locations that support the pit manufacturing flowsheet to ensure alignment between operations, criticality safety, and other safety programs.

In light of last week's contamination spread involving craft workers, the NNSA Field Office is encouraging the contractor to expand their conduct of operations improvement plan beyond programmatic workers.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office transmitted to LANL management their comments on the 2014 revision 2, 2016, and 2017 safety basis submittals. These comments support their overall effort to consolidate and modernize the safety basis. The associated project execution plan indicates a revised submittal by August 3, 2018.

Chemistry and Metallurgy Research Building: Facility personnel completed venting of the drum containing americium-241 from an offsite commercial vendor (see 2/16/2018 report).

Area G: Operations in Area G remain minimal following the recent contract transition (see 5/4/2018 report). Radio and cellphone communications have been established, as well as partial network access, though operations staff are largely reliant on paper-based procedures. Vegetation control to reduce wildfire risk has not been performed due to transition issues with the respiratory protection program. Routine surveillances in the area have noted increased vegetation growth.

Transuranic Waste Facility: Last week, the NNSA Field Office transmitted to LANL management their comments on a draft safety basis change necessary to upgrade the fire suppression system to safety significant. The final version addressing the changes is due June 8, 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 1, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 1, 2018

Plutonium Facility–Safety Basis: LANL Safety Basis personnel completed the New Information (NI) process to evaluate the airborne release fraction (ARF) and respirable fraction (RF) for dispersible plutonium powders involved in seismic events (see 5/18/2018 report). They concluded that the ARF/RF values currently used in the Documented Safety Analysis (DSA) for the Plutonium Facility are sufficiently conservative, and that there is no Potential Inadequacy of the Safety Analysis. They based this conclusion on an evaluation of spill and impact ARF/RFs contained in *DOE-HDBK-3010-94*. The current DSA uses an ARF/RF from the handbook for free falling powders dropped from a 10 foot height which is bounding for a material enclosed in a glovebox that falls on its side. The NI evaluation further concludes that it is not credible to have objects fall on the spilled powder creating an additional airborne release as there are no postulated building or equipment collapses that could generate sufficient impact energy. The Board's staff plans to further evaluate this position as part of their ongoing review of the Plutonium Facility's Safety Basis.

Plutonium Facility–Fire Protection: During a routine surveillance, facility personnel discovered an acetylene bottle left in a room. The bottle was left in the location when the personnel using it exited because of a contamination spread (see 5/18/2018 report). In response, facility management has recognized that processes for evacuating rooms following radiological or other events should include a more formal process to determine if exiting workers left any conditions that need to be addressed as part of room recovery.

Weapons Engineering Tritium Facility: During morning rounds, a worker discovered that the safety-significant environmental chamber overtemperature protection system (ECOPS) had actuated and performed its safety function to cut power to one environmental chamber. There was no actual hazard since no tritium containment vessel was present in this chamber. The exact cause of the trip is not known, however there is no evidence of an actual temperature transient and this unit tripped again during investigation. All of the other units, some of which are currently protecting chambers with tritium present, appear functional and historically these systems have been highly reliable. However, the ECOPS units are old so facility management plans to begin the design process for a project to replace them with a newer system.

Confinement Vessel Disposition (CVD) Project: CVD personnel resumed vessel cleanout activities this week after halting due to performing non-destructive assays of daughter drums in an unauthorized location (see 4/13/2018 report). The team is now using a new location for non-destructive assay that is covered by a criticality safety evaluation document. They also have a new criticality safety evaluation that authorizes use of the location that had not been evaluated.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 8, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending June 8, 2018

Plutonium Facility–Conduct of Operations: On Wednesday, Plutonium Facility personnel held a post-job review after a plastic carboy of plutonium-238 aqueous processing waste solution experienced an unexpected level drop of about 5 of 6 liters. Programmatic operations personnel speculated that the solution evaporated through the threads of an intentionally loose cap after experiencing thermal heating from a proximately stored container of plutonium-238 fuel materials. They were unable to arrive at a more definitive explanation because at least two other solution spills recently occurred in this location and current practice does not involve the recording of precise carboy volumes. Post-job personnel discussed corrective actions to ensure greater balance between production and waste processing operations so as to minimize the backlog of waste solutions, as well as to evaluate processes for staging and spill response. Longer-term, the group is looking toward establishing engineered tanks in lieu of continued reliance on plastic carboys (see 3/16/2018 report).

Plutonium Facility–Radiological Control: On Tuesday, workers alarmed survey monitors when exiting a room where they were performing visual examination of items in preparation for bag-outs. Responding personnel discovered contamination on the personal protective equipment of two individuals and no skin contamination. Surveys of the work area found a contamination spread on areas of the room floor with evidence that a loose clamp on a bag-out port may have been the source of the contamination. The floor has been decontaminated and the room released back to operations. There have been several other discoveries of contamination on personal protective equipment during the past two weeks due to various reasons including breached glovebox gloves and work in elevated areas that are not routinely surveyed.

Area G: During a visual inspection on Thursday, workers noted two drums with evidence of possible degradation. They paused, reported their observations, and facility personnel entered the appropriate abnormal operating procedure to respond to drums with suspect integrity. Further investigation found the drums were intact. Facility management held a hotwash to evaluate emergency response performance. They concluded that the overall response went well and identified areas for improvement, notably in communications with resources located outside of Area G.

Radiological Laboratory Utility Office Building (RLUOB): On Monday, the NNSA Field Office approved the revised Safety Design Strategy for upgrading RLUOB to hazard category 3 (see 2/16/2018 report). The approval included two directed actions. First, the next revision of the strategy must include a technical justification for excluding the Central Utilities Building as part of the facility. The second was to address chemical mixtures in accordance with DOE-STD-3009-2014.

RANT Shipping Facility: Last Friday, the NNSA Field Office concurred with the contractor's Safety Basis Strategy for revising the RANT Documented Safety Analysis and Technical Safety Requirements (see 5/4/2018 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 15, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 15, 2018

DNFSB Staff Activity: On Monday, members of the Board's staff held a teleconference with site personnel to discuss the uninterruptable power supply for the Plutonium Facility and other topics related to electrical distribution systems (see 5/25/2018 report).

Plutonium Facility–Conduct of Operations: On Wednesday, two separate groups of programmatic personnel attempted to move materials through a glovebox trolley system. This trolley line has a discontinuity where material must be lowered into a dropbox and transferred to the other half of the trolley line. The work teams were not aware of each other's material moves, and one team discovered the other team's material when lowering a trolley bucket to complete their move. The groups appropriately paused and declared a potential process deviation. This configuration exceeded the mass limits for the drop box, but was within the credible upset condition analyzed in the criticality safety evaluation. The materials have been moved back to their original locations. Facility personnel are evaluating interim administrative measures to prevent recurrence of this type of event. There is a longer term design project to replace the glovebox trolley system and facility management requested that engineered controls to prevent this type of event be evaluated in the design process.

On Thursday, LANL management briefed the NNSA Field Office on the corrective actions associated with the recent unexpected level drop of plutonium-238 aqueous processing waste solution (see 6/8/2018 report). Based on further actions, they now believe it is more likely that the mechanism for the solution loss was a leak or spill instead of evaporation. Accordingly, they are taking a broad look at strengthening and unifying responses to spills across the plant. They also reported that they had secured resources to begin design development work next year on engineered metal tanks to minimize use of the plastic carboys. Additionally, they created a new operations team focused on processing these solutions in order to achieve a balance between production and waste processing.

Plutonium Facility–Training: Plutonium Facility management started training fissile material handlers to a new revision of the material handling and movement procedure. Key changes include a more explicit requirement that the person in charge of a move remain at the job site during the move and validate that the material inventory report is updated. In response to events during the past year, management has also reinvigorated programmatic training with several initiatives including: (1) hired experienced handlers to conduct training, (2) started a 'study hall' in the cold lab training facility where workers can bring questions to experienced personnel and practice activities using the high fidelity mockup equipment; and (3) launched a new training course to improve glovebox awareness for craft workers.

Area G: On Tuesday, N3B personnel conducted an operational drill involving response to a contaminated individual. Notably, the chief drill coordinator emphasized the need to eliminate the historical tolerance for simulation of response actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 22, 2018

MEMORANDUM FOR: S.A. Stokes, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 22, 2018

Weapons Engineering Tritium Facility: Last Thursday, the NNSA Field Office approved the third six-month extension of the Evaluation of the Safety of the Situation (ESS) associated with the Flanged Tritium Waste Containers (FTWC). LANL management previously recognized the potential that the FTWCs could be pressurized with an explosive mixture of hydrogen isotopes and oxygen (see 11/11/2016 report). WETF safety basis personnel are in the process of updating the ESS to consider this potential hazard for AL-M1 containers stored outside of FTWCs. They also continue to develop a safety basis addendum in support of future FTWC venting operations. The current schedule indicates performance of a contractor readiness assessment in mid-November 2018, pending submittal and NNSA Field Office approval of the addendum.

Confinement Vessel Disposition (CVD) Project: Last week, CVD personnel declared the seventh vessel completed.

Transuranic Waste Facility (TWF): On Wednesday, TWF management entered the New Information process after workers questioned whether waste drums received from the CVD project were covered by oxidizer testing documentation created for the Plutonium Facility. The nature of the vessel wastes are such that they are not expected to contain oxidizers; however, this may indicate a weaknesses in the implementation of the waste acceptance criteria. TWF currently holds about 150 waste containers.

Plutonium Facility–Planning: On Wednesday, LANL management conducted a workshop focused on identifying the impacts associated with establishing backshift operations at the Plutonium Facility. The discussions included mission drivers, lessons-learned from other sites, and supporting functions such as safety basis, occupational medicine, and radiological control.

Plutonium Facility–Conduct of Operations: Facility personnel held fact-finding meetings this week for two potential process deviations that occurred last week and both involved transuranic waste. In one event, workers paused after noting that a waste drum had not been fully characterized as waste and therefore questioned whether it complied with a criticality safety posting specifying “plutonium in waste.” Personnel are evaluating the clarity of this definition in the criticality safety program which does not appear to require material be fully characterized as waste per the procedural definition of “plutonium in waste.” In the second event, workers discovered bagged items were labeled incorrectly due to a communications breakdown.

Radioactive Liquid Waste Treatment Facility (RLWTF): The NNSA Field Office unconditionally approved a revised Hazard Analysis Report for the Low-Level Waste Subproject of the RLWTF Upgrade Project that supports categorization as a less than hazard category 3 nuclear facility. This Hazard Analysis Report revision updates the following: (1) expands the facility boundary to include chemical storage sheds; (2) updates process descriptions and inventories for radionuclides and chemicals; (3) confirms that an Emergency Planning Hazard Assessment is not required; and (4) adds detail to planned administrative controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 29, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 29, 2018

DNFSB Staff Activity: On Wednesday, a staff team discussed their observations from their review of the nuclear criticality safety program with NNSA Field Office personnel.

Weapons Engineering Tritium Facility (WETF): On Thursday, facility personnel commenced normal operations after successfully completing the activities defined in their startup plan from the 2015 federal readiness assessment.

Plutonium Facility–Conduct of Operations: As part of the corrective actions in the Conduct of Operations Sustainment/Improvement Plan, Plutonium Facility managers are receiving new training on expectations for management presence in the field as part of the Management Observation Verification (MOV) program. The training emphasized that engaged management presence in the field is a key means to drive improved behaviors, provided guidance on different types of MOV activities, explained how to do a high quality MOV, and introduced a MOV mentorship program where more senior managers will evaluate the MOV activities of lower tier managers.

Plutonium Facility–Infrastructure: The NNSA Field Office approved the Safety Design Strategy for the Fire Alarm System replacement project. The new fire alarm system will not have a credited safety function consistent with the existing system. The approval included direction for the LANL contractor to address comments from the Chief of Defense Nuclear Safety, notably that an evaluation of the interfaces between the new Fire Alarm System and the safety-significant Facility Control System to justify the assertion that there are no safety related risks associated with that interface.

Emergency Management: Last Thursday, Security and Emergency Operations issued their after-action report for this year's full-scale exercise at WETF (see 5/11/2018 report). The report notes findings associated with: (1) a service degradation in the mass notification system used to disseminate protective actions to the workforce and subsequent failure to manually notify the workforce via phone or radio following recognition of the service degradation; (2) an incorrect protective action issued by WETF management for a remain indoors versus shelter-in-place; (3) incomplete implementation of safety protocols concerning segregation of contamination zones at the Los Alamos Medical Center; and (4) failure to ensure a compensatory measure was performed for a previous finding. The report further identifies a further 6 deficiencies and 16 opportunities for improvement including: lack of basic controller/evaluator training for about 47 % of the applicable individuals, repeat concerns regarding reliability issues with cellular phone and radio connectivity at the emergency operations center and WETF area, and the need for WETF management to make timely and complete announcements to residents of the technical area. The report commends the performance of the WETF radiological technicians for briefing and controlling contaminated patients at the medical center.

This week, Security and Emergency Operations personnel conducted a new training course for all members of the Emergency Response Organization that are expected to fill Emergency Operations Center positions. The training provided an introduction to the major functions of the emergency management program and concluded with a tabletop drill.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 6, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 6, 2018

Management: On Tuesday, LANL management formally assigned the TA-55 Facility Operations Director (FOD) with control of the RANT Shipping Facility and the Waste Characterization, Reduction, and Repackaging Facility (WCRRF). This change is intended to better leverage the safety management programs in place at TA-55. As a result of this consolidation, the TA-55 FOD now covers all of the NNSA nuclear facilities with the exception of the Weapons Engineering Tritium Facility. The priority for RANT will be restarting operations this winter. WCRRF will remain in cold standby for the foreseeable future while NNSA continues to study the need for remediation of its existing waste inventory. In addition, LANL management is considering the potential for some out-year facility stabilization activities including the removal of the size reduction enclosure.

Transuranic Waste Facility (TWF): Last week, TWF safety basis exited the New Information process associated with questions regarding the implementation of a Specific Administrative Control (SAC) covering the waste acceptance criteria for waste containers received from the Confinement Vessel Disposition project (see 6/22/2018 report). They determined that the situation did not warrant a potential inadequacy of the safety basis, but required revision of the safety basis at the next annual update. Their justification includes, “The fact that the references are lacking does not necessarily mean the SAC has not been implemented or has been implemented incompletely; on the contrary, the information required to verify the SAC is effective does exist (and has existed for some time).” The New Information form then goes on to explain how each of the SAC performance criteria are met for the vessel disposition waste.

Nuclear Materials Management: Last month, LANL hosted a quarterly program review for the NNSA’s Material Recycle and Recovery and Storage programs. LANL personnel reported accomplishments including: transuranic waste shipping efforts to TWF, disposition of a 100 containers as part of the vault work-off effort; identification of process improvements on through-put for non-destructive assay; progress with the Chemistry and Metallurgy Research (CMR) facility de-inventory; efforts to identify a replacement for polyvinyl chloride bag-out bags; and progress on developing an in-glovebox certified container. They also highlighted impediments with CMR de-inventory associated with the disposition of various uranium-233 containing items.

Plutonium Facility–Waste Management: Plutonium-238 operations personnel are exploring methods to improve the efficiency of the waste management practices. In particular, bench-scale aqueous operations generate substantial quantities of glovebox gloves from frequent changes, as well as plastics from carboys used for staging solutions. Other challenging waste forms include hydroxide cakes and cheesecloth used for the decontamination of fuel clads. This waste generation creates challenges for housekeeping and compliance with transient combustible loading limits. Currently, all plutonium-238 waste is required to be dispositioned in pipe overpack containers, which have restrictive payload volumes. Notably, the use of the pipe overpacks even applies if the inner contents include other certified containers types (i.e. SAVY containers). Logistics personnel are examining the feasibility of relaxing this limitation and utilizing 55-gallon drums and standard waste boxes for certain materials in order to improve the throughput and minimize worker radiological exposure during waste management processes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 13, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 13, 2018

Management: Transition activities for the laboratory management and operations contract commenced this week. Triad National Security, LLC will take over management of the laboratory from Los Alamos Nuclear Security, LLC after a transition period of not less than 120 days.

Plutonium Facility–Infrastructure: Facility personnel have started work to address the degraded glovebox spool piece in the aqueous chloride processing area (see 11/17/2017 report). A newly designed collapsible replacement piece will be installed. The design eliminates the need to move adjacent gloveboxes during the replacement. A similar degraded spool piece remains in the heat source plutonium area where interim confinement is still being provided by tape (see 10/3/2014 report). It is also scheduled to be replaced with a similar new spool piece.

Area G: At the completion of the eleventh week of operations under the new contract, Area G activities remain limited. Supporting programs and functions are also operating at a rudimentary level as N3B works to develop their own infrastructure. For example, personnel are using radios and mobile phones while new telecommunications circuits are established to replace removed land lines; however, signal coverage is incomplete and the lack of network circuits means that not all operations center staff can print documents. Training and qualification status is being tracked manually with uncertainty on the availability of courses as they come due. Respiratory protection is required for a variety of activities including some abnormal responses and routine operations such as vegetation and pest control; however, the required medical screening, training, and fit test programs are not yet established resulting in limited personnel that are certified to use a respirator. In the Resident Inspectors' opinion, this development of duplicate infrastructure stems from a relationship between LANS and N3B that is inconsistent with similar arrangements at other multi-contractor DOE sites where the management and operations contractor provide many of these services to other entities.

Confinement Vessel Disposition Project: Personnel moved the eighth confinement vessel from the Plutonium Facility yard to the Chemistry and Metallurgy Research Building for processing.

Weapons Engineering Tritium Facility: Facility personnel removed the Halon fire suppression system from the operations center (see 11/17/2017 report). The system had reached its end of life and replacement components were no longer available from the manufacturer. The system has not served a credited safety function since 2016 and will not be replaced. The safety-significant wet-pipe sprinkler system continues to provide credited fire protection for the facility.

RANT Shipping Facility: On Thursday, LANL management submitted an amended startup notification report to the NNSA Field Office that includes restart of the RANT Shipping Facility with a proposed NNSA readiness review. The projected startup date is mid-December 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 20, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 20, 2018

DNFSB Staff Activity: On Wednesday, a staff team conducted a teleconference with LANL and NNSA Field Office personnel to discuss questions concerning the technical justification for using a dose conversion factor discussed below. This was a follow-up to questions originally submitted to the site in September 2017. B.K. Caleca observed a kick-off meeting for the column capital testing program that supports the ongoing seismic analysis of the Plutonium Facility.

Plutonium Facility–Safety Basis: Subsequent to discussion with the Board’s staff, LANL safety basis personnel entered their New Information process. The concern is a lack of technical justification for using dose conversion factors associated with Type-S biokinetic solubility for plutonium-238 oxides. Specifically, ICRP-71, which supports the ICRP-72 coefficients referenced in DOE-STD-3009-2014, details multiple human and canine studies that indicate the behavior of plutonium-238 oxide is more consistent with Type-M solubility. This matters because Type-M has a dose conversion factor about three times higher than Type-S. Additionally, LANL’s internal dosimetry team issued a report that examined how well various biokinetic solubility models fit bioassay data for a population of 160 Plutonium Facility workers that experienced plutonium-238 intakes between 1997 and 2017. The report indicates that approximately 50 percent of the intakes were best explained by biokinetic solubility models with dose conversion factors of Type-M or greater.

Plutonium Facility–Fire Protection: Last Friday, workers observed smoke in a glovebox containing a welding system within the Power Source Assembly Area, which is a building adjacent to the Plutonium Facility that handles encapsulated plutonium-238 heat sources. At the time, no radioactive or hazardous materials were in the glovebox, as they were conducting a test weld following adjustments to the fixture. The workers pressed the emergency stop button and one sought further guidance from the operations center. Operations center staff instructed them to pull a fire alarm and evacuate. Subsequent response actions revealed that paper media within three filters had burned. Fact-finding participants noted an overall good response and coordination with the fire department, but also identified some areas for improvement. The areas included inconsistencies in work control documents regarding the reliance on inert atmosphere within the welding box, the need to utilize infrared imagery earlier in the response, the need to replace the filters with non-combustible media, and the lack of drills within this facility.

Transuranic Waste Facility (TWF): On Wednesday, TWF personnel held a post-job review after a worker inadvertently actuated the seismic power cutoff system by placing a piece of a combo square tool on one of the sensor units. Post-job personnel noted excellent response and quicker recovery from the event than previous instances. Notably, the work was associated with the installation of covers over the sensor units to prevent inadvertent actuation from hailstones. TWF personnel plan to replace the units with redesigned components intended to correct this and other problems in September 2018.

Weapons Engineering Tritium Facility: On Wednesday, facility personnel successfully loaded a second hydride transport vessel (HTV). Once LANL is reinstated for use of the Bulk Tritium Shipping Package, use of HTVs will facilitate removal of bulk tritium gas from the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 27, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 27, 2018

DNFSB Activity: Board Member Joyce Connery and staff member P.J. Migliorini were at the laboratory this week. They held discussions on progress toward standing-up operations at Area G under N3B, ongoing improvements to federal oversight at the NNSA Field Office, completed and planned improvements to the safety posture of the Plutonium Facility, and transition plans under Triad National Security, LLC. Their visit also included walk-downs of Area G, the TA-48 Radiochemistry Facility, the new Low-Level Waste radioactive liquid waste treatment facility and the Plutonium Facility. Ms. Connery also met with several local public interest groups.

Area G: N3B is currently using a List of Qualified Individuals, as they can no longer use the laboratory's electronic system for training and verification of worker qualification. During a management oversight verification of the list, a reviewer discovered that the list did not include all of the requirements that were in the qualification standard for waste operators. In response, N3B facility management paused all waste handling operations and started an extent of condition review. The immediate concern was to verify that the personnel required to comply with the minimum staffing in the Technical Safety Requirements had the proper training and qualifications. N3B facility management verified that they were compliant with the Technical Safety Requirements. The extent of condition review continues to evaluate other job responsibilities such as maintenance workers and radiological control technicians. Waste operations remain paused.

Plutonium Facility–Infrastructure: Facility personnel completed installation of a new glovebox spool piece in the aqueous chloride processing room (see 7/13/2018 report). They are currently monitoring the spool piece to ensure it is performing its intended confinement function. The work crew performed a post-job review to evaluate lessons learned and develop improvements to use for the next planned spool piece replacement.

Plutonium Facility–Conduct of Operations: On Wednesday, Plutonium Facility management issued their ConOps report for June 2018. The report includes discussion of two adverse events; the unexpected solution loss of plutonium-238 aqueous processing waste solution (see 6/8/2018 report) and the overmass in a dropbox associated with concurrent trolley operation (see 6/15/2018 report). The report also includes a discussion of noteworthy actions associated with operations staff self-reporting six potential process deviations that resulted in four categorized as non-infractions and the other two as severity index level 4 and 5. Additionally, the report includes a notable productivity improvement on the completion of a successful time-lapse video of casting operations, the first of a series to support knowledge transfer and training. The focus areas for management observations in July are reader-worker performance of Use Every Time programmatic operating procedures and conduct of operations for maintenance and construction activities.

Nuclear Criticality Safety: LANL management recently announced a new leader for the Nuclear Criticality Safety Division.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 3, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending August 3, 2018

Plutonium Facility–Emergency Management: Workers in the heat source plutonium wing opened a slip lid container holding process residues in a glovebox. They observed what appeared to be fine dust or smoke rising from the opened container. They closed it and pulled the fire alarm. The fire department responded and all facility personnel performed a controlled egress. The fire department responders performed thermal imaging and found no evidence of a fire. The facility has been restored to normal operations with the exception of this room pending further investigation.

Plutonium Facility–Seismic Safety: NNSA Field Office and LANL personnel briefed the NNSA Associate Administrator for Safety, Infrastructure, and Operations on seismic studies for PF-4 (see 7/7/2017 report). They provided their recommended approach and options for procurement of resources to perform nonlinear dynamic analysis. They also provided an update on the recently started column capital testing effort (see 7/20/2018 report).

Plutonium Facility–Infrastructure: A vacuum pump that supports solution transfers within PF-4 is undergoing repairs. One activity impacted by this loss of capability is an effort to replace valves on a series of tanks that are storing liquids destined for an upcoming limited scope cementation campaign (see 2/2/2018 report). The valve replacement activity is on hold awaiting the ability to transfer liquids between tanks using the vacuum pump.

Area G–Readiness: N3B personnel held their first Joint Evaluation Team meeting to determine what level of readiness review to use for resumption of Mobile Loading Unit operations to resume shipments of transuranic waste from Area G to the Waste Isolation Pilot Plant (WIPP). They concluded that a formal contractor or DOE readiness assessment was not required and a Management Self Assessment would be adequate. The basis for this decision was that the activity is an expansion of existing capability as the majority of the scope will be performed or directed by the WIPP Mobile Loading Team. Startup is expected prior to full development of N3B's new safety management programs so they will continue to use the existing programs adopted from the previous contractor. Last year, LANL started Mobile Loading Operations at TA-55, which included a safety basis addendum, with a federal readiness assessment (see 7/21/2017 report).

Area G–Safety Systems: A worker accidentally backed a small utility vehicle into one of the safety-class concrete vehicle barriers that reduce risk to waste stored in certain areas from vehicle impacts and pool fires. The worker immediately reported the incident and engineering personnel evaluated the integrity of the barrier through an in service inspection. There was no damage to the barrier.

Workers performing daily rounds discovered low pressure readings on the nitrogen supply for the fire suppression system in Building 412. Maintenance personnel found that valves on the nitrogen bottles were in the incorrect position. They corrected the position and are checking for possible system leaks. The Building 412 fire suppression system does not have a credited function in the safety basis and remains operable.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 10, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 10, 2018

Plutonium Facility–Emergency Management: On Monday and Wednesday, Plutonium Facility and emergency response personnel held hot-washes to review and learn from the response to last week’s potentially smoking container (see 8/3/2018 report). Key points that emerged from these discussions include: (1) the container involved originated in the late 2016 to mid-2017 timeframe and held waste debris from the plutonium-238 aqueous scrap recovery line, including a clump of degraded absorbent wipes; however, further information characterizing the contents is limited due to the lack of logs; (2) operations and waste management personnel assessed the container for disposal last Wednesday at which time they first observed the smoke/dust phenomenon, including at least one worker reporting the container to be warm to the touch; they informed line management on their observations, but not facility management or fire protection experts; (3) additional personnel observed the container on Thursday and conservatively concluded the phenomenon was smoke, at which time they contacted the operations center for guidance and were instructed to pull the fire alarm (similar to last month’s event, see 7/20/2018 report); and (4) the fire department’s current technology is insufficiently sensitive for heat-sensing applications inside gloveboxes; consequently, the determination that the situation was stable relied upon the observation that tape on the metal container had not degraded. The suspect container has been moved to an inert glovebox and management is developing corrective actions. The Resident Inspectors also note the many gloveboxes in the facility, including the one used to open the suspect container, await completion of fire hazard evaluations to determine the need for additional automatic or manual fire suppression capability (see 12/22/2017 report).

Plutonium Facility–Housekeeping: Plutonium Facility personnel recently completed an inventory. As part of the inventory, NNSA management requested extensive housekeeping activities that generated about 85 waste drums and about 24 other containers. This housekeeping activity improved the overall safety posture of the facility, particularly given that a large fraction of this waste represented unnecessary combustible materials that had been staged inside glovebox lines.

Plutonium Facility–Safety Basis: Laboratory personnel continue executing their New Information process on the question of plutonium-238 biokinetic solubility (see 7/20/2018 report).

Safety Systems: Last week, the NNSA Field Office issued their assessment report on diesel generator emergency and standby power systems at several of the nuclear facilities. They identified five findings, 13 observations, and one noteworthy practice. Findings of note include: (1) several work packages were considered complete despite incomplete performance of work steps and (2) in each case reviewed, diesel generator maintenance had not been identified, scheduled, and/or completed in accordance with NFPA 110 recommendations and LANL internal requirements. The field office requested issues management documentation within 15 days.

RANT Shipping Facility: Last Friday, the LANL contractor submitted the fourth quarter Startup Notification Report to the NNSA Field Office. The proposed restart date for the RANT Shipping Facility has been delayed from December 2018 to September 2019 (see 7/13/2018 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 17, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 17, 2018

DNFSB Staff Activity: On Tuesday, B.K. Caleca and M.T. Wright conducted a teleconference with NNSA Field Office and LANL contractor personnel to discuss actions taken to address the Board's letter dated May 12, 2016, related to the fire suppression system for the Plutonium Facility. On Wednesday, a Resident Inspector briefed the New Mexico State Legislature's Interim Committee on Radioactive and Hazardous Waste.

Plutonium Facility–Safety Basis: On Wednesday, Plutonium Facility management declared a potential inadequacy of the safety analysis related to the biokinetic solubility of plutonium-238 oxide (see 7/20/2018 report). In particular, safety basis analysts determined that all plutonium-238 powders that have not been calcined above 800 °C should use the dose conversion factor associated with Type M solubility. Operations personnel paused work and are implementing material-at-risk (MAR) restrictions. Facility management requested an extent of condition to examine the processing temperature history of plutonium-238 oxides received from offsite, as well as other materials that may be subject to this concern.

Last Friday, the LANL contractor submitted the safety basis annual update for 2018. This document represents their effort to modernize the hazards analysis and consolidate legacy safety basis documents (see 1/12/2018 report). The transmittal letter notes that upon approval and implementation, this new safety basis will close 13 different legacy documents. The NNSA Field Office is targeting approval this October. Facility management is developing an implementation schedule.

RANT Shipping Facility: Last Friday, the LANL contractor submitted a revised safety basis to the NNSA Field Office to support restart and address the Board's letter dated December 9, 2014.

Transuranic Waste Facility: Last week, workers inadvertently performed a MAR surveillance on the wrong building during a waste movement, which violated the technical safety requirements. They realized the error, performed the correct surveillance, and found that they did not exceed the MAR limits. Facility management has implemented a standing order requiring an additional check that the correct surveillance is being performed while they evaluate a long-term solution. Other recent developments include: (1) Facility personnel completed installation of a protective cover for the safety-class seismic power cutoff switch to prevent inadvertent actuation due to hail (see 7/20/2018 reports), (2) They also completed installation of a patch to replace the temporary repair to the insulation on the firewater tank (see 3/2/2018 report), and (3) On Tuesday, safety basis personnel submitted a revised safety basis to the NNSA Field Office that addresses upgrading the fire suppression system to safety-significant, modifies the control for chemical compatibility based on NNSA comments, and adds a new filter for pipe overpack container to address the results of recent fire testing.

Confinement Vessel Disposition Project: On Thursday, a worker inadvertently bumped the emergency stop button for the safety-significant ventilation system for the enclosure. The workers inside the enclosure started to exit and during their egress, two continuous air monitors alarmed. Facility personnel entered two limiting conditions for operations. There was no contamination spread during the egress, the ventilation has been restored, and a re-entry team returned the work area to a stable configuration before the end of the day. They plan to evaluate the stop button.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 24, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 24, 2018

Plutonium Facility–Infrastructure: On Saturday, a worker replacing degraded braided wire cable for a glovebox door counterbalance received a skin contamination due to a glovebox glove breach. The skin was not damaged and was successfully decontaminated. There is a substantial effort to replace these cables in plutonium-238 gloveboxes; one cable failed during use earlier this year. The sharps review process had not been used for this work package. During recent construction activities, workers received permission to cut a lock on a position controller for the Zone 1 ventilation system because the key could not be found. Following a cut, they accidentally dropped the bolt cutters, which impacted a glovebox window. The window cracked, but contamination surveys indicated it was not breached. Workers replaced the window later in the day.

Plutonium Facility–Conduct of Operations: In July, facility personnel removed two of the safety-significant fissionable material transport carts from service after the carts failed their in-service inspections. Last week, facility personnel observed that one of these carts was still in use and loaded with nuclear material. They removed the material and properly removed the cart from service. Previously, the cart had not been physically controlled and de-posted when it was originally taken out of service. Facility management is evaluating corrective actions.

Last Thursday, workers opened a legacy container in a glovebox where the criticality safety posting required a watertight container for the form and quantity of plutonium present. Once the outer container was opened, this requirement was no longer met. The work team initially opened the container in a hood then started a move to a glovebox due to surface contamination levels. On the path to this glovebox, they opened the container in a different glovebox to get a surveillance photograph. The team recognized the error and reported it after they completed the moves to the planned destination glovebox where the criticality safety posting would have allowed them to open the container.

Plutonium Facility–Operations: Plutonium-238 operations personnel continue to develop a work package to investigate the container that was observed to generate a smoke/dust phenomenon earlier this month (see 8/10/2018 report). This activity is important to validate the previously completed extent-of-condition review given it was guided by limited information on the container contents.

Weapons Engineering Tritium Facility–Safety Basis: Earlier this month, the LANL contractor submitted to the NNSA Field Office a safety basis strategy. The strategy notes the facility is currently operating with two documented safety analyses, three technical safety requirement documents, and an evaluation of the safety of the situation, with three of these documents of 2016 vintage. The strategy further notes that the 2017 safety basis annual update consolidated most of these documents, but has not been approved by the NNSA Field Office. As such, the LANL contractor proposed consolidating using the 2018 annual update with a scheduled delivery date of September 28, 2018.

Contract Transition: On Monday, LANS and Triad management held an all-hands meeting to update the workforce on the transition, including additional details on the planned organizational structure. The expected transition date remains November 1, 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 31, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 31, 2018

DNFSB Staff Activity: M. McCoy, P.J. Migliorini, F. Sutherland, and M.T. Wright conducted a review of the proposed new safety basis for Area G and also walked down the facility.

Area G–Readiness: Subsequent to feedback from the DOE Headquarters subject matter expert on readiness, N3B managers convened their Joint Evaluation Team on Monday to reconsider the level of readiness required to restart Mobile Loading Unit operations (see 8/3/2018 report). In particular, the team further considered that mobile loading operations were last performed at Area G in 2013, thereby triggering the need for a federal readiness review. Given the low complexity of the activity, the team proposed conducting the review using a checklist approach.

Area G–Operations: On Monday, N3B personnel conducted a learning team to review the response that occurred last week after a worker observed potential concerns with the integrity of a waste container. Ultimately, N3B personnel determined that the container was not compromised; however, the learning team identified several weaknesses in the response. In particular, the response was delayed because the industrial hygiene technician did not have unexpired calibration check gas and had incomplete training and qualification elements related to both facility access and proficiency on the gas monitoring instrument. The learning team raised further questions associated with the appropriateness of the available instrumentation to detect all of the potential constituents of concern known to be present within the waste container population, the control of calibration gases, and the need to ensure a waste specialist is included as part of the response to the discovery of potentially compromised containers. More broadly, N3B managers questioned whether additional actions were needed to ensure the workforce was properly trained and equipped to support all elements of facility operations.

On Tuesday, the necessity of the above mentioned corrective actions was reinforced after an operator spotted a corroded drum that appeared to be leaking liquid. Monitoring indicated no radiological release; however, a review of the drum contents indicated the potential presence of a chemical that could not be detected with the available equipment. Consequently, facility management called in the LANL hazardous materials team, who overpacked the drum.

RANT Shipping Facility: On Tuesday, the NNSA Field Office responded to the latest proposed startup notification report (see 8/10/2018 report). The field office concurred with the need to perform a federal readiness review to restart RANT operations, but directed the LANL contractor to maintain the projected startup date as December 14, 2018, noting that the proposed date of September 1, 2019, was too distant.

Plutonium Facility–Infrastructure: Facility personnel recently restored the operability of one of the pumps serving the wet vacuum system that is used to transfer solutions in the facility. This action allowed programmatic operations personnel to move some aqueous waste solutions enabling the replacement of degraded valves that are needed to cement these solutions in the near future.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 7, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 7, 2018

DNFSB Staff Activity: On Thursday, a Resident Inspector observed the DOE hearing in Albuquerque to allow members of the public to comment on the proposed changes to 10 CFR 830, *Nuclear Safety Management*. No members of the public attended either of the two sessions.

Plutonium Facility–Accident Investigation: Last Thursday, LANL management received bioassay results that indicated the worker involved in the breached glove event during glovebox door cable replacements (see 8/24/2018 report) had received an uptake of plutonium-238. Subsequent wound monitoring indicated the presence of a contaminated puncture wound. The worker received treatment and is undergoing additional bioassay monitoring. Last Friday, the LANL Director chartered a team to investigate the abnormal event. The seven-person team commenced activities on Wednesday. Their scope involves work planning and control, conduct of the job, and the response up to the point of the wound monitoring. Given the uncertainty associated with the initial dose estimate relative to the DOE criterion for a federal investigation, NNSA has assigned two personnel to monitor the investigation.

Plutonium Facility– Emergency Management: On Saturday, the operations center received indications that a thermal fire detector activated in a plutonium-238 glovebox. Los Alamos Fire Department (LAFD) personnel responded and found no indications of fire. During release contamination surveys, radiological control technicians detected contamination on the skin of a firefighter's hand, as well as his turnout trousers. Subsequent decontamination efforts were successful. At the fact-finding held on Friday, personnel noted excellent communications between the operations center and LAFD. Facility personnel noted the need to strengthen training and revisit response protocols to reinforce expectations that LAFD avoid touching potentially contaminated surfaces. They also noted the continued need to explore alternative thermal sensing technology for gloveboxes (see 8/10/2018 report)—in this case the firefighter used his hand to confirm the lack of heat in the glovebox. LAFD personnel also noted that the state of housekeeping made it difficult to visually confirm the lack of fire in some of the gloveboxes.

Plutonium Facility–Operations: On Tuesday, Plutonium Facility management issued a standing order to implement operational restrictions associated with the recent Potential Inadequacy of the Safety Analysis related to plutonium-238 biokinetic solubility (see 8/17/2018 weekly). The operational restrictions include using a multiplier of 2.875 when determining the material-at-risk equivalent value for certain heat-source plutonium compounds that have not been calcined above 800 °C, limiting heat-source aqueous batch processing, and restricting material not related to aqueous processing in the heat-source room to a new lower limit.

Abnormal Events: Three other significant abnormal events recently occurred that all involve aspects of safety management programs that are essential to the safe operations of the defense nuclear facilities. The events include: (1) a less than adequate emergency response to smoking magnets at the LANSCE accelerator facility; (2) a partial reaction of an explosive detonator during handling at a high explosives facility; and (3) a near-miss during a lift when rigging equipment snapped and released a 47 foot long, 7000 pound column at the TA-3 electrical substation replacement project. LANL management is investigating the first two and the US Army Corps of Engineers is investigating the third.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 14, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 14, 2018

DNFSB Staff Activity: L. Schleicher was on site to observe paleoseismic trenching activities supporting the effort to update the seismic hazard analysis. B. Weathers was on site for resident inspector training for assignment at another DOE site.

Plutonium Facility–Accident Investigation: On Wednesday, programmatic management directed all operations personnel to conduct an extent of condition review for sharps/shards. The need for the review was based on preliminary information from the team investigation indicating that a sharps/shards review may not have been performed for all operations that include this potential hazard. As such, all glovebox and other operations associated with contaminated environments will not be conducted until a sharps/shards screening is conducted and appropriate controls identified. Management requested documentation of initial actions completed and subsequent plans by November 2, 2018. Similar actions were taken after previous puncture wound incidents (see 9/7/2007 and 12/5/2008 reports).

Plutonium Facility–Operations: This week, Plutonium Facility personnel stabilized accumulated plutonium-containing waste solutions through the aqueous nitrate cement fixation process. They conducted this process as a safe and stable operation under a senior supervisory watch since aqueous nitrate operations have not operated for about five years and have not completed formal readiness reviews. Of note, the revised procedure that governs the safe and stable exception to formal readiness reviews remains in approval.

Weapons Engineering Tritium Facility–Safety Basis: On Tuesday, the NNSA Field Office approved the updated Evaluation of the Safety of the Situation (ESS) for Flanged Tritium Waste Containers (FTWC) loaded with AL-M1 containers (see 6/22/2018 report). The revised ESS addresses ignition of potential flammable atmospheres in AL-M1 containers not stored in FTWCs and concludes that there are no credible internal or external ignition sources for the atmosphere within the AL-M1 and that pressure monitoring and venting activities can resume.

Last month, the LANL contractor submitted to the NNSA Field Office a safety basis addendum to support moving and venting the FTWCs. Once approved and implemented, the addendum will supersede the ESS discussed above. The addendum includes two new specific administrative controls related to lift height limitations and a lookout during lifting.

Transuranic Waste Facility–Safety Basis: The NNSA Field Office approved a safety basis addendum related to the safety-class seismic power cutoff switch. The addendum supports the redesign of this system which is currently unable to meet one of its original performance criteria.

Area G–Readiness: N3B personnel performed a management self-assessment to support restart of Mobile Loading Unit Operations (see 8/31/2018 report). The assessment included a drill on the response to high winds. Formal readiness reviews are planned for the end of the month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 21, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 21, 2018

DNFSB Staff Activity: Y. Li observed paleoseismic trenching activities and the expert panel review supporting the effort to update the seismic hazard analysis. B. Weathers was on site for resident inspector training for assignment at another DOE site.

Seismic Hazards Analysis: The ongoing paleoseismic trenching activities are intended to use the geological record to provide refined inputs to update to the site-wide probabilistic seismic hazards analysis. This analysis is used to ensure acceptable seismic performance of systems, structures, and components in the nuclear facilities. Preliminary results from the trenching interpretations, pending results of laboratory age dating, suggest reduced uncertainty on the number of Holocene era events, which is a key parameter in defining the seismic hazard. LANL personnel are currently developing a plan to complete the necessary analyses and peer reviews to issue a new probabilistic seismic hazards analysis in the 2023 timeframe.

Plutonium Facility–Operations: On Wednesday, workers performing maintenance on electrolytic decontamination equipment inadvertently knocked a fitting loose. This resulted in a spill of several gallons of electrolyte solution into the glovebox. The spill exceeded the criticality safety posting limit for liquid in an unsafe geometry so the workers stopped and called a potential process deviation. As this process is undergoing restart, there was no fissile material in the glovebox, only depleted uranium.

Plutonium Facility–Work Planning: Programmatic operations personnel conducted multiple sharps identification walk-downs across the facility. Of note, some first line managers have highlighted the sharps hazards posed by the cutting of wire cables that are widely used as tamper indicating devices. Recognition of this hazard appears to be primarily communicated through mentoring.

Plutonium Facility–Nuclear Criticality Safety: On Tuesday, operations personnel declared a potential process deviation after a document review revealed that a criticality safety posting was inconsistent with the associated evaluations. Fact-finding personnel took an action to strengthen the processes for the implementation verification and annual operations reviews that failed to identify this issue since 2015.

Continuous Improvement: On Monday, the LANL Deputy Director issued a Healthy Culture Platform Charter. The intent of this document is to unify disparate efforts focused on impacting a healthy culture.

Contract Transition: On Monday, LANS and Triad management held another all-hands meeting to update the workforce on the transition. An important development this week is the transmission of job offers to the workforce. The current LANL Director also provided a brief presentation emphasizing recent adverse events (see 9/7/2018 report). He noted the importance of remaining focused and procedure compliant during the transition period. The expected transition date remains November 1, 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 28, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 28, 2018

Area G–Readiness: This week, a four-person team conducted the contractor readiness assessment of mobile loading operations. The team reviewed documents, conducted interviews, and observed an operational demonstration and a drill. At their out-brief, the team concluded that all objectives were met without findings. The federal assessment is expected to conclude next week. N3B personnel hope to complete any necessary corrective actions and receive restart authorization in order to utilize the five shipments to the Waste Isolation Pilot Plant that are scheduled for N3B during the next two months.

Plutonium Facility–Conduct of Operations: On Tuesday, a worker conducting pre-requisite checks of a glovebox discovered that the inventory of nuclear material exceeded the posted criticality safety limit. The worker responded appropriately and made the required notifications. Management and criticality safety personnel then agreed to move an item to a different glovebox thereby restoring compliance with the limits. At the fact-finding, a different worker explained that he had moved material into the glovebox on Monday afternoon as part of a housekeeping activity. This activity was not discussed at the pre-job briefing and the worker did not utilize the material movement procedure, which required a use-every-time checklist and peer check for the amount of material that was moved. The division leader announced several corrective actions including a work pause for next Monday to emphasize elements of conduct of operations, as well as temporarily mandating use of the material movement checklist with a supervisor-level approval for all material moves—the procedure currently only requires this level of rigor for moves that exceed 3 kg.

Plutonium Facility–Glovebox Safety: Last Friday, while executing a maintenance procedure on the newest direct-metal oxidation furnace, a worker snagged and breached a glovebox glove on a handle while reaching with a wrench to remove a stuck bolt. The response to the breach was consistent with procedure and there were no indications of an airborne release of radioactive material. Fact-finding personnel noted that the handle did not present an obvious sharp hazards and discussed that the worker was not wearing protective over-gloves because of the dexterity required for the job. Glovebox safety experts suggested trying a newer type of over-gloves that offer improved dexterity. Some of the discussion also indicated opportunities to strengthen the design process used for new equipment. For example, the worker was removing bolts on a flange that requires periodic removal for maintenance. However, no special tooling had been provided to access bolts that have limited clearance from a nearby cooling water conduit and no torque specifications were provided in the maintenance procedure. The work team identified these as areas for further consideration.

Plutonium Facility–Safety Basis: On Wednesday, facility management declared a technical safety requirement violation after an operator determined that a surveillance on an accelerometer had exceeded its required periodicity. Facility personnel successfully executed the surveillance later that afternoon. Fact-finding personnel noted that surveillances are currently tracked in an electronic database, but that dates are manually entered for the roughly 2700 surveillances performed annually. Facility personnel completed an extent-of condition review and found no further errors. As an interim corrective measure, they plan to introduce independent verification of the dates in the database while they work to utilize improved software functionality.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 5, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 5, 2018

Area G–Readiness: On Thursday, N3B personnel successfully restarted mobile loading operations with a shipment of 21 transuranic waste containers to the Waste Isolation Pilot Plant (WIPP). They received EM Field Office approval for restart on Tuesday after completing a federal readiness review and addressing the findings. The federal review team identified a pre-start finding regarding the use of hands and feet to guide suspended loads. The team also identified post-start findings associated with the need to conduct drills for the full range of potential abnormal scenarios and the need to develop a qualified program to perform inspections of forklift attachments. Of note, N3B had planned on a larger shipment, but one of the shipping containers they received from WIPP had an expired certification.

Emergency Management: Last Thursday, federal and contractor personnel convened an emergency communications working group to characterize and address challenges with cell phone and radio coverage identified during exercises. In particular, during this year's full-scale exercise emergency management personnel noted spotty to non-existent coverage at the Weapons Engineering Tritium Facility, as well as a nearby fire station and the emergency operations center (see 6/29/2018 report). They previously noted similar issues going back to at least 2011. The group agreed to conduct a communications assessment on a prioritized listing of defense nuclear facilities and other key facilities. Of note, the group includes EM Field Office and N3B personnel. This is particularly relevant since communications at Area G are currently heavily dependent on cell phone and radios.

Plutonium Facility–Conduct of Operations: On Monday, one of the programmatic divisions paused work in order to review conduct of operations fundamentals with the workforce as a corrective action from the recent overmass (see 9/28/2018 report). The presentations emphasized technical expertise, questioning attitude, precise communications, and the need to stop and brief when changes occur to planned work.

Plutonium Facility–Safety Basis: Safety Basis personnel entered the New Information process to evaluate whether a discrepant as found condition constitutes a Potential Inadequacy of the Safety Analysis. The concern is two argon drying furnaces in the facility's basement that are not described in the Documented Safety Analysis.

Operations Assessment: On Monday, LANL management chartered an assessment team to examine the circumstances surrounding a violent reaction that destroyed a beaker and injured a worker with lacerations to the neck and hands. The reaction occurred during a synthetic chemistry activity at TA-35 on September 14, 2018. Of note for the defense nuclear facilities, the scope of the assessment is to include operational discipline, work authorization and control, and emergency management. They expect to complete their report by October 23, 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 12, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 12, 2018

Safety Basis: Once removed from an engineered structure, transuranic waste containers (drums and standard waste boxes) provide the only means to reliably confine radioactive materials. Containers can be handled outdoors at the Plutonium Facility, Chemistry and Metallurgical Research (CMR) building, Transuranic Waste Facility (TWF), Radioactive Liquid Waste Treatment Facility (RLWTF), RANT Shipping Facility, Waste Characterization Reduction and Repackaging Facility (WCRRF), and Area G. The resident inspectors compared the treatment of transuranic waste containers in the technical safety requirements (TSR) across these facilities knowing that waste containers routinely move between these facilities and are subject to a number of potential degradation mechanisms. The TSR provides the specific parameters and requisite actions for the safe operation of a nuclear facility.

The comparison revealed differences in the actions required by facility management upon discovery of a degraded container. For example, the TSR for TWF contains limiting conditions for operation (LCO) that require operators to overpack a degraded container into a compliant container or remove it from the facility within 7 calendar days. At the Plutonium Facility, waste containers are considered design features and failure of an in-service inspection of a container triggers consideration as a potential inadequacy of the safety analysis—a process that under current local procedures may take up to 15 calendar days. At Area G, the TSR also considers waste containers as design features, but dictates the need to overpack a degraded container into a metal container without a time requirement as part of the Hazardous Material and Waste Management Program. The TSRs for CMR and RLWTF do not address waste containers. RANT and WCRRF are currently not operating. In practice, facility management typically addresses degraded containers in a prompt manner; however, LANL management had identified the need to strengthen consistency across the TSRs and create LCO-like actions statements for design features as part of an earlier Safety Basis Improvement Plan (see 6/5/2015 report).

Area G—Safety Basis: On Tuesday, N3B personnel conducted a fact-finding to re-evaluate an incident that occurred in July where a worker brought a vehicle into a Combustible Restrictive Area without first notifying the Operations Center contrary to a procedure. In July, N3B management concluded that this incident represented a procedural violation; however, subsequent review by N3B safety basis and engineering personnel questioned whether this actually represented a TSR violation because the necessary surveillance to ensure compliance with combustible liquid limits was not performed at the proper time (i.e., before the vehicle entered the area). After a healthy discussion on the challenges interpreting the existing safety basis, N3B management concluded that the event constituted a TSR violation. The long-term solution to this type of confusion will be implementation of the new documented safety analysis (see 2/23/2018 report); however, the EM Field Office approval date has been delayed from previous schedules and N3B's overall implementation strategy remains in development.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 19, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 19, 2018

DNFSB Staff Activity: On Monday, the Board's staff held a teleconference with EM Field Office and N3B personnel to discuss the control strategy for postulated fuel fires and vehicle crash incidents associated with transuranic waste mobile loading operations at Area G.

Contract Transition: On Wednesday, management from Triad, LANS, NNSA Headquarters, and the NNSA Field Office conducted a transition readiness review. Triad managers provided NNSA leadership with their justification for readiness to assume responsibility for management and operations of the laboratory. Triad personnel also presented what they believe are the top risks to successful operations: conduct of operations, the waste cycle, project execution, and human capital. They also presented risks specific to nuclear facility operations that included the need to improve planning, operational discipline, criticality safety performance, and organizational learning

Area G–Safety Management Programs: At the end of September, N3B personnel provided the EM Field Office with the majority of their proposed safety management program documents. The field office has so far approved the Nuclear Criticality Safety Program. N3B has not yet submitted their Radiation Protection Program as they work to either obtain their own accreditation or acquire services from a DOE Laboratory Accreditation Program (DOELAP) accredited entity. The current service agreement with LANS that provides limited Radiation Protection Services expires on January 30, 2019, and N3B does not expect DOELAP accreditation in place by that time. N3B is tracking this as a high operational risk as dosimetry is required for entry into mission critical parts of Area G.

RANT Shipping Facility: On Wednesday, the NNSA Field Office requested that LANS provide by next Friday a schedule to ensure the safe restart of the facility with a goal of January 2019. The strategy and schedule for restarting RANT—a capability that is essential to risk reduction across the laboratory—has been the subject of multiple perturbations since going into cold standby in 2014. For example, NNSA initially desired to restart using a modern safety basis developed in accordance with DOE-STD-3009-2014 (see 10/8/2017 report). LANS also spent years conducting geotechnical investigations and designing a seismic retrofit (see 12/2/2016 report) only to recommend not pursuing upgrades. The current strategy relies on a DOE-STD-3009-1994 derived safety basis that limits material-at-risk such that the unmitigated accident consequences are below thresholds requiring safety controls (see 5/4/2018 report). NNSA expects to approve this safety basis in the coming weeks, leaving implementation and readiness to pace restart; however, NNSA and LANS continue to align schedule expectations (8/31/2018 report).

Coincidentally, the need for a viable indoor transuranic waste shipping capability was underscored after Plutonium Facility personnel spent the week attempting a mobile loading shipment, but were unable to proceed due to inclement weather. They will try again next week, though this delay will likely curtail N3B's planned shipment from Area G, impacting overall risk reduction at the laboratory. The NNSA Field Office specifically emphasized the need for timely RANT restart in order to capitalize on shipping opportunities that arise in the winter. Previous LANS studies indicate that less than half the days per year have wind and temperature conditions that support outdoor mobile loading.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 26, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 26, 2018

DNFSB Staff Activity: Staff members P. Migliorini, A. Powers, R. Tontodonato, and M. Wright were on site to review the safety basis of the Plutonium Facility. They also walked-down the mobile loading pad at Area G, as part of an ongoing review of the adequacy of the control set for that activity.

Transuranic Waste Facility: On Wednesday, the NNSA Field Office issued a Safety Evaluation Report approving the contractor's safety basis revision to address upgrading the fire suppression system to safety-significant, chemical compatibility controls, and new filters for pipe overpack containers (see 8/17/2018 report). The Safety Evaluation Report includes one condition of approval that directs the contractor to revise certain hazard analysis events to specifically credit the fire suppression system for risk reduction.

Emergency Management: On Wednesday, Emergency Operations Center personnel conducted their quarterly drill with simulated field play. The scenario involved a vehicle accident in the Transuranic Waste Facility resulting in a pool fire potentially impacting the sixteen waste drums on the vehicle. The scenario used actual meteorological conditions, which created the challenge of measuring alpha contamination in the rain. Many members of the incoming Triad management team observed the drill.

Transuranic Waste Management: On Monday, Plutonium Facility personnel were able to mobile load 16 containers of sealed sources into two shipping containers for disposal at the Waste Isolation Pilot Plant, completing the attempt that started last week. They had hoped to load a third shipping container, but were prevented by poor weather conditions on Tuesday and Wednesday.

Confinement Vessel Disposition Project: Last Thursday, the safety-significant ventilation system for the enclosure unexpectedly shut down near the end of a job. There were no continuous air monitor alarms. Engineering personnel responded and were unable to determine the cause of the ventilation failure. They were able to restart one fan through a system modification; however, the work was not performed as part of an approved work package. They continued troubleshooting this week, but have not restored the system operability. As such, the facility remains in the limiting condition for operations with the material-at-risk in the enclosure in a stable configuration.

Nuclear Criticality Safety: Last week, the division leader issued their performance metrics summary for fiscal year 2018. Overall, the metrics indicate a rating of needs improvement; however, the report indicates a number of encouraging developments. The group exceeded their field time targets in each of the quarters and completed annual fissionable material operations reviews coming due each month at a rate of 97 % or better. During the year, the group also reduced the number of infractions open longer than 12 months from 9 to 1 and removed 36 operations from the compliance backlog. Staffing continues to improve with an increase during the year of 2 each for in-training and qualified analysts for a total of 25 direct employees supported by an additional 8 sub-contractors. The metrics indicate that the primary areas for improvement are program implementation and process deviations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 2, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 2, 2018

Management: On Thursday, Triad National Security LLC assumed responsibility for the management and operations of the NNSA scope at LANL.

Area G–Safety Systems: On Tuesday, N3B engineering personnel performing a walk-down discovered a discrepancy between the drawings and field configuration for safety class vehicle barriers protecting high risk areas. An immediate operability evaluation determined that all of these vehicle barriers are configured improperly and are inoperable. Facility operations personnel subsequently implemented compensatory measures consistent with the technical safety requirements (TSR) actions associated with repair, relocation, or maintenance of the vehicles barriers by restricting vehicle access. N3B personnel are developing a design and a work package to restore the barriers to the required configuration.

Plutonium Facility–Radiological Safety: Last Friday, a worker received a puncture wound while performing electrical installation work for a new glovebox. Facility personnel followed the radiation protection standing order implemented following the discovery of a puncture related uptake (see 9/7/2018 report) and ensured the worker received a wound count. There was no evidence of an uptake. The work package for this task required puncture resistant gloves for tasks with potential sharps hazards; however, the worker was not wearing the required gloves because the puncture occurred during a wire brushing activity that was not recognized as having potential sharps. The investigation report from the earlier puncture is with DOE Headquarters for review.

RANT Shipping Facility: On Thursday, the NNSA Field Office conditionally approved the revised safety basis. The conditions of approval require Triad to: (1) elevate controls on acetylene and electric forklifts to Specific Administrative Controls in the next TSR revision and (2) revise the safety basis within 30 days to ensure adequate criteria to verify containers meet Waste Isolation Pilot Plant certification. Last Friday, the NNSA Field Office received a schedule to support facility restart (see 10/19/2018 report). The schedule anticipates achieving startup authorization on January 30, 2019, assuming a number of factors including success-based reviews and parallel contractor and federal performance demonstrations.

Safety Basis: Protecting the limit of radioactive material inventory assumed in the safety analysis is an important function of a TSR. The resident inspectors found that this function is inconsistently specified in the TSRs at LANL. For example, operators must execute a surveillance to ensure compliance with the limit *prior to* any receipt of inventory at the Confinement Vessel Disposition project, Transuranic Waste Facility, the Waste Characterization, Reduction, and Repackaging Facility, and certain locations at Area G. Surveillances are required on a monthly or greater periodicity at the Weapons Engineering Tritium Facility, the Plutonium Facility, and the Chemistry and Metallurgy Research building. The recently approved TSR for the RANT Shipping Facility requires the inventory surveillance, which is the primary TSR control, within 8 hours of receipt. The TSRs are also inconsistent with the required completion times to restore inventory. For example, the Plutonium Facility is immediate, while RANT allows up to 7 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 9, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 9, 2018

DNFSB Staff Activity: On Friday, P. J. Migliorini conducted a teleconference with N3B and EM Field Office personnel to discuss the results of the staff's review of the safety control strategy for mobile loading operations at Area G. K. L. Sullivan was at the laboratory providing resident inspector support with emphases on observing conduct at facility operations centers and work release practices.

Management: On Wednesday, the new LANL Director conducted an all-hands briefing. Of note, he discussed four specific actions that Triad had committed to NNSA: (1) delivering an integrated plan for mission activities at the Plutonium Facility within 6 months; (2) assessing outstanding criticality safety evaluations within 6 months; (3) revalidating capital project baselines within 6 months; and (4) training first line managers of hazardous operations areas within a year. He also announced immediate focus on improving operational practices, the waste cycle, human capital, and project execution. Triad is also developing a common lab agenda that focuses on simultaneous excellence between operations and mission execution, while enhancing confidence from the community.

Plutonium Facility–Readiness: On Monday, a 13-person contractor readiness assessment team commenced their review of Uranium Electrolytic Decontamination (UED) operations. The operation is primarily conducted in two gloveboxes and uses an electrolytic process to remove plutonium surface contamination from uranium parts. The operation also includes a solution processing step where actinides are precipitated from the electrolyte, filtered, and dried prior to disposal. Overall, UED provides clean uranium parts that can then be converted to oxide for eventual transfer to facilities in Tennessee. This week, the team conducted interviews and observed operational demonstrations including a drill. They plan to complete their assessment next week.

Plutonium Facility–Operations: This week, Plutonium Facility personnel completed the limited aqueous nitrate cement fixation campaign (see 9/14/2018 report). The third and final drum containing cemented legacy radioactive waste solution is curing over the weekend.

Plutonium Facility–Glovebox Safety: On Thursday, Plutonium Facility personnel held a post-job review after a glovebox glove apparently breached during a maintenance activity. Post-job personnel noted that the worker appropriately detected the contamination on his inner glove during self-monitoring at the glovebox and that response by radiological control technicians was excellent. There were no other indications of contamination. Notably, glovebox safety personnel had recently conducted a sharps review for this maintenance activity. Next week, they plan to examine the glove and reassess the activity for sharps hazards.

Transuranic Waste Management: The Waste Isolation Pilot Plant resumed receiving shipments this week allowing departure of the trailer that Plutonium Facility personnel had previously mobile loaded with 21 transuranic waste containers (see 10/19/2018 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 16, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 16, 2018

DNFSB Staff Activity: D. J. Cleaves was at the laboratory this week to gain familiarization of the pit manufacturing flowsheet and evaluate lessons learned for execution at the Savannah River Site.

Plutonium Facility–Readiness: On Wednesday, the contractor readiness assessment (CRA) team out-briefed their findings for their review of Uranium Electrolytic Decontamination operations. The CRA team noted one pre-start finding, two post-start findings, three recommendations that did not rise to the level of a finding, three deficiencies that were outside the CRA scope, and four noteworthy practices. The pre-start finding was that the worker hazard assessment and abatement required by 10 CFR 851, *Worker Safety and Health Program*, was less than adequate. One post-start finding was the lack of objective evidence that glovebox components were evaluated per NFPA 70, *National Electrical Code* to address the hydrogen gas created by the process. The other pre-start was that LANL personnel had not fully satisfied the requirements of their internal readiness preparation processes. They expect to issue their final report early next month. Of note, the CRA team applauded the operational excellence displayed by the work crew. NNSA anticipates conducting their readiness review in January 2019.

Plutonium Facility–Work Control: On Tuesday, Triad management issued a standing order to implement a Weapons Integrated Production Schedule. The order realigns area controllers' functions and management reporting, as well as adjusts several aspects of the work scheduling and release process with the intent of maximizing the effectiveness of the plan-of-the-day.

Plutonium Facility–Glovebox Safety: On Wednesday, glovebox safety personnel walked down the location of last week's glovebox glove breach. They identified a burr on a reach tool that plausibly contributed to the breach.

Area G–Safety Systems: On Tuesday, N3B management began issuing a daily shift order implementing a temporary modification that permits limited vehicle traffic into Area G while the safety class vehicle barriers are inoperable (see 11/2/2018 report). The shift order designates a required vehicle route that avoids high-risk locations containing transuranic waste by transiting across a low-level waste burial pit. Vehicle access remains restricted outside of the specified route. N3B completed the design to return the vehicle barriers to service and is developing a work package, including worker training for vital safety systems, to implement the design.

This vehicle allowance was intended to facilitate mobile loading operations to execute a planned shipment of transuranic waste from Area G to the Waste Isolation Pilot Plant (WIPP). However, mobile loading did not take place this week due to cold temperatures. N3B will attempt to mobile load another shipment after the Thanksgiving holiday.

RANT Shipping Facility: On Wednesday, Triad management provided the NNSA Field Office with an update to the previous schedule for restart of the RANT Shipping Facility (see 11/2/2018 report). The new schedule shows contractor and federal readiness reviews in February 2019 with start-up authorization anticipated by the end of that month. Operation of RANT is essential to reliably make use of shipping opportunities to WIPP thereby reducing risk across the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 23, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 23, 2018

DNFSB Staff Activity: A resident inspector observed briefings to the New Mexico State Legislature's Interim Committee on Radioactive and Hazardous Materials. The briefings included the New Mexico Environment Department's update on the Waste Isolation Pilot Plant and the new LANL Director's overview of the Triad transition.

Plutonium Facility–Criticality Safety: Last Thursday, Plutonium Facility personnel discovered an unexpected condition with a plutonium and uranium item taken from the vault for surveillance. The item had oxidized significantly and was arranged in a configuration with a sample staged inside of it similar to a previous instance (see 3/9/2018 report). Neither condition was compliant with the criticality safety posting for the glovebox where the item was introduced and unpackaged. Fact-finding participants noted that the work team responded appropriately and called in a potential process deviation when they discovered the oxide. Upon review, criticality safety personnel determined the situation was safe and stable. A similar item with unknown deterioration will be taken from the vault in the near future to undergo the same surveillance. Facility personnel plan to pre-stage a response team to address any potential deviations with this item.

During an annual fissionable material operational review conducted last Friday, a reviewer discovered an error in the criticality safety evaluation for a safe adjacent to a floor storage location. Specifically, the general location description in the evaluation for the safe did not acknowledge the presence of the adjacent floor storage location. Criticality safety personnel subsequently determined that interaction was not a controlled parameter in the evaluation and plan to address the error in the description.

Confinement Vessel Disposition Project: Project personnel recently completed debris removal from vessel 8. Earlier this month, engineering personnel completed a prompt operability determination that concluded that the safety-significant Enclosure Ventilation System is operable but in a degraded condition as only one of two trains is functional (see 10/26/2018 report). This configuration meets all safety basis requirements. Facility personnel plan on restoring the second train to service to improve safety of the operation. Project personnel expect to begin cleanout of vessel 9 early next calendar year.

Weapons Engineering Tritium Facility–Safety Basis: NNSA Field Office personnel are completing their review of a safety basis addendum intended to facilitate venting of the three Flanged Tritium Waste Containers (FTWC) with the potential for explosive headspaces mixtures of oxygen and hydrogen isotopes (see 9/14/2018 report). In parallel, NNSA and EM Field Office personnel and their contractors continue to evaluate options for the four FTWCs with similar concerns currently located at Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 30, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 30, 2018

Area G: On Monday, N3B personnel discovered that personnel maintaining the minimum staffing requirements per the Technical Safety Requirements had expired for a required qualification on lockout/tagout training. Facility management promptly placed all designated areas into warm standby and obtained the required training for personnel. They later declared a violation of the Technical Safety Requirements and completed an extent-of-condition review. The list of qualified individuals was incorrectly tracking this requirement based on information provided by LANS that subsequently changed following transition. N3B continues to explore acquiring a comprehensive learning management system as there have been other instances of issues associated with the list of qualified individuals.

Once the appropriate personnel were verified to be appropriately qualified, N3B completed a mobile loading shipment that included eight drums of cemented waste and five drums from the offsite source recovery program. Vehicles involved in the shipment used the designated vehicle route as the safety class vehicle barriers remain inoperable (see 11/16/2018 report).

Plutonium Facility–Nuclear Criticality Safety: On Monday evening a faucet malfunctioned in the same restroom as the water overflow event from this past March (see 3/16/2018 report). Similar to the first event, the water flowed from the mezzanine to the first floor and then further on to the basement. The water flow resulted in some ponding, in part due to the fact that a sump pump was de-energized because of concurrent breaker maintenance. Given the recurrence of this event, Triad management plans to conduct a fact-finding next week to better understand the extent of this condition and its implications for assumptions in nuclear criticality safety evaluations.

Emergency Management: On Tuesday, the NNSA Field Office, after consultation with NNSA Headquarters, concurred with a proposal from the previous laboratory contractor to use the Computer Assisted Protective Action Recommendation System (CAPARS). This software will be used for improved analysis in support of Emergency Planning Hazard Assessments (EPHA). CAPARS uses a three-dimensional Lagrangian model that includes site specific terrain and weather data that is expected to improve accuracy compared to the existing analysis software packages that use a simple Gaussian model. LANL is the first site in the DOE complex to use CAPARS for emergency planning. Triad intends to complete updating all of the EPHAs using CAPARS by the end of fiscal year 2020.

Weapons Engineering Tritium Facility–Safety Basis: On Wednesday, the NNSA Field Office unconditionally approved the safety basis addendum to vent the Flanged Tritium Waste Containers (see 11/23/18 report).

Fire Protection: On Thursday, the NNSA Field Office approved the 2018 Baseline Needs Assessment. In their approval, NNSA noted that increasing minimum staffing at the fire department and replacing two fire stations are key issues to be addressed through negotiations between NNSA and the Los Alamos County Fire Department.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 7, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending December 7, 2018

DNFSB Staff Activity: The Resident Inspectors were in Washington, D.C. to brief the Board and attend meetings. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 14, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 14, 2018

DNFSB Staff Activity: Staff members J. Anderson, Z. Beauvais, C. Berg, M. McCoy, and P. Migliorini were at the laboratory to review weapons response basis information in support of safe operations at the Pantex Plant.

Area G: N3B personnel completed a mobile loading shipment of one HALFPACT and two TRUPACT-II containers to the Waste Isolation Pilot Plant (WIPP). The shipment contained cemented waste overpacked in standard waste boxes. Prior to the shipment, Central Characterization Project personnel noted a discrepancy in the databases at WIPP and LANL between the coding of inner drums compared to their overpacks. All drums in this week's shipment were re-verified to meet requirements. Vehicle operations, including mobile loading, continue to use the designated alternative vehicle route as the safety-class vehicle barriers remain inoperable (see 11/16/2018 report). N3B personnel completed the design and work package for returning the vehicle barriers to service; however, their attempt this week to begin the repairs was thwarted when a necessary tool was not available.

Plutonium Facility–Work Control: Last week, a four-person work crew was found to have contamination on their booties after two members of the crew alarmed the hand and foot monitors at the facility exit. There was no skin contamination. The crew had been investigating a potentially degraded glovebox spool piece in a plutonium-238 processing room. Another worker not involved with the job was also found to have contaminated booties. The work crew had been wearing respirators and two pairs of anti-contamination clothing in the work area. When departing the work area, they doffed their outer coveralls and surveyed, but did not remove, their outer booties. Follow-up surveys discovered a contamination spread in the room, which is being decontaminated. No airborne radioactivity related to this contamination spread was detected. The spool piece currently has a temporary confinement barrier installed while engineers evaluate options for a longer-term replacement.

Readiness: On Wednesday, Triad personnel executed their process to determine the appropriate level of readiness review for two new activities. They determined that resumption of a pinch welding operation at the Weapons Engineering Tritium Facility requires contractor and federal readiness assessments. They determined that a new pit cutter in the Plutonium Facility, which will use a cutting tool similar to a pizza wheel, constituted an expansion of an existing capability and does not require a formal readiness review. The team considered the new operation to be similar to an existing robotic lathe.

Chemistry and Metallurgy Research Building: Last Thursday, the NNSA Field Office approved a temporary modification to the safety basis in support of the next phase of processing activities associated with americium-241 materials received from an off-site location (see 5/25/2018 report).

Transuranic Waste Facility: Last month, Triad management sent the NNSA Field Office an update to the project execution schedule in support of reclassifying the fire suppression system to safety significant. The schedule indicates that the system will be implemented by April 30, 2019.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 21, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 21, 2018

Plutonium Facility–Work Control: Last Friday, facility management issued a new standing order applicable to all work performed in gloveboxes. The order requires that all glovebox workers use cut/puncture resistant over-gloves or additional tools when working with or generating sharps. Any deviation from this requirement must be granted in writing. The standing order will remain in place until longer term implementation initiatives regarding sharps are determined.

Plutonium Facility–Operations: Last Tuesday, workers drumming out gloves from a glovebox line noted liquid in the box. They determined that a valve in the box on a sodium hydroxide solution line had been bumped. More than 100 liters of solution entered the box. The criticality safety analysis for this box does evaluate the fully flooded condition and there was no nuclear material other than contamination in the box at the time. The work crew vacuumed the solution into tanks in a nearby glovebox. However, these tanks were designed for acidic solutions and have gaskets that are not recommended for use with sodium hydroxide. Therefore, this week the solution was moved via two liter bottles to tanks in another room with compatible materials.

Plutonium Facility–Safety Basis: Two weeks ago, safety basis personnel performing an unreviewed safety question screen of a waste analysis plan for treatment of radiologically contaminated magnesium perchlorate entered the new information screening process. They noted that the currently approved Documented Safety Analysis states that perchlorate salts are no longer present in the facility. This Monday, Triad personnel determined that this constituted a potential inadequacy of the safety analysis. The material is currently stored in a metal can and will be moved to the Chemistry and Metallurgy Research building for treatment next year.

Last Tuesday, Triad Safety Basis personnel provided to the NNSA Field Office for concurrence a revised project execution plan for updating and improving the Plutonium Facility safety basis (see 9/15/2017 report). The key change in the new plan is including revisions to bring the safety basis into compliance with DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*. This will be done concurrently with the modeling updates. The plan proposes submittal of the new safety basis and updated accident analysis to the NNSA Field Office in March 2022.

Last Friday, Triad submitted to the NNSA Field Office the evaluation of the safety of the situation and justification for continued operations for the potential inadequacy of the safety analysis associated with the biokinetic solubility of plutonium-238 oxides (see 8/17/2018 report). The new proposed compensatory measure eases the existing one by using an intermediate solubility for oxides that have not been high fired. They originally entered this issue into the new information screening process on July 19, 2018, declared a potential inadequacy of the safety analysis on August 15, 2018, and then determined the issue constituted a positive unreviewed safety question on September 9, 2018. DOE Guide 424.1-1B provides timeliness expectations for these steps because the safety basis is outside the envelope approved by DOE.

Emergency Management: Triad personnel continue efforts to improve emergency communications across the site (see 10/5/2018 report). They have conducted radio and cellular signal surveys at several identified critical communications areas including the TA-55 Operations center and the Weapons Engineering Tritium Facility. The results of these and future surveys will be used to prioritize communications upgrades. A cellular signal booster was recently installed at the Emergency Operations Center, and a radio signal booster will be installed early next year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 28, 2018

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending December 28, 2018

The Year on a Page: A summary of the key developments of 2018.

- N3B and Triad assumed operational responsibility for their respective EM and NNSA mission scopes at LANL. Both companies have begun executing actions to strengthen formality and organizational learning within their operations.
- For the first time since 2014, Area G personnel were able to reduce their aboveground nuclear material inventory by mobile loading transuranic waste for disposition at the Waste Isolation Pilot Plant. Plutonium Facility personnel also executed a mobile loading shipment in order to maintain proficiency. Both organizations hope to increase the frequency and reliability of transuranic waste shipments through the restart early next year of indoor loading operations at the RANT Shipping Facility.
- The Transuranic Waste Facility received about 370 waste containers alleviating storage locations that were approaching capacity at the Plutonium Facility and Chemistry and Metallurgy Research building. Facility personnel continue into their second year of efforts to replace the seismic switches, upgrade the fire suppression system to safety significant, and convert the dry pipe system from nitrogen to air. They also plan to complete installation and achieve authorization for the waste characterization capabilities that were previously removed from the project's scope.
- A Plutonium Facility worker received an uptake of plutonium-238 after a wire cable strand punctured a worker's glovebox glove and embedded plutonium into the hand. Although the accident investigation report awaits final approval, management has taken action to strengthen sharps safety. Additionally, they have instituted new training on contaminated systems and glovebox safety as part of previously planned corrective actions from multiple radiological contamination events.
- After nearly three years of planning, NNSA awarded a contract to an outside vendor to conduct a three-year program of column capital testing and commenced a separate, but related, initiative to perform a non-linear dynamic analysis of the Plutonium Facility. Per the Board's letter dated December 17, 2014, these efforts are essential to make sound technical determinations regarding the necessity for any additional structural modifications.
- Weapons Engineering Tritium Facility (WETF) personnel successfully loaded tritium onto a hydride transport vessel for the first time in approximately a decade. This process is essential to support risk-reduction by removing significant quantities of legacy tritium from the facility that are no longer needed for programmatic purposes.
- After two years of development, WETF personnel received approval of a safety basis addendum to support safely venting the Flanged Tritium Waste Containers that may be pressurized with an explosive mixture of oxygen and hydrogen isotopes. They plan to complete readiness activities and execute the campaign early next year. NNSA and Triad will then need to coordinate with EM and N3B in order to address similar containers currently stored in a shed at Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 4, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 4, 2019

Inclement Weather: The laboratory remained closed for two additional days following the holiday closure due to heavy snowfall.

Weapons Engineering Tritium Facility–Readiness: Last month, Triad transmitted their second quarter fiscal year (FY) 2019 Startup Notification Report to the NNSA Field Office. The new report changes the recommendation for the level of readiness review for the movement and venting of the Flanged Tritium Waste Containers (FTWC) with potentially explosive headspaces. The predecessor contractor had previously proposed a contractor readiness review for this activity. Triad’s new report withdraws the recommendation for a formal readiness assessment and states that a safety basis Implementation Verification Review and management self-assessment are sufficient. The stated basis for this change is an assertion that ignition of the potentially flammable oxygen and hydrogen isotope mixtures within the FTWCs is not credible during the venting operation. However, we note that the recently approved safety basis addendum (see 11/30/2018 report) includes credited controls to prevent a FTWC from tipping as it states a complete tip cannot be excluded as an energy source for ignition. The startup report also included the recommendation for a federal readiness assessment for the startup of the Pinch Welder (see 12/14/2018 report).

Plutonium Facility–Infrastructure: On December 20, 2018, Triad management transmitted the annual revision of the TA-55 Project Execution Strategy (PES) to the NNSA Field Office for information. The predecessor laboratory contractor originally developed the PES in August 2011 as deliverable 5.4.5 in support of the Board’s Recommendation 2009-2. The PES describes the strategy, cost, scope, schedule, and identified funding sources for the upgrades the contractor has identified as necessary to ensure that the mitigated consequences from a seismically-induced accident at the facility will no longer challenge the DOE Evaluation Guideline of 25 rem. The PES revision notes the tangible progress that has been achieved since 2011, highlights recommended scope for this fiscal year, and sets out-year goals.

Some of the proposed scope for this FY continues efforts started last year (see 1/5/2018 report), including completion of the following: installation of the generators and transfer equipment for the electric firewater pumps; designs to remedy seismic interaction issues with the fire suppression system; and continued development of fire hazard evaluations and seismic analyses for gloveboxes. While the PES has resulted in many infrastructure improvements, some upgrades to key safety systems have experienced delays due to unexpected engineering challenges, funding perturbations, and reprioritizations for emergent scope as the facility seismic analyses progressed. For example, the current schedule estimates show slippages compared to the baseline projections as follows:

- 11 years for the upgrade of the fire suppression system to seismic performance category (PC)-3, now estimated for completion in FY-24
- 6 years to complete modifications to ensure laboratory walls provide a 2-hour fire barrier, now estimated for completion in FY-21
- 5 years to achieve a PC-3 active confinement ventilation capability and replace the fire alarm system, now both estimated for completion in FY-25
- 4 years to separate the non-seismically qualified buildings from the firewater loop, now estimated for completion in FY-26

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 11, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 11, 2019

Area G: On Tuesday, the EM Field Office approved a one-time variance to the technical safety requirements for Area G in order to allow snow removal equipment into the locations with inoperable safety-class vehicle barriers (see 11/16/2018 report). The variance required N3B to keep all waste storage areas in the impacted areas in warm standby mode and have a spotter in contact with the snow removal equipment at all times. On Wednesday, a worker returned into the vehicle restricted area with snow removal equipment without a spotter in order to clean up another patch of snow. This was observed by the shift operations manager who promptly paused work. N3B management determined this constituted a violation of the technical safety requirements. They also decided to conduct an apparent causal analysis on this and a number of recent similar events.

On Monday, N3B personnel observed that two waste storage domes were damaged by recent snow accumulation. The snow load resulted in bent and broken structural cross members, bent cross member brackets, and bent conduit. Existing tears in the dome fabric also expanded allowing snow to enter the waste domes. The dome structures do not have a credited safety function. The safety basis treats the domes as light construction so impacts from lightweight falling structural members on waste drums are not considered. However, there are heavier black steel fire suppression pipes supported by the affected dome structures.

Federal Oversight: This week, NNSA and EM released the 2018 performance evaluation reports for their contractors. NNSA noted the following relevant points for their fiscal year 2018 contractor:

- LANS completed planned improvements to conduct of operation in the Plutonium Facility, but progress was inconsistent to improve construction and maintenance activities.
- LANS was not fully effective in supporting the transition of the N3B.
- Poor housekeeping and operational practices in the Plutonium Facility exacerbated material control and accountability issues.
- The quality of nuclear criticality safety evaluations had improved, but inconsistent limit sets were creating implementation challenges.
- LANS worked collaboratively with the NNSA Field Office to enhance tracking and oversight of safety basis documents and coming nearer to meeting emergency management requirements.

EM noted strengths for N3B including safety culture, readiness of mobile loading operations, and the operational standup of Area G. They noted relevant areas for improvement including data and quality programs, issues management, and timely revision of blue sheeted procedures.

Accident Investigation: On Monday, NNSA and Triad personnel commenced a joint investigation of an accident that severely injured a sub-contracted construction worker in a non-nuclear activity on December 19, 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 18, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 18, 2019

Plutonium Facility–Issue Recurrence: On Monday, facility management entered a limiting condition for operations after system engineers performing a surveillance determined that conflats containers were incorrectly listed in the tracking system as a type certified to reduce the damage ratio in certain accident scenarios. This issue is similar to a previous occurrence that prompted considerable corrective actions that apparently were not fully effective (see 4/25/2015 and 11/6/2015 reports). For this instance, management elected to reinforce awareness of certified container types in upcoming briefings and study whether container names or types could be further refined to reduce error traps for the workforce.

Area G: Repairs to the out of service safety class vehicle barriers (see 11/2/2018 report) are on hold pending procurement of additional wire cabling. As the planned vendor is not Nuclear Quality Assurance-1 qualified, N3B personnel are developing a commercial grade dedication package and Technical Evaluation Acceptance Plan to ensure the procured cabling will meet safety class quality assurance requirements.

On Tuesday, N3B requested another one time variance to allow snow removal equipment into the area where vehicles are restricted. The controls are the same from last week. The variance was not used as the snow melted prior to approval from the EM Field Office. Of note, this variance explicitly noted that any violations of the controls would be equivalent to a violation of the technical safety requirements.

Waste Characterization Reduction and Repackaging Facility: On Thursday, facility management entered the New Information process after reviewing results of non-destructive assay measurements. The measurements, performed in late November 2018, indicate the possibility that a 55-gallon drum placed in an 85-gallon drum currently located within the glovebox enclosure may contain materials that exceed the radionuclide limit for transuranic waste, a condition that is prohibited by the safety basis. However, this determination is difficult because the measurement uncertainty and possibility that the radionuclides are actually associated residual contamination in the enclosure (the safety basis assumes that the residual contamination levels are less than 10 percent of the Hazard Category 3 limit). Based on anecdotal reports and visual confirmation, the nested drums have been in their present location for at least 20 years, do not have their lids, and contain vermiculite and plastics materials possibly associated with previous cleanup attempts of a nearby hydrocarbon spill. The facility remains in COLD STANDBY mode and management initiated planning for improved radiological characterization of the enclosure and the drum. The overall future of the facility remains under study.

Weapons Engineering Tritium Facility: Last Friday, the NNSA Field Office approved the annual update for the safety basis. This annual update was intended to consolidate previously approved changes into one document. NNSA included one condition of approval which directed incorporation of open comments from their review of this revision be incorporated in the next annual update.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 25, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 25, 2019

DNFSB Staff Activity: D. Andersen, R. Jackson, Y. Li, and P. Migliorini met with Triad engineering personnel to review plans for upcoming column capital testing and advanced seismic modeling of the Plutonium Facility. They also walked down the Plutonium Facility.

Safety Basis: On Tuesday, the NNSA Field Office approved Triad's schedule to update safety bases for the defense nuclear facilities to comply with DOE-STD-3009-2014. The schedule shows Triad submittals compliant with this standard are expected for the Radiological Laboratory Utility Office building in fiscal year (FY) 2019, the Plutonium Facility in FY-22, the Weapons Engineering Tritium Facility in FY-22, the RANT Shipping Facility in FY-24, and the Transuranic Waste Facility in FY-26.

Plutonium Facility–Error Likely Situation: On Thursday, the resident inspectors and visiting staff observed a floor storage location in a laboratory processing room that contained a backlog of about 80 individual containers of special nuclear material awaiting disposition by the transuranic waste organization. The consequence of this situation is that any material transfer associated with this location requires workers to verify information for each of the containers—a time consuming and error likely situation. This large number of containers also increases the area radiation exposure hazard to the workers.

Weapons Engineering Tritium Facility–Readiness: On Tuesday, the NNSA Field Office approved Triad's recent startup notification report (see 1/4/2019 report) that rescinded formal readiness review requirements for the venting of the Flanged Tritium Waste Containers that contain potentially explosive headspace mixtures of oxygen and hydrogen isotopes.

Chemistry and Metallurgy Research Facility: Last Friday, the NNSA Field Office unconditionally approved the annual update to the safety basis. However, the approval letter noted three points associated with outdated information and requested these be addressed in the next annual update. The points included: (1) referencing an obsolete version of DOE Order 420.1C, *Facility Safety*; (2) using local population data from 2005 rather than the most recent census data obtained in 2010; and (3) using wind data from 1999 and 2006 contrary to the statement in DOE-STD-3009 that states methodology should be consistent with Nuclear Regulatory Commission specifications indicating that the wind data should not be older than 10 years.

Plutonium Facility–Safety Basis: Last Wednesday, the NNSA Field Office approved a revision to an Evaluation of the Safety of the Situation (ESS) originally developed in 2015 (see 9/4/2015 report) regarding pipe overpack containers (POC). The revised ESS incorporates recent DOE guidance based on experimental testing indicating that POCs with a certain plastic replacement filter installed on their outer container can be considered to have a damage ratio of zero for credible fire scenarios. Triad expects to replace all affected POC filters by December 2019. The field office noted that Triad's request to extend the expiration date of the ESS for two years was contrary to DOE expectations, agreed that replacement of filters on the outdoor storage locations was the correct priority, and requested quarterly updates via email on the progress of filter replacements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 1, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 1, 2019

Plutonium Facility–Infrastructure: A water main leak on Tuesday morning caused a potable water loss to most of Technical Areas 35, 50, and 55, including the Plutonium Facility. Fire suppression water for the Plutonium Facility was not impacted since it is supplied from dedicated storage tanks adjacent to the facility. However, facility management curtailed operations at the Plutonium Facility and the Radioactive Liquid Waste Treatment Facility due to the lack of water for safety showers, eye washes, and decontamination. Utilities personnel restored water service Tuesday evening.

Plutonium Facility–Worker Safety: Last Tuesday, two electricians were inadvertently locked inside a caged storage location for approximately 40 minutes. During this time, the workers would have been unable to properly respond to alarms associated with a nuclear criticality, an airborne radioactive material release, fire, or other emergency situations requiring egress. Triad management held two fact-finding reviews to review this event and determine corrective actions, which include: conducting a pre-job briefing that integrates overlapping functions when multiple work groups are involved, conducting an extent-of-condition review of other locations that may need modifications for life safety egress, and examining use of a lock-out/tag-out process for entry into these types of areas.

Plutonium Facility–Safety Basis: On Wednesday, facility management entered the New Information (NI) process to determine whether the hazards analysis considers failures of the freight elevator and a programmatic dumbwaiter while transporting material-at-risk.

Plutonium Facility–Radiological Control: On Monday, facility management conducted a fact-finding after a worker's bootie was found to be contaminated during self-monitoring at the facility exit. Participants discussed potential improvements to the control of hot job exclusion areas (see 12/14/2018 and 9/1/2017 reports). Separately, management is considering options to strengthen monitoring of known contamination areas, including a room with a wall of legacy gloveboxes previously used for plutonium-238 operations but unused for at least the last 20 years, the room where the significant contamination event occurred in 2017, and the area of the basement that was subjected to flooding late last year.

Plutonium Facility–Readiness: A nine member NNSA team performed a readiness review for restart of the Uranium Electrolytic Decontamination process.

Area G: On Tuesday, N3B management declared a violation of the Technical Safety Requirements following discovery of a prohibited vehicle outside of the designated travel route in place until the safety-class vehicle barriers are restored (see 11/16/2018 report). On Monday, N3B entered their NI process to evaluate the apparent discrepancies in the safety basis between material-at-risk assumptions for the overall waste inventory and those used for individual accident scenarios.

Transuranic Waste Facility: This week, facility management entered the NI process for two separate apparent discrepancies: (1) material-at-risk assumptions for sealed-sources and (2) dimensions and thicknesses for fire-rated safes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 8, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 8, 2019

Plutonium Facility–Accident Investigation: Last week, the LANL Director signed the final investigation report (LA-UR-19-20258) from the August 2018 event where a worker received a puncture wound during glovebox cable maintenance that resulted in an intake of plutonium-238 (see 9/7/2018 report). Overall, the investigation team identified five judgements of need covering the following: (1) inadequate management implementation of work control, training, and conduct of operations requirements; (2) inadequate performance steps in the work control document associated with the use of skill of the craft requirements; (3) inadequate management follow-up to eliminate the previously identified frayed wire hazard; (4) workers did not identify the need to pause work in accordance with procedures; and (5) management did not fully appreciate the injection hazard posed by isotopes with greater specific activity. Facility management is developing associated corrective actions.

Plutonium Facility–Nuclear Materials Management: This week, machining personnel began the process of moving containers of plutonium metal turnings to another room in the facility for stabilization. Multiple containers of turnings have been stagnant in the machining room since prior to the operational pause of the facility (see 7/4/2014 report). Processing the turnings creates a safer material form by eliminating the pyrophoric hazard and removes unnecessary material-at-risk from the machining gloveboxes.

RANT Shipping Facility–Readiness: On Monday, a thirteen member team commenced the contractor readiness assessment for the restart of the RANT Shipping Facility. Restart of this facility will restore the Triad’s capability to load transuranic waste for offsite shipment in an indoor environment thus avoiding the vagaries of weather that constrain outdoor mobile loading. This week, the team observed a performance demonstration of transuranic waste loading and conducted interviews. The performance demonstration also included an operational drill involving discovery of radiological contamination during surveys of the shipping container. The assessment is scheduled to complete next week. A federal readiness assessment team is scheduled to commence their review the week of February 18, 2019. The plan of action for the federal assessment was issued on Thursday.

Plutonium Facility–Readiness: The federal readiness assessment team for the Uranium Electrolytic Decontamination (UED) process issued their final report last Friday. The report recommends that upon correction of two pre-start findings and establishment of a corrective action plan to address two post-start findings, the UED process be allowed to restart in accordance with its startup plan. One pre-start finding was in the area of configuration management and involved the process for determining equipment management levels for quality assurance purposes. The second pre-start finding notes that the radiological work permit for UED operations is not consistent with site procedures. The post-start findings were both in the area of feedback and improvement and related to treatment of corrective actions from the contractor readiness assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 15, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 15, 2019

Plutonium Facility–Transuranic Waste Management: On Saturday, workers were replacing filters on the outer drums of pipe overpack containers (POC) with the new filters needed to support a damage ratio of zero for postulated fire scenarios (see 1/25/2019 report). The work crew inadvertently removed the filter from a 7A drum on the outdoor waste pad that did not contain a POC, but instead contained bagged waste. Note that 7A drums are used as the outer container on POCs making them visually indistinguishable. There was no contamination spread. Facility management paused this activity pending revision of the procedure to reduce the potential for errors.

RANT Shipping Facility–Readiness: On Monday, the contractor readiness assessment team completed their review and briefed the results to facility management. The team identified one pre-start and one post-start finding. The pre-start finding was that two doors were not configured in accordance with life safety code and could be locked from the outside. The post-start finding was to complete an updated industrial hygiene assessment as one has not been performed in more than five years. The team made positive observations on the thoroughness of the management self-assessment and the coordination between different organizations working at RANT. The pre-start finding was corrected before the end of the week and the federal readiness assessment will start next week.

Plutonium Facility–Safety Basis: On Tuesday, the NNSA Field Office issued a safety evaluation report unconditionally approving the contractor’s annual update to the Plutonium Facility’s safety basis (see 8/17/2018 report). This particular update addresses long-standing conditions of approval, many of which originated in 2008, and includes efforts to modernize the hazard analysis and consolidate multiple safety basis documents. The field office requested an implementation plan for concurrence within two weeks.

Area G–Safety Basis: On Monday, N3B safety basis personnel completed their New Information evaluation regarding the protection of material-at-risk (MAR) assumptions for mobile loading operations (see 2/1/2019 report). They concluded that there was no potential inadequacy in the safety analysis and that MAR limits for non-combustible waste types during mobile loading do not need to be protected in the Technical Safety Requirements. Their justification was that conservatism in the development of the composite source term used for site-wide accidents exceed the uncertainties associated with the unprotected distribution of non-combustible wastes during mobile loading.

Chemistry and Metallurgy Research (CMR) Building–Nuclear Criticality Safety: On Tuesday, workers opened a legacy item retrieved from the vault and encountered a liquid when they were expecting a solid compound based on the label information. They had opened the item in a location where liquids were prohibited by the criticality safety posting. Subsequent to discussion with their supervisor, they moved the item to another location in the facility for non-destructive assay. At the fact-finding, NNSA Field Office personnel questioned why the workers and their supervisor did not respond in accordance with the procedure for process deviations and waited approximately five hours before notifying the operations center. CMR management plans to reinforce expectations for response to process deviations and conduct an extent-of-condition review to strengthen planning for future legacy item processing activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 22, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 22, 2019

The laboratory was closed on Tuesday due to snow.

DNFSB Activity: On Wednesday, Board Member Santos visited the laboratory accompanied by staff members J. Gilman, P.J. Migliorini, and C.J. Roscetti. Mr. Santos met with senior leadership from the NNSA and EM Field Offices and their contractors. He also walked down the Plutonium Facility, Weapons Engineering Tritium Facility, and Area G. On Thursday, the Board conducted a public hearing in Albuquerque that included the EM and NNSA Los Alamos Field Office Managers as panelists. The subject of the hearing was the new DOE Order 140.1, *Interface with the Defense Nuclear Facilities Safety Board*.

RANT Shipping Facility–Readiness: On Thursday, a five member federal team completed their two-day readiness assessment for restart of the RANT Shipping Facility. Overall, they concluded that the facility is ready to safely operate with no pre-start or post-start findings. They further noted that LANL continues to demonstrate excellence in its achievement of readiness.

Transuranic Waste Management: With the RANT Shipping Facility nearly ready to operate and provide all-weather loading capability, the critical path for resuming risk reduction across the laboratory is the approval of transuranic waste streams for receipt at the Waste Isolation Pilot Plant. Currently, N3B has a limited population of containers that are approved for shipment, but they are still working with Triad management to develop arrangements to use RANT. Triad expects to receive approval in the next month for about 120 waste containers originating from the Confinement Vessel Disposition project. Triad expects approval of additional containers later this spring, which should facilitate improved optimization of shipment payloads

Transuranic Waste Facility (TWF): Last Wednesday, TWF personnel received their first shipment of 2019, which included 15 transuranic waste drums previously staged at the Plutonium Facility. The drums originated at the Chemistry and Metallurgy Research building. This brings the total inventory at TWF to 363 drums or about 30 percent of the facility’s overall capacity. While TWF has provided some relief, waste container storage locations at the Plutonium Facility remain at about 90 percent of their capacities.

On Wednesday, the NNSA Field Office concurred with Triad’s revised project execution plan to reclassify the TWF fire suppression system as safety-significant. The plan anticipates implementation of the revised safety basis by April 30, 2019. Separately, TWF engineering personnel are finalizing details for seismic qualification testing of the redesigned seismic power cutoff switches. They anticipate providing the NNSA Field Office with a revised schedule that reflects a slip from the directed completion date of January 14, 2019 (see 8/4/2017 report).

Area G–Safety Systems: N3B personnel have procured wire cabling to complete repairs of the inoperable safety class vehicle barriers (see 1/18/2019 report). Repair work is in progress and is being prioritized based on dome inventory and impacts to vehicle restrictions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 1, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 1, 2019

Federal Oversight: On Wednesday, NNSA Field Office management conducted the final oral board for a facility representative assigned to the Plutonium Facility. The final qualification walk-through occurred last week. The candidate successfully completed these evaluations bringing the total of fully qualified personnel assigned to facility representative duties up to two with one each assigned to the Plutonium Facility and the Weapons Engineering Tritium Facility. The field office has a pool of eight facility representatives in training to increase their field oversight capabilities.

RANT Shipping Facility: On Thursday, the NNSA Field Office approved restart of the facility. On Wednesday, subsequent to the transmission of a review agenda from the Board's staff, Triad personnel entered the New Information process to evaluate an apparent inconsistency in the damage ratios used in the safety basis in the analysis of payload drops.

Area G: On Wednesday, N3B management paused all operations after they learned that workers were executing the corrective maintenance on the safety class vehicle barrier cables in a manner inconsistent with the specified sequence. Engineering personnel are consulting with the vendor to confirm the acceptability of this alternate assembly method. This is N3B's third work pause in recent weeks. Following the current pause, management is releasing individual activities after the work documents are revalidated.

Plutonium Facility–Transuranic Waste Management: Based on current waste storage utilization levels of about 90 % of capacity, Triad management has begun tapering certain residue generating activities from lower programmatic priority activities such as vault cleanout. Some residue generating activities, such as metal production, continue and are maximizing use of floor storage locations for their residues. During the next month, Triad management plans on executing multiple shipments to the Transuranic Waste Storage Facility to alleviate the situation and reduce the amount of waste in the facility.

Plutonium Facility–Safety Basis: On Thursday, Triad management transmitted to the NNSA Field Office for concurrence an implementation plan for the recently approved updated safety basis (see 2/15/2019 report). The plan anticipates declaration of implementation on or before December 20, 2019. Implementation will involve changes to approximately 99 procedures, associated training, and conduct of a major implementation verification review. The plan notes that implementation may need to be phased as a result of unknown completion dates for certain related key projects that include: MAR Tracker software update, installation of automatic transfer switches for the diesel generators that support the electric firewater pumps, and installation of the modern chlorine gas delivery system. Triad also informed the field office that they anticipate the need to submit a revision to this safety basis to support operational flexibility and correct previously identified issues, including the inadvertent omission of a process description for a needed activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 8, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 8, 2019

DNFSB Staff Activity: R. Davis and P. Migliorini were on site to review the safety basis for the RANT Shipping Facility.

Transuranic Waste Management: This week, as part of the initiative to alleviate waste accumulation challenges at the Plutonium Facility, Triad personnel executed three shipments to the Transuranic Waste Facility (see 3/1/19 report). Overall, they transferred 98 containers, which included a shipment of 40 containers representing the largest single batch received to-date. Triad personnel continue working with the Carlsbad Field Office to obtain approval to send containers to the Waste Isolation Pilot Plant (WIPP). There are now several hundred containers from two different waste streams that have obtained some of the necessary approvals.

Plutonium Facility–Safety Basis: Last Friday, the NNSA Field Office approved Triad’s evaluation of the safety of the situation (ESS) for the positive unreviewed safety question (USQ) related to biokinetic solubility of heat source plutonium (see 12/21/2018 report). The approval notes that the analysis is reasonably conservative and that references not included in the ESS provide an adequate basis to use the Type S dose conversion factor for all oxides fired above 800 °C for two hours. Oxides and some other compounds that have not undergone this heat treatment will continue to use an intermediary dose conversion factor between Type S and M. The approval contained one directed action to revise the ESS to include Technical Safety Requirements for the new material-at-risk limits. The Board’s staff await interaction with Triad and the NNSA Field Office on questions concerning the technical validity of this approach.

Last Thursday, Triad safety basis personnel concluded that the potential inadequacy of the safety analysis related to transportation of nuclear material in the Plutonium Facility’s freight elevator constitutes a positive USQ (see 2/1/2019 report). The currently analyzed drop height for a container falling from a vault shelf does not bound the height from a fall due to an elevator failure. As a compensatory measure, management directed that all nuclear materials conveyed using the elevator or dumb waiter are to be packaged in accordance with existing requirements.

Chemistry and Metallurgy Research Building: On Wednesday, safety basis personnel entered the New Information process to evaluate transportation of nuclear material in the elevators after determining the positive USQ for the elevator in the Plutonium Facility.

Area G: Last month, the EM Field Office and N3B approved the performance based incentives for fiscal year 2019. Notable activities include: restart two processing lines to sort, segregate, and size reduce transuranic waste; utilize these lines to remediate 192 containers in preparation for disposal at the WIPP; reconfigure Area G access and radiological controls; implement N3B’s new safety management programs; and develop and begin executing a strategy to create a new safety basis.

Worker Safety: Last week, workers lost control of a laser table weighing about a metric ton while moving it into a laboratory in the Radiological Laboratory Utility Office Building. On Thursday, Triad management commenced a team investigation after identifying a recent trend in rigging incidents.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 15, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plau and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 15, 2019

Chemistry and Metallurgy Research (CMR) Building–Conduct of Operations: During the past year, operators had been retrieving items from tube vaults in the floor of Wing 9, repackaging them into various shipping containers, and returning them to the floor space above the tube vaults. Last Friday, a relatively new operator appropriately questioned whether the criticality safety limit approval allowed him to store the shipping containers on the floor, given that the limits are specified as “per floor hole location.” Nuclear criticality safety personnel determined that situation was safe and stable and recommended categorizing the infraction as a level-1 non-compliance. Their procedures define a level-1 non-compliance as an operation conducted with fissionable material such that a criticality safety evaluation would have been required, no analysis has been conducted, and no credited controls are in place. Triad management conducted two fact-findings this week that revealed significant weaknesses in conduct of operations, training, and implementation of the nuclear criticality safety program. Given these and other recent issues (see 2/15/2019 report), Triad management paused Chemistry Division activities in CMR, the Plutonium Facility, and the Radiological Laboratory Utility Office Building pending corrective actions.

Plutonium Facility–Radiological Safety: Last Thursday, while changing gloves on a glovebox used for plutonium-238 aqueous processing, an operator inadvertently lost control of the gloves resulting in contamination levels in excess of the monitoring instrument’s range to a large portion of the protective clothing covering his arm. All workers involved were wearing air purifying respirators and there were no indications of an uptake. At the fact-finding, Triad managers noted the remarkable response of the radiological control technicians who were able to fix the contamination and remove the protective clothing from the worker without further spreading contamination. Management also directed further study on opportunities to improve the glove change process to avoid this problem, which had occurred previously a few years ago. The resident inspectors note that radiation protection personnel continue to pursue routine use of powered air-purifying respirators (PAPR) for these types of high-hazard jobs. PAPRs offer workers greater comfort and better respiratory protection. The primary impediments to deployment include locating storage space and completing necessary training.

Plutonium Facility–Safety Basis Compliance: On Tuesday, Triad personnel conducted a fact-finding to learn from an unplanned entry into the limiting condition for operations associated with an exceedance of the material-at-risk (MAR) limits for the outdoor transuranic waste storage pads that occurred last Wednesday. Fact-finding personnel discussed issues with the formality of procedural execution used to pre-check limit compliance ahead of material movements, as well as human performance concerns associated with the MAR Tracker software. In particular, Triad personnel noted that MAR Tracker has necessitated numerous work-arounds since about 2015. For example, the current MAR surveillance procedure requires about 60 separate manual data manipulations. Fact-finding personnel determined that some of these data manipulations were skipped resulting in an inaccurate result for the pre-check conducted last week. Updates to MAR Tracker to eliminate these manipulations have been underway for nearly a year and are expected to be implemented in about a month.

Severe Weather: On Wednesday, the laboratory experienced snow and high winds prompting Triad management to declare a discretionary emergency. They staffed the Emergency Operations Center for several hours to improve response to many downed trees and power outages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 22, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 22, 2019

Emergency Management: On Monday, Emergency Management personnel restored full operability of the Emergency Operations Center (EOC). At the end of January, they declared portions of the primary and secondary EOC rooms inoperable due to safety concerns following damage to one of the safety glass panes in the glass partition wall between the rooms. Alternative locations remained available to continue EOC Operations. Late last week, utilities and infrastructure personnel taped the damaged pane to prevent further degradation; a new pane is on order. The EOC activation last week for severe weather was able to use the alternate primary location. A structural evaluation to determine why this glass was damaged is in progress.

Plutonium Facility–Conduct of Operations: On Monday, Plutonium Facility management implemented a new standing order to augment programmatic requirements for the person in charge (PIC) program and to apply new expectations for performance of the reader worker method. The first new requirement states that PICs are not allowed to perform hands on work for tasks involving processing greater than 500 g of special nuclear material, processing heat source plutonium, or during high hazard work. The second requirement mandates that use every time Detailed Operating Procedures or Integrated Work Documents for operations involving processing heat source plutonium or greater than 500 g of special nuclear material be performed using the reader worker technique.

Transuranic Waste Facility (TWF)–Safety Basis: On Monday, the NNSA Field Office issued a Safety Evaluation Report approving the annual update to the TWF Safety Basis with no conditions of approval. This annual update addresses a condition of approval from NNSA’s 2016 safety basis approval (see 12/9/2016 report). The prohibition on receipt of pipe overpack containers has been removed and the new safety basis includes performance criteria for pipe overpack containers.

Area G: Last Friday, the Environmental Management Field Office (EM-LA) transmitted the new, unapproved safety basis for Area G to N3B. This safety basis was prepared by a subcontractor directly for EM-LA office prior to N3B assuming control of the Los Alamos Cleanup Contract (see 3/23/2018 report). The contract stipulated that EM-LA would provide N3B with an approved safety basis for use at Area G. However the prepared document does not align with current contract direction to N3B and their technical approach to the Area G mission. Therefore, EM-LA provided the unapproved safety basis to N3B along with their review comments with the direction that N3B initiate a new update of the Area G safety basis consistent with their current project direction and technical approach.

Last week, N3B personnel resumed repair work to restore the safety class vehicle barriers to service (see 3/1/2019 report). This week, they paused again following discovery that a change adding use of a new tool to the Integrated Work Document was made following the initial unreviewed safety question (USQ) evaluation. The Integrated Work Document did not go back through the USQ process after this change. A USQ evaluation is currently in progress and work on the barriers is expected to resume shortly.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 29, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plau and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 29, 2019

Weapons Engineering Tritium Facility (WETF)–Conduct of Operations: Last week, WETF personnel improperly executed a rearrangement of the Flanged Tritium Waste Containers (FTWC) in preparation for venting operations. The safety basis addendum that supports FTWC movement and venting includes Specific Administrative Controls (SAC) associated with a lift height restriction and lookout in order to preclude toppling and possible ignition of potentially flammable headspace mixtures of oxygen and hydrogen isotopes. WETF management implements these SACs using two procedures. The work crew determined that the FTWC movement procedure did not support rearrangement and chose to use an inappropriate work document that did not include the SACs; however, the crew stated that they nonetheless implemented the SACs. Subsequent to commentary from a member of the NNSA Field Office, WETF management preliminarily concluded that this event did not constitute a violation of the Technical Safety Requirements (TSR) because of the verbal statement that the SACs were implemented. Reliance on verbal implementation is contrary to DOE-STD-1186, *Specific Administrative Controls*, which states, “SACs are implemented to control facility operations using formally controlled procedures.”

Transuranic Waste Management: N3B was unable to capitalize on their allocated shipment from Area G this week because the Waste Isolation Pilot Plant (WIPP) mobile loading team sent a key member that was unfit for work in a radiological environment due to an open surgical wound. They will try again next week. The mobile loading team is part of Triad’s Repository Science and Operations program that supports the DOE Carlsbad Field Office. On Thursday, Triad received the complete set of approvals to send 19 drums to WIPP. They expect additional approvals to be forthcoming and are planning the first shipment from RANT for next month.

Transuranic Waste Facility (TWF): On Tuesday, TWF management declared a TSR violation after workers recognized that they failed to properly execute a surveillance on material-at-risk prior to moving containers into a waste storage building. The TSR surveillance protects an initial condition used in the safety analysis. At the fact-finding, personnel indicated that Waste Compliance and Tracking System (WCATS) records showed personnel had double scanned three drums and skipped scanning three other drums. TWF personnel discussed improvements to the formality of the surveillance, WCATS device network connectivity concerns, and questions on WCATS apparent inability to flag errant movements. TWF management plans to implement standing orders for all facilities that use WCATS and notify N3B.

Plutonium Facility–Safety Systems: On Saturday, during quarterly preventive maintenance on the safety class uninterruptable power supply (UPS), the system shut down and the facility lost power for a few minutes. Facility operations personnel restored all the systems impacted by the outage and entered the appropriate limiting condition for operations due to inoperability of the UPS. The cause of the shutdown is not yet known, and troubleshooting is in progress.

Conduct of Operations: Triad management has released Chemistry Division activities in the Plutonium Facility and the Radiological Laboratory Utility Office Building following validation of safety management program implementation and management walk-downs. Chemistry Division activities in the Chemistry and Metallurgy Research building remain paused (see 3/15/2019 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 5, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaué and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 5, 2019

Flanged Tritium Waste Containers (FTWC): On Friday, Weapons Engineering Tritium Facility (WETF) personnel successfully vented the first of three FTWCs that have the potential for headspaces with a flammable mixture of oxygen and hydrogen isotopes. This is an important milestone in resolving a safety issue that was discovered in 2016 (see 9/9/2016 report). WETF personnel found that the inner contents had not leaked and plan to disposition them prior to venting the remaining two FTWCs of concern located in that facility.

The NNSA and EM Field Offices continue to deliberate on the fate of the FTWCs currently located at Area G. The primary question is whether the FTWCs should be vented *in situ* prior to transportation back to WETF for final disposition. Once a decision is reached, additional work will be needed to solidify the technical approach, schedule, safety basis, and roles and responsibilities.

Plutonium Facility—Conduct of Operations: In response to an observed uptick in the number and severity of potential process deviations, Triad management initiated a safety pause to brief all fissile material handlers. The briefing emphasized that 16 of 18 potential process deviations that have occurred in calendar year 2019 resulted from errors associated with executing the material movement process. Managers solicited feedback and workers provided a number of opportunities to improve the material movement process. The one-hour briefing also emphasized recent standing orders intended to enhance procedural execution and control of sharps (see 3/22/2018 and 12/21/2018 reports).

Transuranic Waste Management—Inconsistencies: The incidents at the Waste Isolation Pilot Plant in February 2014 and the Idaho National Laboratory in April 2018 demonstrated that improperly prepared transuranic waste can result in energetic events that release radioactive materials from drums in a manner that was not previously envisioned by DOE Standard 5506-2007, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*. In the absence of DOE direction, safety basis personnel have inconsistently incorporated this information into the safety bases for the LANL nuclear facilities. For example, the safety basis for the Transuranic Waste Facility acknowledges the potential for an energetic release of radioactive material from a container with non-compliant waste could be 2–3 orders of magnitude greater than is analyzed per the DOE Standard 5506. As such, the NNSA Field Office directed development of a Specific Administrative Control to ensure only compliant waste is received at the facility (see 4/13/2018 report). A similar control does not exist at the Plutonium Facility, Chemistry and Metallurgy Research (CMR) building, and Area G—all facilities that handle transuranic waste in outdoor locations in the absence of engineered confinement.

Developments: N3B personnel successfully completed a mobile loading shipment of waste from Area G. CMR personnel executed their recovery plan and transferred the containers of fissionable materials to appropriate locations (see 3/15/2019 report). Plutonium Facility personnel restored operability to the uninterruptible power supply (see 3/29/2019 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 12, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 12, 2019

RANT Shipping Facility: Triad personnel resumed shipping operations of transuranic waste to the Waste Isolation Pilot Plant (WIPP) using the RANT Shipping Facility. The facility had been in cold standby since 2014. They moved the first shipment of 42 transuranic waste drums from the Transuranic Waste Facility (TWF) to RANT on Monday. The shipments were loaded into TRUPACT-II shipping containers on Tuesday and Wednesday then departed for WIPP on Thursday. The importance of restoring an indoor shipping capability for transuranic waste was evident this week as high winds associated with the explosive cyclogenesis event in the central United States curtailed outdoor operations at TWF, Area G, and RANT on Wednesday.

Weapons Engineering Tritium Facility: Triad personnel unloaded the inner containers from the Flanged Tritium Waste Container (FTWC) that was vented last Friday. Of the five inner containers, one was processed this week to reduce internal pressure. One container has exterior contamination indicating the potential for leakage. Facility personnel will continue to process these inner containers and plan to vent and unload the second FTWC in May.

Area G: On Tuesday, N3B personnel discovered a drum outside of a fire-rated safe labeled as containing 38 sources. Eleven of these sources are listed in a Specific Administrative Control in an Evaluation of the Safety of the Situation (ESS) which requires they be stored in a fire-rated safe when not in use. The workers immediately implemented a fire watch then opened the drum and performed a physical inventory per their source movement procedure. They discovered that the drum label was not fully accurate and there were thirteen sources that had to be moved into a safe. As these were placed into safes, an extent of condition review of sources listed in the ESS found several more that required movement. Facility personnel have completed these moves and are performing a broader extent of condition review on other types of sources. Facility management declared a violation of the Technical Safety Requirements due to the non-compliance with the ESS control.

Transuranic Waste Management–Inconsistencies: Transuranic waste can be staged in outdoor locations in proximity to vehicle traffic at the Plutonium Facility, the Waste Characterization Reduction and Repackaging Facility, TWF, RANT, and Area G. With the exception of the mobile loading operation at Area G, the safety bases for each of the last four of these facilities considers as part of the accident analysis a vehicle crash into waste containers and a subsequent fuel pool fire. While the analytical assumptions (e.g., number of breached containers) used in each of these analyses differ, the results identify the need for vehicle barriers to prevent such accidents. The accident analysis for the Plutonium Facility examines other types of accidents to outdoor transuranic waste, but it does not analyze a vehicle crash with subsequent fuel pool fire. As such, vehicle barriers are not used even though the material-at-risk is similar to the other facilities. In our opinion, this situation may warrant reconsideration at the Plutonium Facility as construction activities and associated heavy equipment traffic is increasing adjacent to the outdoor transuranic waste storage areas.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 19, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 19, 2019

DNFSB Staff Activity: Z.S. Beauvais and P.J. Migliorini were onsite to supplement routine oversight activities. On Thursday, a staff team conducted a teleconference with Triad and NNSA Field Office personnel to discuss the technical veracity of the recently approved evaluation of the safety of the situation concerning the biokinetic solubility of plutonium-238 materials (see 3/8/2019 report).

Worker Safety–Accident Investigations: Last month, Triad management approved corrective actions responding to the issues identified in the investigation report from the August 2018 event where a worker received an intake of plutonium-238 from a puncture wound (see 2/8/2019 report). As part of the process, they screened and developed actions for more than 50 issues associated with the judgements of need and opportunities for improvement identified in the report. Corrective action due dates range from some that have already completed to the end of September 2019. Notable corrective actions include: strengthening work planning processes for programmatic maintenance and facility construction; redesigning the cable crimp to eliminate the puncture hazard; replacing the locations that have inappropriate galvanized steel cabling with stainless steel or titanium; identifying similar hazards for all cable applications throughout the plant; evaluating training and qualifications for the person in charge position; evaluating the feasibility of a rapid bioassay methodology; and generating management observations verification guidance on work instruction usability.

On Thursday, the investigation team out-briefed the results of their review of the dropped load resulting in a near-miss at the Radiological Laboratory Utility Office Building and eleven other similar events that have occurred since 2016 (see 3/8/2019 report). The team recommended actions associated with strengthening lift categories and plan content, ensuring non-working supervision is present for all moderate and high hazard jobs, and enforcing better work pause, planning, and pre-job briefing practices. Notably, the team identified that many past corrective actions have not been applied systematically across the laboratory to address what are actually cross-functional/organization issues. As such, management decided to ensure that the final corrective actions were integrated with the corrective actions planned in response to the joint investigation of the sub-contracted construction event (see 1/11/2019 report).

Plutonium Facility–Conduct of Operations: This Tuesday, workers made an error in the material movement process while returning containers to the floor storage location in the processing room with a large number of individual special nuclear material cans (see 1/25/2019 report). They did not complete a step in the material movement procedure that requires verification that the database matches the physical configuration of the nuclear material. Performing this step should have caught the discrepancy between the database and physical configurations. There are currently 144 containers in this floor storage location, creating the potential for a lengthy verification process. Another team discovered the error the next day.

Area G: On Tuesday, N3B workers inadvertently parked a fueled vehicle in a combustible restricted area. Another worker questioned whether the entry had been authorized and logged by Operations Center personnel. As it had not, this constituted a violation of a Technical Safety Requirement for combustible liquid control. N3B management recognized this as repeat violation (see 10/12/2018 report) and recommended performing a formal causal analysis to prevent further recurrence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 26, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 26, 2019

Nuclear Criticality Safety: Last week, Triad management sent the NNSA Field Office their plan to reduce the backlog of criticality safety evaluations. The plan notes that 211 of the 420 fissionable material operations at the laboratory currently have evaluations with compliance issues. After accounting for other needs, they developed a prioritized listing of 236 evaluations and plan to complete 98 of them this fiscal year. While the plan does not specify an overall completion date, Triad management is currently estimating completion in 2023. The plan discusses strategies to reduce workload including: eliminating NNSA Field Office approvals for evaluations produced to remove safety basis controls related to glovebox flooding; increasing emphasis on the identification of engineered controls; utilizing corporate reach-back to support development of operational requirements documents; developing a map of the Plutonium Facility indicating criticality safety limits in each location for use in planning material movements; and increasing use of standardized limit sets. The NNSA Field Office is reviewing the plan.

Chemistry and Metallurgy Research Building–Conduct of Operations: On Monday, Triad management released the majority of Chemistry Division operations from their pause following safety management program validations and walkthroughs (see 3/15/2019 report). Uranium operations and staging and storage activities remain paused. Formal causal analyses for the events that led to the pause are in progress.

Transuranic Waste Management: Senior leadership from Triad, N3B, and their field office counterparts recently met with the Carlsbad Field Office to strengthen the waste management plans for the laboratory. They identified a number of opportunities to improve integration, enhance shipping capability, and maximize risk reduction across the laboratory by optimizing payloads using NNSA and EM waste inventories. They plan joint communications to permeate this vision to their respective workforces and dissolve misconceptions. This week, N3B executed a successful mobile loading shipment. Last week, Triad successfully executed their second shipment from RANT.

Area G: Last week, N3B personnel restored all remaining safety-class vehicle barriers to operability and lifted the shift order on vehicle restrictions (see 11/2/2018 report).

Plutonium Facility–Conduct of Operations: Last Wednesday, facility personnel entered the limiting condition for operations for material-at-risk (MAR) after an individual performing trending analyses discovered a glovebox exceeded its limit for heat-source plutonium. Further investigation determined that a worker had mistakenly applied a multiplier on a material form, and the actual MAR present did not exceed the glovebox limit. This multiplier comes from the standing order issued in response to questions on biokinetic solubility of heat-source plutonium (see 9/7/2018 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 3, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 3, 2019

Radiological Laboratory Utility Office Building (RLUOB): Last Wednesday, facility operations personnel entered a service room and noticed a leak emanating from a valve on the radioactive liquid waste (RLW) system. Upon subsequent visual inspection by a radiological control technician, RLUOB engineers believe that this valve, and 6 similar valves, may be constructed of carbon steel. The RLW system handles radioactive liquid waste streams from chemistry operations that include nitric and hydrochloric acids—carbon steel valves would be incompatible with these solutions. The suspect valves are also in contact with stainless steel piping, which would create another corrosion mechanism. RLUOB management plans to drain the affected piping sections and develop a work package to replace all of the suspect valves. They will also confirm the valve materials and if shown to be incorrect, investigate the cause of this failure in the design, procurement, and installation processes. The valves were installed in 2013 as part of a modification to add straining and sampling capabilities that were not included in the original design.

Transuranic Waste Management–Inconsistencies: Facilities that handle transuranic waste often rely on 55-gallon containers as the sole barrier to the release of radioactive materials. A degraded container poses a direct risk to workers and may increase the risk to members of the public due to an inability to perform the function assumed in the safety analysis (e.g., supporting a damage ratio). The Technical Safety Requirements (TSR) documents at the various LANL facilities specify different responses to the discovery of a container with suspected degraded integrity. For example, the TSRs for the Transuranic Waste Facility (TWF) and the RANT Shipping Facility require a degraded container to be restored, overpacked, or removed from the facility; however, this action must be completed in 7 days at TWF and 14 days at RANT. The TSRs for the Plutonium Facility and Area G consider 55-gallon waste containers as a Design Feature and as part of safety management program, respectively. As such, the TSRs do not specify response actions and completion times, which are left to management discretion. The approaches at LANL contrast with other sites where TSR coverage ranges from non-existent to specific direction to immediately place the container in a safe configuration and overpack within 48 hours (i.e., Waste Isolation Pilot Plant).

Confinement Vessel Disposition Project: Last week, Triad personnel loaded the ninth confinement vessel into the enclosure. This is the last vessel known to contain nuclear material. Processing awaits repair of the dry chemical fire suppression system in the workstation.

Area G: This week, N3B marked the completion of its first year as the Los Alamos Legacy Cleanup Contractor. Their most significant accomplishment has been the resumption of mobile loading operations to ship transuranic waste to the Waste Isolation Pilot Plant. They completed seven waste shipments with the most recent being this Thursday. Other transuranic waste activities have yet to ramp up partly due to challenges in establishing business systems and safety management programs to support nuclear operations. These are starting to be rolled out now, and the operational tempo is expected to increase in the coming year as additional activities restart.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 10, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 10, 2019

DNFSB Staff Activity: The Resident Inspectors were in Washington, D.C. to brief the Board and attend meetings. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 17, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 17, 2019

Transuranic Waste Facility: During the course of implementing a safety basis update that upgrades the fire suppression system to safety significant, engineers determined that the current performance flow curve for the firewater pump does not meet the commissioning test curve as specified in the new Technical Safety Requirements. Facility engineers are currently troubleshooting the system and examining alternatives to the commissioning curve. The NNSA Cognizant Secretarial Officer previously directed the upgrade to the fire suppression system. The safety basis update is also needed to support the receipt of pipe overpack containers, which currently constitute the majority of waste containers awaiting removal from the Plutonium Facility. Additionally, the fire suppression system upgrade was intended to help relax combustible loading and spacing controls; however, these changes have not yet been incorporated into the safety basis. Facility personnel expect to complete later this summer the replacement of the seismic power shutoff system and the conversion of the dry-pipe system from nitrogen to air.

Plutonium Facility–Work Planning and Control: On Wednesday, facility personnel conducted a fact-finding after a pipefitter dropped a hot brazing rod and burned his lip. Fact-finding participants discussed several points of confusion regarding appropriate personal protective equipment including: the worker was wearing four sets of gloves (liners, nitriles, cut resistant, and welding), which was beyond the number specified in the work document; unclear eye and face protection requirements in the work document; conflicting institutional guidance on face protection for molten metal splash hazards; and subject matter experts who were unfamiliar with one of the institutional guides specific to construction work. The group also discussed difficulties associated with the timeliness of making changes to work packages. Facility management has paused all welding, brazing, and soldering activities until the work documents are corrected.

Plutonium Facility–Nuclear Criticality Safety: Last week, the NNSA Field Office returned comments to Triad management regarding their proposed alternative approach to addressing water ingress into gloveboxes that could potentially result in criticality. The proposed approach relies on arguments that criticality is not credible from non-fire-related water ingress into gloveboxes, nor water ingress associated with fires either outside or inside of gloveboxes.

Area G: N3B and mobile loading team personnel loaded another shipment for transport to the Waste Isolation Pilot Plant. However, the load exceeded the gross transportation limit of 80,000 pounds and could not be shipped. The loaded shipment remains in Area G. The mobile loading team plans to swap the tractor with a slightly lighter unit and complete the shipment next week.

N3B completed a management self-assessment for resumption of limited waste remediation activities in a tent inside Building 412. The allowable activities will include de-nesting drums from standard waste boxes, liner pulls, and replacing plastic liner bags. Contractor and federal readiness reviews are planned for later this summer.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 24, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 24, 2019

Flanged Tritium Waste Containers (FTWC): On Tuesday, the NNSA and EM Field Office Managers issued a joint letter to Triad and N3B providing direction to remediate the FTWCs stored at Area G (see 4/5/2019 report). The letter directs the contractors to develop a joint plan to vent the FTWCs at Area G and then move the vented containers to the Weapons Engineering Tritium Facility to complete the remediation. Triad will be responsible for developing the safety basis to support this activity and performing the work at Area G. The EM Field Office Manager will be the safety basis and startup approval authority with the NNSA Field Office Manager's concurrence.

Plutonium Facility–Transuranic Waste Management: Last week, during routine inspections, Triad personnel discovered a transuranic waste drum with a corroded filter vent in the basement of the Plutonium Facility. Aside from the vent, the drum appears to be in good condition and no contamination or other anomalies were detected. Waste operations personnel believe that there is no indication that the drum and its filter vent are not able to perform their safety functions. Safety basis personnel entered the New Information process and additional data is being collected regarding this drum and others. The drum was packaged last year and contains primarily leaded glovebox gloves from heat source plutonium operations. No other drums that have been inspected including some with the exact same waste profile show any evidence of vent corrosion. The deposits around the filter are acidic and additional chemical analysis is in progress.

Plutonium Facility–Safety Basis: The NNSA Field Office approved the Evaluation of the Safety of the Situation and Justification for Continued Operations for freight elevator failures with no conditions of approval or directed actions (see 3/8/2019 report). The higher drop heights for material in the elevator do result in slightly higher accident consequences to the public, however they remain well below the evaluation guideline, and no additional controls were recommended. The operational restriction put in place at the time a Potential Inadequacy in the Safety Analysis was declared will remain in place until the Documented Safety Analysis is revised to incorporate the more accurate consequences from this scenario.

On Thursday, Triad safety basis personnel recommended declaration of a Potential Inadequacy in the Safety Analysis associated with the hazards analysis for vehicle accidents impacting transuranic waste stored on pads outside the Plutonium Facility (see 4/12/2019 report).

RANT Shipping Facility: Triad transmitted to the NNSA Field Office a revised safety basis to address the first condition of approval to elevate acetylene and electric forklift controls to specific administrative controls from NNSA's original approval (see 11/2/2018 report). NNSA approved changes addressing the condition of approval related to WIPP certification in December 2018.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 31, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 31, 2019

Flanged Tritium Waste Containers (FTWC): Last Friday, Triad provided the DOE Field Offices with a schedule for remediation of the FTWCs with potentially flammable headspaces currently stored at Area G (see 5/24/2019 report). The proposed schedule has venting at the end of June at Area G then transportation to the Weapons Engineering Tritium Facility in early August. The DOE Field Offices are evaluating this proposal. Safety basis documents for both venting at Area G and transportation of the vented FTWCs to the Weapons Engineering Tritium Facility are under development. The venting process for the Area G FTWCs will be similar to that currently in use to remediate FTWCs at WETF although the Area G FTWCs are expected to be more challenging.

Plutonium Facility–Nuclear Criticality Safety: Last Thursday, Triad personnel submitted to NA-LA a revised safety basis addendum addressing changes to nuclear criticality safety related to water ingress into gloveboxes. This revision addresses comments from DOE’s review of the initial submittal which was transmitted in January. The addendum provides an alternative approach to address moderator ingress into gloveboxes. Under the current safety basis, a fissile material operation requires additional controls for moderator ingress unless there is an implemented process-specific evaluation showing these controls are not needed or the location is de-inventoried. Under the new addendum, operations will not need additional moderator controls if they meet criteria established in two Criticality Safety Technical Documents issued in January 2019 that provide general analyses for moderator ingress due to seismic events with and without fires.

Transuranic Waste Facility (TWF): Facility personnel partially implemented the revised safety basis that allows TWF to accept pipe overpack containers (POCs) and upgrades the fire suppression system to safety significant (see 5/17/2019 report). The upgrade to the fire suppression system and its associated limiting condition for operation were not implemented. To address the growing number of POCs in waste storage areas at TA-55, NA-LA and Triad personnel agreed to partially implement the safety basis amendment allowing POCs to be moved to the modern TWF facility. The fire suppression system is still undergoing troubleshooting. This week, TWF personnel were not able to restore flow to match the acceptance test curve as required by the new safety basis. However, the pumps are still capable of providing adequate flow and pressure to meet the sprinkler demand.

Transuranic Waste Management: Triad Safety Basis personnel entered the New Information process for both TWF and TA-55 to evaluate whether direction from the Carlsbad Field Office to the Waste Isolation Pilot Plant and the Idaho National Laboratory transuranic waste program regarding nitric acid and polyol interactions in waste have any impacts on the transuranic waste program at LANL.

Area G: N3B personnel completed another mobile loading shipment of transuranic waste to the Waste Isolation Pilot Plant.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 7, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 7, 2019

DNFSB Staff Activity: Staff members Z. Beauvais, C. Berg, M. McCoy, and P. Migliorini were at the laboratory to review weapons response basis information in support of safe operations at the Pantex Plant.

Plutonium Facility–Quality Assurance: During commercial grade dedication of new conduit and drive train supports associated with installation of new process equipment, workers discovered that the installed supports were not the type identified in the approved design. The components procured for this project were still in a controlled storage warehouse. They will be replaced with the correct components at the appropriate procurement level. Proposed corrective actions include ensuring that existing construction practices are adhered to, evaluating said processes for improvements, and evaluating the need to clean out the facility basement where construction materials are usually staged once obtained from controlled storage locations. Longer term corrective actions under evaluation include adding a controlled storage location in the facility.

Plutonium Facility–Operations: On Wednesday, facility workers noted a fog or haze in an adjacent glovebox following completion of a metal chlorination activity. No activities with the potential to form vapors were occurring in that box. The haze traveled through connecting boxes, and there were solid deposits on the floors and windows of some of the boxes. The workers immediately paused operations and made the appropriate notifications. With the chlorine system secured and purged, the haze dissipated. The nature of this event is under investigation although unintended chlorine entry into the boxes through mass flow controllers is a likely cause. Chlorine is piped to two boxes and ball valves in the line are left normally open during operations leaving the mass flow controllers functioning as isolation points. The mass flow controllers will be tested for leakage and the operating procedure will be evaluated for inclusion of a valve lineup.

Senior Management briefed the facility workforce on last year's Pu-238 uptake from a puncture wound (see 9/7/2018 report). The briefing included a discussion of that event as well as earlier puncture wounds at Los Alamos in 2008 and the Savannah River Site in 2010. The training emphasized the importance of conduct of operations and the integrated safety management process. Other key points included the need for strong organizational learning in order to avoid repetitive, ineffective corrective actions and recurring events.

Plutonium Facility–Infrastructure: On Wednesday, the NNSA Field Office unconditionally approved a revised Safety Design Strategy for the Fire Alarm System replacement project (see 6/29/2018 report). The revised strategy addresses the comments from NNSA on last year's revision. Key changes include: a more detailed discussion of the interface between the new alarm system and existing credited safety equipment, explanation of the prioritization of criticality alarms versus fire alarms, and a commitment to develop a demolition plan as part of preliminary and final design to ensure all such activities are bounded by existing hazards analyses.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 14, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 14, 2019

Confinement Vessel Disposition Project: Triad personnel recently completed repairs to the dry chemical fire suppression system at the workstation and started processing the ninth vessel, which is the last known to contain nuclear material. After removing the port cover, workers noticed a slit in the plastic they had wrapped it in. While taping up this slit, a continuous air monitor alarmed. The work crew placed the area in a safe configuration and exited the enclosure. There was no spread of contamination to the workers or outside of the enclosure.

Legacy Materials: Last Thursday, the NNSA Field Office approved a variance to the Triad's criticality safety program that allows use of a sum of ratios method to determine that a criticality is incredible for TA-59 Building 1. The criticality safety program currently applies the Pu-239 threshold significant quantity to mixtures of fissile isotopes. Triad made the request to support processing of legacy low-enriched uranium solutions from the Solution High-Energy Burst Assembly (SHEBA) into a more stable solid uranium oxide. The SHEBA solutions have been stored at the Chemistry and Metallurgy Research Building (CMR) since they were deinventoried in the mid-2000's from the TA-18 criticality experiments facility. Triad personnel plan to process them at TA-59-1 where small Pu-239 sources may also be stored. Solidification of the SHEBA solutions will eliminate a large volume of fissile solution currently stored in plastic bottles representing a substantial improvement to the criticality safety posture of CMR.

On Wednesday, CMR personnel discovered that shielded casks made from depleted uranium constituted a violation of the Technical Safety Requirements as the depleted uranium was of sufficient mass to require double containment. Given the low dispersibility and relative hazard of monolithic depleted uranium metal, safety basis personnel are evaluating whether to develop an exception to the double containment control for these casks. The casks have not been used for decades and are believed to be empty based on process and worker knowledge.

Radiological Laboratory Utility Office Building (RLUOB): On Saturday, while a work crew was performing planned breaker maintenance, the facility fire alarms sounded. Contrary to procedure, the work crew did not evacuate immediately, but briefly investigated the situation. The fire department responded and found no evidence of a fire. However, they found that one of the deluge systems that protect the ventilation system had actuated and flooded the associated filter plenum. A fire water pump ran for several hours; subsequent testing of the pump found no damage. The cause of this actuation is still under investigation. There was no spread of contamination during the event.

Facility personnel have confirmed that the corroded valves in the radioactive liquid waste system are carbon steel rather than the required stainless steel (see 5/3/2019 report). They are continuing to assess where the breakdown occurred that allowed the wrong type of valve to be installed.

Transuranic Waste Management: Triad Safety Basis personnel entered the New Information process for the Transuranic Waste Facility, CMR, and TA-55 to evaluate a Safety Alert issued by the DOE Office of Environmental Management related to the drum over-pressurization event at Idaho National Laboratory. The Safety Alert covers concerns related to pyrophoric materials, metal carbides, reactive materials, and requests information on the presence of flammable or near-flammable headspace gas concentrations in waste containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 21, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 21, 2019

Plutonium Facility–Transuranic Waste Management: On Monday, Triad personnel discovered five drums on an outdoor waste storage pad that were not present in the nuclear material control and accountability system. Facility operators entered the limiting condition for operation pertaining to exceedance of material-at-risk (MAR) in this location. Operators verified the contents of the drums, determined that the MAR limits had not been exceeded, and exited the condition on Tuesday. These drums were intended to be part of last year’s mobile loading shipment to the Waste Isolation Pilot Plant. However, only 16 of the planned 21 drums were shipped as weather delays extended operations to the point where one of the shipping casks’ certification expired. Facility management paused material movements from this storage pad while corrective actions are completed.

Plutonium Facility–Quality Assurance: During a final drawing verification walk-down, engineering personnel noted that several installed components for a new machining glovebox did not match the design drawings. Further checks found that almost half of the valves and gauges were incorrect. Some of these components are supposed to be safety-significant. The installed components were equivalent; however, the field change process had not been followed to allow for substitution. As a result of this discovery and another recent installation error (see 6/7/2019 report), facility management commenced an extent of condition review of construction projects.

Flanged Tritium Waste Containers (FTWC): Last week, Triad determined that they will recommend performing both a contractor and a federal readiness assessment for the venting of FTWCs in Area G. Triad will perform the contractor review, while NNSA will perform the federal review with the EM Field Office Manager as the startup authorization authority. Three safety basis documents for the process are in development by Triad: an addendum to the Area G Basis for Interim Operations to support venting, a Transportation Safety Document covering moving the FTWCs to the Weapons Engineering Tritium Facility (WETF), and an addendum for the WETF Documented Safety Analysis that will allow for handling of these FTWCs at WETF—the previous FTWC venting amendment for WETF is specific to three units currently being remediated at WETF. EM is the safety basis approval authority for the Area G addendum and NNSA is the authority for the other two documents.

Plutonium Facility–Configuration Management: Two weeks ago, engineering personnel updating drawings discovered that there was a positive pressure chilled water system entering a glovebox that has a criticality safety posting stating no liquid lines were plumbed into the box. The system had not been used in many years and was locked out upon discovery pending its removal as part of new equipment installations. A subsequent detailed walkdown this Friday determined the lines did not enter the box but terminated at a seal-welded plate heat exchanger.

Area G: Following less than 24 hours in their Initial Confirmatory process, N3B declared a potential inadequacy of the safety analysis related to MAR limits in Building 412. The safety basis has an inconsistency between hazard categorization and MAR limits for this facility. Management has prohibited introduction of MAR to the facility while they further investigate this issue.

Emergency Management: Last week, Triad replaced the damaged pane in the glass partition wall in the Emergency Operations Center (see 3/22/2019 report). The cause of the failure remains unknown; an engineering inspection concluded that snow load was not the failure mechanism.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 28, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 28, 2019

Plutonium Facility–Criticality Safety and Conduct of Operations: On Tuesday, workers attempting to reduce the backlog of production residues in a processing room (see 1/25/2019 report) moved six of the approximately 170 containers from floor storage to a material management area for disposition. Due to congestion in that area, they placed special nuclear material containers on the floor instead of inside a hood as planned. The work team then questioned whether this was allowable and concluded it was not. Nuclear criticality safety personnel determined that the situation was safe and stable and recommended categorizing the infraction as a level-1 non-compliance, since no analysis exists and no credited controls are in place for storage of fissionable material in this location.

Nuclear Material Management: While the oldest container of the production residues discussed above was generated in January 2017, the majority of the 170 containers were generated in the past year as part of meeting a programmatic milestone to complete a certain number of electrorefining metal production runs. This accumulation of residues is inconsistent with DNFSB/TECH-39, which highlighted that the disposal of residues ought to be an integral part of the production process. We note that Triad management does not currently keep metrics regarding production residue accumulation/disposition and that NNSA does not explicitly factor residue disposition as part of its production milestone criteria.

RANT Shipping Facility: While performing prerequisites for accepting potential payload builds for shipment to the Waste Isolation Pilot Plant, a worker noted that the Waste Compliance and Tracking System (WCATS) showed the proposed payload exceeded the material-at-risk limits. Further investigation discovered that the WCATS software did not credit a damage ratio for pipe overpack containers. Triad's safety software testing of WCATS to support RANT safety basis compliance had not found this discrepancy. Triad personnel have updated the code. During contract transition, Triad identified the need to review WCATS to improve compliance and efficiency.

Transuranic Waste Facility (TWF): On Monday, Triad personnel determined that an unreviewed safety question (USQ) existed associated with the safety-class seismic power cutoff system (SPCS) due to potential interference with the laboratory's new counter unmanned aerial vehicle system (CUAS). During testing of the CUAS, TWF personnel had a compensatory measure to perform an existing surveillance requirement on the SPCS following any actuation of the CUAS. TWF personnel were not notified that the CUAS went live and therefore were unable to perform the surveillance requirement to assure functionality of the SPCS.

Transuranic Waste Management–Safety Basis: Facility management at TWF and TA-55 declared potential inadequacies of the safety analysis (PISA) concerning recent information on nitric acid interactions with polyols (e.g., cheesecloth) in waste (see 5/31/2019 report). The PISAs note that the potential for autocatalytic reaction is not currently evaluated in the safety bases; however, it also states that there is currently no cheesecloth waste at the facilities that have been contacted with greater than 12 M nitric acid. We note that 15.8 M nitric acid is used in the Plutonium Facility and that an important aspect of resolving these PISAs will be addressing the potential for an increased respirable release fraction from energetic reactions involving oxidizer-bearing organics. Separately, safety basis personnel determined the PISAs concerning vehicle impacts and fires at both outdoor waste pads at TA-55 represent positive USQs (see 5/24/2019 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 5, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plae and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 5, 2019

Plutonium Facility–Conduct of Operations: Last Thursday, workers in a material management room discovered an unexpected powdery residue underneath a brush in a glovebox that is supposed to be swept clean following activities. They paused work and reported their discovery. The material did contain plutonium. Pit Technologies Division management initiated a safety pause for work in this area due to concerns with this discovery and the recent criticality safety infraction (see 6/28/2019 report). They briefed the workforce and resumed activities using deliberate operations.

Area G–Safety Basis: The plan and schedule for achieving an improved, modern safety basis remains uncertain. When standing up the EM Field Office in 2015, DOE-EM leadership recognized that the Basis for Interim Operations (BIO) that served as the safety basis since 2012 was no longer appropriate given that nuclear operations were reasonably expected to extend well past the nominal 5-year lifetime envisioned by DOE-STD-3011. As such, in May 2016 the EM Field Office contracted with a vendor to write a new Documented Safety Analysis developed in accordance with DOE-STD-3009-2014. The EM Field Office received that safety basis (see 3/23/2018 report) and after review and revisions ultimately transmitted it unapproved to N3B for further alignment with their current approach (see 3/22/2019 report). In April 2019, N3B responded to the EM Field Office proposing an alternate approach that instead involved improving the existing BIO in order to realize mission benefits. Notably, N3B proposed continuing to follow DOE-STD-3011-2002 for the improvements, representing a departure from the previous desires of DOE-EM leadership to move forward to a DOE-STD-3009-2014 derived safety basis. The EM Field Office subsequently established a draft review schedule and began developing a review plan to capture the overall safety basis strategy. EM-LA has not yet formally responded to the N3B approach.

Last Thursday, N3B personnel determined the recent potential inadequacy of the safety analysis related to material at risk limits in Building 412 constituted a positive unreviewed safety question (see 6/21/2019 report). Restrictions on introduction of material to the facility will remain in place until the BIO is updated.

Nuclear Criticality Safety and Safety Basis: Last week, a nuclear criticality safety analyst updating a criticality safety evaluation document (CSED) for building TA-35-02 discovered that the facility could exceed the upper safety limit for criticality if the bounding material configuration were analyzed with a more representative methodology. The analyst noted similar concerns for TA-35-27 and TA-66-1. The Nuclear Engineering and Nonproliferation Division primarily uses these facilities, which are all less than hazard category 3 (HC-3). While their inventories exceed HC-3 threshold quantities, a sufficient portion of the material is in the form of sealed sources, of which some do not contribute against material-at-risk inventory limits because they are certified. The CSEDs had originally concluded that criticality accidents were not credible due to the nature of the process. If criticality accidents were credible, the facilities would need to be hazard category 2 per DOE-STD-1027. Management paused fissile operations in these facilities and criticality safety analysts determined that all three facilities are in a safe condition. Criticality safety personnel determined that the current material limits for TA-66-1 were acceptable, although a non-implemented material limit increase was not acceptable. They plan to revise the current CSED for TA-66-1 to include the more representative methodology to demonstrate that the current TA-66-1 limits are acceptable. Triad and NNSA personnel are evaluating the impacts of the new model on criticality safety for TA-35-27 and TA-35-2. The current actual inventories in these facilities are safe. Fissile material movement restrictions will remain in place until the CSEDs for these facilities are revised.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 12, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 12, 2019

Transuranic Waste Management–Conduct of Operations: Last Tuesday, Plutonium Facility workers were unable to locate a waste drum. After further investigation, they determined that the nuclear material control and accountability system had not been updated when 39 waste drums were moved the previous week. Waste operations personnel commenced a full inventory of drums in relevant locations and found a new concern—tamper indicating devices (TID) were not installed correctly on some drums. After a multi-facility review, they found 35 drums at the Plutonium Facility and seven at the Transuranic Waste Facility (TWF) with incorrectly installed TIDs. Most of the drums with incorrect TIDs originated from 2018 Confinement Vessel Disposition project activities at the Chemistry and Metallurgy Research Building. Workers replaced all of the incorrectly installed TIDs without opening drums and re-inspecting the contents after consulting with the Central Characterization Project. To prevent recurrence, Triad personnel are evaluating the procedure for moving waste drums, as well as the training that took place two years ago when the process for installing TIDs changed.

Transuranic Waste Management–Safety Basis: Triad personnel determined that the potential inadequacy of the safety analysis related to nitric acid interactions with cheesecloth (e.g., polyols) constitutes a positive unreviewed safety question for the Plutonium Facility (see 6/28/2019 report). The current safety basis only evaluates drum deflagrations which behave differently than the rapid over-pressurization event that could be caused by incompatible materials. Facility personnel noted that while high concentration nitric acid and polyols exist in the facility, there are no drums in the current waste inventory that contain polyols that have been contacted with such nitric acid.

Area G: While reviewing existing criticality safety evaluations for storage of high fissile gram equivalent (FGE) waste containers, N3B personnel noted that there is an insufficient technical basis for the existing criticality control set for these containers. Criticality safety personnel have determined that the eight high FGE containers currently present are safe. Management has isolated the area and prohibited receipt of container with greater than 300 FGE.

On Monday, a team commenced the contractor readiness assessment for resumption of drum liner pulls and solid waste box de-nesting operations in Building 412 (see 5/17/2019 report).

Flanged Tritium Waste Containers (FTWC): Triad is continuing to develop safety basis documentation for venting, transportation, and receipt of the FTWCs currently stored at Area G (see 6/21/2019 report). They are evaluating means to prevent the release of tritium even if the consequences would not trip the threshold for credited safety controls. Remediating the four FTWCs at Area G and the two unvented FTWCs of concern at the Weapons Engineering Tritium Facility (WETF) is challenged by the lack of useable space at WETF. Tritium-containing waste may need to be shipped offsite prior to continued venting of the FTWCs at WETF and receipt of vented FTWCs from Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 19, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 19, 2019

DNFSB Staff Activity: D. Gutowski was at DNFSB Headquarters in support of agency planning initiatives for fiscal year 2020.

Plutonium Facility–Nuclear Materials Management: Last Friday, operators found that the box furnace they were using to oxidize legacy nuclear material had experienced an unexpected thermal excursion from about 380 to 640 °C. This rapid temperature increase caused the furnace to automatically shut off. The exothermic reaction also spread fine black powdered residue within the glovebox and an adjacent glovebox. There was no release of material outside of the glovebox system and the glovebox does not appear to have been damaged. The legacy items originated from research activities in the 1980's and were being processed as part of the Materials Recovery & Recycle program. The oxidation process is intended to produce a stable material form for disposition, typically as transuranic waste. Facility personnel intend to develop a recovery plan to clean and inspect the gloveboxes and furnace, replace the filter, obtain and analyze samples of the materials to ascertain the chemistry, and review the inventory to identify any similar materials. Safety basis personnel also entered the New Information process to examine implications for the safety basis.

Plutonium Facility–Safety Basis: On Wednesday, Triad management transmitted to the NNSA Field Office their evaluation of the safety of the situation (ESS) regarding vehicle impacts with transuranic waste containers stored on the outdoor pads (see 6/28/2019 report). The ESS examined two cases of impact with subsequent fuel pool fire: (1) a security vehicle with a high energy impact and small fuel pool volume and (2) a refueling truck with a low energy impact and large fuel pool volume. The ESS determined that the consequences do not warrant safety class or safety significant controls, but noted the vehicle barriers provide an important preventive, engineered safety function and recommended them to remain as Other Hazard Controls. The NNSA Field Office is reviewing the ESS.

Last week, Triad management transmitted to the NNSA Field Office a safety basis strategy and an updated project execution plan in support of the effort to upgrade the safety basis to comply with DOE-STD-3009-2014 (see 12/31/2018 report). The update includes clarifications to expectations for quality assurance and team interactions. The expected final submittal date remains March 31, 2022.

Transuranic Waste Management: This week, Triad personnel resumed loading operations at the RANT Shipping Facility after completing an outage to repair the roof. They completed one shipment and are working toward establishing a desired steady-state rate of about five shipments a month. However, their ability to ship is currently paced by waste container certification activities controlled by the Carlsbad Field Office. In another positive development, last week Triad personnel moved the first batch of pipe overpack containers (POC) with the new fusible filters to the Transuranic Waste Facility. These new filters support a damage ratio of zero for postulated fire scenarios (see 1/25/2019 report). Triad is also planning the first shipment of POCs to the Waste Isolation Pilot Plant in the coming weeks. This is important because POCs represent a substantial fraction of the current waste container population.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 26, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 26, 2019

Transuranic Waste Management–Safety Basis: Last week, the Carlsbad Field Office issued LANL a non-conformance report concluding that 9 transuranic waste containers did not meet the waste acceptance criteria for the Waste Isolation Pilot Plant. All of the non-conforming containers are currently stored at Area G, though two are owned by Triad. These containers specifically failed to meet the Basis of Knowledge requirements for oxidizing chemicals that DOE established to preclude another energetic chemical reaction and radioactive material release at WIPP. These energetic reactions can result in greater airborne respirable releases of radioactive material than is typically analyzed. Triad recognized this fact with their recent declarations of potential inadequacies of the safety analysis (PISA) for their facilities (see 6/28/2019 report) due to interactions between polyols and nitric acid—just one consideration in the BoK. When N3B reviewed the polyol information, they did not declare a PISA because they believe these reactions are adequately covered by existing accidents that are modeled as flammable gas deflagrations. In contrast, the approved safety basis for the Transuranic Waste Facility acknowledges that releases from these energetic events could be 2–3 orders of magnitude greater than is analyzed for deflagrations (see 4/5/2019 report). Controls for an energetic event may also be different than for a flammable gas event. N3B is reviewing the situation.

Plutonium Facility–Nuclear Materials Management: On Wednesday, facility personnel held a fact-finding for an issue that occurred on July 9, 2019, when safeguards personnel discovered liquid on the floor of a glovebox used to stage several plastic carboys containing plutonium-238 aqueous processing residues. Further investigation identified that a carboy had cracked and released some of its contents, an exposed electrical wire was in the liquid, and a cable assembly on a spool piece door had failed. Since then, personnel isolated the conductor, properly cleaned the spill, and replaced the door cable. Notably, the replacement of this cable and the cable involved in last year's puncture wound were the first to be replaced since that August 2018 accident (see 2/8/2019 report). This incident had several similarities to last year's unexpected drop in solution level (see 6/8/2018 report). While previous corrective actions to improve spill response were successful, planned actions to minimize the backlog of these production residues, improve tracking of carboy volumes and age, and eliminate reliance on plastic carboys have not yet been achieved.

TA-48 Radiochemistry Facility–Radiological Control: Last Wednesday, the questioning attitude of several workers prevented the possibility of contaminated material being transported offsite. They were cleaning radiologically uncontrolled laboratory space in the Radiochemistry Facility, noted water staining, and decided to take precautionary radiological smears. They discovered contamination, paused, and called a radiological protection technician to confirm the presence of contamination. The following morning, the technician began controlling and surveying items already removed from the room, as well as performing extensive surveys of personnel, the facility, and equipment. No personnel contamination was detected; however, the surveys did discover contaminated items in a recycling bin. The source of contamination was a leak in a radioactive liquid waste line from the radiological laboratory on the floor above.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 2, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 2, 2019

Plutonium Facility–Nuclear Materials Stabilization: Plutonium Facility personnel recently completed their historical analysis and received approval for their recovery plan for the furnace involved in the recent thermal excursion (see 7/19/2019 report). The recovery plan specifies that personnel will take samples of the black residue for analysis, inspect the furnace crucible and glovebox filter, replace all of the gloves, and test the operability of the furnace. The historical analysis notes that an exothermic reaction is likely responsible for the unexpected 220 °C excursion that initiated at about 378 °C. The analysis notes that some of the legacy items present in the batch contained bismuth and zinc, and that it is likely that exothermic reactions between these metals and oxygen caused the excursion. Additional research is ongoing to identify similar items to be flagged for special processing. Safety basis personnel entered the new information process to evaluate this event and concluded that there was no potential inadequacy of the safety analysis as the event was bounded by existing analyses.

Plutonium Facility–Transuranic Waste Management: Waste Operations personnel are continuing to develop work control documents to allow flammable gas sampling and intrusive investigation of the drum with a corroded filter vent discovered in May (see 5/24/2019 report). The contents of this drum included gloves made of a chlorinated polymer. Historically, the Rocky Flats Plant experienced significant internal corrosion of drums where radiolysis of carbon tetrachloride resulted in internal container corrosion and filter plugging in some cases. At Rocky Flats, operators developed an apparatus to confirm flow through potentially corroded filters rather than relying on visual and auditory observation to determine operability.

Area G–Work Control: On Wednesday, a subcontractor performed work to remove the Lightning Protection System for Dome 229 that had not been released on the Plan of the Day. This work was intended to start on Dome 230 once the work package was approved and released. N3B personnel paused the work when they discovered it was occurring and held a Fact Finding Meeting to evaluate the breakdowns in the work control process including lack of a formal pre-job briefing, incomplete training for the subcontractor person in charge, work scheduling and release, and responsibility for subcontracted work. N3B Management is planning to perform an apparent cause analysis of this event. The Lightning Protection System does not have a credited safety function in the Area G safety basis and N3B engineering personnel and the subcontractor believe the Dome 229 system still provides adequate cones of coverage. As a precaution, facility personnel are implementing a fire watch while the system is evaluated and repaired. The system is being removed to support reskinning of the domes which were damaged by heavy snowfall (see 1/11/2019 report).

Chemistry and Metallurgy Research Building: Facility management approved a second extension for completion of a root cause analysis for the March level 1 non-compliance criticality safety infraction (see 3/15/2019 report). The analysis is now expected to be complete at the end of August.

Weapons Engineering Tritium Facility–Readiness: An eleven member contractor team completed their readiness assessment for resumption of pinch welder operations at the Weapons Engineering Tritium Facility. The team had one prestart finding related to the level of detail in the startup plan and one post-start finding related to analysis of hot work conditions. A Federal Readiness Assessment will follow.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 9, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 9, 2019

Transuranic Waste Management–Safety Basis: On Tuesday, the LANL Central Characterization Program (CCP) issued Triad and N3B new non-conformance reports related to transuranic waste containers that failed to meet the Basis of Knowledge (BoK) requirements associated with the waste acceptance criteria for the Waste Isolation Pilot Plant (see 7/26/2019 report). This means that WIPP will refuse to receive the containers because their contents may be susceptible to exothermic chemical reactions and propagating fires. Triad and N3B will need to either provide additional information to substantiate compliance with the BoK or perform treatment to eliminate the hazard. These reports bring the number of containers that are currently non-compliant with the BoK to 24 stored within the fabric domes at Area G and 4 stored on the outdoor waste pads at the Plutonium Facility. The non-conformances challenge various aspects of the BoK. For example, CCP rejected the containers on the outdoor pads because the information Triad provided indicated that an unknown liquid was absorbed by an engineered organic polymer sorbent in an unknown ratio and therefore compliance with the BoK could not be demonstrated. Triad waste management personnel have since submitted to CCP further information regarding the nature of the liquids that they gathered during interviews with two workers involved in generating these waste containers in 2015. CCP is evaluating this information.

TA-21 Environmental Remediation: During potholing activities to locate utility lines in TA-21, N3B and subcontractor personnel encountered soil contamination adjacent to an industrial waste line. Radiological control technicians (RCT) who were present with the work team paused the activity and found contamination on the line, excavated soil, and the workers tools. There was no worker contamination and the work area is currently in a safe configuration. Discovering contamination is anticipated during this type of activity, and continuous RCT coverage is a corrective action from a January 2019 potholing job in the same area when workers uncovered an industrial waste line and backfilled it before RCTs could survey it. N3B management is evaluating the clarity of the command media for potholing tasks to ensure that all relevant requirements are included without ambiguity.

TA-35 Nuclear Criticality Safety: On Tuesday, Triad management lifted the pause on fissile material operations at TA-35-002 and TA-35-027 following re-evaluation of the criticality safety evaluations (see 7/5/2019 report). The re-evaluation concluded that the original control set is conservative.

Plutonium Facility–Radiological Safety: On Tuesday, a hand and foot monitor at the exit of the Plutonium Facility detected contamination on a workers hand. The worker had been performing assembly operations and had cleared a full body survey and a hand and foot monitor at the room exit. RCTs responded and successfully decontaminated the individual. Follow-up surveys found no contamination spread in the work area and none of the other approximately 40 workers in the same room had any contamination detected. In response to this discovery, facility management plans to reinforce training and expectations for doffing of protective equipment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 16, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 16, 2019

Infrastructure: NNSA's Office of Safety, Infrastructure, and Operations held a Master Asset Plan Deep Dive. The deep dive covered out-year planning for infrastructure needs across the laboratory.

Transuranic Waste Management–Safety Basis: Last Thursday, Triad transmitted to the NNSA Field Office their evaluation of the safety of the situation (ESS) on the nitric acid and polyol interaction issue (see 7/12/2019 report). This type of chemical reaction interaction between organic and oxidizer is one of the types of energetic chemical reactions that the safety basis for the Waste Isolation Pilot Plant (WIPP) precludes through the implementation of the Basis of Knowledge (see 8/9/2019 report). The ESS concludes that no controls other than the existing safety management program are needed. It notes that the facility will continue to use visual inspections and the current waste management processes to prevent the combination of cheesecloth (a polyol) and greater than 12 M nitric acid. The ESS further notes that an energetic chemical reaction can be conservatively modeled as a single waste container over-pressurization and shows that the unmitigated consequences do not challenge thresholds for requiring additional controls. Notably, at the Board's June 20, 2019, public hearing on solid nuclear wastes, DOE Headquarters personnel stated that the Department learned from the February 2014 radiological release at WIPP that it might be appropriate to use an effective respirable release fraction for energetic chemical reactions that is about a hundred times higher than the value used by Triad; however, DOE has not promulgated direction on the applicability and use of this release fraction beyond the WIPP contractor (see 11/20/2015 report). Use of a release fraction a factor of ten higher for this scenario would exceed the threshold for crediting safety controls.

Area G: Last week, Triad informed N3B about the presence in Area G of waste containers with contents similar to the container they discovered in the Plutonium Facility basement with a corroding vent (5/24/2019 and 8/2/2018 reports). These containers also have many glovebox gloves made from a chlorinated polymer that were previously used for plutonium-238 applications. N3B personnel checked the two containers and found that one appeared visually acceptable and the other had been overpacked in March 2019 after corrosion was detected during routine inspections.

Flanged Tritium Waste Containers (FTWC): The integrated project team continues to develop the procedures, personnel, and equipment necessary to vent the FTWCs with the potential for flammable headspaces that are stored at Area G (see 7/12/2019 report). In a letter dated June 28, 2019, Triad projected commencing the venting operation in October 2019 with completion of the remediation activities by January 2020. The latest schedule anticipates these activities in January 2020 and May 2020, respectively.

Two other FTWCs stored in the Weapons Engineering Tritium Facility with the potentially flammable headspace remain in an unvented state due to a shift in priority to repackage the contents of other FTWCs containing contaminated parts for offsite disposal. However, recent developments at the Nevada National Security Site have introduced uncertainty to the planned disposal option.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 23, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 23, 2019

DNFSB Activity: DNFSB Chairman Hamilton visited the laboratory on Tuesday and Wednesday. He met with leadership from both field offices and contractors, received briefings on planned nuclear material inputs and outputs from the Plutonium Facility, the exit strategy for the Chemistry and Metallurgy Research (CMR) building, and the project to disposition the Flanged Tritium Waste Containers. He also walked down the Radiological Laboratory Utility Office Building, Plutonium Facility, Area G, and the Transuranic Waste Facility.

On Friday, one of the resident inspectors briefed the New Mexico Legislature's Radioactive and Hazardous Waste Committee on the status of DNFSB oversight at LANL and the impacts of DOE Order 140.1.

Plutonium Facility–Criticality Safety: Last week, waste management personnel successfully overpacked a transuranic waste container into a standard waste box. This container had been infractioned for an overmass condition and has been covered through a recovery plan that was approved in April 2016.

Safety Basis: On Wednesday, the NNSA Field Office unconditionally approved the evaluation of the safety of the situation (ESS) for depleted uranium shield issue at CMR (see 6/14/2019 report). On Tuesday, the NNSA Field Office unconditionally approved the ESS for the issue concerning the counter unmanned aircraft system issue at TWF (see 6/28/2019 report). Also on Tuesday, the NNSA Field Office approved a revision to the RANT Shipping Facility documented safety analysis closing a condition of approval related to acetylene and electric forklifts (see 11/2/2018 report). The safety basis revision elevated administrative controls related to acetylene and forklift use to new specific administrative controls. The approval included one new condition of approval requesting the analysis of hazards of acetylene cylinders be broadened to include internal cylinder explosions. As the control for acetylene prohibits its presence when waste containers are in the facility, a more thorough analysis is not expected to change any controls.

Area G–Readiness: Last month, a ten member contractor team completed a readiness assessment for resumption of limited operations in the sort, segregate, and size reduction (SSSR) enclosure in Building 412 as a prerequisite to a federal readiness assessment. The specific operations being assessed for resumption are denesting of drums from standard waste boxes and waste container liner repacking of compromised containers. These activities have not been performed in Building 412 since May 2014. The review team found four pre-start and four post-start findings. Of note, two of the pre-start findings addressed configuration management, specifically for the critical lift plan and the drawings and electrical configuration of the SSSR enclosure.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 30, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 30, 2019

Flanged Tritium Waste Containers (FTWC): On Wednesday, Triad submitted to the NNSA Field Office a safety basis addendum in support of venting and handling the FTWCs with potentially flammable headspace currently stored in Area G. The addendum proposes credited design features including the FTWC vessel, an overpressure barrier, and a restricted flow orifice. Additional proposed controls include Specific Administrative Controls (SAC) regarding the use of the vent rig and the pressure monitoring manifold. The NNSA Field Office is currently reviewing the addendum for ultimate approval by the EM Field Office.

Radiological Laboratory Utility Office Building: On Wednesday, Triad submitted to the NNSA Field Office the safety basis supporting future hazard category 3 nuclear operations. The safety basis is written to the new DOE-STD-1228-2019, *Preparation of Documented Safety Analysis for Hazard Category 3 DOE Nuclear Facilities*. Notably, DOE has not yet approved the proposed revision of 10 CFR 830, *Nuclear Safety Management*, which incorporates this new standard. The safety basis primarily relies on a SAC to protect the material-at-risk inventory in the facility at a level that ensures offsite and collocated worker consequences are well below the threshold for additional controls. Engineered defense-in-depth controls include: the building structure, fire suppression system, glovebox enclosures, fume hood ventilation, and building ventilation. Triad requested approval by December 2019 to support the pit production mission.

Safety Basis: On Wednesday, the NNSA Field Office approved a temporary safety basis modification to support the transportation of a 231 ton motor generator rotor offsite for repair. Triad submitted the modification on Monday to cover the fact that the rotor will pass several hazard category 2 and 3 nuclear facilities on its travel path, and the mass of this transport challenges assumptions in the vehicle crash analyses for these facilities. The safety basis modification states that the RANT Shipping Facility, Waste Characterization Reduction and Repackaging Facility (WCRRF), and the Transuranic Waste Facility (TWF) could be impacted by the transport based on topography. The required controls in the modification are: ensuring that WCRRF and RANT are in cold standby mode during the activity, ensuring that the vehicle travels below five miles per hour to ensure the kinetic vehicle barriers for TWF can protect the facility, a rolling road closure, and a vehicle inspection. The NNSA Field Office directed two changes to ensure the controls were appropriately worded for the return trip.

Emergency Management: Earlier this month, N3B completed their after-action report for the drill that was conducted during the Building 412 contractor readiness assessment (see 8/23/2019 report). Of relevance for the entire laboratory, the report notes that there are significant differences in the terminology used between radiological control technicians and Los Alamos County Fire Department (LAFD) personnel to convey readings. Fire department personnel specifically raised this concern during the player hot wash with the particular examples of confusion regarding surface contamination levels and airborne radioactivity. The report further notes that this is an ongoing, known problem across the laboratory. N3B procures emergency management support services from Triad, which works with the NNSA Field Office to contract services from LAFD.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 6, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 6, 2019

DNFSB Staff Activity: On Thursday, a staff team held a teleconference with EM Field Office and N3B personnel to discuss the safety basis implications of the recent non-conformances against the Basis of Knowledge (BoK) (see 7/26/2019 report). The team examined the safety implications of two of the 24 rejected containers. The Central Characterization Program rejected these containers because their conservative review of records indicated that one potentially contained organic cat litter and neutralized nitric acid and the other an engineered organic absorbent and nitric acid. In the BoK, DOE has prohibited certain ratios of these materials without a *de minimis* threshold mass given their potential to support chemical exothermic reactions or propagating fires. EM Field Office management maintain the existing safety basis adequately analyzes the hazards posed by these containers. N3B has placed hold tags on the containers until they have the capability to remediate them in a few years.

Management–Abnormal Event Notifications: The resident inspectors recently discussed with Plutonium Facility senior management their observations regarding an apparent trend of decreased formal notifications for abnormal events. Event notifications are part of Triad’s Contractor Assurance System and, in our opinion represent one important tool to ensure awareness across the institution, including to the NNSA Field Office. We found that, while the overall number of fact-findings has actually increased, the number of notifications has dropped by about half compared to the first 8 months of calendar year 2018. The data show that notifications were sent for only about 20 percent of the events that management had deemed appropriate to conduct a fact-finding. For example, review of the data indicate that formal notifications of potential process deviations, the term typically used for concerns associated with complying with nuclear criticality safety requirements, no longer consistently receive an event notification. Additionally, some significant recent events are not being notified such as the recurrent leaking carboys of Pu-238 process residue solutions (see 7/26/2019 report), the furnace thermal excursion (see 7/19/2019 report), and the corroding waste drum filter (see 5/24/2019 report). Plutonium Facility management is reviewing the situation, but believes their current approach to reporting improves focus on more meaningful events.

Plutonium Facility–Safety Systems: Waste management personnel have identified an additional five transuranic waste containers with varying degrees of rust-like buildup around their filters (see 8/2/2019 report). All of the containers include glovebox gloves made from chlorinated polymer that were used in plutonium-238 operations. Waste management personnel continue preparations to sample the headspace gas and intrusively investigate the containers.

Plutonium Facility–Infrastructure: Last week, workers discovered liquid in the basement of the Plutonium Facility. The responders discovered it was from an overflowing sump (see 11/30/2018 report). Further investigation determined that the overflow was likely due to blockages in the industrial waste line and troubleshooting was hindered by the lack of clear technical drawings. Facility personnel have cleaned up the liquid and decontaminated much of the area. Areas that were not accessible by the decontamination team remain posted as a contamination area. Planned corrective actions include improving drawings and evaluating periodic testing of the drainage system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 13, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 13, 2019

Transuranic Waste Management–Safety Basis Inconsistencies: Last Friday, the NNSA Field Office conditionally approved Triad’s evaluation of the safety of the situation (ESS) concerning the interaction between polyols and nitric acid (see 8/16/2019 report). The field office noted that Triad did not provide a supporting basis for modeling the energetic reaction using a respirable release fraction of 2×10^{-3} , which corresponds to a pressurized release from a container that fails at 25 psig. They further noted that the DOE handbook release fraction for failure above this pressure threshold is an order of magnitude higher and would raise the dose estimate such that safety class controls would be required. As such, the NNSA Field Office requested that Triad provide within 30 days a basis for the bounding pressure of a drum failure. They also directed Triad to elevate the current visual examination practices to a Specific Administrative Control to prevent the comingling of polyols and nitric acid.

Similar potentially incompatible materials may exist within waste containers stored at Area G; however, the EM Field Office and N3B maintain their existing safety basis adequately covers this hazard. They assert that the hazard is appropriately modeled as a flammable gas deflagration using a release fraction of 5.4×10^{-4} consistent with DOE-STD-5506-2007. Notably, DOE has yet to update this standard to reflect lessons learned from energetic reactions in waste drums at the Waste Isolation Pilot Plant and Idaho National Laboratory.

Area G–Safety Basis: Several safety basis documents await action by the EM Field Office including: (1) a response to N3B’s April 2019 proposal to upgrade the Basis of Interim Operations (BIO) in lieu of using a Documented Safety Analysis (see 7/5/2019 report); (2) formal comments on the BIO annual update that N3B submitted in March 2019; and (3) approval of the ESS (see 6/21/2019 report) and Justification for Continued Operations (see 8/9/2019 report) regarding the Building 412 material-at-risk issue.

Conduct of Operations: Last month, Triad analysts completed the causal analyses for the March and June level one non-compliance nuclear criticality infractions at the Chemistry and Metallurgy Research (CMR) Building and the Plutonium Facility (see 3/15/2019 and 6/28/2019 reports). In both events, workers erroneously placed containers with nuclear material in unanalyzed floor locations. For the CMR event, the analysis determined that there were inadequacies in the assessment of changing work scope and training. For the Plutonium Facility, the analysis determined that there was a lack of first line management engagement during practice and during the first performance of the activity. Both reports provide a series of recommended actions to address the issues. For CMR, recommended actions include revising command media to address timely use of nuclear material control and accountability software, revising the fissile material operations review procedure to evaluate collocated operations, addressing training deficiencies, and promulgating lessons-learned. For the Plutonium Facility, recommended actions include formalizing expectations for persons-in-charge, evaluating the creation of a floor storage location, and addressing several training issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 20, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plau and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 20, 2019

Plutonium Facility–Transuranic Waste Management: Last Thursday, a waste management worker lost control of a 320 pound pipe overpack container (POC) as he was attempting to tip and roll it off of a metal pallet. The POC toppled to the ground missing the worker. Three workers then righted the POC and contacted the operations center. Radiological protection and container engineering personnel then determined the container was undamaged. The work crew recognized their failure to properly pause work and held an immediate post-job. At the fact-finding this week, workers discussed a control in the procedure that specifies the use of two people for the movement of heavy items “if item is beyond your level of comfort.” Several workers noted that their formal training indicated it was safer for an individual to perform such moves. Management noted the current saturation of waste containers contributed to the event and took an action to investigate narrow engineered drum handling equipment. This Thursday, a waste management worker lost control of a different POC while moving it with a drum handler—no injury occurred and the POC was undamaged. Management has paused all waste container movements pending a review of procedures and training.

Last week, waste management workers sampled the headspace of the containers with corroded filters and found them to be compliant with flammable gas requirements (see 9/6/2019 report). They continue efforts to procure and establish a capability to open the drums for intrusive investigation. Notably, neither Triad nor N3B currently possess the capability to open transuranic waste containers for remediation if prohibited contents are found or other issues emerge.

Plutonium Facility–Safety Basis: Triad safety basis personnel determined that unanalyzed heat source plutonium hold-up in dropboxes constituted a positive unreviewed safety question. The currently implemented safety basis states that holdup in locations other than analyzed gloveboxes is “insignificant.” Recent measurements of several dropboxes found holdup in the gram range. Safety basis personnel are evaluating the appropriate way to account for this material.

Triad personnel also concluded that the storage of non-destructive assay sealed calibration sources in non-fire rated storage locations also constituted a positive unreviewed safety question. The issue of storage within the facility grew out of a similar concern with sources on an outside waste storage pad (see 8/12/2016 report). The currently implemented safety basis contains fire scenarios beyond the temperature limits for the sources. The approved, but not yet implemented safety basis includes a new fire analysis that does not exceed temperature limits based on actual combustible loading in the area.

Area G–Radiological Protection: N3B recently adjusted their approach to facility radiological protection. They reviewed radiological survey data and found that since 2012 no contamination levels exceeded release criteria for vehicles, personnel, domes, and buildings. As a result, they removed the requirement to perform a radiological survey for personnel, and in most cases vehicles, prior to exiting Area G. Instead, personnel are required to survey only at the radiological buffer areas associated with the three Sort, Segregate, and Size Reduction enclosures. N3B has compensated for the reduced number of personnel surveys by increasing routine monitoring of domes from monthly to weekly. Triad personnel also continue to perform retrospective analyses for environmental compliance of the monitored stacks on a weekly basis and perimeter boundary stations on a quarterly basis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 27, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 27, 2019

DNFSB Staff Activity: D.J. Brown and M.W. Dunlevy observed a peer review workshop on the disposition options for the inappropriately remediated nitrate salt wastes currently stored at the Waste Control Specialists facility. Dunlevy also completed walk-downs focused on transuranic waste management at Area G, the Chemistry and Metallurgy Research Building, and the Plutonium Facility.

Management: Senior federal and contractor officials from other NNSA sites conducted a three day peer review of the governance system. The team received briefings, observed routine mission assurance interactions, and held round table discussions with personnel involved in mission assurance. Overall, they found that the vector is positive for all of the reviewed elements. They also identified a number of notable practices and feedback for consideration concerning Triad, the NNSA Field Office, and NNSA Headquarters.

Emergency Management: On Wednesday, Triad conducted their annual emergency exercise. This year's scenario involved a dropped payload of transuranic waste at the RANT Shipping Facility and a near concurrent wildland fire at TA-49. Conduct of the exercise was challenged by the need for assets to respond to several real-world emergencies including a spill of an unknown liquid, a truck fire, and the evacuation of the Emergency Operations Center due to high carbon dioxide levels. Triad and NNSA personnel believe they were able to adequately complete the objectives of the exercise despite these interruptions and are evaluating performance.

Plutonium Facility–Infrastructure: Last weekend, Plutonium Facility personnel successfully executed an outage of the fire suppression system to complete a number of maintenance activities. Notably, they completed the field work associated with eliminating the seismic interaction issues where insufficiently qualified ventilation handling equipment was located above sprinkler piping. This action resolves one of the issues identified in the Board's letter dated May 12, 2016. Work is ongoing to analyze additional upgrades that may be required to achieve seismic performance category 3 for the fire protection system.

Plutonium Facility–Work Control: On Monday, a craft worker inadvertently cut a line on the potentially pressurized side of a locked out valve. The system was fortunately unpressurized and there were no injuries. The worker who performed the cut did not have a personal lock in place. Facility management noted that while this specific event had no consequences, it bore similarities to other events and could easily have led to more significant problems. Facility construction management instituted a pause on lock out/tag out activities. Triad will perform a formal causal analysis and will evaluate corrective actions from previous events for effectiveness.

Plutonium Facility–Transuranic Waste Management: On Wednesday, management lifted the pause on transuranic waste drum handling activities following training of personnel on techniques and equipment for safe handling of drums.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 4, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 4, 2019

NNSA Field Office: On Monday, Mr. Steve Goodrum retired from federal service. Mr. Gabriel Pugh replaced him as manager in an acting capacity.

Emergency Management: Last Thursday, workers discovered two bulging plastic drums in a warehouse adjacent to the Sigma Facility. The drums contained a nitric acid mixture recovered from the Sigma Facility's electroplating baths that are under refurbishment. They reported their discovery and emergency management personnel and the hazardous materials team responded. While the situation did not trip any emergency action levels, the Emergency Operations Center activated in monitoring mode and directed a precautionary evacuation of Sigma and the Beryllium Technology Facilities. The hazardous materials team used a remotely operated robot to vent the two drums and manually vented a third drum containing a hydrochloric acid mixture. On Monday, Triad personnel held a fact-finding and discussed issues concerning chemical management, aisle spacing, and other factors concerning drum storage.

Radiological Laboratory Utility Office Building: Last Thursday, all critical electrical loads were lost while workers performed a preventive maintenance task on the uninterruptible power supply. The issue resulted from an error in the work package. Key systems lost included ventilation, most communication systems, computer networks, and facility condition monitoring. Operations center personnel directed an evacuation of radiological areas of the facility which went smoothly despite the lack of the public address system. Power was restored in approximately 30 minutes. Facility management is evaluating means to improve work control for critical tasks, such as this one, that have high potential impacts on operations.

Last month, Triad engineering personnel completed system adequacy analyses of the ventilation, air supply, and fire suppression systems. The analyses compare the as-found systems against the minimum codes and standards required for operations as a future Hazard Category 3 (HC-3) nuclear facility. The analyses identified 6 observations and 1 requirement that could not be verified for the fire suppression system and 5 observations and 3 requirements that could not be verified for the ventilation and air supply. An example of an observation is that the ventilation system contains non-fire rated flexible connectors contrary to DOE and industry requirements. An example of a requirement that could not be verified is whether the sway bracing on the fire suppression system meets current seismic criteria. Engineering personnel are developing strategies to physically or administratively remedy each of the identified issues.

Area G–Operations: On Wednesday, N3B personnel commenced liner pull operations in Building 412. The EM Field Office approved the restart of operations last week after concluding that a federal readiness assessment was not required if operations remain at or below the HC-3 quantities of material-at-risk.

Area G–Readiness: N3B personnel determined that a federal and contractor readiness assessment is required for the retrieval and staging of corrugated metal pipes containing condensed, cemented waste from the former TA-21 Radiological Liquid Waste Facility. A safety basis addendum to support this task is in progress. These pipes were buried in Area G in the 1980s. Size reduction and packaging of these pipes will be treated as a separate activity with different safety basis and readiness activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 11, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 11, 2019

DNFSB Staff Activity: The Resident Inspectors were in Washington, D.C. to brief the Board and attend meetings. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 18, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 18, 2019

DNFSB Staff Activity: Members of the Board's staff held teleconferences with both field offices and contractors in support of a complex-wide review on the implementation of Technical Safety Requirements.

Plutonium Facility–Transuranic Waste Management: Last Tuesday, a third incident occurred involving a dropped transuranic waste container (see 9/20/2019 and 9/27/2019 reports). While workers were lifting a pallet with an electric jack, an unrestrained pipe overpack container fell off. The container was not damaged. Triad management subsequently instituted a new pause on drum handling activities. This Thursday, they issued a recovery plan that authorizes drum movements when released by management with compensatory measures including: (1) work must be overseen by both a non-working person-in-charge and approved enhanced temporary oversight; (2) only a specific list of drum handling equipment is allowed; and (3) workers must complete revised training on drum handling. Longer-term corrective actions include an extent of condition review and a formal causal analysis.

Plutonium Facility–Safety Basis: On October 4, 2019, Triad safety basis personnel transmitted to the NNSA Field Office for approval a revision to the evaluation of the safety of the situation regarding the interaction between nitric acid and polyols (see 9/13/2019 report). The revision acknowledges the potential for an event that is more severe than envisioned in DOE-STD-5506-2007 based on experience since the standard was issued. As such, Triad included an autocatalytic exothermic runaway reaction similar to an explosion that they modeled using an airborne respirable release fraction of 0.07. This value results in calculated offsite consequences that exceed the DOE Evaluation Guideline. As a result, Triad proposed preventing the accident using a Specific Administrative Control that prohibits the mixing of polysaccharides with greater than 12 molar nitric acid. Triad also previously asserted that these materials are not present in the existing population of waste containers.

Area G–Safety Basis: For comparison, N3B analyzes energetic chemical reactions like the polyol issue using a release fraction about 130 times lower than the value proposed by Triad. Accordingly, the same potential accident at Area G, which is closest to the site boundary, does not challenge the Evaluation Guideline. As a result, N3B does not explicitly credit controls to prevent or mitigate this hazard. The EM Field Office continues to support this position.

Last month, N3B transmitted a strategy for development of revision 7 of the Basis for Interim Operations. This strategy supplants the April 2019 proposal that the EM Field Office did not formally address (see 7/5/2019 and 9/13/2019 reports). Key aspects of the strategy for revision 7 include: (1) reliance on DOE-STD-3011-2002, DOE-STD-3009-94, and DOE-STD-5506-2007; (2) incorporation of atmospheric dispersion parameters and hazard analysis information from the abandoned safety basis that was developed using DOE-STD-3009-2014; (3) use of an updated statistical analysis for the aboveground waste inventory, and (4) removal of underground waste retrieval operations. The overall schedule assumes an exemption from the annual update requirement for 2020 and shows deliverables to the EM Field Office beginning in December 2019 with overall completion and implementation in calendar year 2021. The EM Field Office is reviewing this strategy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 25, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 25, 2019

DNFSB Staff Activity: The resident inspectors met with a team from the Government Accountability Office as part of their review of DOE Order 140.1 and its effect on the Board's ability to meet its statutory responsibilities.

Nuclear Criticality Safety: On Wednesday, the team leader out-briefed the preliminary results of the management assessment on the nuclear criticality safety program at the Plutonium Facility. The team, which included external membership, identified one finding concerning an inappropriate approval of a change during contract transition to the roles and responsibilities in the institutional program document. They also identified 11 opportunities for improvement, including: developing an implementation matrix; the institutional Nuclear Criticality Safety Committee is not satisfying all elements of its charter; strengthening the identification of assumptions in evaluations; and the procedures and records associated with the fissionable material holdup program either have not been developed or have not been reviewed by the Nuclear Criticality Safety Division. The team also identified six noteworthy practices including: a sound staffing plan; a commendable commitment to hands-on criticality training; and a sound vision for the criticality safety officer program.

Plutonium Facility–Safety Basis: Early in October, Triad personnel discovered five additional pipe overpack containers (POC) containing cheesecloth and greater than 10 grams of heat-source plutonium. Following a 2017 potential inadequacy of the safety analysis, POCs with cheesecloth have been limited to 10 grams of heat source plutonium (see 2/3/2017). When the evaluation of the safety of the situation was developed in 2017, there were five known POCs with greater than 10 grams. These were exempted from the limit as thermal modeling suggested POCs up to 25 grams would be acceptable, however the limit of 10 grams was chosen for conservatism and to comply with onsite transportation limits. The discovery of the five additional POCs triggered entry into a limiting condition of operation which requires that the POCs be repackaged immediately. Triad is currently working on a capability to repackage these containers in a tent, which is scheduled to be completed in late November. However, Plutonium Facility senior management is concerned about the substantial worker hazards involved with repackaging heat source plutonium without robust engineered controls. They therefore directed work on a parallel path to amend the safety basis to allow additional exempted containers for the NNSA Field Office's consideration. All of the new POCs contain well below 25 grams of heat source plutonium.

Flanged Tritium Waste Containers (FTWC): Last Friday, Triad transmitted the addendum to the packaging and transportation safety document supporting moving FTWCs from Area G to the Weapons Engineering Tritium Facility to the NNSA Field Office for approval. They also transmitted a revision to the safety basis addendum for Area G which will be reviewed by both field offices with the EM office as the final approval authority.

Area G–Readiness: N3B personnel determined that both federal and contractor readiness assessments are required for resumption of additional sort, segregate, and size-reduce activities which have not been performed since 2014. The activities to be resumed include draining liquids from drums, stabilizing free liquids, and remediating prohibited items and will be performed in a glovebag within a Perma-Con in Dome 231

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 1, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 1, 2019

Organizational Learning: On Wednesday, Triad management paused all “Jack and Roll” activities across the laboratory to hold a series of briefings. Triad defines “Jack and Roll” as the use of specialized equipment to vertically or horizontally move materials where the possibility of upset exists. Notably, this category excludes the drum handling activities discussed below, including the “tip and roll” maneuver, which were recently paused at the Plutonium Facility. Triad’s briefings included a review of significant recent abnormal events at the laboratory, as well as a near-miss at the Idaho National Laboratory. They emphasized ongoing collaborations with other sites to compensate for a regulatory void, reinforced policy expectations, and highlighted available mechanisms for assistance.

Plutonium Facility–Transuranic Waste Management: On Wednesday, Triad management released most work teams from the requirement of enhanced oversight for drum handling (see 10/18/2019 report). However, management has not lifted the expectation that crews are overseen by a non-working person-in-charge.

Area G: Earlier this month, N3B personnel provided the Central Characterization Project (CCP) with additional information concerning five of the containers with non-conformances against the Basis of Knowledge (see 8/9/2019 report). CCP is reviewing the information, as well as information previously provided by Triad. Thus far, N3B has been unable to find additional mitigating information associated with the other 19 non-conforming containers, including the two containers that CCP conservatively determined to contain organic cat litter and neutralized nitric acid. As a result, N3B plans to eventually treat these containers, along with several hundred other aboveground containers that have reactive or ignitable waste characteristics and are prohibited for safety reasons from the Waste Isolation Pilot Plant.

Plutonium Facility–Radiological Control: Two weeks ago, a continuous air monitor alarmed in a containment tent associated with the refurbishment of a plutonium-238 glovebox. All workers were in respiratory protection and there was no evidence that contamination spread out of the tent. Last Friday, a worker in the room, but not working in the tent, found contamination on their personal protective equipment during exit monitoring. Investigation discovered the most probable source of the contamination was a torn waste bag containing components from the glovebox refurbishment. Workers at the fact finding noted that planning for waste disposition should be improved to avoid situations where materials are staged in bags on the floor for extended periods of time. Waste management personnel are evaluating how to accomplish this while meeting visual examination requirements for transuranic waste.

Sigma Facility: On Thursday, the NNSA Field Office issued a letter rejecting Triad’s revised Final Hazard Categorization and criticality safety evaluation for the facility. NNSA personnel had several issues with the accuracy and completeness of the submitted documents which were intended to provide more flexible limits while precluding the potential for an inadvertent criticality accident through a nature of process argument. The field office requested Triad to revise and resubmit the documents for re-review and approval.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 8, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaeue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 8, 2019

DNFSB Staff Activity: R.L. Jackson and Y. Li observed the Plutonium Facility Seismic Performance Reassessment workshop. This workshop covers the non-linear dynamic analysis.

Plutonium Facility–Operations: Last Wednesday, during chlorination activities, the lower-threshold room alarm for chlorine gas activated. The approximately 12 workers in the room promptly evacuated, reported the alarm to the operations center, noted the smell of chlorine, and awaited radiological control technician support. At the fact-finding, workers noted that the chlorine system recently passed a leak test and completed a run successfully. However, a portion of the system had been locked out for maintenance during that test and had not been retested after being returned to service. Facility personnel are doing a full inspection and test of the chlorine piping and it remains locked out at the source bottle until those results are satisfactory.

Transuranic Waste Management: On Thursday, the NNSA Field Office unconditionally approved Triad's evaluation of the safety of the situation regarding autocatalytic exothermic chemical reactions involving polysaccharides and nitric acid (see 10/18/2019 report). This is the first approved safety basis document at LANL that quantitatively analyzes the potential consequences associated with an energetic chemical reaction involving transuranic waste using an overall respirable release fraction of 0.07. The resident inspectors note that this approach might apply to other facilities that have the potential to generate or receive transuranic waste containing polysaccharides that have contacted nitric acid, such as the Chemistry and Metallurgy Research (CMR) Building, Radiological Laboratory Utility Office Building, Transuranic Waste Facility, and Area G.

Nuclear Criticality Safety: On Thursday, NNSA personnel out-briefed their assessment of Triad's implementation of their program improvement plan. They noted a number of positive developments including improved quality and output of evaluations, strengthened relationships with operations, good timeliness of annual reviews, and evaluation backlog reduction is progressing as scheduled. The four member team also identified three preliminary findings associated with: (1) scheduling program assessments to ensure all elements are covered at least once every three years; (2) incomplete functioning of the institutional Nuclear Criticality Safety Committee; and (3) lack of a plan/procedure to identify and evaluate inadvertent holdup of fissionable materials. Of note, Triad's recent management assessment identified the issues associated with the last two findings as opportunities for improvement (see 10/25/2019 report).

Flanged Tritium Waste Containers (FTWC): On Wednesday, Triad safety basis personnel submitted to the NNSA Field Office the third safety basis document supporting the project to vent and move FTWC containers stored at Area G. This addendum covers receipt and remediation of the FTWCs to the Weapons Engineering Tritium Facility. The current schedule estimates FTWC venting will occur in mid-March 2020.

CMR–Risk Reduction: Earlier this year, Triad hired a subcontractor to begin materials removal, primarily as low-level or non-radiological waste, from CMR to support future decontamination and demolition. The current scope of work is primarily focused in the unused Wings 2, 3, and 4, and attic areas of other wings. A second subcontractor is beginning work to perform bulk disconnects of electrical utilities in unused wings. The second phase of work, which should begin in the middle of next year will involve more invasive work including development of decontamination procedures, glovebox removal, hood removal, and limited scope removals of ventilation and piping.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 15, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 15, 2019

Transuranic Waste Management: Last week, the Central Characterization Program (CCP) suspended waste certification activities at LANL following questions concerning the accuracy of acceptable knowledge documentation. The concern involved the presence of unreacted calcium metal in salt residues from the direct oxide reduction (DOR) process. DOR uses excess amounts of calcium metal as an initial reactant meaning that some will remain after completion of the process. Under certain circumstances, calcium metal can pose a pyrophoric reactive hazard, which is prohibited by the waste acceptance criteria for the Waste Isolation Pilot Plant (WIPP). As a result, certain Triad waste generating activities in the Plutonium Facility, as well as WIPP shipments from LANL, were also curtailed.

On Tuesday and Wednesday, personnel from NNSA and EM Headquarters, the Carlsbad Field Office, CCP, Triad, N3B, and both local field offices held discussions to resolve the situation. They concluded that insufficient evidence of a reactive calcium hazard exists to warrant continued suspension of waste generating and certification activities. However, waste containers with DOR salts are being held pending additional analysis, documentation, and the completion of testing. Notably, they identified the need to update the waste database to include additional information on when and how items were generated. Overall, management developed an action plan and committed to increased teleconferences to strengthen communications. In the opinion of the resident inspectors, management missed an opportunity to identify the process and procedural deficiencies that contributed to the situation. In particular, management deferred discussions on reviewing the formal interface agreement and ensuring acceptable knowledge documents generated by Triad and CCP correctly reflect processes.

Area G: On Thursday, the situation discussed above contributed to a decision to unload two previously prepared shipments of transuranic waste destined for WIPP. In this case, N3B needs to verify the absence of DOR salts in the shipments, which could not be accomplished prior to exceeding shipping container time constraints. N3B relies on Triad to access many of the processing records and procedures necessary to review the origins of the waste at Area G.

Emergency Management: On Wednesday, Triad conducted their annual full-scale exercise. The scenario involved multiple security threats including regional and local attacks to the power grid, drone incursions into laboratory airspace, cyberattacks, an active shooter at the Radiochemistry Facility, and explosive devices on laboratory property. This was the first full scale exercise to practice activation of the Policy Group, a gathering of federal and contractor senior managers intended to provide strategic decision-making and support, but not direct management of the incident. Policy Group members noted a need to better define the roles and responsibilities of this group.

Last Wednesday, Triad transmitted their after-action report for last year's annual full-scale exercise (see 9/27/2019 report). There were no findings, six deficiencies, 23 opportunities for improvement, and one noteworthy practice. Four of the deficiencies related to fire department command and control at the TA-49 wildfire scene. They also noted a repeat issue concerning lack of reliable cell phone and radio communications in the Emergency Operations Center.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 22, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 22, 2019

DNFSB Staff Activity: M.W. Dunlevy and P.J. Migliorini, supported by other staff via teleconference, conducted reviews associated with transuranic waste management in Triad and N3B nuclear facilities. They also walked down the Plutonium Facility.

Area G–Safety Basis: Last Friday, the EM Field Office unconditionally approved N3B’s strategy for upgrading the safety basis (see 10/18/2019 report). On Thursday, N3B submitted to the EM Field Office for approval a safety basis addendum to support retrieval and storage of the corrugated metal pipes. The addendum proposes new Specific Administrative Controls for the activity associated with material-at-risk, refueling, crane standoff, and elevated waste movements and critical lifts. N3B requested approval by the end of this calendar year in order to support retrievals beginning in May 2020. The field office is reviewing the addendum.

Transuranic Waste Facility (TWF): Earlier this month, TWF personnel successfully completed replacement of the safety class seismic power shutoff system. The new system remedies deficiencies with the original. Effective use of TWF is essential to improving safety at the waste generating facilities; however, personnel continue efforts to rectify several features of this new facility to enable its intended use, including: a replacement firewater pump is scheduled to be installed next year in hopes of eliminating a water flow anomaly needed to support upgrading the fire suppression system to safety significant; plans remain to convert the dry-pipe system from nitrogen to air to eliminate an asphyxiation hazard; and planning to establish the intended characterization functions after personnel determined that the assay trailer could not be used because designers did not account for spacing with the adjacent radiography trailer—the radiography trailer could not itself be used because of equipment issues and will be replaced and likely relocated to outside of the Plutonium Facility.

Confinement Vessel Disposition: Earlier this month, project personnel completed debris removal on the ninth vessel. This is the last vessel known to contain significant quantities of nuclear material, and its cleanout generated 85 drums of transuranic waste. The removal of these waste containers is currently hampered by some of the outstanding issues at TWF discussed above. The eventual removal of these waste containers from the Chemistry and Metallurgy Research building will represent a step improvement to the facility’s safety posture because of the reduction in material-at-risk.

Plutonium Facility–Safety Basis: Last Wednesday, Triad submitted to the NNSA Field Office for approval a revision to the evaluation of the safety of the situation related to heat source plutonium and cheesecloth (see 10/25/2019 report). This revision includes 55 gallon drums in addition to pipe overpack containers and increases the heat source plutonium limit in containers from 10 grams to 28 grams. The NNSA Field Office is reviewing this submittal.

On Monday, Triad submitted to the NNSA Field Office a temporary safety basis modification to support use of a crane at a non-nuclear construction site adjacent to an outdoor transuranic waste storage pad. Use of a crane was identified in the original hazard analysis for construction, but potential impacts on the waste pad were not analyzed. The temporary modification concludes that a crane impact on waste drums does not create consequences that would drive additional controls. The NNSA Field Office approved the temporary modification on Thursday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 29, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 29, 2019

N3B–Organizational Learning: On Saturday, N3B senior management paused all work following three concerning events that occurred last week. They held a series of all hands meetings for the workforce on Monday to go over the events, their safety implications, and the importance of disciplined operations. The first event occurred last Tuesday when a subcontractor sent soil samples from TA-21 with improper markings and paperwork due to a calculation error regarding the amount of radioactivity in the samples. This error was discovered when the samples arrived at the Sample Management Office. The second, and most significant, event occurred at a groundwater sampling well. The crew was having trouble keeping a pump running so they bypassed an interlock that kept the 480 volt control panel shut while it was energized in order to reset the pump. The crew then opened the energized panel repeatedly throughout the shift to reset the pump. The final event involved potentially contaminated personnel at Area G. A worker brushed up against equipment and opted to do precautionary contamination monitoring. The monitor detected contamination resulting in a shelter-in-place at Area G. Later analysis discovered that the contamination was naturally occurring radon. For this event, management emphasized the positive questioning attitude of precautionary monitoring, but also noted that there were other changing conditions in the job area that warranted questions. No workers were injured or hazardous materials released in any of these events. The all hands meetings emphasized the importance of stop and pause work authority, pausing and questioning when conditions change, and the integrated safety management system for planning and executing work. Several workers at one meeting expressed concern with the recent change to exit monitoring requirements at Area G (see 9/20/2019 report). Area G management resumed limited activities on Tuesday. Electrical work currently requires senior management approval for release.

Environmental Management Field Office: As of last month, the EM Field Office's four authorized positions for facility representatives are unfilled. The current field oversight staffing has dropped to one technical assistance contractor performing functions similar to a facility representative. Previously there was one federal facility representative supported by two technical assistance contractors. While the office works to hire and qualify additional facility representatives, oversight is being prioritized to operations in Area G.

Performance Management: The NNSA Field Office's performance evaluation and measurement plan for Triad provides a framework including goals, objectives, and key outcomes. This fiscal year, each of the four programmatic goals includes a key outcome to execute the programs safely, securely, and compliantly with an emphasis on conduct of operations and waste management during program execution. The mission enablement and leadership goals also include key outcomes focused on: executing the transuranic waste management system to support off-site shipments; implementing actions to drive cultural change, including subcontractors; and implementing performance indicators associated with conduct of operations, criticality safety, safety basis, emergency management, and work planning and control.

The EM Field Office continues to develop their fiscal year 2020 performance plan for N3B. This plan is important to establish certainty regarding safety-related objectives; however, timely approval has been challenging due to a number of factors. For example, last year's plan was officially signed in February 2019 (see 3/8/2019 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 6, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plae and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 6, 2019

Plutonium Facility–Conduct of Operations: Last month, machinists and quality inspection personnel moved a machined part to a location different from the location they had planned in the nuclear material control and accountability system. The next day, other workers declared a process deviation during a pre-movement walk-down when they identified that the posted inventory sheet did not match the as-found condition. Criticality safety personnel recommended an infraction severity index of level 5, since all controls remained intact. At a follow-up fact-finding held this Monday, personnel involved in this process deviation self-identified a number of significant conduct of operations issues, including failures to: (1) assign a person-in-charge for the material move; (2) conduct a pre-job briefing for the move; (3) complete the use-every-time attachment required for the material move; (4) post the updated inventory sheet to the correct glovebox; and (5) correctly verify the as-found glovebox inventory when updating the posting. Management suspended the qualifications of the individuals involved and planned other corrective actions to include evaluation of the material move procedure and spot audits to ensure completion of the required attachment for material moves. The material move procedure has been revised about ten times since the plant-wide pause of operations in 2013 in order to improve execution and reduce the potential for worker error.

Transuranic Waste Facility (TWF): This week, TWF personnel completed security upgrades to each of the waste storage buildings to accommodate greater flexibility with respect to the storage of waste containing low-grade materials. However, TWF and Central Characterization Program personnel continue to work through the associated challenges of requiring cleared workers, restrictions on electronics, and new access controls.

Plutonium Facility–Safety Basis: Last week, a four person team completed an Implementation Verification Review of the updated safety basis (see 3/1/2019 report). This updated safety basis addresses long-standing conditions of approval, modernizes the hazards analysis, and consolidates multiple safety basis documents. The team verified that new or changed controls from the revised safety basis were incorporated into the appropriate procedures and that facility personnel at all levels understand the new controls and requirements. The team identified two findings: (1) several procedures that have not been fully updated or contain errors and (2) a self-identified issue that the new in-service inspection for plutonium ion exchange resins was not completed since the procedure is not ready. The team concluded that all review objectives were met and the new safety basis is ready for implementation with the exception of a few procedures that need revision and three activities excluded from scope that will remain under the current safety basis. Facility management is reviewing the team's report.

Flanged Tritium Waste Containers (FTWC): On Thursday, the NNSA Field Office unconditionally approved the safety basis addendum to the Weapons Engineering Tritium Facility supporting receipt and remediation of FTWCs from Area G. The safety basis documents supporting venting at Area G and transportation from Area G are still under review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 13, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 13, 2019

Plutonium Facility–Readiness: Last Friday, Triad management requested NNSA Field Office approval on a proposal to maintain operational readiness of the TA-55 Mobile Loading Unit (MLU). Triad personnel last operated the MLU in October 2018 and would ordinarily be required to conduct a readiness review prior to restarting nuclear operations in accordance with DOE Order 425.1D. However, Triad is proposing to credit the ongoing loading operations at the RANT Shipping Facility for operational proficiency of MLU. Their argument is that the same personnel perform both activities using similar procedures. The primary difference is that MLU operations involve the use of a mobile crane that is operated by workers that do not work at RANT. Triad also proposed establishing a Senior Supervisory Watch for future MLU operations. The NNSA Field Office is reviewing the proposal.

On Wednesday, Triad convened their Joint Evaluation Team to evaluate a proposal to consider a new, one-time shipping cask loading activity as an expansion of MLU operations. The two operations are inherently similar; however, Triad expects to submit a safety basis addendum for the new casks as there are differences with the materials being loaded, the location for the loading, the shipping container and trailer, and the work crew associated with the shipping container. The team concluded that the activity qualified as an expansion of an existing capability and as such does not require a readiness review—pending approval of the proposal discussed above. Of note, neither DOE Order 425.1D nor the associated DOE-STD-3006 provide explicit guidance related to the definition of an expansion of an existing capability, which has previously created confusion at LANL (see 8/31/2018 and 5/5/2017 reports).

Plutonium Facility–Safety Systems: On Sunday, facility operations personnel detected an apparent fault condition with the safety-significant Criticality Incident Detection and Alarm System and entered the limiting condition for operation by placing the facility into Mode 2—Standby. At the time, no work was underway. On Monday, vendor support personnel replaced a power supply and the facility resumed operations that evening. Facility management determined that since the fault was with a power supply that did not have credited functionality, their retrospective view was that the system was never degraded. As a result, facility management concluded this event did not meet any of the criteria for internal institutional or external reporting.

Flanged Tritium Waste Containers (FTWC): On Tuesday, the EM Field Office, with concurrence from the NNSA Field Office unconditionally approved the safety basis addendum that allows venting and handling of the four FTWCs. Credited controls to reduce the risk to workers from a FTWC deflagration include two design features, the FTWC and a relief valve orifice, as well five specific administrative controls.

On Thursday, personnel at the Weapons Engineering Tritium Facility (WETF) held their quarterly emergency drill. The scenario was an explosion of a FTWC from Area G upon arrival at WETF. The explosion injured a worker and caused a release of tritium. The coached training drill will be used for further development of processes to handle FTWCs from Area G at WETF.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 27, 2019

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 27, 2019

The Year on a Page: A summary of the key developments of 2019.

- Triad completed 15 shipments of transuranic waste to the Waste Isolation Pilot Plant after restarting operations at the RANT Shipping Facility. They are working to increase the weekly pace of shipments and eventually integrating N3B shipments from Area G.
- Confinement Vessel Disposition project personnel completed cleanout of the last sphere. This represents completion of the last action resulting from the Board's Recommendation 94-1 *Improved Schedule for Remediation in the Defense Nuclear Facilities Complex*. As a result, the Chemistry and Metallurgy Research building is postured for a near-term significant reduction in material-at-risk as the exit strategy advances.
- Plutonium Facility personnel completed upgrades to eliminate seismic interaction hazards from the fire suppression system piping. This represents an important step toward ultimately qualifying the system for service in a performance category 3 seismic event; however, additional out-year efforts remain associated with reanalyzing the piping, installing additional bracing as needed, and separating the non-seismically qualified buildings from the fire water loop.
- NNSA completed testing of two column capital specimens and advanced the nonlinear dynamic analysis to improve the understanding of the seismic performance of the Plutonium Facility. NNSA began these efforts in 2012 and they are notionally scheduled to inform the safety basis in 2023.
- In its third year of operations, the utilization of the Transuranic Waste Facility reached about 40 percent of capacity. Facility personnel completed replacement of the seismic switches and continue longstanding efforts to upgrade the fire suppression system to safety significant, convert the dry pipe system from nitrogen to air, and establish the waste characterization capabilities that were deferred from the original project.
- Triad took steps in support of the production mission including: implementing a new safety basis for the Plutonium Facility that addresses long-standing conditions of approval and helps consolidate safety basis documents; strengthening plan of the day processes; reducing the backlog of criticality evaluations; and advancing the upgrade of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility.
- Triad personnel vented one of the three Flanged Tritium Waste Containers that have the potential for explosive headspace mixtures of oxygen and hydrogen isotopes that are stored at the Weapons Engineering Tritium Facility. They also received approval for three safety basis documents needed to support the venting and disposition of the four similar containers currently stored in a shed at Area G. They plan to execute these activities in spring 2020.
- At Area G, N3B executed 12 mobile loading shipments and restarted limited open container remediation capabilities. They also began a multi-year effort to upgrade the legacy safety basis after the EM Field Office mostly abandoned the new safety basis developed during the past 4 years using DOE-STD-3009-2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 3, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 3, 2020

Performance Management: Last month, NNSA approved the Performance Evaluation Report for fiscal year 2019. Overall, NNSA rated Triad as “Good” with a 66 percent score. The score was impacted by challenges in the nuclear threat reduction and operations and infrastructure goals. Of interest to the defense nuclear facilities, NNSA noted increased sensitivity to entry into the New Information process; a high-level of responsiveness to safety basis quality issues; numerous challenges with construction project management, schedule execution, and oversight; continuing conduct of operations issues; struggles implementing an effective transuranic waste management program; and schedule delays for the disposition of the Flanged Tritium Waste Containers at Area G.

Radioactive Liquid Waste Treatment Facility (RLWTF): Triad inherited from the predecessor contractor challenges associated with the projects for the low-level liquid waste (LLW) and transuranic liquid waste (TLW) enduring capabilities that are necessary to replace the RLWTF built in 1963. In particular, the LLW effort achieved project completion in November 2018; however, Triad’s current estimate for transition to radiological operations is 2022 based on the need to complete a number of equipment modifications required for operations. The TLW effort has recently resumed development of Critical Decision 2/3. Based on process equipment refurbishment efforts completed in 2005, Triad believes the existing system can support operations until approximately 2034.

Transuranic Waste Management: Last month, EM and NNSA jointly responded to the New Mexico Environment Department’s request for additional information on transuranic waste containers that had received non-conformances against the Basis of Knowledge for the Waste Isolation Pilot Plant. The response provides additional details on seven containers and states that based on current information five of the containers do not exhibit ignitable, corrosive, or reactive hazards. There is insufficient information for the other two containers which will require future characterization and remediation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 10, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 10, 2020

Federal Oversight: On Monday, Mr. Michael Weis became the manager of the NNSA Field Office. He briefed his 30-60-90 day plan to understand, evaluate, and optimize field office operations.

Plutonium Facility–Infrastructure: Last month, Triad issued the annual update for the TA-55 Project Execution Strategy (see 1/4/2019 report). Overall, Triad’s projections to achieve the desired end-states for the ventilation and fire suppression systems remain in fiscal years 2025 and 2026, respectively. Key accomplishments for fiscal year 2019 include:

- Completion of seismic evaluations for the electrical distribution and instrument air systems
- Commenced Phase I testing of column capitals at the University of Nevada, Reno
- Completed seismic analyses for six clusters of gloveboxes
- Resolved seismic interaction issues with the fire suppression system (see 9/27/2019 report)

The recommended scope for work in fiscal year 2020 includes:

- Remediating ventilation penetrations with approved firestop systems
- Commissioning the diesel generators and accoutrements supporting the electric firewater pumps
- Continuing column capital testing
- Evaluating additional supports needed to bring the fire suppression system to seismic design category 3, limit state C

Area G: On Tuesday, N3B management declared a potential inadequacy of the safety analysis after identifying a discrepancy between the waste container array aisle spacing described in the approved safety basis and the as-found configuration of the facility. Specifically, the safety basis states that aisle spacing is 36 inches due to regulatory requirements, which a supporting fire protection calculation conservatively treats as 28 inches. However, the actual regulatory requirement and facility practice is 24 inches. Safety basis personnel determined that the decreased spacing results in an increased number of waste containers that could be impacted by a potential fuel pool fire. Their preliminary calculations indicate increased mitigated doses to the public and the collocated worker, but these increases do not exceed any DOE criteria. As a result, facility management concluded that no compensatory measures were needed, but identified corrective actions to evaluate the extent of this condition in the command media and other safety basis calculations.

Transuranic Waste Management: This week, Triad personnel completed their first two shipments since early October 2019 from the RANT Shipping Facility to the Waste Isolation Pilot Plant (WIPP). Shipments had been impacted by container movement issues, concerns about pyrophoric materials, and an equipment issue at WIPP. They plan to execute two shipments each week until the annual WIPP maintenance outage in mid-February. Following the outage, they are exploring increasing the shipping cadence to three shipments per week if it can be sustained by the rate of container certification. N3B also has not shipped since October 2019 and is not currently included on the WIPP shipping schedule. They have a certified container population sufficient for about 50 shipments and continue to work with Triad to resolve integration processes to support co-mingled shipping operations at RANT.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 17, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 17, 2020

Plutonium Facility–Operations: Last week, during the first use of the chlorine system since a previous system leak (see 11/8/2019 report), the chlorine alarm activated and workers responded as required. The system had been successfully pressure tested in late November using a revised procedure and a new failure criterion. Facility management has suspended chlorination activities pending determination of the cause of the alarm and additional leak inspections.

Triad personnel have nearly completed installation of a newly designed replacement chlorine delivery system. The new system features several improvements including predominantly welded construction, new safety interlocks that include automated shutdown and argon purging, and construction using mostly Monel components. The new system is expected to be operational this summer.

Radiological Laboratory Utility Office Building (RLUOB): Last month, a janitor performing routine floor cleaning activities in a radiologically controlled area discovered contamination on his protective bootie during an exit survey using a personnel contamination monitor (PCM). Radiological control personnel further investigated and discovered that the contamination was promethium-147, which is primarily a beta emitter. This radionuclide is detectable by PCMs and most hand-held devices used by radiological personnel, but is not detectable by the hand and foot monitors or continuous air monitors in the facility, since it predominantly handles alpha emitters. At the fact-finding meeting this week, involved personnel noted that the radionuclide had been used for a project several years ago, but remained in the back of a fume hood pending a waste disposition path. Management identified corrective actions including: determining the current inventory of beta emitting isotopes in RLUOB; developing a process to inform radiological protection personnel when new beta emitting isotopes arrive at the facility; and determining disposition paths for non-routine waste streams.

Area G: N3B personnel recently resolved most of a backlog associated with inspection, testing, and maintenance (ITM) activities for fire protection systems in the facility. In October 2019, a N3B management assessment determined that 8 of 12 categories of fire protection systems had delinquent ITM activities. Examples of the delinquencies include: all 3 of the fire alarm panels were missing their annual inspections; all 12 of the major lightning protection systems were missing their annual inspections; and all 5 of the gaseous suppression systems were missing all of their required ITM activities. While none of these fire suppression systems are credited in the approved safety basis, N3B management elected to implement compensatory measures, such as fire watches, while maintenance personnel completed the ITM activities.

Power Outage: On Monday, electrical power from one of the laboratory's primary high voltage feed lines was lost for about an hour subsequent to Triad personnel attempting switching operations following corrective maintenance. Numerous facilities were impacted including the Plutonium Facility, Chemistry and Metallurgy Research building, and the DNFSB onsite office. Facility personnel did not report any issues with the response. Utility personnel are investigating the cause of the outage.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 24, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 24, 2020

DNFSB Staff Activity: P.J. Migliorini supplemented the onsite office this week. On Thursday, a staff team conducted a teleconference with personnel from the NNSA Field Office and Triad. The discussion supported a complex-wide examination of how 10-year natural phenomena hazard updates are executed and integrated into facility safety bases.

Transuranic Waste Operations: On Thursday, Triad personnel declared a potential inadequacy of the safety analysis for the Transuranic Waste Facility associated with the use of a spatula-like tool for headspace gas sampling of waste containers (see 12/20/2019 report). This sampling is a part of the certification process needed to send waste containers to the Waste Isolation Pilot Plan and is performed by Central Characterization Program personnel. About sixty percent of Triad's existing container population awaits this testing. Gas sampling activities remain paused in Triad facilities. This issue has not affected gas sampling activities at Area G, which remain ongoing using the same tool.

Readiness: On Wednesday, Triad personnel executed their Joint Evaluation Team process to evaluate the level of formal readiness review for upcoming new activities. The team concluded that a new hot press and a new repack, consolidate, and discard operation constituted expansions of existing capabilities because they were substantially similar to ongoing operations. As a result, Triad will be proposing to the NNSA Field Office that these activities do not require a formal readiness review. The team also reviewed the planned upgrade of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility. They determined that this change in operating status warranted an NNSA Operational Readiness Review.

Radiological Laboratory Utility Office Building: Triad personnel continue to investigate system adequacy and develop proposed remedies for gaps between the as-built systems and the codes and standards required for operation as a hazard category 3 nuclear facility (see 10/4/2019 report). In addition to these efforts, as part of the periodic update to the fire hazards analysis, fire protection engineers have identified significant deficiencies in the fire barriers throughout the building, including stairwells, elevator shafts, doorways, floor-to-floor penetrations, and 2-hour fire rated barriers separating fire areas. Triad has commenced additional extent-of-condition reviews, repairs, and compensatory measures since these deficiencies challenge life safety and fire protection code requirements.

Federal Oversight: A six person team consisting of senior federal and contractor personnel from other DOE and NNSA sites performed a Radiological Waste Peer review for both the NNSA Field Office/Triad and the EM Field Office/N3B. These reviews are happening across the DOE complex and are intended to be complementary to waste reviews being performed by the DOE Office of Enterprise Assessments. The peer review used a model similar to the NNSA Governance Peer Review (see 9/27/2019 report) in that it consisted primarily of discussions with federal and contractor personnel with a goal of identifying best practices and lessons learned to strengthen radioactive waste practices and processes. A key item noted by the team in their outbrief was for the EM and NNSA Offices and their respective contractors to continue efforts to better integrate their waste management missions. The review team plans to issue a final report in mid-February; a report that consolidates results from all of the assessed sites will follow.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 31, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 31, 2020

Plutonium Facility–Fire Protection: Earlier this month, subcontractor personnel started installing new fire doors between the laboratory rooms and the corridors. As of this week, approximately half of these doors are partially installed. The new doors currently lack astragals, leaving substantial exposure gaps. Some of the doors are also not aligned correctly and do not properly self-close or self-latch. These conditions will need to be resolved in order to credit the doors in the fire hazards analysis and safety basis in the future.

Facility personnel resolved installation issues associated with the anchorage of one of the new seismically qualified backup diesel generators for the electric fire pumps (see 7/28/2017 report). The generator is expected to begin commissioning next week. Once operable, the generator will ease some of the safety basis requirements on the diesel fire pumps. The diesel fire pumps have been undergoing troubleshooting due to recent smoky exhaust, knocking, and lubrication system issues. Triad plans to replace the diesel pumps with delivery expected in October 2020.

Transuranic Waste Operations: Earlier this month, Triad personnel received the results of independent laboratory analyses on surrogate materials intended to verify the acceptability of residue salts from the direct oxide reduction process used to produce plutonium metal (see 11/15/2019 report). The results show that surrogate salts prepared with up to 30 percent stoichiometric excess of calcium metal generate gas with hydrogen concentrations that do not exceed the criteria under UN Division 4.3, *Dangerous When Wet*. As a result, Triad expects Central Characterization Program (CCP) personnel will be able to revise chemical compatibility evaluations to support the certification of waste containers with pyrochemical salt residues generated in process runs using up to 30 percent excess calcium. For greater amounts of calcium or failed runs, Triad is exploring the need to perform additional oxidation campaigns to minimize reactivity and simplify the waste certification process.

Last month, CCP issued a revision to the interface document used to govern their relationship with Triad. The revision includes important corrective actions to ensure Triad subject matter experts review various enhanced acceptable knowledge documents, including chemical compatibility evaluations. In particular, the calcium metal concern discussed above involved factually inaccurate statements that propagated through at least three acceptable knowledge documents.

Last Thursday, Triad safety basis personnel transmitted to the NNSA Field Office an evaluation of the safety of the situation (ESS) concerning the interaction of nitric acid and polysaccharides in the Chemistry and Metallurgy Research building. The ESS provides similar analysis and the same control set as previously proposed and approved for the Plutonium Facility (see 11/8/2019 report).

Area G: On Monday, N3B personnel entered their initial confirmatory process subsequent to Triad's declaration of a potential inadequacy of the safety analysis (PISA) related to using a spatula-like tool during flammable gas sampling operations at the Transuranic Waste facility (see 1/24/2020 report). On Thursday, N3B declared a PISA for flammable gas sampling operations at Area G. Flammable gas sampling, which is performed by CCP personnel, is now paused at Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 7, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 7, 2020

DNFSB Activity: On Friday, NNSA personnel briefed the Board in response to their letter dated November 15, 2019, regarding improvements to the safety posture for the Plutonium Facility.

Plutonium Facility–Transuranic Waste Operations: On Monday, workers appropriately paused work after a radiological control technician measured an unexpectedly high gamma radiation field on a newly generated transuranic waste drum. In particular, a location near the bottom of the drum measured about 650 mrem/h on contact, which exceeded the 200 mrem/h limit established for contact handled transuranic waste. The workers were disposing of waste materials from the americium-241 oxide production operation. Given the potential for high gamma fields associated with this waste stream, the workers had surveyed the individual waste items prior to placement in the drum. At the fact-finding held on Wednesday, participants determined that either a survey error or a change in configuration of a waste item likely contributed to the unexpected condition. They identified corrective actions intended to prevent the generation of high radiation transuranic waste drums, since Triad current currently lacks the capability to repackage these non-compliant containers into a form acceptable for disposal. The corrective actions include evaluation of the radiation survey process, as well as examining the routine use of pipe overpack containers (POC)—which offer greater radiation shielding—for this waste stream.

Plutonium Facility–Formality of Operations: During the fact-finding discussed above, the radiation protection manager aptly noted that materials with elevated gamma fields have the potential to inadvertently activate the nuclear criticality alarm system. While they recently updated a requirements document to reflect an administrative control to prevent this issue, workforce awareness of this control appeared lacking. As such, management took an action to discuss the control in an upcoming briefing.

Transuranic Waste Operations: On Monday, Triad personnel were moving drums from the Plutonium Facility to the RANT Shipping Facility. The load included five POCs from the Offsite Source Recovery Program (OSRP). These POCs do not have the new filter type used to preclude a release from a fire (see 1/25/2019 report). While the contents of the OSRP POCs are not readily dispersible in a fire, the RANT safety basis requires that all POCs have the new type of filter. Verifying filter types is not part of the prerequisite checks prior to shipping to RANT; however, RANT workers do verify filter type to ensure safety basis compliance as part of their acceptance process and rejected these containers. Other OSRP POCs currently stored at the Plutonium Facility use this older filter, which is allowed by the Plutonium Facility safety basis. Triad personnel are evaluating whether to replace all POC filters with the new type rather than changing the RANT safety basis to allow the older filters for OSRP POCs.

Area G: Last Thursday, N3B workers inadvertently knocked a non-radiological mockup of a corrugated metal pipe (CMP) from its cradle with a forklift. The 4.8 metric ton pipe then rolled approximately 12 meters downhill before stopping at a fence. The workers did not inform the operations center of the event, but did move the dislodged CMP mockup to a more stable position perpendicular to the slope. Facility management noted the condition later in the day when driving past and initiated reporting.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 14, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 14, 2020

Transuranic Waste Operations–Safety Basis Inconsistencies: Last Thursday, Triad personnel determined that the potential inadequacy of the safety analysis related to covering drum vents at the Transuranic Waste Facility (TWF) during flammable gas sampling constitutes a positive unreviewed safety question (see 1/24/2020 report). The TWF safety basis requires that transuranic waste container vents be visually inspected and have no evidence of clogging as a surveillance requirement to ensure that the safety-class containers meet their functional requirement to prevent buildup of flammable or other gases. Safety basis personnel determined that the spatula-like tool used to cover the vent during sampling defeats this functional requirement. Flammable gas sampling activities remain paused at TWF; however, gas sampling activities resumed this week at the Plutonium Facility because of differences in safety basis requirements. In particular, the Plutonium Facility safety basis, which credits transuranic waste containers as safety-significant, has a functional requirement to prevent hydrogen buildup, but does not provide any requirements on filter condition or a surveillance requirement related to the adequacy of venting. Flammable gas sampling at Area G also remains paused. The Area G safety basis treats filters in a third way. While venting is not a functional requirement of compliant safety-significant drums, unvented drums are separately defined as a drum with a visibly obstructed vent path. Unvented drums are allowed at Area G, but must be kept in an isolated area with restricted access and cannot be stacked.

Federal Oversight: On Wednesday, EM Headquarters personnel performed a walk-down of Area G with site office technical support contractors. Given low federal staffing at the EM Field Office, headquarters personnel have been providing supplemental support. The team observed criticality safety postings at the high fissile-gram equivalent waste drums storage area, treatment of non-conformance reports, and use of weather protecting tarps over filtered drums.

Radiological Laboratory Utility Office Building: On Wednesday, the NNSA Field Office transmitted their formal comments on the safety basis planned to support operations as a hazard category 3 nuclear facility. Notable comments include that Triad: provide a path forward to correct known significant deficiencies and achieve compliance with applicable national consensus codes and DOE Order 420.1C, *Facility Safety*; clarify that ASME NQA-1 requirements apply to defense-in-depth systems such as fire protection and ventilation; and consider elevating controls that provide event detection (i.e., continuous air monitors) to defense-in-depth.

Continuous Improvement: During the past three years, LANL has experienced two near-miss events where workers without appropriate controls entered rooms with low oxygen alarms actively sounding. Both events were the subject of DOE Office of Enforcement investigations. Recent data indicate that recent corrective actions taken by Triad have been effective so far. For example, the LANL emergency response organization has been contacted to respond to low-oxygen alarms about 22 times in the past three months compared to a previous history of essentially zero.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 21, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 21, 2020

Federal Oversight: On Wednesday, the EM Field Office issued their first staffing plan for Facility Representatives. They identified the need for four Facility Representatives and an additional supervisor. They currently have one newly hired individual undergoing qualification and two technical support contractors (see 11/29/2019 report). The most recent staffing plan for the NNSA Field Office identifies the need for a 15 member Facility Representative team with six vacancies. Many of NNSA's Facility Representatives are undergoing qualification resulting in key facilities that lack fully qualified coverage. For example, the Plutonium Facility has had only approximately four months where a fully qualified Facility Representative was present since November 2018.

Radiological Laboratory Utility Office Building: Last Friday, the NNSA Field Office sent a letter to Triad concerning deficiencies in the fire barriers, fire penetration seals, fire doors, and fire sprinkler restraints in the building. They noted that Triad identified the initial deficiencies as impairments on September 9, 2019, and that the full extent of condition remains unknown without an agreed upon schedule for completion. The field office directed Triad to: (1) submit an extent of condition report for all fire deficiencies by February 28, 2020; (2) submit for concurrence a prioritized strategy for dispositioning the deficiencies by March 20, 2020; and (3) provide a justification for why the building is safe to operate considering all fire deficiencies and the potential for similar construction deficiencies in other functional areas by March 20, 2020.

Plutonium Facility–Work Planning and Control: Last Wednesday, during performance of the weekly surveillance on the safety class firewater pumps, operations personnel observed that the level of fuel in the diesel day tank failed to meet the specified minimum. They took appropriate actions and restored the system. At the fact-finding conducted this Wednesday, participants determined that the likely cause of the condition was that a fuel sample had been taken the previous week as part of enhanced monitoring of the pumps (see 1/31/2020 report). The work authorizing document used to perform the sampling was a “Quick Fix” and did not provide important work steps such as replacing the volume of sampled fuel. Fact-finding participants determined that other work documents are available to support future sampling; however, they did not explore how the work control process allowed a “Quick Fix” to be used on safety class equipment, which is not authorized.

Emergency Management: On Wednesday Triad and N3B personnel conducted an emergency exercise. A five member team from DOE's Office of Enterprise Assessments was on site to evaluate the exercise. The scenario occurred in Area G and involved a truck hauling transuranic waste containers that crashed into a transuranic waste storage dome resulting in a pool fire. Triad personnel completed the formal critique and are evaluating exercise performance. During the critique, participants noted that miscommunications resulted in the Emergency Operations Center issuing inappropriate protective actions at Area G. A separate issue resulted in incorrect protective action recommendations for offsite communities.

Flanged Tritium Waste Containers (FTWC): Last Friday, Triad personnel took operational control from N3B of the sheds within Area G that house the FTWCs. Control will revert back to N3B, once the FTWCs are vented and moved to the Weapons Engineering Tritium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 28, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 28, 2020

DNFSB Staff Activity: P. J. Migliorini supplemented the onsite staff. His activities included walk-downs of the Plutonium Facility and Area G, as well as observation of the management review board held by the Associate Laboratory Director for Weapons Production.

Emergency Management: Last Wednesday, there was a small fire in a non-radiological laboratory at the Technical Area 48 Radiochemistry Facility. A researcher working in a fume hood added an organic solvent to flasks that contained a water reactive reagent when the solvent ignited, flame traveled back to the solvent bottle, and the researcher dropped the flaming bottle on the floor. Due to confusion regarding proper operation of an approved fire extinguisher, another researcher extinguished the fire using liquid nitrogen. The researchers notified their programmatic line management, but nobody notified the fire department or the Emergency Operations Support Center (EOSC). Facility management became aware of the situation the next morning and subsequently called the EOSC. Due to concerns regarding this event, Triad management debuted their new process for rapid sharing of information. This Wednesday, Triad issued an Immediate Lessons Learned that noted the following three items: (1) If there is any fire, even if it is extinguished, the Los Alamos Fire Department must be called; (2) Anytime there is an abnormal event, the EOSC must be called; and (3) Liquid nitrogen is not an approved fire extinguisher. Individuals not properly reporting events to the fire department and the EOSC has been a recurring issue at the laboratory (see 5/12/2017 and 2/9/2018 reports). The EOSC launched a new, mnemonic phone number in May 2019. The launch included training and provided a multitude of reminder paraphernalia across the laboratory.

Flanged Tritium Waste Containers (FTWC): On Thursday, Triad and N3B personnel conducted an emergency drill at the shed in Area G containing the FTWCs. The scenario involved an explosive pressure release during FTWC venting that knocked one worker over badly injuring an arm and dazed two other workers. All three casualties were potentially tritium contaminated. This training drill was the first conducted in Triad's new operational control area within Area G, and it demonstrated many areas where coordination between the two contractors and responders will need to improve. Of particular note, the EOSC improperly directed personnel to shelter-in-place in a damaged fabric waste storage dome—repeating the same error that occurred during last week's exercise (see 2/21/2020 report).

Technical Area 18–Legacy Materials: In early February 2020, a radiological control technician identified legacy radioactive materials stored outside in Technical Area 18, the former home to the Critical Experiments Facility. The problematic radioactive material is in a 5 gallon plastic bucket containing various bagged and wrapped objects. Radioassay measurements detected isotopes of curium, americium, and californium. On Monday, Triad personnel discovered that these materials had been identified for disposal in 2016. Consequently, they initiated an evaluation of breakdowns in the waste management process. Triad personnel overpacked the bucket in a metal drum and are evaluating whether the known information on this material is sufficient for waste disposal or whether additional characterization, likely at the Chemistry and Metallurgy Research Building, will be needed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 6, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 6, 2020

DNFSB Staff Activity: On Tuesday, R.C. Eul, P.J. Migliorini, and A.J. Miller conducted a teleconference with NNSA Field Office personnel to understand the basis for their rating of Triad in DOE's Annual Metrics Report to the DNFSB on Nuclear Criticality Safety Programs.

Area G: On Monday, N3B responded to EM Field Office contracting direction issued on February 21, 2020, to implement compensatory measures and take actions concerning the safe storage of high fissile gram equivalent (FGE) containers in Dome 49. In their letter, the field office expressed concerns that documentation may not accurately reflect the number, as-found configuration, and safety controls associated with high FGE containers. N3B's response provided a listing of all high FGE containers and indicated the containers had been stored in accordance with approved criticality safety controls and operating procedures. N3B noted that the number of high FGE containers had changed since mid-2019 as a result of their initiative to implement criticality safety controls based on the measured FGE content plus two times the uncertainty, as a best management practice. In our opinion, it appears that better communications could have avoided this exchange.

Transuranic Waste Management: On Wednesday, Plutonium Facility personnel conducted a fact-finding to learn from two issues encountered during a shipment last month of containers to the Transuranic Waste Facility. The first issue concerned the fact that a container that was prohibited from being shipped made it to a payload; fortunately, an attentive worker observed a physical hold tag and prevented the shipment. The second issue involved a container that was not physically moved as part of the shipment, but had been transferred to TWF in the electronic inventory. Both issues occurred despite numerous procedural and software checks involving multiple groups of workers. As a result, management decided to conduct a human performance review of waste container handling processes.

Plutonium Facility—Operations: Last month, workers encountered two anomalies while oxidizing legacy plutonium items from the vault along with cans of sweepings. Historical data on these items suggested they were already oxidized; however, the furnace run was planned for additional assurance that the material was stabilized. During the furnace run, an unexpected thermal excursion occurred resulting in a cracked crucible and damaged thermocouples. The contact dose rate of the product also unexpectedly increased from approximately 1.5 rem/hour to approximately 2 rem/hour. The high radiation levels required the workers to split the product into smaller batches to meet storage requirements; however, they were unable to complete this task due to frequent alarms on their electronic dosimeters. An expedited reading of the worker's dosimeter showed an unexpectedly high dose for February. At a fact-finding to learn from the radiation exposure, facility management identified the need to evaluate: blending plans for processing run; compliance with the radiological work permit for removing materials from the vault, and a path forward to complete packaging of this material. Given the similarity to a previous excursion that spread fine black powder inside a glovebox in the same room (see 7/19/2019 report), Triad management requested a causal analysis of the events.

Federal Oversight: On Monday, Mr. Thomas Johnson Jr. became acting manager of the EM Field Office. On Wednesday, the EM Field Office issued their first formal transmittal of oversight surveillance reports to N3B for resolution in the issues management process. The field office continues to work through challenges and achieve compliance with their oversight command media.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 13, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 13, 2020

Emergency Management: On Monday, Triad activated the emergency operations center in a monitoring mode capacity to support COVID-19 preparedness activities, including refinements on minimal essential staffing plans. Laboratory personnel are actively working to address the State of New Mexico's public health order prohibiting gatherings of more than 100 people and the closure of all public schools for at least three weeks.

Plutonium Facility–Emergency Management: On Monday evening, workers in the basement reported a smoky haze to the operations center. Facility operators directed them to the other half of the facility, visualized smoke using video cameras, pulled a fire alarm, and made proper emergency notifications. In parallel, an engineering manager, who was in the operations center, entered the basement to assess the source of the smoke. He noted that there were no continuous air monitor (CAM) alarms and was aware of a programmatic vacuum pump that was being operated in a compromised condition to support a programmatic need. He quickly identified a failed plastic tubing line on the pump that was releasing aerosolized oil, de-energized the pump at the local disconnect, and departed the facility to meet the fire department. Fire fighters entered the basement in full protective gear with self-contained breathing apparatus and confirmed the situation was safe. Of note, the engineering manager indicated that he would not have entered the basement had a smoke detector alarmed or he smelled smoke; however, the smoke detectors in the basement are limited to certain enclosed areas and do not provide broad coverage of the basement. Phase III of the TA-55 Reinvestment Project includes scope to remedy this gap in coverage.

Plutonium Facility–Glovebox Safety: On Wednesday, facility personnel conducted a fact-finding on a recent glove breach on a plutonium-238 processing glovebox that significantly contaminated (about 300k dpm alpha) an operator's modesty clothing and alarmed a CAM. Participants surmised that the operator did not fully survey all areas of his coveralls that had potentially contacted the glovebox exterior which resulted in him carrying the contamination to another work area adjacent to the CAM. Triad management has observed that incomplete contamination surveys has been a recurring problem and is developing improved training and assessing placement of additional personnel contamination detectors throughout the facility.

Another important aspect of this event is the location of the glove breach. The location is similar to a breach that occurred last month. That breach was traced to a batch of gloves where Triad personnel observed multiple defects. Subsequent to this latest breach, management took action to promptly assess the installed population for gloves from this batch and either replace or thoroughly inspect the glove prior to use. Corrective actions from the previous event to evaluate opportunities to strengthen inspection processes, including as part of installation, remain underway.

Federal Oversight: On Wednesday, EM Field Office personnel were provided training on oversight surveillance report preparation and the use of the issues management system. The training comes after quality assurance support personnel noted problems encountered during preparation of last month's formal surveillance report transmittal (see 3/6/2020 report). EM Field Office personnel were also recently provided refresher training on stop/pause work after confusion arose during a field demonstration.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 20, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending March 20, 2020

COVID-19 Impacts: Triad's emergency operations center remains in monitoring mode with its pandemic advisory team meeting regularly to address the rapidly evolving situation. Overall, Triad is encouraging use of telework as a default if permitted by job function. Currently, about a third of the workforce is teleworking. Operations in the nuclear facilities remain ongoing with social distancing and enhanced disinfection protocols in use. N3B is also promoting telework while normal operations continue at Area G. Both the NNSA and EM Field Offices workforces have transitioned to largely teleworking with some physical presence of Facility Representatives and management. Known impacts of interest include:

- Triad has postponed readiness reviews for the venting and disposition of the Flanged Tritium Waste Containers. However, they continue to complete management self-assessment activities and conduct operational training.
- N3B has postponed its management self-assessment for retrieval of the corrugated metal pipes.
- The Waste Isolation Pilot Plant (WIPP) cancelled a planned shipment from the RANT Shipping Facility this week. Triad has payload containers staged and hopes to execute the shipment next week.

Transuranic Waste Facility: On Monday, the NNSA Field Office unconditionally approved Triad's evaluation of the safety of the situation (ESS) regarding the impacts of temporarily blocking waste container vents with a spatula-like tool (see 2/14/2020 report). On a related note, Triad waste management personnel have taken an action to evaluate safety basis controls for consistency across Triad's facilities that generate or store transuranic waste. On Tuesday, Triad submitted a safety basis revision to the NNSA Field Office for approval. The revision is needed to support use of the Mobile In-Situ Object Counting System Large Container Counter (MILCC). The MILCC is used to support non-destructive assay measurements for WIPP certification. Triad intends to relocate the MILCC from an outdoor pad at the Plutonium Facility.

Area G–Safety Basis: On Thursday, N3B and EM Field Office personnel conducted a teleconference to discuss proposed revisions to the safety basis strategy for the safety basis upgrade effort (see 10/18/2019 report). Notably, N3B is considering substantially more new analysis than anticipated, including a new hazards analysis, dispersion modeling, fire modeling, and an accident analysis using DOE-HDBK-1224-2018, *Hazard and Accident Analysis Handbook*. They are also proposing adopting elements of the draft revision of DOE-STD-5506, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*. However, the overall document is still planned to be developed in accordance with DOE-STD-3011-2002, *Guidance for Preparation of Basis of Interim Operation (BIO) Documents*. The resident inspector questioned whether development to DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis* now, rather than in a subsequent future upgrade, is advantageous given the increased amount of new analysis. N3B expects to submit a finalized strategy for approval in the coming weeks.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 27, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending March 27, 2020

COVID-19 Impacts: Triad's Emergency Operations Center remains in monitoring mode with its pandemic advisory team meeting as needed. On Tuesday, emergency management personnel largely transitioned to virtual operations to reduce personnel in the Emergency Operations Center. Overall, about three quarters of Triad personnel are now teleworking. Nuclear facilities began reducing operations this week.

- The Weapons Engineering Tritium Facility and Chemistry and Metallurgy Research building transitioned to minimal operations. Both facilities are maintaining reduced staff for limited days to perform surveillances and other required activities.
- Transuranic waste operations at the Transuranic Waste Facility, the Plutonium Facility, and the RANT Shipping Facility remain active. Activities include non-destructive assay and flammable gas headspace measurements in support of certification for the Waste Isolation Pilot Plant (WIPP), as well as preparation of payloads for possible continued shipments to WIPP. A shipment of drums departed RANT for WIPP on Tuesday.
- The Plutonium Facility has reduced programmatic activities with additional social distancing and cleaning protocols in place. Maintenance and some construction activities are also continuing.
- Area G operations transitioned to near minimal on Thursday. N3B personnel will be completing all required daily and weekly rounds for safety and environmental compliance. Equipment maintenance activities will also continue.
- The EM and NNSA Field Offices are nearly exclusively teleworking. NNSA has begun planning for resumption of operations once warranted by conditions.

Radiological Laboratory Utility Office Building: Two weeks ago, Triad responded to the NNSA Field Office's request for a prioritized strategy for resolution of the fire protection deficiencies in the building (see 2/21/2020 report). The strategy provides options for physical remedies as well as administrative variances and permanent exemptions. Triad emphasized that the most important element is to repair the five stairwells in the facility to meet occupant life-safety code—an effort currently expected to take at least another year. Triad's proposed prioritization of the other deficiencies include: (1) restore occupant life-safety impacted fire barriers as much as feasible; (2) provide compliant and reliable operations for the fire suppression system; (3) address property protection requirements; (4) address other code compliance issues; and (5) address lower priority deficiencies in the central utility building. Triad estimated overall completion of the effort to require four to five years depending on funding sources and profiles.

Transuranic Waste–Readiness: Last Friday, the NNSA Field Office approved Triad's request to credit activities at the RANT Shipping Facility to forgo a formal readiness review for mobile loading of transuranic waste at TA-55 (see 12/13/2019 report).

Area G–Safety Basis: Last Thursday, N3B transmitted to the EM Field Office for approval its evaluation of the safety of the situation concerning discrepancies in waste container aisle spacing (see 1/10/2020 report). N3B performed calculations for pool fuel fires demonstrating that the potential consequences from the as-found configuration do not change the currently accepted risk profile.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 3, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plau and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 3, 2020

COVID-19 Impacts: The laboratory's operational posture remains similar to the end of last week (see 3/27/2020 report). Developments this week include:

- On Tuesday, the NNSA Field Office approved Triad's request for a 90-day extension for training required by DOE Order 426.2, *Personnel Selection, Training, Qualification, and Certification for DOE Nuclear Facilities*, because of social distancing impacts on the ability to conduct required courses.
- The NNSA Field Office is coordinating with DOE Headquarters on the need for other regulatory relief.
- Triad generated and distributed a video tailored towards craft workers discussing COVID-19 transmission, occupational risks, and best practices to minimize fomite spread and infection.
- On Thursday, Triad completed a shipment of waste to the Waste Isolation Pilot Plant.

Federal Oversight: In 2018, the NNSA and EM Field Offices both revised their processes for line management oversight and independent assessment activities of their contractors. Both offices experienced challenges implementing these processes in fiscal year 2019 and are working on improvements. For example, the EM Field Office completed 1 out of about 7 planned assessments of N3B functions related to safety at the nuclear facilities. Similarly, the NNSA Field Office completed 1 out of about 6 planned assessments of Triad functions related to safety at the nuclear facilities—the balance were either cancelled or delayed into this fiscal year. Notably, overall execution varied substantially between organizations. For example, the Quality Assurance organization completed 10 of 13 planned independent assessments mainly related to product acceptance, while the Field Operations organization did not complete any of its 3 planned independent assessments—2 were cancelled and one was actually executed as a shadow assessment.

Both offices were also challenged with their line management oversight. The data for the NNSA Field Office indicate that 20 people identified issues out of a staff of about 85; however, just 6 people were responsible for about 75 percent of the entries in the formal issues management system. Further review indicates that most issues have been dispositioned in a manner directed by senior management (typically email or verbal), rather than capturing in a contracting letter requesting formal resolution. While procedure allows this process for low risk issues, the lack of formality increases the difficulty for tracking, trending, and effectiveness reviews. Until recently, the EM Field Office had not been maintaining the results of its line management oversight in a systematic manner (see 3/6/2020 report). As a result, the resident inspectors cannot find credible data from last year to assess their federal oversight.

Last month, the NNSA Field Office completed an independent assessment of their Integrated Safety Management program and their oversight of the contractor's program. Notable results include: a finding that field office procedures have been chronically out-of-date and not reviewed per requirements; an observation that the field office has not completed a staffing evaluation; and a noteworthy practice regarding the effectiveness of the laboratory's Integrated Safety Management System Steering Committee.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 10, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending April 10, 2020

COVID-19 Impacts: The laboratory's operational posture remains similar to the end of last week. Developments this week include:

- Plutonium Facility leadership issued a policy describing the requirements for ramping up work, including additional specifics regarding occupancy limits in laboratory rooms and a process for subject matter expert review of activities where adequate spacing cannot be maintained.
- N3B and Triad provided guidance for wearing face coverings in facilities.
- Triad personnel completed two shipments to the Waste Isolation Pilot Plant (WIPP). Further shipments are on hold as WIPP management paused shipments for the next two weeks.
- N3B and Triad have implemented extensive remote learning programs offering lectures on topics such as criticality safety, conduct of operations, and plutonium metallurgy.

Area G–Safety Basis: On Thursday, the EM Field Office transmitted to N3B comments to be addressed regarding the draft safety basis in development for Area G (see 10/18/2019 and 3/20/2020 reports). The comments cover chapters 1 and 2 of the document with the most detailed comments related to the use and implementation of vehicle barriers protecting defined areas (locations specified within the safety basis as requiring controls to carry out process and storage activities). The field office comments propose more consistency and improved linkage of the safety basis and implementing procedures. Determining compliance with this control has been challenging (see 10/12/2018 report).

Transuranic Waste Management: Last week, the NNSA Field Office sent a letter to the Carlsbad Field Office requesting two revisions to the Basis of Knowledge (BoK), including: (1) accepting polysaccharides (e.g., cheesecloth) that have contacted nitric acid in concentrations of less than 12 molar and (2) broadly indicating that nitric acid at concentrations of less than 12 molar is not an oxidizer. DOE generated the BoK as part of a strengthened waste acceptance criteria for WIPP as a corrective action from the 2014 radiological release event. Specifically, DOE uses the BoK to screen for potential oxidizers in waste materials that could result in chemical exothermic reactions and propagating fires. As support for this request, Triad submitted testing results that indicate cheesecloth exposed to less than 12 molar nitric acid does not meet the UN Division 5.1 definition of a solid oxidizer. Triad also cited the Department of Transportation's oxidizer criterion for nitric acid of greater than 14.3 molar nitric acid. The resident inspectors note that application of these results should be treated cautiously, as pristine combinations of nitric acid and polysaccharide absorbents are unlikely to be found in nuclear process environments. Instead, metals are often present that form metal nitrate salts during evaporation resulting in complicated chemistries that can create materials that possess the EPA hazardous waste characteristic of ignitability (D001). For example, other LANL investigators found cheesecloth could not be sufficiently rinsed with water to remove the oxidizer property imparted through contact with five weight percent potassium nitrite (LA-UR-17-23809) and that cellulosic wipes contacted with nitrate salt surrogate solutions were ignitable (LA-UR-16-24408).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 17, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending April 17, 2020

COVID-19 Impacts: Staffing levels and work activities remain similar to last week. Developments this week include:

- Two Triad affiliated workers tested positive. They are associated with construction projects that have continued as part of reduced operations. The laboratory total is now four, including two N3B affiliated workers that tested positive earlier this month.
- In anticipation of increasing programmatic operations in the coming weeks, Plutonium Facility management conducted training on COVID-19 related safe work practices. Additionally, they began performing procedure reviews to determine whether processes can be performed while maintaining six feet of standoff between work crew members. They plan to implement additional mitigation measures for those actions that cannot meet this requirement.
- Triad personnel continued transuranic waste characterization and movement activities. They completed two shipments of waste from the Plutonium Facility to the Transuranic Waste Facility.

Plutonium Facility–Safety Basis: Late last month, Triad safety basis personnel noted that material-at-risk (MAR) tracking software applied a damage ratio of less than unity for credited containers that are nested within non-credited containers. They conservatively concluded that the actual damage ratio of a nested container configuration is unanalyzed. Analysts recalculated the MAR in the basement without applying a damage ratio for nested configurations and determined that they are approaching the limit. Last Friday, Triad submitted a safety basis change to the NNSA Field Office requesting a two-fold increase in the limit for basement waste MAR. Their technical justification for this increase states that doubling the basement MAR increases the mitigated consequences for the bounding accident from 3.0 to 3.3 rem to the public. Longer term, Triad plans to evaluate an appropriate net damage ratio for nested containers.

Federal Oversight: On Wednesday, NNSA Field Office management conducted a telephonic oral board for an emergency management specialist. The candidate passed the examination, which was executed well under the remote-work conditions. The NNSA Field Office is currently staffed with two emergency management specialists.

Continuous Improvement: Since November 2018, Plutonium Facility management has requested 50 causal analyses, including 42 during the first twelve months of operation, for events that procedures would not have required performance of a causal analysis. For comparison, the predecessor contractor requested eight non-mandatory analyses during their last year of operation. To enable this analysis workload, Plutonium Facility management increased the number of its causal analysts from one to five. They recently completed two reviews of the causal program. The first review initiated a periodic examination for trends and common causes, but found there was not yet sufficient data to draw defensible conclusions. The second review examined eight completed causal reports and found that only about 55 percent of the recommendations were being tracked to closure in the issues management system. Plutonium Facility management is developing an issues management improvement plan to strengthen several processes, including better integration of the causal analysis process with the issues management system. The resident inspectors note that the effectiveness of the program could be strengthened by formalizing some existing practices into a procedure covering the lifecycle of the causal process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 24, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 24, 2020

COVID-19 Impacts: Staffing levels and work activities remain similar to last week.

Developments this week include:

- Triad management continued development of COVID-19 related institutional command media and tabletop reviews of programmatic activities in the Plutonium Facility in anticipation of increasing operations.
- Triad personnel continued transuranic waste characterization and movement activities. They completed a shipment of waste from the Plutonium Facility to the Transuranic Waste Facility on Tuesday. On Thursday, they completed a subsequent shipment from the Transuranic Waste Facility to the RANT Shipping Facility in preparation of resuming shipments to the Waste Isolation Pilot Plant.

Plutonium Facility–Fire Protection: On Monday, Triad personnel completed an implementation verification review for safety basis changes associated with new diesel backup generators for the electric fire-water pumps (see 1/31/2020 report). There were no findings from the review. The generators now provide credited backup power to the pumps, which allows for additional operations flexibility. This is because required actions now only need to be taken when both a diesel fire water pump and an electric pump or its associated backup generator are inoperable. Prior to installation of the generators, the actions were required when only the diesel fire water pump was inoperable.

Federal Oversight: Last Friday, the NNSA Field Office issued an independent assessment report from their review of Triad’s Emergency Management Program. The review was conducted last August and September and used new criteria and review approach documents developed using guidance from the DOE/NNSA Office of Emergency Operations and Policy. The review identified one finding related to radiological control technician adherence to contamination control protocols at the hospital.

Readiness: On Thursday, N3B personnel telephonically convened their Joint Evaluation Team to review the proposed level of readiness review for the size reduction of the Corrugated Metal Pipes. N3B plans to install a manual roller conveyer and a diesel-powered hydraulic shear at the Dome 375 Permacon to enable movement of the pipes to be cut into sections appropriate to fit into a Standard Waste Box. After limited discussion, the team approved a recommendation for contractor and federal readiness assessments to be conducted in parallel in consideration of the COVID-19 circumstances. N3B will be submitting their proposal to the EM Field Office for approval.

On Tuesday, Triad sent their startup notification report for the third quarter to the NNSA Field Office for approval. Restart of aqueous nitrate operations is on hold for the calendar year; the projected startup of the venting of the Flanged Tritium Waste Containers at Area G is now summer 2020; and the projected startup of the Radiological Laboratory Utility Office Building as a hazard category 3 nuclear facility is July 2021.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 1, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 1, 2020

COVID-19 Impacts: Developments this week include:

- The Emergency Operation Center demobilized on Thursday from the monitoring mode they entered on March 9. COVID-19 coordination tasks will now be performed by Emergency Management Division personnel as part of their normal duties.
- The LANL Director conducted an all-managers virtual online meeting on Thursday to introduce a new institutional policy for COVID-19 risk and control measures for onsite work. The policy establishes controls for increased onsite work; however, the policy does not include prerequisite conditions or a schedule for resuming increased onsite work.
- Plutonium Facility personnel resumed additional mission critical manufacturing activities that had been paused for a regularly scheduled inventory of nuclear material.
- Chemistry and Metallurgy Research building personnel continued their second week of resumed operations in support of plutonium manufacturing.
- Triad personnel continued transuranic waste characterization and movement activities. They completed two shipments from the RANT Shipping Facility to the Waste Isolation Pilot Plant.
- N3B issued a standing order on Monday that defines COVID-19 expectations for performance of ongoing onsite activities.

Plutonium Facility–Training: During this period of reduced operations, Plutonium Facility personnel have continued to conduct oral review boards for a new “working person-in-charge” qualification. The board examines candidates on a variety of principals and policies associated with integrated work management and conduct of operations. Triad management has been adjusting practices and policies associated with the person-in-charge role in response to several abnormal events (see 3/22/2019, 4/19/2019, 12/6/2019 reports). On Thursday, a resident inspector observed one of the new boards and noted adequate conduct, including implementation of social distancing, and good performance by the candidate.

Weapons Engineering Tritium Facility: Last Saturday, the facility experienced a total loss of electrical power and facility personnel were unable to use the backup generator due to the location of the fault and equipment problems. The safety basis does not credit these systems; however, loss of power triggers certain required actions to be taken. In anticipation of an extended outage, operators took the safety basis required actions and reduced the facility mode to warm standby. On call linemen arrived, determined the issue to be a phase to phase arcing in a substation transformer primary, possibly due to an insect, and restored normal power to the facility. Facility personnel have been deliberately restoring systems during the course of the week. On Monday, they held a telephonic fact-finding to review the event. Overall, they noted an excellent off-hours response despite the COVID-19 situation. They also identified a repeat issue with the backup generator that would not have prevented this outage and the need to develop a procedure to facilitate use of a portable generator.

Management: On Thursday, Triad management announced changes to organizational reporting and personnel that transfers divisional accountability for transuranic waste management activities within the Weapons Production directorate to the Senior Director of Environment and Waste Programs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 8, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 8, 2020

COVID-19 Impacts: Developments this week include:

- Triad rolled out mandatory training for onsite work based on its new institutional policy.
- Plutonium Facility personnel continued to resume additional mission critical manufacturing activities that had been paused for a regularly scheduled inventory of nuclear material.
- Triad personnel continued transuranic waste characterization and movement activities. They completed two shipments from the RANT Shipping Facility to the Waste Isolation Pilot Plant.

Safety Basis: On Monday, the NNSA Field Office formally transmitted its review comments on Triad's revised Unreviewed Safety Question (USQ) procedure, which was submitted for approval in January. The field office requested a revised procedure incorporating necessary comments and official responses for any that remain unresolved. Comments from the field office included concerns regarding exclusions of certain types of documents, drawings, and activities from the USQ review; linkage of the USQ process with the New Information/Initial Confirmatory process; and a lack of timeliness requirements for preparation of Evaluation of the Safety of the Situation documents.

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office unconditionally approved the safety basis change associated with increased material-at-risk in the basement (see 4/17/2020 report).

Fire Protection: Arid, windy conditions drove the regional fire danger risk to its highest level, extreme, on Thursday. COVID-19 has not significantly impacted Triad's wildland fire mitigation team's vegetation control efforts. N3B personnel are also continuing with fuel mitigation efforts within Area G.

Transuranic Waste Management: Triad and N3B personnel continue to establish processes and procedures to enable the use of the RANT Shipping Facility for the EM owned waste stored at Area G. Eventual achievement of this capability will represent a positive step toward risk reduction for the overall laboratory, particularly since the waste at Area G is the least well protected and mobile loading operations are highly weather constrained. So far this fiscal year, Triad has been able to complete 15 shipments to the Waste Isolation Pilot Plant, while N3B has completed just one.

Area G: On Wednesday, N3B personnel held a teleconference with EM Field Office and Headquarters personnel to discuss their proposal to conduct an upcoming contractor and federal readiness assessment in parallel for size reduction of corrugated metal pipes. No decision was reached, but they agreed to research historical EM direction that prohibited such a parallel approach and conduct a more thorough analysis of the benefits and disadvantages for this and future readiness assessments. N3B managers also noted that in order to utilize the parallel approach, they need field office approval of the revised readiness process procedure that was submitted in November 2019.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 15, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plae and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending May 15, 2020

COVID-19 Impacts: The nuclear facilities continue with routine entry into their normal operation modes as defined in their safety bases to support programmatic work. Developments this week include:

- Positive cases at the laboratory are now at 11, including an individual confirmed this week that recently performed duties at the Plutonium Facility.
- Triad personnel completed a pilot effort for drive-up COVID-19 specimen collection and onsite analysis. They tested 49 priority workers (e.g., first responders, medical staff, and mission essential personnel) and plan to ramp up mandatory, random testing from such priority work groups in the coming weeks pending the availability of collection supplies. They are also experimenting with an alternative approach for self-collection of saliva that could substantially increase the number of weekly onsite tests.
- Triad personnel continued transuranic waste characterization and movement activities. They completed two shipments from the RANT Shipping Facility to the Waste Isolation Pilot Plant. They also relocated non-destructive assay equipment to the Transuranic Waste Facility and plan to begin certified measurements next week.

Safety Basis: Subsequent to a discussion with the NNSA Field Office, Triad safety basis personnel entered their New Information process on Wednesday to evaluate whether the safety basis appropriately considers hazards from an aluminum-skinned plywood trailer parked adjacent to transuranic waste containers. The trailer has an interior consisting of substantial wooden shelving used to store combustible supplies. Plutonium Facility management also engaged fire protection engineers to evaluate this condition. On Tuesday, Triad safety basis personnel entered the New Information process to evaluate whether the collapse of the canopy area at the RANT Shipping Facility is analyzed to impact transuranic waste containers.

Federal Oversight: On Wednesday, the NNSA Field Office closed the final three issues from the last biennial review conducted by NNSA's Chief of Defense Nuclear Safety (see 3/17/2017 report). Overall, they addressed 178 individual issues through the execution of 378 corrective actions. The next biennial review of the field office was planned for last month, but has been delayed due to the pandemic.

Plutonium Facility–Operations: Last Thursday, a worker dropped a container of nuclear material while passing it between gloveboxes on his fingers resulting in a bone fracture. There was no glove breach. The manual transfer was needed because the engineered material transfer system supporting these boxes is out of service. Facility management is evaluating guidance on how to manually move heavy containers in gloveboxes. They also added a note in the shift orders reminding personnel to ensure all required notifications are made for injuries, since that did not occur with this event.

Plutonium Facility–Construction Safety: Last Tuesday, an excavation subcontractor struck an electrical conduit while working on the Construction Support Facility, which is located adjacent to an outdoor waste storage pad. The subcontractor's excavation exceeded the boundary of where utility potholing had been performed. Workers immediately paused work and excavation activities remain paused for this project. Triad personnel later verified that the conduit was de-energized and believe it to be abandoned from a past security infrastructure upgrade project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 22, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 22, 2020

COVID-19 Impacts: The nuclear facilities continue with routine entry into their normal operation modes as defined in their safety bases to support programmatic work. Triad implemented new controls for onsite work including mandatory use of face coverings in common areas and random testing of priority worker populations (e.g., first responders, mission essential staff, and positions that require high social contact). Triad personnel continued transuranic waste characterization and movement activities. They completed two shipments from the RANT Shipping Facility to the Waste Isolation Pilot Plant.

Plutonium Facility–Operations: Last week, facility personnel opened a shipping cask containing plutonium heat source material received from the Idaho National Laboratory in 2016. On Wednesday, facility personnel noted that the SAVY container, which was the credited barrier in the configuration, from the cask contained more units than allowed by an associated specific administrative control that protects the thermal limit for the SAVY. Accordingly, facility management declared a violation of the Technical Safety Requirements. At the fact-finding, involved personnel noted that there were gaps between the implementation matrix for the approved safety basis and the procedures used to perform this activity consistent with the applicable specific administrative control (see 12/20/2019 report). Triad personnel plan to perform a formal causal analysis on this event and evaluate the procedures used for this activity. The heat source material has been introduced into a glovebox and no longer relies on its container.

The Resident Inspectors walked down the facility on Thursday. Observations include:

- Workers were actively reducing the number of process residue containers that have been accumulating in the floor storage area of a processing room (see 6/28/2019 report). There are now about 90 containers in the location and the workers have implemented a tracking grid to facilitate easier management.
- The majority of rooms have occupancy limits posted at entrances in a standardized location used to alert workers for room-specific conditions. As a best practice, one room with a high work tempo had a small whiteboard on the door to track occupants. Notably, facility management established occupancy limits that accommodate federal oversight personnel.
- Workers inside the facility were generally adhering to COVID-19 controls and expressed confidence in those controls.
- Waste management personnel relocated the trailer loaded with combustibles further away from transuranic waste drums. Safety basis personnel continue to determine whether the previous location represents a potential inadequacy of the safety analysis.
- Senior Weapons Production managers were performing a facility walkdown.

Radiological Laboratory Utility Office Building: Last week, the NNSA Field Office provided minor adjustments, but overall concurred with Triad's strategy for addressing the fire protection deficiencies in the building (see 3/27/2020 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 29, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 29, 2020

COVID-19 Impacts: The nuclear facilities continue with routine entry into their normal operation modes as defined in their safety bases to support programmatic work. Triad personnel continue to incrementally increase onsite programmatic work at the Plutonium Facility, the Chemistry and Metallurgy Research building, and the Weapons Engineering Tritium Facility. They also continued transuranic waste characterization, movement, and shipping activities.

Flanged Tritium Waste Containers (FTWC): On Wednesday, Triad personnel performed a practice evolution in Technical Area 49 for venting of the FTWCs stored at Area G. Personnel worked through the entire procedure using a combination of mockups and actual equipment. The major activities include: installation of the vent rig, leak testing, initial venting, additional venting as needed, and movement of the FTWC from the shed to a truck using a remote-controlled skid-steer conveyance. They identified the need for changes to the venting procedure and other improvements to the process.

Plutonium Facility–Safety Basis: Last Friday, facility management declared a potential inadequacy of the safety analysis after analysts completed their review of the trailer loaded with combustibles parked in proximity to transuranic waste containers (see 5/15/2020 report). Safety analysts concluded that the as-found configuration was inaccurately reflected in the assumptions associated with the applicable hazard analysis event, which is a refueling accident. In particular, they noted that the presence of the trailer challenged the assumption in the event that the historically low amount of ordinary combustibles present in the location meant that the refueling accident bounds the frequency and consequences of an ordinary combustible fire. We note that there are more fundamental problems with the original event logic, as the controls for a liquid pool fire are different than an ordinary combustible fire. As a compensatory action, management had the trailer relocated further from the containers shortly after the question was raised.

Engineering: Last Friday, Triad management sent the NNSA Field Office a letter requesting review and approval of its ten year assessment plan for natural phenomena hazards (NPH). DOE Order 420.1 C, *Facility Safety*, requires each site to review its NPH assessment every ten years for any significant changes in data, criteria, and assessment methods that would warrant updates. Triad noted the predecessor contractor had completed such an assessment in 2014, but could find no evidence that the field office approved the plan as required. The 2014 plan notes that the primary NPH in need of an update based on the last analyses are seismic (2007); volcanic (2004); wind and wind borne missiles (2004); flood, precipitation, snow and ice cover (2004); and landslides (2004). The letter notes that subsequent analyses for wind and precipitation-related hazards were completed in 2015. However, the letter does not provide an update to the schedule for completing the remainder of the analyses—the schedule in the 2014 plan was incomplete for some analyses (e.g., volcanic) or has deadlines that have passed (e.g., seismic in September 2019). The letter commits to submitting the next ten year assessment plan by 2024. The NNSA Field Office has requested headquarters support to review the plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 5, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 5, 2020

COVID-19 Impacts: The nuclear facilities continue with routine entry into their normal operation modes as defined in their safety bases to support programmatic work. Current activities at the Plutonium Facility include casting, electrorefining, heat source plutonium processing, and elimination of production residues. Triad personnel also continued transuranic waste characterization, movement, and shipping activities with another two shipments completed from the RANT Shipping Facility. These shipments consisted of standard waste boxes with high fissile gram equivalent drums. This is the first shipment of standard waste boxes from the RANT Shipping Facility since its restart in 2019.

Plutonium Facility–Operations: Triad management recently initiated a formal second work shift focused primarily on equipment upgrades supporting pit manufacturing and completion of radiological control tasks. The second shift alleviates some COVID-19 challenges with co-located programmatic and installation work during the day shift. The NNSA Field Office has out-year plans for increased field staff to accommodate shift work and is developing a strategy for oversight in the interim.

Plutonium Facility–Emergency Management: Last Tuesday, workers bumped a glovebox thermal detector while erecting scaffolding resulting in a fire alarm and emergency response. On Monday, facility personnel conducted a fact-finding on this event. This was the third fire response resulting from inadvertent insults to fire protection equipment in 2020. Given the recurrence, fact-finding personnel determined the need to further assess construction type activities near fire devices. They also discussed discrepancies in the institutional reporting of the event that reflected a response to an adjacent administrative building rather than the nuclear facility.

Area G–Contractor Assurance: Last month, N3B closed out its corrective action associated with the technical safety requirement violation for multiple failures to complete vegetation inspections and cutbacks during wildland fire season, as well as maintain the records (see 12/20/2019 report). N3B management screened the issue as low significance in accordance with the DOE occurrence reporting system criteria, which then translated into a low significance categorization in the N3B issues management process. Of note, the N3B process does not preclude management from assigning a higher significance level and even suggests a moderate designation for compliance issues that impact safety. The benefits of a moderate or high significance level include additional rigor such as detailed causal analysis, management review board screenings, and effectiveness evaluations. In this case, as a low significance issue, the N3B responsible manager determined the corrective action to be a revision to the associated procedure. On Tuesday, the resident inspectors observed in-progress shrubbery mitigation and an overall improvement to the state of vegetation control compared to last month.

Federal Oversight: Two weeks ago, the NNSA Field Office issued its self-assessment of their Nuclear Maintenance Management Program. The report included one finding that field office personnel had not performed a comprehensive assessment of the contractor's maintenance management programs within the three year frequency in accordance with DOE Order 413.1B, *Maintenance Management Program for DOE Nuclear Facilities*. This issue was also contained in the 2017 biennial review by the Chief of Defense Nuclear Safety. Field office personnel have an oversight plan in place to complete the required assessment and resolve this issue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 12, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 12, 2020

COVID-19 Impacts: On Monday, the NNSA and EM Field Offices, as well as N3B entered phase 1 of their resumption plans. Triad continues to perform essential functions and is gradually increasing onsite work in accordance with their institutional policy for COVID-19 controls.

Plutonium Facility–Glovebox Safety: On Monday, continuous air monitors sounded when an operator pulled out of the glovebox gloves after weighing and packaging plutonium-238 oxide powder. The worker received significant contamination on his protective clothing, hair, and skin, as well as positive nasal swabs indicating a potential intake. Radiation protection personnel successfully decontaminated the individual, and he was provided chelation therapy. The room experienced significant airborne radioactivity and was contaminated. Fourteen additional workers were placed on bioassay. On Thursday, Triad management conducted a fact-finding to discuss the event, response, and near-term actions. Given the significance of the event, they chartered a team to perform a comprehensive investigation.

Area G–Emergency Management: Last Saturday, high winds damaged an electrical pole near the operations center. The loss of power triggered trouble alarms from impacted fire panels. Upon responding, N3B personnel observed a smoking pole and damage to the electrical equipment so called Triad utilities personnel and the fire department. Following this initial response, N3B personnel noted an emergent brush fire adjacent to the pole which was promptly extinguished by the fire department. While the offshift response was prompt, communications for the brushfire did not reach all parties in a timely manner. Power was restored and the fire panels were back in service by the end of the week.

Transuranic Waste Management: On Monday, workers successfully changed the corroded filters found on seven waste containers first discovered last May (see 5/24/2019 and 9/6/2019 reports). The workers noted varying levels of corrosion, but no occlusion of the filter vent path. They are currently evaluating the need to replace a corroded filter on another container recently returned from the Transuranic Waste Facility. They are also working with the Carlsbad Field Office to determine whether any actions are necessary to prevent recurrence with this waste matrix.

Area G–Readiness: N3B and EM personnel decided to setup a routine standing meeting to discuss upcoming readiness activities. They realized that better attendance, to include EM Headquarters readiness personnel, is necessary to reduce the backlog of approvals needed for the slate of upcoming readiness reviews. For example, the EM Field Office has not acted on one of N3B's quarterly startup notification reports since April 2019. Similarly, N3B has been waiting for approval of its revised readiness process since November 2019.

Legacy Facilities: On Wednesday, EM Field Office personnel and N3B program management accompanied the resident inspectors on a walk-down of Technical Area 21. The focus of the walk-down was familiarization with planned decontamination and demolition of an old radioactive liquid waste treatment facility and associated industrial liquid waste lines that are radioactively contaminated. EM and N3B are currently assessing the impact of higher than expected results from a recent radiological characterization on the path forward for the removal of these structures.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 19, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 19, 2020

DNFSB Staff Activity: On Thursday, a DNFSB Headquarters staff team conducted a telephone conference with Triad and NNSA personnel to discuss the re-designation of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility to be termed PF-400. The discussion covered the safety and control strategy, as well as the current concerns related to the design and installation of key active support systems in the facility (see 3/27/2020 report).

Plutonium Facility–Accident Investigation: On Wednesday, Triad management issued a charter for a team to investigate last week’s airborne exposure of workers to heat source plutonium (see 6/12/2020 report). The team’s mandate includes: development of a comprehensive articulation of the facts and timeline; an assessment of glove surveillance and maintenance to include a review of the past two years of glove breaches; an assessment of the radiation protection and occupational health responses; an evaluation of the effectiveness of the corrective actions taken after the July 2018 puncture wound; and a causal analysis supported by a human performance evaluation to inform recommended corrective actions. The team includes several members from other sites and is expected to complete its work by July 17, 2020.

Chemistry and Metallurgy Research (CMR) Building: In late May, CMR personnel began flammable gas sampling on 9979 containers containing enriched uranium materials in preparation for shipment offsite to support risk reduction at the facility. Several of the containers had unexpectedly high hydrogen levels with one approaching the lower flammability limit. Safety basis personnel entered the New Information process to evaluate this condition. In 2018, a similar entry into the New Information process concluded that the safety analysis was adequate based on predicted hydrogen generation rates. Facility personnel plan to sample more of the 9979 containers in CMR and vent those with elevated readings. This process is awaiting an update to the criticality safety evaluation, which does not explicitly allow sampling or venting of these containers.

Transuranic Waste Facility (TWF)–Operations: Last Thursday, during flammable gas sampling activities, a worker noted that a filter on a transuranic waste drum was loose. The safety basis requires containers that have questionable integrity to be overpacked or the integrity restored within seven days of discovery. In this case, facility operators contacted the laboratory’s HAZMAT team and they overpacked the drum into an 85 gallon drum later the same day. TWF personnel only have the capability to overpack drums into standard waste boxes, and in this case they considered the 85 gallon drum overpack a better option. Last December when a worker found damage to the filter medium, one of the corrective actions was to evaluate adding capabilities for TWF personnel to overpack drums without relying on institutional HAZMAT personnel (see 12/20/2019 report). They concluded there was a need to develop that capability; however, the action to develop a procedure has been extended twice and is currently scheduled to be completed in September. After this event, TWF management took an action to evaluate the need for safety basis coverage and procedures to recover from other common off-normal conditions such as changing filters on waste containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 26, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 26, 2020

Plutonium Facility–Glovebox Safety: On Monday, Triad’s team investigation commenced in response to the heat source plutonium airborne release event (see 6/12/2020 report). This week, the team conducted interviews of the involved workers, radiological control technicians, procurement and training personnel, and line management. In parallel with the investigation, Triad management issued two standing orders defining interim compensatory measures for glovebox glove inspection and replacement criteria. The first standing order, issued last Thursday, was specific to heat source plutonium operations. On Monday, management issued the second standing order, which applies to all glovebox operations within the directorate. Key compensatory measures in both standing orders include: workers must inspect their gloves prior to exiting them, supervisors will review glovebox training with all workers, and the threshold for taking gloves out of service for issues found during inspection has been reduced.

Plutonium Facility–Radiological Safety: On Thursday, Triad management paused repack, consolidation, and discard operations of legacy nuclear materials after an event revealed inadequate radiological controls for a legacy item with high radiation levels. The event resulted in a worker receiving an unexpected level of radiation exposure. Next week, they plan to reconvene a fact-finding that partially completed on Wednesday.

Chemistry and Metallurgy Research Building: On Friday, Triad personnel concluded the discovery of elevated hydrogen levels in 9979 containers constituted a potential inadequacy of the safety analysis because these containers are not currently covered by existing flammable gas controls. Facility personnel started venting the elevated containers on Wednesday. Triad personnel are evaluating why some of the materials in these containers generated gas at a much higher rate than expected.

Weapons Engineering Tritium Facility: On Monday, Triad personnel shipped one Flanged Tritium Waste Container (FTWC) to the Nevada National Security Site. This shipment represents the first successful offsite disposal of a FTWC and the first FTWC disposed of in about a decade. This is one of the five FTWCs without a flammable gas hazard currently stored in the facility. Removing these FTWCs clears up needed floor space for receipt and processing of the FTWCs at Area G that need to be vented.

Federal Oversight: On Monday, Mr. Kirk Lachman assumed the position as manager of the EM Field Office. Also on Monday, a 15 person team from DOE’s Chief of Nuclear Safety commenced the desktop review phase of an audit on nuclear safety functions at the EM Field Office. This first phase focuses on the procedures and oversight actions related to nuclear safety oversight and nuclear readiness activities, as well as nuclear safety staffing resources. A subset of the team plans to perform a future second phase to include onsite interviews of federal and contractor staff, as well as targeted observations of operations and meetings in relevant functional areas. This is a pilot audit for a larger effort to be executed at other Environmental Management field elements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 3, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 3, 2020

Plutonium Facility–Radiological Safety: On Tuesday, Triad personnel reconvened their fact-finding to better understand the unexpected radiation exposure during analysis of a legacy item (see 6/26/2020 report). The item in question originated in 1990 and was removed from the vault in 2018. In November 2019, chemistry personnel received a portion of the item. In December, they received the remaining pieces of the item into a glovebox without leaded gloves or shielded windows. Breakdowns in communications meant that chemistry personnel did not realize the item represented a significant gamma radiation exposure hazard (approximately 3 rad/hour on contact, 300 millirad/hour at 30 cm). Consequently, the chemistry personnel performed the analytical work on the item without using a radiological work permit or with supplemental dosimetry. This meant that management did not discover the elevated radiological exposure until after measurement of the worker's quarterly dosimeter. The item remains in the analytical chemistry box with temporary shielding until a recovery plan is completed. Repack, consolidation, and discard operations of legacy nuclear materials remain paused, and facility management is evaluating radiological controls for high dose items.

Plutonium Facility–Infrastructure: The cross-town trolley has been out of service since it ran into a closed damper door at the beginning of June. This trolley connects the trolleys that service each of the four laboratory area. As a consequence, intra-area trolley transfers have been hampered. The trolley bucket is stuck with a container of nuclear material inside; however, the location is not creating any radiological exposure concerns. Last week, facility personnel entered their potential process deviation process to formally document the evaluation of the criticality safety of the configuration and formalize the recovery path forward. Criticality safety personnel confirmed the existing configuration is analyzed and safe, but also noted the importance of ensuring compliant use of connecting boxes. Maintenance personnel are developing work documents to restore operability in the near future. A replacement project for the trolley system is still in progress. The replacement trolley is expected to use more sophisticated control systems to prevent these types of problems.

Area G–Readiness: On Tuesday, N3B submitted to the EM Field Office their startup notification report for the third quarter of 2020. The report identifies three planned readiness activities and levels that require field office approval. The activities are glovebag drill and drain operations in the Dome 231, retrieval of the corrugated metal pipes, and size reduction of the corrugated metal pipes in Dome 375. They have proposed the cognizant secretarial officer as the approval authority for all three activities. Notably, N3B is no longer proposing parallel contractor and federal assessments due to the COVID-19 pandemic (see 5/8/2020 report). The EM Field Office last formally responded to one of N3B's startup notification report in April 2019 (see 6/12/2020 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 10, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 10, 2020

COVID-19 Impacts: There were nine new positive test results for the laboratory workforce this week for a total of 23, 11 of whom have recovered. Three of the new cases are workers associated with the Plutonium Facility.

Plutonium Facility–Radiological Safety: On Monday, the first of two workers preparing to exit the facility alarmed the contamination monitor. Radiological control technicians (RCT) released that worker, but identified contamination on the second worker, including about 200 dpm of alpha on the left and right sides of the face. RCTs successfully decontaminated the worker. The worker had been adjusting equipment underneath and above a glovebox used to process plutonium-238. During the fact-finding, participants discussed several key points of the event including: (1) integrated work documents for the activity identified the use of the 73 page facility radiation protection program document as a control for contamination hazards without further specificity; (2) the document requires RCT support for entry into non-routinely entered spaces—RCT management understood this to be locations like underneath and the top of gloveboxes, but the operations group did not appreciate this distinction since they accessed these spaces several times a week; (3) during the equipment adjustments, the worker identified contamination on his gloves and changed them, but did not contact an RCT in accordance with the document; (4) the worker also alarmed a hand and foot monitor when attempting to depart the laboratory room, but responding RCTs did not perform a whole body survey as expected; (5) discussion as to whether a whole body survey included the face and head; and (6) the work team expressed concerns that the face covering worn for COVID-19 reasons created the need to instinctually adjust the covering and eye protection without surveying gloved hands.

On Wednesday, Weapons Production management convened an unscheduled management review board (MRB) after considering the event described above, the plutonium-238 release event (see 6/12/2020 report), and the unexpected radiation exposure of a worker (see 7/3/2020 report). The MRB heard details of these events, as well as the results of a causal analysis associated with an uptick in the number of skin contamination events. They identified a number of corrective actions associated with radiological protection requirements and training, as well as strengthening behavioral based safety practices across the directorate.

Legacy Facilities–Safety Basis: On Tuesday, N3B sent a letter to the EM Field Office requesting a variance to their approved unreviewed safety question (USQ) procedure. The variance seeks to use the USQ procedure, which only applies to hazard category 2 and 3 nuclear facilities as currently written, for the TA-21-257 radioactive liquid waste facility and the adjacent inactive underground industrial waste lines (see 6/5/2020 report). These locations are currently considered less than hazard category 3 nuclear facilities. If the variance is approved, N3B would then enter their USQ process to address recent radiological characterization data that was higher than expected.

Area G–Operations: N3B and Central Characterization Project personnel successfully completed two shipments of transuranic waste to the Waste Isolation Pilot Plant using the mobile loading unit. The last mobile loading shipment from Area G was in October 2019.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 17, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 17, 2020

Plutonium Facility–Glovebox Safety: On Tuesday, the Triad investigation team for the glove breach and airborne release event briefed preliminary results to senior leadership at the NNSA Field Office (see 6/26/2020 report). They found the root cause of the event to be a less than adequate glovebox glove integrity program. Three contributing causes included: less than adequate implementation of glove inspections prior to hand removal; management’s failure to ensure compliance with existing requirements for contamination monitoring; and the use of a new type of glove with a different thickness and insufficient spare parts. The team proposed many recommendations to improve glovebox operations in the facility including: improving the glove integrity program; formalizing and training expectations for glove use including self-inspections; and evaluating engineered solutions to high hazard operations for reduce hands on work. The team is finalizing the investigation report which is expected next Friday.

Federal Oversight: On Friday, the team from the DOE Office of Environmental Management’s Chief of Nuclear Safety briefed the results of the desktop review phase of their audit on nuclear safety functions at the EM Field Office (see 6/26/2020 report). The team identified five management concerns (defined as significant issues requiring causal analyses) and five findings (defined as violations of requirements), subject to a factual accuracy review. The final report is expected next month and the schedule for the second phase, which includes onsite activities, remains uncertain. Notably, the audit was entirely executed using telework methods.

Area G–Safety Basis: Last week, N3B management declared two potential inadequacies of the safety analysis (PISA) associated with questions concerning: (1) the assumed depth of a fuel pool fire that could impact the number of waste containers impacted and (2) the presence of pipe overpack containers with greater than 80 plutonium-239 equivalent curies that are placed inside a second container—a practice known as doublepacking. EM Headquarters personnel raised the first question during the ongoing federal review of the evaluation of the safety of the situation concerning aisle spacing that was transmitted to the EM Field Office for approval on March 19, 2020. N3B personnel identified the original issue on January 7, 2020 (see 1/10/2020 report). N3B personnel discovered the second issue while conducting a field validation to respond to a Triad inquiry. As a compensatory measure for both issues, N3B management reduced the amount of liquid fuel allowed from 100 to 70 gallons. At the fact-finding, N3B personnel also discussed the need to fully characterize the inventory of pipe overpack containers for the presence of the new fusible filters and expedite replacements. The use of these filters fully protects these containers from fuel pool fires (a damage ratio of zero).

Weapons Engineering Tritium Facility: On Tuesday, subcontractor personnel supporting HVAC upgrade activities noted they had passed a hold point in their work package and reported this to facility management. Further evaluation determined that an individual performed work on an energized system because a lockout/tagout was not installed as required by the work package. Management has paused the work activity while they evaluate corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 24, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 24, 2020

Plutonium Facility–Glovebox Safety: On Tuesday, a glovebox glove failed when a worker was entering the gloves to perform work. One glove and its support ring separated and moved into the interior of the glove box propelled by the worker's arms. The worker followed standard glove breach protocols and remained with his hands in the box until radiological control technicians could assist. There was contamination on the worker's personal protective equipment, but no skin contamination or indications of an airborne release. The glovebox is used for operations with plutonium metal. This is the first known failure of a glove in this manner during operations. The glove in question was installed in May 2019 and has been frequently used. Triad personnel are attempting to determine the cause of the failure.

Safety Basis: On Monday, the NNSA Field Office transmitted to Triad the Board's letter dated July 10, 2020, regarding complex-wide implementation of the potential inadequacy of the safety analysis process. Their transmittal noted the similarity of some aspects of the report with recent NNSA Field Office review comments on Triad's revised Unreviewed Safety Question procedure. They encouraged Triad to consider the information in the Board's report when addressing the field office comments.

Chemistry and Metallurgy Research Building–Safety Basis: On Monday, Triad transmitted a safety basis addendum to the NNSA Field Office and requested its approval. The addendum adds a new specific administrative control for the hot cells that provides an alternative control to protect workers from high radiation fields in the event the current safety-significant interlocks are inoperable. Triad proposed this administrative alternative since spare parts for the existing system are not available, and programmatic use of the hot cells is expected to be completed within a year.

Radioactive Liquid Waste Transuranic Treatment Facility: On Monday, the NNSA Field Office disapproved revision 6 of the safety design strategy for the Transuranic Liquid Waste project pending resolution of comments. Notable comments include the need to: validate the bases for capability given changes to the programmatic mission; validate the preliminary seismic category and limit state determination; develop a confinement strategy; and address DOE-STD-1189 expectations to list major process assumptions. In parallel with this effort, Triad personnel continue to resolve equipment issues needed to make the new Low Level Liquid Waste facility operational following completion of that project in November 2018 (see 1/2/2020 report).

Emergency Management: During the course of the week, lightning appears to have started four small wildland fires in the vicinity of the laboratory. Triad's emergency management personnel monitored the situation, while assets from a number of entities responded and successfully contained the fires. Increased moisture during the latter part of the week has also contributed to a reduced fire danger.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 31, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 31, 2020

N3B—Organizational Learning: Last Thursday, N3B senior management paused activities at Area G and then held a company-wide stand down. The instigating events at Area G included: a work package did not include beryllium controls, a vegetation cutback crew damaged an out of service communications line, and a shipment of low-level waste arrived at an offsite disposal facility with a container tipped over. Management had also noted a trend of events in transuranic waste operations since the end of June. Following briefings to the workforce, N3B management lifted the pause with the exception of low-level offsite waste shipments.

Flanged Tritium Waste Containers: Earlier this month, Triad personnel completed their management self-assessment of planned venting operations at Area G and subsequent transport to the Weapons Engineering Tritium Facility (WETF). The assessment overcame an interruption and challenges associated with COVID-19 related controls. Of note, they took advantage of video footage, including from an unmanned aerial system, to provide assessors with observations of the demonstrated activities. WETF personnel are working through corrective actions and plan to commence the contractor readiness assessment in mid-August. Triad personnel are working through logistics to bring in members of the assessment team from out-of-state locations, since requirements for self-quarantine differ between NNSA and EM operations at the laboratory.

Chemistry and Metallurgy Research Building—Safety Basis: On Friday, Triad submitted to the NNSA Field Office the evaluation of the safety of the situation for the anomalous hydrogen levels in 9979 containers (see 6/19/2020 report). Triad personnel vented the container that was approaching the lower flammability limit at the end of June as the sole operational restriction. The proposed compensatory measures did not add any formal controls. Rather, they will add gas sampling and venting of 9979 containers to existing processes. The NNSA Field Office is reviewing the submittal.

Chemistry and Metallurgy Research Building—Risk Reduction: On Tuesday, the resident inspectors walked down the facility with Triad personnel to observe progress on activities to support future decontamination and demolition activities (see 11/8/2019 report). The initial phase of material removal is complete with approximately 100,000 pounds of low-level waste removed. Electrical disconnects in inactive wings are in progress. Triad has awarded the subcontract for more invasive equipment removal and work planning is in progress. Triad has also begun emphasizing the need for chemistry personnel to smartly ramp down operations in the coming years (e.g., perform wipes downs, complete characterization swipes, and document knowledge transfer).

Emergency Management: On Thursday morning, a 3.7 magnitude earthquake occurred approximately 50 km northwest of the laboratory. Several locations on site, including the Emergency Operations Center, reported minor shaking. There was no damage.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 7, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 7, 2020

Plutonium Facility–Safety Basis Compliance: Last Thursday, workers checking material-at-risk (MAR) values for waste containers in the basement found one with an unexpectedly high value. They noted the container was a pipe overpack rather than a 55-gallon drum as indicated in the records. The safety basis allows a damage ratio to be applied for pipe overpack containers thereby reducing the effective MAR. Further investigation discovered eighteen drums and pipe overpacks that were incorrectly identified as the other type. The work team paused and reported this discovery to operations center personnel who entered the limiting condition for operation related to MAR. Once personnel completed a MAR surveillance, the limiting condition for operation was exited and the pause lifted. At the fact-finding, personnel noted challenges with the efficacy of training to correctly distinguish between various waste containers in order to select the correct type from drop down listing of many containers. We note that the high reliance on container damage ratios in the safety basis complicates operations and that similar challenges have occurred with containers used for nuclear materials (see 7/3/2015 report).

Radiological Laboratory Utility Office Building: Last week, workers receiving a sample shipment from the Chemistry and Metallurgy Research building noted a discrepancy between the expected condition and data recorded on the shipping paperwork. They paused and reported the discrepancy. Further investigation showed that there are several different forms associated with shipments. The forms are inconsistent and some had incorrect information. All MAR coming into the facility must undergo evaluation to ensure that facility MAR limits are maintained. The shipment in question was small and did not approach any facility MAR limits once operators correctly accounted for the contents. Facility management has paused sample receipt while they evaluate near-term corrective actions. They also plan to more thoroughly evaluate the process for receipt of MAR, which will be elevated to a technical safety requirement when the facility transitions to a hazard category 3 nuclear facility to be referred to as PF-400.

Last Thursday, the NNSA Field Office disapproved revision 1 of the safety basis for the PF-400 facility. The field office noted that several of its previous comments were inadequately addressed and they also identified two new comments that require resolution.

Plutonium Facility–Glovebox Safety: On Monday, Triad management transmitted to the NNSA Field Office the final report for the causal analysis and investigation on the glove breach and plutonium-238 uptake event that occurred on June 8, 2020. The report is largely consistent with the results they previously briefed to field office management (see 7/17/2020 report); however, it does identify recommendations to address twelve related concerns that were not causal to the event. Notable recommendations include the need to evaluate: engineered solutions to reducing hands-on work with plutonium-238; annunciation volumes for continuous air monitors across the plant; responsibilities to identify and obtain critical spares for consumable equipment; and the tradeoff between the reductions in extremity radiation exposure from the use of lead lined gloves against the loss of glove strength.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 14, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 14, 2020

Flanged Tritium Waste Containers (FTWC): On Monday, a team composed largely of external personnel commenced the contractor readiness assessment for the venting and transportation of the FTWCs with potentially flammable headspace mixtures that are stored in Area G. The team observed demonstrations of venting and movement activities performed at the mockup facility at Technical Area 49, observed an emergency drill performed at Area G, and conducted numerous interviews. Three NNSA personnel shadowed these activities and EM personnel performed limited oversight of the drill. The startup approval authority for this activity is EM Headquarters. They are currently discussing with the NNSA Field Office on whether additional performance demonstrations will be conducted for observation by federal personnel.

Emergency Management: At the hotwash for the FTWC drill discussed above, N3B personnel noted that they did not receive protective action information from Triad's site-wide mass notification system. In follow-up discussions, Triad management explained that they send messages based on office locations and that there were no offices associated with the affected portion of Area G. As a result, N3B personnel only received notifications from their operations center and not a second anticipated message from Triad. We note that the office based approach to mass notification is ineffective at Area G due to the lack of offices and transient nature of the workforce—points that apply broadly to the whole laboratory and were documented in the Board's letter dated October 11, 2017. Subsequent to the Board's letter, Triad documented additional instances of problems with this system in several after-action reports, most recently including the exercise conducted at Area G on February 19, 2020. Notwithstanding the above concern, corrective actions from that exercise proved effective during this drill, including improved coordination between the operations center and emergency management.

Legacy Facilities: Last Wednesday, EM Headquarters approved the variance N3B requested to its unreviewed safety question procedure (see 7/10/2020 weekly). Last Thursday, N3B used this variance to declare a potential inadequacy of the safety analysis regarding a higher than expected radionuclide inventory for the TA-21-257 radioactive liquid waste facility and the adjacent inactive underground industrial waste lines. N3B revised the facility hazard categorization and concluded these facilities contain hazard category 3 quantities of nuclear materials. N3B paused work on these facilities. They are developing the facility hazard categorization documentation to allow for additional sampling and characterization activities to support planning of deactivation and decommissioning work. They also plan to perform a formal causal analysis.

Area G—Corrective Actions: Last Friday, N3B safety basis personnel noted that the daily shift order in place to address the recent potential inadequacies of the safety analysis (see 7/17/2020 report) was insufficient. Specifically, they identified that there is no analysis for the behavior in a fire of a pipe overpack container (POC) that is also overpacked. Consequently, the existing shift order that lowered fuel limits did not protect them from a fire insult. The facility's fuel log showed that fuel had been in the vicinity of the two relevant POCs since the shift order was issued on July 1, 2020. On Thursday, N3B personnel issued a new daily shift order that prohibits all fuel in the vicinity of the two POCs. Longer term, they plan to replace the POC filters with the new fusible model that will allow a damage ratio of zero for the POCs. N3B management is also evaluating how an inadequate corrective action was enacted for a safety basis issue.

Engineering: Last Thursday, the NNSA Field Office approved Triad's ten-year update to the natural phenomenon hazards analysis developed in 2014 (see 5/29/2020 report). They further concurred with Triad's plan to complete the update within 3 years not to exceed September 2024.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 21, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending August 21, 2020

Flanged Tritium Waste Containers (FTWC): On Wednesday, the contractor readiness assessment team out-briefed its review of the FTWC venting and handling activities at Area G (see 8/14/2020 report). The team noted the superb dedication of the FTWC crew, but identified four findings concerning: (1) the need to define additional steps and actions in the procedure, including addressing differences between the mockup and actual settings, use of realistic timing, and contingencies; (2) incomplete hazard analysis and identification for actions to support timely resolution of potential abnormal conditions; (3) inadequate use of personal protective equipment, particularly gloves; and (4) the failure to demonstrate required responses to safety basis violations during simulated scenarios. Triad personnel have begun corrective actions in advance of the upcoming federal readiness assessment.

Nuclear Environmental Sites: On Wednesday, N3B management declared a violation of the technical safety requirements for a missed in-service inspection. The safety basis requires an inspection of the inventory isolation systems annually and within 30 days of “non-routine natural phenomena or external man-made events.” Subsequent to a request for a record, N3B personnel reviewed additional records and determined that a required inspection was not conducted for a non-routine rainfall event that occurred in early July. At the fact-finding, N3B personnel identified concerns and corrective actions associated with the lack of institutionalization following the loss of key personnel, insufficient criteria for non-routine events, roles and responsibilities, and maintaining best management practices. This week, N3B found the isolation systems to be satisfactory after they completed inspections for last month’s minor earthquake.

Emergency Management: Last Friday, the DOE Office of Enterprise Assessments (EA) issued the report for its assessment of emergency management (see 2/21/2020 report). EA noted that Triad has established a well-staffed emergency response organization that is equipped with state-of-the-art equipment. Nonetheless, they observed performance challenges during the February exercise. They identified three findings: (1) Triad did not provide accurate and effective initial notifications; (2) Triad did not demonstrate an effective capability to formulate and identify protective actions for onsite individuals and the public; and (3) Triad did not demonstrate an emergency operations system that effectively validates and coordinates incident information to establish and maintain situational awareness and a common operating picture. EA noted that Triad identified findings similar to the last two. Additionally, EA identified one deficiency and 11 opportunities for improvement that notably include: improving the coordination between facility-level and site-level protective actions, consider revising Triad and N3B procedures to ensure habitability at key incident response locations, and conducting an analysis of the Los Alamos County dispatch database to ensure effective integration with LANL. The NNSA Field Office and Triad are reviewing the report.

Infrastructure: On Wednesday, Triad transmitted to the NNSA Field Office for approval the major modification determination and safety design strategy for the Los Alamos Plutonium Pit Production Project. The project includes equipment installation in several rooms within the Plutonium Facility, infrastructure capabilities at Technical Area 55 such as office and training space, and capabilities elsewhere at the laboratory such as warehouse and support facilities. Triad determined that the activities to be conducted inside the Plutonium Facility are bounded by the existing safety basis and therefore do not constitute a major modification. The field office is reviewing the submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 28, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 28, 2020

DNFSB Staff Activity: On Monday, a staff team conducted a teleconference with Triad and NNSA Field Office personnel to discuss the project to update the accident analysis calculations for the Plutonium Facility. This project will update several key models, including the leak path factor (LPF), as part of the upgrade of the safety basis to meet DOE-STD-3009-2014 and support increased production activities. The staff team focused on understanding interim review and approval milestones prior to Triad's planned final submittal in March 2022. NNSA is developing a review plan to identify their approach to reviewing interim deliverables, as well as the necessary expertise. Of note, they have preliminarily identified only one individual who has some familiarity with the software related to LPF; however, they lack the correct software versions and an appropriate computing environment.

Legacy Materials–Work Planning and Control: On Tuesday, operators opened a legacy item inside the hot cell at the Chemistry and Metallurgy Research (CMR) building. They were expecting bulk uranium-233 based on historical records, but instead found metal turnings that began to oxidize and glow. They immediately placed the item into a closed metal container. At the fact-finding held on Wednesday, participants noted that their integrated work document was inappropriate for turnings and did not include basic controls such as staging extinguishing media in the hot cell. Processing of legacy items retrieved from the Plutonium Facility vault, including this one, has resulted in several other recent problematic events (see 6/26/2020, 3/6/2020, and 7/19/2019 reports). Given these events, Plutonium Facility personnel are currently revising procedures in order to take a more conservative approach when processing legacy materials to accommodate a broader degree of unexpected material properties. We note that CMR personnel would benefit from a similar approach.

Transuranic Waste Facility: Triad personnel continue efforts to demonstrate that the firewater pumps can be credited as safety-significant (see 11/22/2019 and 5/31/2019 reports). New firewater pumps are on hand; however, they would prefer to demonstrate the acceptability of the current pumps, since pump replacement would involve a significant effort requiring a week or more of a facility firewater outage. All testing of the existing pumps so far has shown that they meet minimum flow requirements to the most distant sprinkler head; however, the pump curves have deviated substantially from the acceptance curve. Facility personnel are currently awaiting the arrival of additional equipment to perform a complete re-baselining of the pump curves with a manufacturer's representative. If this effort is successful, Triad engineering personnel believe they will be able to credit the existing pumps as safety-significant and use the new ones as spares.

Plutonium Facility–Safety Basis: On Wednesday, Triad personnel concluded they had a deficient safety basis (i.e., a positive unreviewed safety question) related to the detector operability criteria for the criticality alarm system. They entered the new information process on August 6th following questions from the NNSA Field Office and declared a potential inadequacy in the safety analysis on August 12th. They did not implement any compensatory measures given the low frequency of the situation of concern.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 4, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 4, 2020

DNFSB Staff Activity: On Monday, a staff team conducted a teleconference with Triad and NNSA Field Office personnel to discuss the results of its review of the safety basis that will be used to transform the Radiological Laboratory Utility Office Building into a hazard category 3 nuclear facility to be termed PF-400.

Area G: Last Wednesday, N3B personnel received notification from the Central Characterization Program (CCP) that a pipe overpack container had recently been assayed and assigned a value of 86.9 plutonium-239 equivalent curies (PE-Ci). Since this value exceeded the current safety basis limit of 80 PE-Ci, N3B personnel took action to quickly isolate the drum, remove liquid fueled vehicles from the area, and doublepack the container later that day. The container had a previous assay value of 65.6 PE-Ci based on measurements at the Plutonium Facility performed in 2014. Differences in assay values sometimes occur because different instrumentation is used. N3B personnel are reviewing the inventory to determine if CCP has not yet measured other containers with existing assay values approaching the limit.

Plutonium Facility–Fire Protection: Last Wednesday, during work on the backshift in the basement, a small fire occurred during pipe brazing activities that were covered under a hot work permit. After workers observed a small amount of unexpected cheesecloth debris in the pipe ignite, they immediately extinguished and then smothered it with wet cheesecloth. The incident was reported to the operations center several hours later by a radiological control technician. At the fact-finding held this week, attendees discussed what level of small incipient fires were acceptable during hot work activities. In this case, since the cheesecloth debris was unexpected, facility management determined that the job should have been paused and the incident reported more promptly. Triad management is evaluating whether changes to the hot work permit process or abnormal event procedures are warranted for small fires of this type.

Area G–Emergency Management: N3B personnel are preparing for startup of drill and drain activities later this calendar year. On Wednesday, they performed a coached drill involving worker response to a foul odor released by drilling into a drum. The odor caused medical symptoms in support workers outside of the Dome 231 Perma-Con, since they were not wearing chemical respiratory protection. One concern noted during the drill was unreliable radio communications between the control room and the workers inside the Perma-Con.

Flanged Tritium Waste Containers (FTWC): Triad personnel performed additional mockup practice for venting at Technical Area 49 following the feedback from the contractor readiness review (see 8/21/2020 report). During this week's mockups, they tested moving a FTWC on a surface that more closely represents the metal grating found in the actual Area G shed. They also practiced disassembly of the portable ventilation skid while treating it as internally contaminated. Closure of corrective actions and preparations for the federal readiness assessment continue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 11, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 11, 2020

Transuranic Waste Management: Triad personnel continue to make progress shipping containers of newly generated transuranic waste to the Waste Isolation Pilot Plant (WIPP). For this fiscal year, they have completed 35 shipments with about 1100 containers. This progress has helped alleviate accumulation concerns within the Plutonium Facility and its outdoor storage pads. Triad plans to continue shipping two loads per week as the certified container inventory and DOE shipment allotments permit. Triad will use the RANT Shipping Facility, which has no weather limitations.

Since the resumption of operations at RANT, N3B has had more WIPP certified containers ready for shipment than Triad (currently about 200 more), but DOE has allotted them fewer shipments that also remain dependent on favorable weather conditions for mobile loading. N3B has no additional shipments assigned for this month and has completed just 5 shipments with about 50 containers for the fiscal year. N3B and Triad personnel continue to develop the processes needed to support loading legacy waste containers at RANT; however, the progress has been slow and there is no target date for achieving this capability. We note that this week's wintery conditions underscore the need for this shared indoor loading capability to reduce legacy waste inventories at Area G. In particular, the winter months often result in additional shipment allotments to LANL due to cancellations at Idaho National Laboratory.

Radiological Laboratory Utility Office Building: Last Thursday, Triad transmitted to the NNSA Field Office for approval a revised safety basis for the upgrade of RLUOB to a hazard category 3 nuclear facility to be known as PF-400. The submittal includes changes intended to address the field office comments on the previous submittal (see 8/7/2020 report). On Thursday, Triad received NNSA Headquarters approval on its five year exemption request related to the deficient or missing fire barriers in the currently occupied building. Among the conditions of approval, Triad is to conduct semi-annual building evacuation exercises and annually reassess the compensatory measures. The NNSA Field Office also requested that Triad consider the suggestions from the DOE Office of Nuclear Safety, including documenting the deficiencies in the safety basis for PF-400.

Area G–Safety Basis: On Wednesday, the EM Field Office rejected two of N3B's evaluation of the safety of the situation (ESS) submittals. One was the ESS for the fuel pool fire depth issue, which was originally identified on July 1, 2020 (see 7/17/2020 report). One reason for rejection was the lack of detail supporting the evaluation of the operational restrictions for all accident scenarios. The other rejected ESS was for the temporary unvented drum condition created during flammable gas sampling, which was originally identified on January 30, 2020 (see 1/31/2020 report). Reasons for rejection included the need to protect the duration of the unvented condition and the length of time taken to submit the ESS.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 18, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 18, 2020

COVID-19 Pandemic: On Monday, both field offices and N3B transitioned to Phase 2. Triad also transitioned to normal operations with maximized telework. Moving forward, the NNSA Field Office is evaluating the appropriate level of field presence for facility representatives and safety system oversight personnel. The EM Field Office has had a facility representative largely on site prior to Phase 2 and will be adding personnel in the coming weeks.

Onsite Transportation: The uranium-233 metal turnings that underwent a pyrophoric reaction at the Chemistry and Metallurgy Research building last month (see 8/28/2020 report) had been transferred from the Plutonium Facility under Triad's transportation safety document (TSD). At the fact-finding for that event, safety basis personnel questioned whether the actual physical form of a metal turning (as opposed to the assumed solid metal) was compliant with the TSD. This Monday, Triad declared a potential inadequacy of the safety analysis (PISA) for the TSD, since the analysis does not consider pyrophoric materials. In this case, Triad personnel did not enter their new information process, consistent with procedural guidance, when the issue was first raised on August 25, 2020. Instead, they entered the process after the PISA declaration in order to document their findings. In a letter dated July 10, 2020, the Board noted similar concerns with implementation of the PISA process around the complex.

Area G—Safety Basis: Last Thursday, N3B management sent a letter to the EM Field Office communicating their intention to develop a safety basis that complies with DOE-STD-3009-2014 to replace the existing document developed in 2012. N3B indicated they would provide a detailed safety basis strategy and schedule by October 30, 2020. The EM Field Office first acknowledged the need to develop a modern safety basis in 2015. Since then, various initiatives—including using an outside contractor to develop an entirely new safety basis—have not succeeded (see 7/5/2019, 10/18/2019 and 11/22/2019 reports).

Legacy Facilities: Last Thursday, N3B management submitted to the EM Field Office for approval the evaluation of the safety of the situation (ESS) concerning the exceedance of the hazard category 3 nuclear facility threshold for the TA-21-257 radioactive liquid waste facility and the adjacent underground industrial waste lines (see 8/14/2020 report). The ESS notes that the operational restrictions ensure that both structures remain in a safe condition, but that the effects of natural phenomena hazards are unanalyzed. The ESS further asserts that the current state of the systems and physical forms of the radiological contamination would result in a minimal release should the systems be disturbed. The ESS notes they intend to submit a justification for continued operations within six months to support additional sampling and characterization activities.

Area G—Fire Protection: Last Thursday, EM Headquarters approved a June 2018 request from N3B's predecessor regarding a suite of permanent exemptions for fire protection systems. The approval notes that the code of record for most of Area G remains largely dependent on DOE directives issued in the early 1990's, but also that any new structures will fall under DOE Order 420.1C, *Facility Safety*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 25, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 25, 2020

Area G–Safety Basis: On Monday, N3B personnel determined that a potential inadequacy of the safety analysis exists for an as-found condition where the radioactivity values for some sealed sources are incorrectly listed in the evaluation of the safety of the situation (ESS) for fire analysis of sealed sources. N3B personnel discovered the discrepancy while performing an extra check of the source values against data in the waste management tracking software system prior to moving sources into Area G. An additional validation against manufacturer’s data concluded that the error resided in the ESS values. The sources in question have not been in Area G since 2015. Transfers of sources listed in the ESS are currently paused and an extent of condition is in progress. This ESS was originally developed in October 2017 prior to N3B assuming control of Area G. N3B adopted the document as-is and performed implementation reviews following contract transition.

Plutonium Facility–Glovebox Safety: On Wednesday, a glovebox glove failed in a manner similar to a July event where the glove and support ring separated and moved into the interior of the box (see 7/24/2020 report). The event occurred in the same box, with the same type of oval gloveport, and the same worker. A thinner glove was in place this time, and the separation occurred when the worker was reaching to sweep up materials rather than upon entry of the gloves. The response to the breach went according to procedure. There were no airborne radioactivity alarms, and while the worker’s personal protective equipment was contaminated, there was no skin contamination. Radiological control technicians detected a small amount of contamination on the floor directly under the breached gloveport which was immediately cleaned up. Following the July event, testing revealed that the determining factor to fail the oval gloves appears to be force on the glove at an angle, versus straight into the box. Plutonium Facility management paused all operations using this brand of oval gloveport pending additional evaluation.

Plutonium Facility–Readiness: Last month, Triad personnel completed an extent-of-condition review regarding proper screening of new or restarted activities for compliance with DOE Order 425.1D, *Verification of Readiness to Start Up or Restart Nuclear Facilities*. They performed the review after identifying a deficiency that permitted activities that screened below the formal readiness review level to proceed without a quality review performed by the institutional readiness program manager. The review examined all screened-out activities since October 1, 2018, and identified 8 activities that will be forwarded for quality review. They also identified 21 activities that are already operational and validated they did not meet the threshold in DOE Order 425.1D. To prevent recurrence, Triad personnel are revising command media at the institutional and facility level.

Plutonium Facility–Operations: Triad personnel continue to increase backshift operations associated with the removal of contaminated systems and new construction activities (see 6/5/2020 report). On Monday, the resident inspectors observed a recently instituted turnover walk-down intended to support coordination and operational awareness between shifts. Of note, the NNSA Field Office has not yet established oversight coverage for the backshift due to staffing shortages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 2, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 2, 2020

DNFSB Staff Activity: On Wednesday, a staff team conducted a teleconference with NNSA and Triad personnel to discuss the Phase 1 technical studies of the Plutonium Facility Seismic Performance Reassessment Project.

Plutonium Facility–Continuous Improvement: Last week, Triad personnel completed their causal analysis of the unexpected thermal excursion and higher than expected occupational dose during the calcination of a legacy item (see 3/6/2020 report). While the causal team was unable to determine the technical cause of the thermal excursion due to competing production priorities for sample analysis resulting from the COVID-19 pandemic, they identified the direct cause, seven contributing causes, and an overall root cause of inadequate procedural direction on the conditions necessary to engage the radiological control technician to perform dose surveys. The team further identified that no formalized instruction existed regarding the extent of research necessary for legacy feed materials despite the potential for those materials to generate an increased radiation field under certain conditions. The team recommended nine actions including: modifying procedures to ensure radiological control technician and expert engagement when appropriate and consider the use of hold points; enhancing pre-job briefings to be task specific; scheduling an independent operational review for material processing; completing sample analysis to determine the technical cause of this event; and conducting an extent-of-condition review of other legacy items in the vault. As a result of challenges with the timely completion of this causal analysis, Triad personnel will also be conducting a causal analysis of the causal process in order to inform an improvement plan.

Plutonium Facility–Glovebox Safety: Facility management issued a standing order on Thursday outlining the process to resume work in gloveboxes using oval ports of the type involved in the push through events that occurred last week and in July (see 9/25/2020 report). The order requires reviewing all procedures for these boxes to determine if operations can be conducted without putting stress on the oval locking ring and training in the Cold Lab for all impacted workers. The training sessions started this week and include demonstrating the range of motion in glove use for normal operations as well as having the workers make tremendous efforts to deliberately fail a glove ring.

Plutonium Facility–Conduct of Operations: Two Thursdays ago, workers preparing to move an item out of a glovebox checked its contents and noted it was not compliant with the criticality safety posting for the box and represented an overmass condition. There was discrepancy between the planning paperwork and the actual contents of the container which was not identified when the object was moved into this box about two weeks prior to the planned move out. Criticality safety personnel determined the current condition is safe and stable, and a plan to recover the box is in development.

Chemistry and Metallurgy Research Building: Last Thursday, a worker performing re-lamping activities in a room with legacy contamination had radioactive contamination transfer to his personal protective equipment. The supporting radiological control technician experienced instrument issues, but was able to detect contamination on the torso, finger tips, and COVID face mask. There was no skin contamination. At the fact finding for this event, personnel noted that pre-surveys of the area were not performed prior to opening the light fixtures, and that communication regarding the role of radiological support were less than adequate. As a correction action, facility management plans to emphasize the importance of performing radiological surveys prior to working in normally inaccessible areas.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 9, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 9, 2020

DNFSB Staff Activity: On Wednesday, a staff team commenced a series of remote interactions with Triad and NNSA personnel as part of a review of credited safety systems. This week, they discussed the Oxygen Monitoring System and Tritium Gas Handling System at the Weapons Engineering Tritium Facility.

Plutonium Facility–Conduct of Operations: Last month, while attempting to move items into a safe, Triad personnel noted that the criticality safety posting prohibited the type of containers they were using. They also noted that containers currently inside the safe were non-compliant. The posting for this safe had been updated in August with restrictions associated with container geometry and container type. The containers in the safe were compliant with the geometry, but not the type. During the fissile material operations review to change the posting in August, Triad personnel did not identify that the contents of the safe were non-compliant with the new posting. Criticality safety personnel determined the safe is currently in a safe and stable configuration. The safe is posted out-of-service pending completion of a recovery plan.

Nuclear Criticality Safety: Last Wednesday, Triad’s institutional Nuclear Criticality Safety Committee issued to the LANL Director its report on the status and quality of the nuclear criticality safety program for fiscal year 2020. They concluded that the program needs improvement, but is on a positive trajectory and is making improvements at a satisfactory rate. On staffing, the report noted that they still do not have sufficient staff for institutional criticality safety needs; however, they have been making progress with staffing more than doubling since 2015. On the backlog of criticality safety evaluation documents, the report notes that progress is exceeding expectations with the backlog now expected to be eliminated within 18 months. The report also notes the need to sustain disciplined formality of operations especially for construction operations supporting the 30 pits per year mission.

Plutonium Facility–Contaminated Equipment Removal: Last week, Triad personnel removed a large glovebox weighing nearly four tons from the facility. This week, they held a post-job review for the activity in order to improve efficiency for future large equipment removals. The glovebox is currently packaged and staged on an outdoor waste storage pad within Technical Area 55. Triad is developing a strategy to disposition this oversize waste stream, which is expected to increase in the next few years with the planned removal of about 60 gloveboxes alone to support pit manufacturing. There is limited space on the pads for staging of future removed gloveboxes and oversize equipment. Previously, oversize containers were relocated to Area G to free up space on the pads (see 9/17/2017 report); however, neither Triad nor N3B currently possess the capability to size reduce or decontaminate oversized equipment.

Area G: This month, N3B received allocations for shipments to the Waste Isolation Pilot Plant. Using mobile loading, they successfully completed three shipments last week, two this week, and plan two next week. Additionally, they are targeting the week of October 19th to work with Triad and debut the use of the RANT Shipping Facility for two N3B loads.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 16, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 16, 2020

DNFSB Staff Activity: The staff continued remote interactions with Triad and NNSA personnel for a review of safety systems. This week, they discussed the Electrical Distribution System and Seismic Power Cutoff System at the Transuranic Waste Facility (TWF) and the Criticality Alarm System at the Plutonium Facility.

Federal Oversight: Last Thursday, a team from NNSA's Chief of Defense Nuclear Safety briefed the results of its biennial review of nuclear safety oversight by the field office (see 3/17/2017 report). The team evaluated 13 functional areas and concluded that 12 met expectations and four showed improvement since the 2017 review (see 3/17/2017 report). The functional area that did not meet expectations was oversight. There were six findings and two weaknesses associated with oversight. The findings indicate that the field office needs improvement in performing, documenting, and conducting management review of its oversight.

Transuranic Waste Management: On Monday, TWF operators took a safety basis required action to immediately remove two waste containers from the facility after conservatively concluding their contents had a potential for a chemical incompatibility. They based their decision on information received last Thursday from the Central Characterization Program (CCP) regarding a forthcoming non-conformance report on a failure of one of the containers at TWF to meet the Basis of Knowledge requirements for oxidizing chemicals in transuranic waste. The TWF safety basis prohibits such waste. After researching the situation, Triad personnel identified two other containers (one at TWF and the other at the Plutonium Facility) that were generated from the same parent item of legacy residues that had been stored in the Plutonium Facility vault for more than a decade. Triad personnel successfully shipped the two containers from TWF back to the Plutonium Facility within about 2.5 hours of determining the need to take action. All three containers currently reside on one of the outdoor storage pads, since the safety basis for that location does not prohibit incompatible chemicals in waste containers. Triad's subsequent research suggests that the contents are not chemically incompatible and they plan to submit associated evidence to CCP. Several aspects of this situation are addressed in DNFSB/Tech-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*.

Area G–Safety Basis: Last Tuesday, N3B submitted to the EM Field Office a revised evaluation of the safety of the situation (ESS) concerning the temporarily blockage of waste container vents with a spatula-like tool during flammable gas sampling (see 1/31/2020 report). N3B sent the original ESS to the EM Field Office in March, which was rejected in September (see 9/11/2020 report). The revised ESS leaves flammable gas sampling operations paused pending the development of a justification for continued operations, planned for December 10, 2020, that will develop any controls needed to resume gas sampling. The NNSA Field Office approved Triad's ESS for the equivalent issue in March (see 3/20/2020 report).

Plutonium Facility–Safety Basis: Earlier this month, the NNSA Field Office sent a letter to Triad requesting revision of the ESS associated with the trailer loaded with combustibles parked in proximity to transuranic waste containers (see 5/29/2020 report). The field office acknowledged that the relocation of the trailer addressed the immediate hazard it posed, but noted that the ESS did not provide analysis supporting that an ordinary combustible fire is bounded by a fuel pool fire. They further noted that questions could not be answered associated with the need to elevate the safety significance of combustible limits or the need for other controls and requested the analysis within 60 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 23, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 23, 2020

DNFSB Staff Activity: The staff held a third week of remote interactions with Triad and NNSA personnel for a review of safety systems. This week, they discussed the Electrical Distribution System, Seismic Power Shutoff System, Chlorine Gas Delivery System, and the Full Scale Test Facility at the Plutonium Facility.

Flanged Tritium Waste Containers (FTWC): An eight member team, three of whom were present onsite, commenced the federal readiness assessment for venting and handling of the FTWCs stored at Area G. Members of the team were present for mockup evolutions during the contractor readiness assessment (see 8/14/2020 report). This week, they observed additional demonstrations of FTWC movement, as well as the assembly and disassembly of the ventilation system. The team expects to complete review activities next week.

Transuranic Waste Management: N3B worked with Triad personnel to complete two shipments this week from the RANT Shipping Facility. The shipments included 28 drums and four standard waste boxes. This is the first usage of the facility by N3B and represents an important demonstration of indoor loading capability for their legacy waste inventory. Moving forward, Triad and N3B are evaluating how to combine waste shipments for optimal shipments to the Waste Isolation Pilot Plant.

Radioactive Liquid Waste Treatment Facility: On Monday, a worker was struck in the back by a 15 to 20 pound plastic bag of radioactive waste that fell about 20 feet into an underground vault. The vault services an intra-facility transfer line for transuranic liquid wastes and is a permitted confined space. The incident occurred when the tape that was used to attach the bag to lifting equipment failed and the worker was standing under the load. The worker was not contaminated, but received return-to-work restrictions for the injury. On Wednesday, fact-finding participants identified the need for a number of significant corrective actions prior to resuming this activity, including: (1) ensuring the work package complied with institutional requirements for hoisting and rigging; (2) selecting an engineered solution to secure waste to the lift line; and (3) determining an effective means of communications between workers in the vault and aboveground given the personal protective equipment required for the chemical and radiological hazards. Triad personnel concluded that this event did not constitute a reportable near-miss, which DOE defines as when happenstance is the main reason the event did not result in a reportable injury.

COVID-19 Impacts: In recent weeks, the State of New Mexico and the laboratory have experienced an increase of cases. On Monday, the LANL Director issued an all-hands message reiterating the importance of following the COVID controls and the need to maximize telework practices. Notably, Triad has experienced several instances of workers arriving onsite with symptoms. They have also experienced several instances where workers in break rooms resulted in close contacts necessitating the precautionary isolation of many workers. In one example, a large number of radiation protection staff members in the Plutonium Facility were isolated. Fortunately, Triad's onsite testing resulted in a same day negative test result allowing all workers to return the next day. Triad management is reassessing break room configurations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 30, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaque and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 30, 2020

DNFSB Staff Activity: The staff completed a fourth week of interactions with Triad and NNSA personnel for its remote review of credited safety systems. This week they discussed high efficiency particulate air filters for the Plutonium Facility. They also held discussions with Triad management and NNSA Field Office personnel to discuss institutional expectations and oversight for safety systems.

Radiological Laboratory Utility Office Building (RLUOB): Last Friday, the NNSA Field Office approved a revised safety basis for the upgrade of RLUOB to a hazard category 3 nuclear facility to be known as PF-400. There are two conditions of approval. The first directs Triad to develop a quality assurance plan specific to PF-400 to ensure that defense-in-depth controls identified in the safety basis and other controls designated by NNSA comply with the requirements in subpart A of 10 CFR 830, *Nuclear Safety Management*. The second condition of approval directs Triad to resolve the remaining four field office review comments by the first annual update of the safety basis.

Chemistry and Metallurgy Research (CMR) Building: Last Friday, Triad transmitted to the NNSA Field Office a revised evaluation of the safety of the situation (ESS) for the anomalous hydrogen gas generation in containers (see 6/26/2020 report). NNSA approved the first revision of the ESS in August with a condition of approval that required Triad to evaluate the physical hazard to a worker from an explosion. Triad's revised ESS concluded that a previous compensatory measure to sample and vent these containers needs to be elevated to a Specific Administrative Control in order to reduce the likelihood of a hydrogen explosion causing a serious physical injury to a worker.

DNFSB/TECH-46 Update: On September 24, 2020, the Board issued Technical Report 46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at LANL*. DNFSB/TECH-46 uses NNSA and EM operations at LANL as a case study regarding safety bases for transuranic waste operations subsequent to the radiological release events in 2014 at the Waste Isolation Pilot Plant and in 2018 at the Idaho National Laboratory. The technical report highlights: (1) the lack of hazards analyses informed by chemical compatibility evaluations, (2) accident analyses that inappropriately assume initial conditions and do not defensibly estimate the amount of radioactive material released by an energetic chemical reaction, and (3) the need to incorporate multiple layers of protection beyond the waste container to reduce consequences of an accident. Since issuance, N3B has formally entered a process to examine its safety basis for inadequacies, overpacked and relocated potentially vulnerable containers, and commenced a broader extent of condition review. N3B has also reached out to the Board's staff to better understand the report. Triad is studying the implications of the report for its operations. NNSA and EM are striving to develop an integrated response.

Contract Management: Earlier this month, both field offices approved their respective performance evaluation and measurement plans for fiscal year 2021. For EM and N3B, incentives of interest to the Board include remediating or repackaging 262 m³ of transuranic waste and developing a new safety basis for Area G that complies with DOE Standard 3009-2014. For NNSA and Triad, key outcomes include executing various construction projects supporting infrastructure within established baselines and effective implementation of the NNSA-approved enduring waste management plan to safely de-inventory transuranic waste from the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 6, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 6, 2020

Transuranic Waste Management: Triad personnel completed two shipments of transuranic waste using the mobile loading capability from an outdoor pad at the Plutonium Facility to the Waste Isolation Pilot Plant (WIPP). The shipments contained a total of about 48 containers and included a large fraction of containers that could not be shipped to the Transuranic Waste Facility of the RANT Shipping Facility primarily due to material-at-risk limits or other onsite shipping requirements. The last mobile loading shipment from an outdoor pad at the Plutonium Facility was in September 2018 (see 12/13/2019 report).

Area G–Safety Basis: Last Friday, N3B submitted to the EM Field Office for review and approval a safety basis strategy for developing a new Area G safety basis. The field office has been pursuing various strategies to improve or otherwise develop a new safety basis for Area G since 2015 (see 7/5/2019 report). N3B's current strategy states that a new safety basis will be developed using DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*, and DOE-STD-5506-2007, *Preparation of Safety Basis Documents for Transuranic (TRU) Waste Facilities* (or successor) for waste parameter calculations. The strategy states that planned changes from the existing safety basis will incorporate: (1) revised fire standoff distance calculations; (2) material-at-risk calculations using the draft revision of DOE-STD-5506; (3) a revised number of containers involved in a fuel pool fire as a function of revised pool fire size calculations; and (4) lessons learned the WIPP radiological release event and DNFSB/TECH-46, *Potential Energetic Chemical Reactions Involving Transuranic Waste at LANL*. The strategy further indicates that only near-term activities will be analyzed and that planned container retrievals from underground pits and trenches will need to be analyzed in future revisions. The schedule includes submittal of draft chapters during the course of the year leading to a final completed document to the field office in February 2022. Additional time will be needed for a final federal review and approval cycle. N3B plans to develop a separate schedule for implementation and notes that it could be impacted if the new safety basis identifies safety controls that are not currently budgeted. The EM Field Office is reviewing the strategy.

Plutonium Facility–Glovebox Safety: This week, facility management released analytical chemistry personnel to resume use of oval gloveports of the type involved in the recent glove push-through events (see 10/2/2020 report). With this release, work remains paused in only one of the nine gloveboxes using oval ports. Triad has also been closely collaborating with the vendor on designs and testing of prototypes for an engineered solution.

COVID-19 Impacts: The State of New Mexico and the laboratory continue to experience growth in new weekly cases. Plutonium Facility operations were impacted this week by a confirmed positive case with fourteen close contacts requiring precautionary isolation. These individuals largely work in the same group providing a support function for compliant facility operations. The NNSA Field Office and Triad senior leadership discussed additional measures to minimize operational impacts, including an effort to develop lessons learned from recent cases with large numbers of close contacts.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 13, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 13, 2020

Flanged Tritium Waste Containers (FTWC): The DOE team completed its readiness assessment for venting and handling of the FTWCs stored at Area G and out-briefed site personnel on Tuesday. The team concluded that the operation can start safely following resolution of four pre-start findings, one related to radiological protection and the other three in safety basis. The team also provided two management concerns: (1) that insights from the contractor readiness assessment were not fully addressed and (2) safety basis issues identified by the federal readiness assessment should have been captured during the implementation verification review. The team also noted that their review assumed that the actual venting evolution would occur in this calendar year. If weather or other factors cause a significant delay, the team recommended that an additional mockup evolution be performed for onsite members of the readiness team to demonstrate continued proficiency.

Area G–Readiness: On Monday, a ten person team commenced the contractor readiness assessment for restart of Glovebag and Drill & Drain operations at Area G. These activities will remediate transuranic waste containers in the Dome 231 Perma-Con to support compliant shipment to the Waste Isolation Pilot Plant. Glovebag activities include removal of prohibited items such as aerosol cans from waste, splitting contents of high-activity drums, and treatment of ignitable or corrosive waste. Drill & Drain operations will puncture drum liners to drain liquids or sludge, which will be captured and stabilized. The drained drum liners will then be returned to a compliant container.

Readiness: Last Friday, the EM Field Office approved N3B’s startup notification report (SNR) for the fourth quarter of fiscal year 2020. The approval letter further outlines the history and disposition of SNRs submitted by N3B since December 2019. The field office noted concerns that were informally transmitted to N3B with the expectation of remedy in subsequent submittals. The concerns primarily involved schedule discrepancies and the absence of the FTWC venting activity from the SNR. The EM Field Office last approved a SNR in April 2019 and has been evaluating N3B’s revised procedure for its readiness process for the last year (see 6/12/2020 report).

On Monday, the NNSA Field Office approved Triad’s SNR for the fourth quarter of fiscal year 2020. The field office acknowledged some projected dates had changed and reminded Triad of the requirement to update information that changes between quarterly SNR submittals.

Chemistry and Metallurgy Research Building: On Thursday, Triad transmitted to the NNSA Field Office for review and approval the evaluation of the safety of the situation (ESS) regarding the potential for a perchlorate explosive hazard in the facility’s drain system. The ESS notes that the concern is based on a conservative interpretation of visual evidence rather than sampling. The ESS proposes to conduct sampling activities prior to work on drains that may have supported perchlorate processing operations.

COVID-19 Impacts: Case counts at the laboratory continued to increase, consistent with regional trends. The laboratory also continued to experience several events with confirmed positive individuals that had high numbers of close contacts.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 20, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 20, 2020

DNFSB Staff Activity: The staff team performing a review of credited safety systems held several follow-up discussions with Triad and NNSA Field Office personnel to resolve outstanding questions from the initial interactions. On Wednesday, the Technical Director remotely briefed the Northern New Mexico Citizens' Advisory Board on DNFSB activities related to the Environmental Management mission at Los Alamos.

Weapons Engineering Tritium Facility: On Monday, following evaluation of questions raised during the Board's staff review of safety systems, Triad personnel declared a potential inadequacy of the safety analysis (PISA) for the oxygen monitoring system. The alarm setpoint for maximum oxygen concentration may be non-conservative as compared with the most current version of National Fire Protection Association 69, *Standard on Explosion Prevention Systems*. While this is being further evaluated, facility management believes they are in a safe configuration given they check for leaks and initiate purges at oxygen concentrations well below the alarm setpoint.

COVID-19 Impacts: On Wednesday, operations within Area G were impacted by a presumptive case and a number of associated close contacts. Currently, Area G is in a safe configuration with transuranic waste operations suspended while key staff are self-isolating. The impacted operations include the emergency drill and a field evolution for the contractor readiness assessment of glovebag and drill and drain operations (see 11/13/2020 report). N3B and Triad management continue to work the arrangements necessary for N3B employees to participate in Triad's onsite testing program, which has been useful in the timely clearance of presumptive cases (see 10/23/2020 report).

Area G–Safety Basis: Last Friday, the safety basis approval authority for the EM Field Office approved the revised evaluation of the safety of the situation (ESS) for the PISA related to fuel pool fire depth (see 7/17/2020 report). N3B's original ESS submittal was rejected in September on the basis of insufficient detail on operational restrictions (see 9/11/2020 report). In the revised ESS, N3B proposes maintaining the existing compensatory measure that reduces the amount of liquid fuel allowed in defined areas. They will provide a more detailed thermal analysis in a Justification for Continued Operations planned to be submitted in February 2021.

Safety Basis: Last week, Triad safety basis management sent the NNSA Field Office for review and approval a revision to the institutional procedure for the Unreviewed Safety Question (USQ) process. This revision addresses previous comments from the field office (see 5/8/2020 report). Notably, this revision translates the DOE guidance of "hours to days, but not weeks" related to processing new information to declare a PISA to 9 working days. This represents a tightening from the current expectation of 15 days. Triad similarly tightened the expectations for PISA to USQ to 11 working days (from 15) and USQ to ESS to 25 working days (from 30). The lack of clear requirements for the PISA process was the subject of a letter from the Board dated July 10, 2020.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 27, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending November 27, 2020

Area G–Readiness: Last Friday, the contractor readiness assessment team for the glovebag and drill & drain operations paused the review due to operational impacts from a presumptive case of COVID-19 with multiple close contacts. The team out-briefed its interim results and plans to complete necessary field demonstrations and an emergency drill in December pending COVID-19 conditions. The team’s interim results included eight pre-start findings involving: flow-down of criticality safety requirements; design and configuration management issues with the installed glovebag; ability to respond to a fire during glovebag operations; lack of defined compensatory measures associated with phasing out of the startup plan; procedural issues; lack of evaluation of lighting levels to support safe glovebag operations; and deficiencies with the radiation protection review. The team also identified a post-start finding associated with inadequate closure of issues identified during the management self-assessment.

Infrastructure: Earlier this month, Triad safety basis management transmitted to the NNSA Field Office for review and approval a significantly revised major modification determination and safety design strategy for the Los Alamos Plutonium Pit Production Project (see 8/21/2020 report). The revisions address previous comments from the field office that generally improve the level of detail and analysis in the documents; however, the overall conclusion remains that the LAP4 effort does not constitute a major modification. Of particular interest, the documents provide better granularity on the expected changes to material-at-risk. They note an expected increase in the quantity of plutonium metal and a decrease in the quantity of plutonium oxide compared to the current safety basis. The reduction in oxide is expected to result in overall lower dose consequences for the bounding postulated accident scenario of a seismically-induced fire. The need to protect the apportionment of material-at-risk assumed in the safety analysis was discussed in the report attached to the Board’s letter dated November 15, 2019, concerning the safety basis for the Plutonium Facility. The field office is reviewing the submittal.

Weapons Engineering Tritium Facility: Triad safety basis personnel concluded they had a deficient safety basis (i.e., a positive unreviewed safety question) related to the setpoint for the oxygen monitoring system (see 11/20/2020 report).

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office unconditionally approved Triad’s evaluation of the safety of the situation concerning the criticality alarm system (see 8/28/2020 report).

COVID-19 Impacts: Contractor and field office management continue to emphasize the need to maximize telework. For next week, Triad management intends to implement a slow, deliberate return to work that keeps onsite staffing at an absolute minimum following the holiday weekend.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 4, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 4, 2020

Radiological Laboratory Utility Office Building (RLUOB): Last Monday, Triad submitted a safety basis implementation plan to the NNSA Field Office describing their planned approach to implementing the new safety basis for the upgrade of RLUOB to a hazard category 3 nuclear facility referred to as PF-400. The process is anticipated to include a major implementation verification review planned for April 2021. Following that review, facility personnel will implement technical safety requirements in two phases. The first, anticipated for July 2021, will occur prior to a management self-assessment, and includes all controls with the exception of the new, hazard category 3 material-at-risk limit. This final control will not be implemented until the facility has been approved as a hazard category 3 nuclear facility which is anticipated for March 2022.

Area G–Safety Basis: On Wednesday, N3B transmitted to the EM Field Office the results of their extent of condition review for unsupported assumptions in the Area G safety basis and supporting calculations associated with design basis accidents involving fire. The other accidents will be completed in March 2021. The field office directed this review following the discovery of an error in a fuel pool fire calculation (see 7/17/2020 report). The extent of condition for the fire accidents found numerous weaknesses and recommended that new control selection be performed to determine correct mitigated frequencies and consequences for these events. N3B personnel have also entered their initial confirmatory process for many issues identified during the extent of condition to determine if these errors constitute potential inadequacies of the safety analysis.

Plutonium Facility–Conduct of Operations: On Monday, three workers entered a room that was “red lit” to restrict access due to a continuous air monitor alarm that had occurred on the prior Friday. Fortunately, radiological control technicians had indications that the alarm had been false, and there was no evidence of an uptake. On Wednesday, facility personnel convened a fact-finding to learn from this near-miss. Fact-finding participants noted that the permanent red light was inoperable, a portable red light had depleted its battery, and a barrier tape had been incorrectly installed across the door frame. Accordingly, the workers indicated they had not realized they were crossing a barrier. Participants also noted that the workers had entered this room from a side door. All such side doors in the facility display a posting directing workers to consult the primary door posting prior to entry. In this case, the workers did not adhere to the posting and consult the primary door, which would have alerted them to the red lit status of the room. Triad management determined that corrective actions were necessary to reinforce expectations regarding door postings, review preventive maintenance for the lights, and explore the use of long-life light bulbs.

Transuranic Waste Management: On Tuesday, Triad safety basis personnel entered their New Information process concerning a potential for chemical incompatibility hazards in waste containers. They entered in response to information contained in DNFSB/TECH-46, *Potential Energetic Chemical Reactions Involving Transuranic Waste at LANL*, issued on September 24, 2020.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 11, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 11, 2020

Transuranic Waste Management: Last Thursday, N3B management declared a potential inadequacy of the safety analysis (PISA) based on a review of information contained in DNFSB/TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at LANL*, issued on September 24, 2020. The PISA notes that the Area G safety basis does not explicitly evaluate a transuranic waste container with unreacted incompatible chemicals or one for which the contents are unknown. Further, such an analysis would need to reflect higher energy events that could impact the magnitude of the release and resulting radiological consequences. In late September, N3B personnel completed an initial review of the aboveground inventory based on information in TECH-46. They took action to overpack containers and place them in the Dome 375 Perma-Con—a location that includes non-credited confinement ventilation, fire suppression, and continuous air monitoring. N3B personnel continue an extent of condition review of the inventory to identify other containers of concern and are developing a shift order to communicate storage and management controls for other containers with the potential for incompatible materials. Triad personnel continue to work through their New Information process concerning TECH-46 implications (see 12/7/2020 report).

Area G—Readiness: Three members of the contractor readiness assessment team evaluating Glovebag and Drill & Drain operations in the Dome 231 Perma-Con returned to complete their review (see 11/27/2020 report). A presumptive COVID case and related self-isolations paused field operations during the first phase of the review. The presumptive individual received a negative test clearing personnel to return to duty. N3B rescheduled an additional operational demonstration and an emergency drill for this week. The team's second out-brief to N3B on Tuesday noted that the additional observations this week did not result in any new findings or changes to those outlined in the interim out-brief two weeks ago. A federal readiness assessment will follow next year.

Radiological Laboratory Utility Office Building (RLUOB): On Monday, the NNSA Field Office transmitted a letter to Triad directing several actions to be taken as part of the transition of RLUOB to a hazard category 3 nuclear facility to be known as PF-400. The letter notes that there are ambiguities in the code of record for RLUOB supporting the transition to a nuclear facility. Therefore, NNSA directed Triad to develop a plan within 30 days to complete specific actions to address this situation including updating their list of applicable codes and evaluating gaps between current codes and previous codes used for the facility's construction. The Board noted a similar concern in a letter to the Secretary of Energy dated December 8, 2020.

Waste Characterization Reduction and Repackaging Facility: Last Thursday, the NNSA Field Office approved a safety basis addendum to support characterization and removal of a drum of unconfirmed contents in the facility (see 1/18/2019 report). The addendum requires the use of a webbing-type lid restraint during handling of the open overpacked drum until flammable gas measurements demonstrate that deflagration is no longer a concern.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 18, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 18, 2020

Plutonium Facility–Safety Basis: Last Friday, Triad safety basis management transmitted to the NNSA Field Office a revision to the evaluation of the safety of the situation (ESS) associated with the trailer loaded with combustibles parked in proximity to transuranic waste containers (see 10/16/2020 report). The field office had requested analysis for common combustibles and any additional controls that may be required for common combustibles. The revised ESS continues to assert that the consequences from a pool fuel fire bound those of any credible common combustible fire and therefore no additional credited controls are necessary. The ESS does commit to explicitly adding the outdoor pad to the scope of the key element of the fire protection program. DOE-STD-3009-2014 articulates the need to analyze hazards that have their own unique control set even if the consequences are bounded by other similar hazards. In this case, the controls from a fire involving common combustibles are clearly different from those used for a fuel pool fire. The ESS is informational and does not require field office approval.

Management–Abnormal Event Notifications: On Tuesday, Plutonium Facility personnel conducted a fact-finding for a glovebox window that incurred damage during operations on November 2. The work team had taken appropriate actions during the event and fact-finding participants identified corrective actions to help prevent recurrence. This event did not receive a formal abnormal event notification. Triad’s institutional command media for performance improvement from abnormal events no longer includes criteria for minor incidents warranting internal abnormal event notifications. We continue to believe that appropriate use of this system aids tracking, trending, and supports overall organizational learning (see 9/6/2019 report).

Plutonium Facility–Readiness: On Thursday, Triad convened their Joint Evaluation Team to evaluate the proposed readiness plan for a new cabinet radiography unit. They concluded that the new equipment is substantially similar to previous operations and is therefore an expansion of existing capability not requiring a formal readiness review. Triad will perform a management self-assessment prior to startup.

Transuranic Liquid Waste Treatment Facility Project: On Wednesday, Triad submitted to the NNSA Field Office for approval a revision to the safety design strategy and preliminary documented safety analysis. This submittal is intended to resolve comments from NNSA’s earlier rejection of a safety design strategy (see 7/24/2020 report). The safety analysis is based on the 90% design revision and will be revalidated with the final design submittal.

Management: Triad issued their Laboratory Agenda for fiscal year 2021. This document establishes the laboratory’s priorities in alignment with NNSA policy. Goals for this year are similar to last year’s with pit production being a top nuclear security priority. Improving waste management, nuclear criticality safety, and nuclear safety are among the mission operations priorities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 25, 2020

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 25, 2020

Transuranic Waste Management: Last Thursday, Triad management declared potential inadequacies of the safety analysis (PISA) at the Plutonium Facility, the Chemistry and Metallurgy Research building, and the Transuranic Waste Facility. The PISAs were based on a review of information contained in DNFSB/TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at LANL*, issued on September 24, 2020. Specifically, the PISAs identify that the hazard presented by the potential for nitrated anion exchange resins in transuranic waste drums is not analyzed in the safety bases for these facilities. Triad's analysis notes that current resin operations use small quantities (larger scale anion exchange processes remain authorized in the Plutonium Facility, though are not currently operating) and procedural controls are in place to ensure rinsing. TECH-46 cited the resins as one example of a potential chemical incompatibility. Triad's analysis focused exclusively on this example, but they commit to perform an extent of condition for the existing and proposed waste streams to identify other potential chemical incompatibilities. This contrasts with N3B's approach to its PISA for Area G that assumes the potential for incompatible chemicals exists and must be further evaluated (see 12/11/2020 report).

Area G–Safety Basis: On Monday, N3B declared four PISAs. These all stemmed from the recent extent of condition review of design basis accidents involving fire hazards at Area G (see 12/4/2020 report). The PISAs are: (1) the vehicle accident with fuel pool fire may not be representative and bounding of all accident sequences, (2) the fuel pool fire from a container leak accident may not be representative and may not have appropriate controls and risk reduction, (3) the refueling vehicle accident with pool fire has an incomplete analysis that is not bounding and representative, and (4) the vehicle accident with combustible fire may have inappropriate controls applied to its unique sequence of events. N3B personnel are still evaluating issues from the extent of condition to determine if additional PISAs will be recommended. Presently, Area G operations are curtailed and the facility is in a safe condition as compensatory measures for planned activities are developed.

Plutonium Facility–Radiological Control: Last Thursday during a hot job to replace a valve in a contaminated system, multiple continuous air monitors alarmed in a laboratory room. The workers were in respiratory protection and exited the area while covering the equipment to mitigate potential contamination spread. One worker's personal protective equipment was contaminated, but there was no skin contamination or evidence of an uptake. The room remains under restricted access until recovery is completed.

Flanged Tritium Waste Containers: Last Thursday, Triad issued their corrective action plan for the findings and other issues identified by the federal readiness assessment for venting and handling activities at Area G (see 11/13/2020 report). Triad also completed a causal analysis to evaluate the findings from the readiness assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 1, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending January 1, 2021

The Year on a Page: A summary of the key developments of 2020.

- Triad and N3B implemented a control set and an onsite testing program to allow some programmatic and construction activities to continue during the COVID-19 pandemic.
- Triad personnel completed contractor and federal readiness assessments of the planned activity to vent and relocate the four Flanged Tritium Waste Containers stored in Area G. In 2016, safety basis personnel determined that these containers have the potential for flammable headspace mixtures. Triad plans to execute the venting activity in 2021.
- In June, Plutonium Facility personnel experienced a glovebox glove breach involving heat-source plutonium that resulted in personnel intakes and room contamination. Triad's investigation revealed the need to strengthen the glovebox glove integrity program and execute many other corrective actions.
- Plutonium Facility personnel completed the final upgrades needed to credit the new electric firewater pumps to safety class status. They continue efforts to ensure in-facility piping meets seismic demands and eliminate fragile facilities from the water supply loop.
- Triad completed its column capital testing program in support of the ongoing studies of the seismic performance of the Plutonium Facility. The test results found that the facility's column capitals will perform as designed during an earthquake. This result provides a necessary input to the nonlinear dynamic analysis, which should provide a final answer on the structure's performance and is expected to be completed in 2022.
- Triad completed 36 shipments of transuranic waste to the Waste Isolation Pilot Plant, including 34 that used the RANT Shipping Facility. N3B completed 17 shipments of transuranic waste. Six of these shipments went through the RANT Shipping Facility per a new agreement allowing legacy waste shipments to use the NNSA facility. In total, more than 1500 containers were shipped offsite in 2020.
- Triad and N3B each declared potential inadequacies of the safety analysis in response to DNFSB/TECH-46, *Potential Energetic Chemical Reactions Involving Transuranic Waste at LANL*. They will continue executing their respective processes to remedy the impacted safety bases and implement additional controls, as determined to be necessary.
- Triad received approval for the safety basis to upgrade the Radiological Laboratory Utility Office Building from a radiological facility to a hazard category 3 facility to be termed Plutonium Facility, Building 400. They continue a multi-year effort to resolve fire protection deficiencies in parallel with commencing the readiness review process.
- The EM and NNSA Field Offices gained new managers, continued to acquire needed staff, and underwent assessments from their headquarters organizations revealing the need to strengthen some key aspects of their federal oversight.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 8, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 8, 2021

Area G–Safety Basis: On Thursday, N3B management declared three additional potential inadequacies of the safety analysis (PISA) after further investigating concerns identified by its robust extent of condition review on fire related accidents (see 12/4/2020 report). They plan to finalize compensatory measures by next Monday. N3B management also declared two additional PISAs late last month after the EM Field Office rejected a September 2020 request to extend two safety basis documents for other longstanding PISAs. N3B suspended the affected operations when these two documents expired in November 2020. This week, N3B safety basis personnel commenced the second phase of the extent of condition review on the existing Area G safety basis.

These five declarations bring the total number of PISAs that originated in calendar year 2020 against the Area G safety basis to 17. While the PISAs indicate a healthy scrutiny of the safety basis, N3B and EM have struggled to efficiently develop, approve, and implement the required safety basis documents to ensure safety and support the important risk reduction mission at Area G. For example, N3B declared a PISA in January 2020 regarding the use of a spatula-like tool that occluded drum vents during headspace gas sampling (see 1/31/2020 report). This PISA remains without an approved safety basis due to issues with the initial submittal (see 9/11/2020 report) and protracted approval cycles within EM (Field Office and Headquarters). Flammable gas sampling operations remain paused eliminating this specific concern, but the pause also hinders N3B's ability to ensure that waste containers can be certified for permanent disposal. N3B and EM management are starting various initiatives to improve the situation.

Plutonium Facility–Criticality Safety: Last month, Triad nuclear criticality safety personnel issued a memo regarding the credibility of fissionable solutions leaking from the aqueous chloride processing room on the first floor into the basement during normal operations and following a seismic event. This evaluation was a corrective action from an event in November 2018 where an overflowing restroom sink led to water ingress into the facility's basement. This leak was similar to an earlier incident (see 3/16/2018 report). The concern is that there are no criticality safety controls in the basement for large volume geometries, including structural aspects (sumps) or transient items (voluminous equipment). The memo concludes that fissionable solutions cannot credibly enter the basement, since the solutions are contained in gloveboxes during normal operations and the building remains "intact" following a seismic event. Criticality safety personnel plan a future evaluation of leaks from the aqueous nitrate processing areas. Those areas are not currently in operation, but pose challenges of larger fissionable liquid volumes and tanks external to gloveboxes. Facility management is currently evaluating the bases for supporting the conclusion that there could be no leakage through the floor and examining the process to develop the memo.

Weapons Engineering Tritium Facility: On December 22, 2020, Triad management transmitted to the NNSA Field Office for approval the ESS concerning the oxygen monitoring system setpoint (see 11/20/2020 report). The ESS notes that facility personnel have adjusted the oxygen setpoint to 2.6 percent to ensure consistency with the current applicable National Fire Protection Association standard.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 15, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 15, 2021

Transuranic Waste Management: On Thursday, Triad and N3B personnel completed the first shipment of co-mingled transuranic waste from the RANT Shipping Facility to the Waste Isolation Pilot Plant. The shipment contained 24 drums of legacy waste managed by N3B along with 4 drums of newly generated waste from Triad operations. This is a significant development—preparing shipments of co-mingled wastes allows the DOE to optimize payloads thereby reducing the number of empty dunnage drums that are sent and emplaced in the Waste Isolation Pilot Plant.

Plutonium Facility—Operations: Last Monday, workers performing practice runs in preparation for the eventual restart of aqueous nitrate operations noted a cloudy solution after running water through the system. While running the solution through a filtration unit, the workers obtained an unexpected semi-solid accumulation upon which they paused and reported the discovery. Aqueous nitrate operations have been suspended since the LANL Director paused operations in 2013, and there is known holdup in some of the equipment. The work crew was operating using an integrated work control document that allowed operations with a plutonium mass limit of 50 g; however, the total estimated plutonium holdup in the tank was about 70 g. Both values are well below the criticality safety limits for the process. The precipitate will be analyzed for plutonium content which is expected to be well below 50 g. Restart of aqueous nitrate operations is currently planned for fall 2021.

Plutonium Facility—Infrastructure: Last month, Triad management transmitted the annual revision of the TA-55 Project Execution Strategy (PES) to the NNSA Field Office for information (see 1/10/2020 report). For last fiscal year, the PES reports key accomplishments including: completion of the column capital testing program; installation of 37 new fire doors and fire barriers for certain duct penetrations; commissioning of the diesel electric generators for the electric firewater pumps; completion of three fire hazard evaluations; progress with the design to resolve the cast iron fitting issue with the sprinkler piping; and completion of seismic analyses for 41 gloveboxes. For this fiscal year, the PES recommends actions including: continued seismic analysis of the instrument air system; additional fire barrier modifications; completion of the new chlorine gas delivery system; continued seismic analyses and fire hazard evaluations for gloveboxes; and completing the design for the new facility control system.

Plutonium Facility—Criticality Safety: On Tuesday, Nuclear Criticality Safety management rescinded the memo that examined the potential for solutions of fissionable liquids to leak into the basement (see 1/8/2021 report). A new approach for this evaluation is under development.

COVID-19 Impacts: On Wednesday, Triad management paused radiological work inside enclosures within the Radiological Laboratory Utility Office Building Due to a presumptive COVID-19 case that impacted staffing within the facility's operations center. Despite this case, the lab has generally experienced a decline in incidents with large numbers of close contacts. Last week, Triad commenced vaccination of the laboratory workforce in accordance with New Mexico Department of Health policy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 22, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 22, 2021

Transuranic Waste Management: On Thursday, N3B management transmitted to the EM Field Office for approval its evaluation of the safety of the situation (ESS) for the potential inadequacy of the safety analysis concerning DNFSB/TECH-46 (see 12/11/2020 report). The ESS proposes compensatory measures for transuranic waste containers that are identified to have incompatible chemicals or unknown contents. The compensatory measures include overpacking or placing a lid restraining device on the container and moving the container to the Dome 375 PermaCon. The ESS notes that N3B plans to submit a justification for continued operations within 90 days of the field office approving the ESS. The field office is reviewing.

Plutonium Facility–Infrastructure: On Thursday, the NNSA Field Office transmitted comments and direction to Triad management regarding the previously submitted revisions to the major modification determination and safety design strategy for the Los Alamos Plutonium Pit Production Project (LAP4) (see 11/27/2020 report). The field office direction, which was informed with formal advice from NNSA's Chief of Defense Nuclear Safety, notes that several of the screening criteria for determination of a major modification to the safety basis should have been tripped in accordance with DOE-STD-1189-2016, *Integration of Safety into the Design Process*. In particular, the field office noted that the design options for some of the installation activities may require relocation of interior walls and perturbing portions of the safety class confinement structure. Other significant comments include: improving discussions of material-at-risk changes to include integration of other potential mission work changes (i.e., Advanced Recovery and Integrated Extraction Recovery System); addressing interim conditions during construction; improving integration of safety basis deliverables with the parallel upgrade of the safety basis to comply with DOE-STD-3009-2014; and addressing the hazards associated with the removal of existing contaminated equipment.

In advance of this direction, Triad management chartered a safety-in-design integration team to revise the safety design strategy and submit an acceptable safety design strategy by February 24, 2021. The team began meeting last week and has held several discussions.

Last week, NNSA personnel conducted an integrated project review of LAP4 in advance of a critical decision-1 milestone planned for April 2021. The team's out-brief noted several preliminary concerns, including: adjusting the conceptual design to the major modification determination, including impacts to scope, cost, and schedule; strengthening integration across nuclear safety disciplines; insufficient code of record development for this stage of design; and an incomplete staffing analysis with unrealistic hiring assumptions.

Radiological Laboratory Utility Office Building (RLUOB): Last month, NNSA directed several actions to support upgrade of RLUOB to a hazard category 3 nuclear facility to be known as PF-400 (see 12/11/2020 report). On Wednesday, Triad submitted to the NNSA Field Office their response, including the plan for clarifying the RLUOB code of record. They plan to compare the existing code of record for RLUOB and determine any gaps with current codes and standards. The review is scheduled for completion in June 2021 to support a safety basis update in September 2021.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 29, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 29, 2021

DNFSB Staff Activity: On Monday, members of the Board's staff held a call with N3B and EM Field Office personnel to discuss their current approach to addressing items described in DNFSB/TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*.

Flanged Tritium Waste Containers (FTWC): On Thursday, Triad transmitted to the NNSA Field Office for approval their corrective action plan from the federal readiness assessment for FTWC venting and handling activities at Area G. They also provided evidence of completed actions including: an evaluation of how recommendations and observations from the contractor readiness assessment were dispositioned; promulgation of lessons-learned regarding instrument positioning for remote readability; and validation of the operating procedure to confirm compliance with the technical safety requirements. If NNSA agrees that the corrective actions are adequate, they will transmit them for final approval to the Office of Environmental Management who is the startup authority for this activity.

Plutonium Facility–Infrastructure: This week, NNSA and Triad personnel continued multiple safety design integration team meetings in support of developing an acceptable safety design strategy for the Los Alamos Plutonium Pit Production Project (see 1/22/2021 report). This week's focus topics included structural impacts, the ventilation system, and integration with the overall effort to upgrade the safety basis for the Plutonium Facility to DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*.

Transuranic Liquid Waste (TLW) Treatment Facility Project: Last month, Triad safety basis management transmitted to the NNSA Field Office for approval a revision to the preliminary safety basis and safety design strategy for the project. These revisions address field office comments on the versions submitted once project activities recommenced from suspension (see 9/22/2017 report). TLW will be a hazard category 3 nuclear facility that treats caustic and acidic transuranic liquid wastes resulting from production activities within, and subsequently transferred from, the Plutonium Facility. Significant changes include updating the requirements basis to DOE-STD-1189-2016, *Integration of Safety into the Design Process* from the 2008 version and DOE-STD-1228-2016, *Preparation of Documented Safety Analysis for Hazard Category 3 DOE Nuclear Facilities* from DOE-STD-3009-94-CN3, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Documented Safety Analyses*. The field office is reviewing the submittal.

Area G: N3B management recently declared two temporary stop works. One was taken in response to questions raised by safety basis personnel during the review of documents and the other was taken in response to a number of vehicle-related incidents.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 5, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 5, 2021

Transuranic Waste Management: On Wednesday, Triad management transmitted to the NNSA Field Office for approval three evaluations of the safety of the situation (ESS) concerning DNFSB/TECH-46 (see 12/25/2020 report). The ESSs note that anion exchange resins that have not been rendered nonreactive could result in a potential energetic chemical reaction that overpressurizes a waste container. The ESSs analyze the potential radiological consequences from this event using an effective respirable release fraction of 0.07 that results in unmitigated doses that challenge or exceed DOE's criteria for credited controls to protect the public and workers. The ESS for the Plutonium Facility notes that waste containers stored outside have no viable controls to mitigate a release. Accordingly, each ESS proposes a credited control to ensure that spent resin in excess of 150 mL in a single waste container is rendered nonreactive. The ESSs also note an ongoing extent of condition review to identify other potentially incompatible chemicals in waste; however, a schedule to complete that effort was not provided.

Federal Oversight: On Monday, DOE Office of Enterprise Assessments personnel out-briefed Triad and the NNSA Field Office on the results of their remote assessment of the Nuclear Criticality Safety Program. Overall, they concluded that the program has improved since the 2013 Director's pause and that the field office has been providing comprehensive oversight. The final report is expected to be completed by May 2021. The team is planning a second assessment focused on control implementation and conduct of operations once an in-person review is feasible.

Plutonium Facility–Material-at-Risk: On Tuesday, operations personnel suspended heat-source plutonium activities after discovering an error in the calculated elemental weight of plutonium during aqueous processing. Operations personnel performed initial calculations that suggest that no material-at-risk limits were exceeded; however, heat-source activities will remain suspended until a formal validation of the material-at-risk is completed.

Area G–Safety Basis: On Monday, the DOE Office of Environmental Management rejected the latest iteration of N3B's approach to upgrade the safety basis for Area G (see 9/18/2020 report). The rejection letter noted that the safety basis strategy submitted at the end of October 2020 did not provide adequate information to balance upgrading the safety basis while managing issues with the existing safety basis that supports current operations.

Weapons Engineering Tritium Facility: On Thursday, facility operations personnel discovered that a tritium room monitor had failed overnight due to loss of flow. They took the required safety basis actions and were later able to restore operability to the unit. These monitors are old and the facility has experienced several of these failures in the past few years. Consequently, facility personnel are already in the process of replacing the units and expect to complete the effort in the next month. On Monday, the NNSA Field Office approved Triad's ESS concerning the oxygen monitoring system (see 1/8/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 12, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 12, 2021

DNFSB Staff Activity: On Wednesday, members of the Board's staff conducted a web conference with Triad and NNSA Field Office personnel to discuss the combustible trailer formerly parked adjacent to an outside transuranic waste storage pad at the Plutonium Facility (see 12/18/2020 report).

Area G—Safety Basis: Last Friday, the EM Field Office approved the evaluation of the safety of the situation (ESS) concerning the use of a spatula-like tool during headspace gas sampling (see 9/11/2020 report). N3B intends to submit a justification for continued operations within 30 days, which is necessary to restore gas sampling operations that have been impacted since January 2020. Last week, N3B operations management implemented a standing order that consolidated compensatory actions associated with 16 ESSs from the safety basis issues identified last year (see 1/8/2021 report). The extent-of-condition review on the existing safety basis continues.

Transuranic Waste Management: N3B personnel continue their extent-of-condition review of the waste container population concerning DNFSB/TECH-46. Recently, they identified four containers with ion exchange resins and seven containers with unknown absorbents—all were treated as containing potentially incompatible chemicals consistent with the recently submitted ESS and moved into the Dome 375 PermaCon (see 1/22/2021 report).

On Wednesday, Triad personnel transported a shipment of 28 containers of cemented transuranic waste to Area G. N3B and Central Characterization Program personnel will conduct non-destructive examination activities on these containers for Triad. Currently, Triad relies exclusively on visual examination to fulfill the non-destructive examination requirements and does not possess radiography capability appropriate for cemented waste forms or standard waste boxes. This is the first instance that Triad has exercised the service agreement with N3B to send newly generated wastes to Area G for storage or services.

Onsite Transportation: Last Thursday, the NNSA Field Office conditionally approved Triad's ESS for the shipment of pyrophoric materials not being addressed in the onsite Transportation Safety Document (see 9/18/2020 report). The ESS states that shippers will attempt to validate that shipments labeled 'solid metal' of less than 50 grams are actually solid metal rather than potentially pyrophoric turnings. If they are unable to conclusively determine that the shipment does not contain potentially pyrophoric material, it will not be shipped without further evaluation. The ESS also states that pipe overpack containers may be used to transport potentially pyrophoric metals with masses less than 50 grams. As a condition of approval, the field office noted that there is no documented basis demonstrating the adequacy of a pipe overpack to contain such material and therefore prohibited transport until a basis is approved. The Transportation Safety Document will be updated in the future to allow transportation of pyrophoric materials when contained in Type B equivalent packages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 19, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 19, 2021

Area G–Safety Basis: On Tuesday, the EM Field Office rejected the evaluation of the safety of the situation (ESS) concerning pipe overpack containers with greater than 80 plutonium-239 equivalent curies (see 7/17/2020 report). The field office noted that N3B has identified additional inadequacies with the accident scenario as part of its ongoing extent-of-condition review that occurred after the ESS was submitted in October 2020. Consequently, the field office could not approve the ESS without additional evaluation and discussion of the impacts of these inadequacies.

This week, N3B personnel conducted fact-findings for two additional potential inadequacies of the safety analysis (PISA) resulting from their ongoing extent-of-condition review. The first PISA involved postulated single container deflagrations and identified that the controls are irrelevant to the accident scenario. The second PISA involved postulated dropped transuranic waste payloads during TRUPACT II mobile loading operations and identified discrepancies with the assumed material-at-risk and credited controls. N3B management identified compensatory measures to be implemented through shift orders and eventually integrated into a revision of the standing order consolidating controls from many ESSs.

Plutonium Facility–Conduct of Operations: Last Thursday, workers in the Plutonium Facility discovered a non-compliance in a dropbox while completing checks prior to performing a movement of nuclear material. They found an item had been moved into the box the previous day that exceeded the mass limit on the criticality safety posting for the location. Criticality safety personnel determined that the condition is bounded by the analysis in the criticality safety evaluation document for this operation. As a corrective action, the group that performed the movement of the item will use a more rigorous section of the material movement procedure. They also plan to hold a safety day to brief personnel on this event and how to avoid similar events in the future.

Plutonium Facility–Work Control: Last Tuesday, Plutonium Facility personnel performed activities without the knowledge of operations center personnel. At the time, the laboratory room in question was in Standby mode per the Technical Safety Requirements following an earlier material-at-risk discrepancy (see 2/5/2021 report). The work being performed would have been allowed in this operations mode as it did not involve special nuclear material, and personnel believed they had received permission to perform the activity through a series of informal communications that lacked precision. Triad personnel have an ongoing effort to improve scheduling and work release processes.

Weather Impacts: Snowfall impacted onsite operations at the laboratory resulting in closure on Tuesday and a delayed start on Thursday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 26, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 26, 2021

DNFSB Staff Activity: On Wednesday, a staff team conducted a web conference with Triad and NNSA Field Office personnel to discuss key inputs that will be used in the ongoing update of the leak path factor analysis supporting the safety basis for the Plutonium Facility. They also discussed the current process for managing transient combustibles within the facility and how that is tied to safety basis assumptions regarding fire behavior.

Area G–Safety Basis: On Monday, N3B personnel declared two additional potential inadequacies of the safety analysis (PISA) as a result of the second phase of their extent of condition review of the safety basis (see 2/19/2021 report). The first PISA relates to excessive frequency reduction applied to a spotter control to prevent a crane from impacting waste drums. As a compensatory measure, mobile crane operations are currently paused in Area G. The second PISA is due to an incomplete frequency analysis of the mitigated event for a forklift tine puncture of an unvented or recently vented waste drum. As a compensatory measure, forklift activities now require a spotter.

Safety Basis: Last week, Triad safety basis management transmitted to the NNSA Field Office a revised protocol to perform calculations of atmospheric radionuclide dispersion for safety basis applications. The revision incorporates updated meteorological data and addresses outstanding field office comments (see 11/3/2017 report) including a justification for the use of linear plume meander and questions regarding the potential to concentrate releases in canyon topography. Triad did not request approval, but the NNSA Field Office intends to provide comments to be considered in future applications of the protocol. Consequently, the current approach results in a case-by-case approval as part of the field office's review of future safety basis submittals.

Plutonium Facility–Infrastructure: On Thursday, Triad safety basis management transmitted to the NNSA Field Office for approval a complete rewrite of the safety design strategy (SDS) for the Los Alamos Plutonium Pit Production Project. This SDS revision addresses NNSA direction to treat the project as a major modification to the safety basis (see 1/22/2021 report). The SDS presents an approach to identify project scope requiring preliminary documented safety analysis coverage and proposes these will take the form of safety basis addenda to avoid duplication with the existing safety basis. The project will develop safety basis addenda for a new radiography system, a final assembly station, and parts staging gloveboxes. The SDS also provides design upgrade analyses for interface with the existing safety systems associated with the criticality alarm, fire suppression, gloveboxes, site paging, and ventilation. To address DOE requirements concerning active confinement ventilation, the SDS includes a discussion on the active and passive confinement systems currently in use at the facility. The SDS asserts these existing systems meet requirements, but note that an ongoing series of incremental projects are being executed with the ultimate goal of achieving a safety-class active confinement ventilation. NNSA's most recent report to Congress indicates the need date for the completion of these projects is 2025; however, we note that NNSA has not established a date when an implemented safety basis will reflect this upgraded configuration for the enduring facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 5, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 5, 2021

DNFSB Staff Activity: On Wednesday, a staff team conducted a series of web conferences with personnel from EM Headquarters, the EM Field Office, and N3B to discuss current issues with the safety basis for Area G and the approach to assure safe operations while developing a modern safety basis.

Transuranic Waste Management: Last Friday, Plutonium Facility workers observed sparks while drumming out transuranic waste. They followed proper procedure and left the room, pulled a fire alarm, and contacted the operations center. Fire department personnel responded and determined that no fire condition existed. Triad's subsequent evaluation indicated no obvious damage to the glovebox, no release of radioactive material, and no injuries to the workers present at the time.

On Monday, Triad personnel conducted a fact-finding for this event. Attendees discussed the fact that the waste being disposed of included filters from an inert atmosphere glovebox used to weld non-radioactive metals including titanium alloy. Consequently, the group believes the likely explanation for the event was that metallic welding condensates on the filters underwent a pyrophoric reaction when a different waste item was added to the drum and breached a bagged filter allowing the influx of oxygen. Triad management: paused waste bag-out operations associated with materials from the welding gloveboxes; commenced a review of the waste records to determine if these filters exist in waste containers elsewhere at the laboratory or at the Waste Isolation Pilot Plant (WIPP); and entered the New Information process to determine whether the safety basis properly considers this energetic chemical reaction.

We note that this energetic chemical reaction underscores the need for Triad to fully address the concerns outlined in DNFSB/TECH-46 (see 12/25/2020). To date, Triad has identified and taken action for potential energetic reactions associated with cellulosic materials and ion exchange resins. They have also recently begun an extent-of-condition review to look for other potentially incompatible waste constituents; however, this search will be challenging because most of the waste from the facility falls under a single waste stream. For example, WIPP produced a chemical compatibility evaluation for this stream that indicates that there are more than 100 primary chemicals and materials of concern present, as well as about 150 others found at insignificant levels. This evaluation identified titanium as a material of concern, but concluded that powdered forms do not exist in the facility or that actions would be taken to render it unavailable for adverse reactions.

Plutonium Facility–Radiological Control: On Wednesday, a worker alarmed the hand and foot monitor at the exit of a laboratory room. Responding radiological control technicians found all six individuals in the room with high levels of contamination on their personal protective equipment and three of them also had skin contamination. During decontamination activities, a continuous air monitor alarmed in the decontamination room. There was also a continuous air monitor alarm in the original laboratory room following egress of the workers. Facility management will hold a fact-finding next week.

Safety Basis: Last month, Triad transmitted to the NNSA Field Office the 2021 annual update to the safety basis for the RANT Shipping Facility. This is the first annual update produced at LANL where such updates no longer require federal approval under the revision to 10 CFR 830, *Nuclear Safety Management*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 12, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 12, 2021

DNFSB Staff Activity: Members of the Board's staff observed a briefing from Triad to DOE Headquarters and NNSA Field Office personnel covering planned changes to site specific atmospheric dispersion parameters used in safety analyses (see 2/26/2021 report).

Transuranic Waste Management: Triad personnel continued their efforts to identify waste containers with contents similar to those involved in the incident that occurred two weeks ago (see 3/5/2021 report). They identified potential containers at the Plutonium Facility, Transuranic Waste Facility (TWF), and the Waste Isolation Pilot Plant. They shipped the suspect containers from TWF back to the Plutonium Facility despite the ongoing issue with the transportation safety document concerning the lack of analysis for pyrophoric materials (see 2/12/2021 report). Triad personnel are finalizing calculations to determine the maximum potential mass of pyrophoric metal fines in these containers, the resultant impact on the waste container from an oxidation reaction with these metals, and the time required for these metal fines to passivate with oxygen diffusing through a plastic bag. NNSA and Triad leadership are determining an appropriate course of action for a formal investigation.

Area G: On Monday, N3B management notified the EM Field Office that they were immediately restricting operations at the facility to essential activities as a result of the large number of simultaneous safety basis issues (see 2/19/2021 report). These restrictions limit activities to those associated with surveillances required by the safety basis, environmental compliance, life safety, maintenance, and minimal essential movements of material-at-risk (MAR) needed to execute operational restrictions or other compensatory measures to support safety and compliance activities. In general, the most significant changes against the previous operational posture include suspension of MAR activities associated with planned open container remediation activities and container certification activities. The restrictions do not impact N3B's ability to mine and transport containers to the RANT Shipping Facility for offsite shipment. N3B also noted they will be providing a schedule for resolution of the safety basis issues to the EM Field Office by March 25, 2021.

Plutonium Facility–Infrastructure: On Wednesday, the NNSA Field Office approved the revised Safety Design Strategy for the Los Alamos Plutonium Pit Production Project (see 2/26/2021 report). There were no conditions of approval; however, the field office directed Triad to pursue an exemption for the vulnerabilities to the ventilation system per DOE O 420.1C, *Facility Safety*, as described in one of the options presented in the design upgrade analysis for the ventilation system.

Continuous Improvement: On Wednesday and Thursday, the Weapons Production Directorate held a safety stand-down for organizational learning, overlapping with a laboratory-wide re-emphasis on COVID controls. Senior management provided briefings on COVID controls and current operational concerns regarding radiological control, special nuclear material movement, waste management, and housekeeping, especially as related to combustible loading. Management is collecting input from small group breakout sessions where the workforce will discuss these concerns and methods for improving operations.

Weapons Engineering Tritium Facility–Readiness: On Thursday, Triad's Joint Evaluation Team recommended that a new operation involving testing plutonium coupons undergo contractor and federal readiness assessments. Safety basis changes analyzing the impact of adding plutonium to the facility are in progress.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 19, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending March 19, 2021

DNFSB Staff Activity: Members of the Board's staff held discussions with NNSA Field Office and Triad personnel as part of a review of the onsite Transportation Safety Document. The review examined adherence to applicable requirements, the completeness of the hazard and accident analyses, and the ability of the control set to ensure worker and public safety.

Transuranic Waste Management: On Monday, Triad personnel commenced an investigation for the event associated with the suspected titanium welding fume condensate that readily ignited into sparks during a waste drum-out (see 3/5/2021 report). The team's chartered outcomes include: (1) a comprehensive articulation of the facts and timeline, (2) an assessment of procedures governing the introduction of materials into the glovebox environment, (3) an assessment of the event response and recommendations for improvement, (4) a review of corrective actions taken in response to the radiological release event that occurred at the Waste Isolation Pilot Plant (WIPP) on February 14, 2014, and (5) a determination on the extent-of-condition regarding other processes that may be at risk of inadequate waste characterization. The team includes a mix of onsite and virtual participants from internal and external sources, including representatives from the Central Characterization Program (CCP) and the WIPP contractor. NNSA has assigned two observers. This week, the team walked-down the gloveboxes and locations within the Plutonium Facility that were involved in the waste generation and conducted a number of interviews.

Operationally, Triad has released most waste drum-out activities; however, CCP management has paused all characterization activities at the Plutonium Facility effectively meaning that no waste drum-outs can occur. Triad personnel have concluded that there are four containers at LANL with similar titanium welding fume condensates. These containers are isolated and within the Plutonium Facility confinement structure. No safety basis level restrictions or controls have been placed on the containers.

Area G–Safety Basis: On Tuesday, N3B submitted to the EM Field Office the second half of the extent-of-condition review of design basis accidents in the current Area G safety basis. During the course of this part of the extent-of-condition, seven issues were evaluated through the Initial Confirmatory process with four resulting in potential inadequacies of the safety analysis.

On Tuesday, the EM Field Office acknowledged N3B's letter describing their restricted operations (see 3/12/2021 report). On Wednesday, N3B transmitted to the EM Field Office for approval a revised safety basis strategy to update and upgrade the Area G safety basis. This revision is intended to address DOE comments from the previously rejected strategy noting that it did not include adequate information regarding managing safe operation of the facility while addressing the large number of issues with the current safety basis (see 2/5/2021 report). In their transmission letter, N3B noted that, per their restricted operations letter of last week, they would be providing an integrated plan for interim safety basis management by March 25, 2021. This plan is expected to detail a phased approach including development of a consolidated evaluation of the safety of the situation for a restricted operational envelope and additional analyses to support expanded operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 26, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director

FROM: J.W. Plaue and D. Gutowski, Resident Inspectors

SUBJECT: Los Alamos Activity Report for Week Ending March 26, 2021

Area G–Safety Basis: On Tuesday, N3B transmitted to the EM Field Office a consolidated evaluation of the safety of the situation (ESS) covering 18 of the potential inadequacies of the safety analysis (PISA) that were discovered between January 2020 and February 2021. These PISAs all resulted in positive unreviewed safety questions. The consolidated ESS summarizes the existing immediate compensatory measures for the 18 PISAs which were consolidated into a single standing order last month. This standing order in conjunction with the further restriction of operations enacted two weeks ago is intended to provide assurance that the facility is in a safe condition.

Also on Tuesday, N3B declared a new PISA related to the treatment of rotary wing aircraft crashes in the Area G safety basis. The calculation supporting the Area G safety basis does not include rotary wing aircraft impacts because of standoff distances imposed by a Triad site procedure. However, the standoff distances for local helicopter flights mandated by the Triad procedure are insufficient to preclude the possibility of a helicopter impacting facilities within Area G based on the glide path distances in DOE-STD-3014-96, *Accident Analysis for Aircraft Crash into Hazardous Facilities*. N3B personnel are revising their aircraft crash calculation and have notified their Triad counterparts.

On Wednesday, N3B personnel determined that an additional 10 waste containers should be treated as containing high fissile gram equivalents (see 3/6/2020 report). Facility operations staff have paused container movements, restricted access to the containers, and are working through a recovery process. Based on discussions at a fact-finding held on Thursday, these containers were re-assayed last year and the procedure used for reviewing the data had not been revised to reflect the changed approach of including measurement uncertainty for compliance with criticality safety limits.

Area G–Federal Oversight: Last summer, the DOE Office of Environmental Management’s Chief of Nuclear Safety completed the first phase of its assessment on nuclear safety functions at the EM Field Office (see 7/16/2020 report). The assessment identified significant weaknesses in the federal nuclear safety function as indicated by five management challenges (defined as a systematic problem) and five findings (defined as a violation of a requirement). Representative examples of each of these include: the field office has not ensured timeliness expectations are met for safety basis submittal and approvals; there is no demonstrated ownership of the field office safety basis documents; and the draft safety basis review procedure is non-compliant with DOE requirements. The field office accepted the team’s conclusions on July 30, 2020. As of this week, the EM Field Office reports about half of the corrective actions are complete and have begun working with EM Headquarters personnel to ensure the actions are adequate. As a compensatory measure for this continued situation, EM Headquarters continues to retain all nuclear safety approval authorities.

Transuranic Waste Management: Triad personnel continued the investigation into the titanium welding fume condensates that readily ignited during a waste drum-out (see 3/19/2021 report). This week’s activities largely consisted of interviews. The team’s charter requests a final report by April 23, 2021. Additional waste related developments include the discovery about a month ago of two containers with corroded filters similar to those that were replaced last summer (see 6/12/2020 report) and a facility-wide pause on liquid waste absorption activities due to questions from nuclear criticality safety.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 2, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plau and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 2, 2021

Plutonium Facility–Conduct of Operations: On Wednesday, a worker adding water to the vault water baths jammed open the spring-closed fill valve and departed for another task resulting in the baths overflowing. The local high-level alarm did activate; however, the alarm communication to the operations center did not function as intended. A radiological control technician discovered flooding in the vault corridor several hours later and reported the incident. The valve was promptly closed. Facility and criticality safety personnel concluded there was no immediate hazard from the estimated 1800 gallons of spilled water and started cleanup activities. There was no spread of radioactive contamination discovered during water sampling. Facility management has proposed many corrective actions to prevent recurrence including reviewing their alarms, evaluating an overflow line to a sump, and reviewing their fill procedure.

Plutonium Facility–Glovebox Safety: On Monday, workers performing hand lapping of a piece of plutonium metal breached a glovebox glove. The workers received contamination on their personal protective equipment, but there was no indication of an uptake. This was a repeat of an event that occurred last month (see 3/5/2021 report). Based on worker comments, it appears that corrective actions to improve tooling created a different sharps hazard. Management is reviewing the tooling.

Transuranic Waste Management: Last month, Triad safety basis personnel completed their New Information process related to the reactive titanium and tantalum metal fines that ignited and sparked during waste drum-out activities on February 26, 2021. For the Plutonium Facility, they entered the New Information process 5 days following the event. Fourteen days later, they completed the process. For the Transuranic Waste Facility (TWF), they entered the New Information process 10 days following the event and reached their conclusion 11 days later. Triad's procedure for its New Information process requires declaration of a potential inadequacy of the safety analysis (PISA) if a decision cannot be reached within 13 calendar days of entry into the process; however, Triad analysts received an internal variance to this requirement because of the one day safety stand-down.

Triad's analysis for both facilities concluded that a PISA did not exist, largely based on calculations demonstrating that reaction of the metal fines could not overpressurize or initiate a fire inside a waste container. The analysis for TWF also addressed whether the two containers that potentially contained reactive metal fines violated the safety basis prohibition on receipt of D001 (ignitable characteristic) waste. Safety basis personnel demonstrated compliance with the restriction using an email with an analysis from the division leader responsible for waste. The analysis indicated that any reactive fines placed in the waste container would have oxidized to a nonreactive state given the time elapsed since container closure.

Overall, Triad's analysis for the Plutonium Facility recommends improving discussion in the safety basis to explicitly describe the non-radioactive pyrophoric hazards (e.g., stainless steel, tantalum, titanium) in the welding and solid waste sections.

Area G–Safety Basis: On Monday, the EM Field Office rejected N3B's evaluation of the safety of the situation concerning DNFSB/TECH-46 (see 1/22/2021 report). The rejection noted the need to integrate with the other PISAs and provide a discussion on the safety of moving containers thought to have incompatible chemicals.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 9, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 9, 2021

Plutonium Facility–Safety Basis: On Monday, facility personnel took safety basis required actions after receiving information questioning whether they were appropriately accounting for encapsulated plutonium-238 heat sources in the calculation of material-at-risk (MAR). Specifically, personnel performing an extent-of-condition review on sealed-sources found that individual liners, rather than the full three-layer assembly, were being credited with a damage ratio of zero. While the liners have the testing and pedigree to support the use of this damage ratio, the safety basis has not yet fully implemented this control. Facility personnel removed the credit for the partial assemblies and satisfactorily performed the MAR surveillance on Wednesday. Facility management plans corrective actions related to the implementation verification review process and assignment of dedicated safety basis analysts for each programmatic operations group.

Transuranic Waste Management: On Monday, Plutonium Facility and Central Characterization Program (CCP) personnel resumed visual identification and examination activities in support of waste drum-outs. To resume these activities before the completion of the ongoing causal investigation into the reactive titanium fines (see 3/19/2021 report), waste management personnel instituted compensatory measures including: only processing waste streams from air atmosphere gloveboxes, implementing a new database to capture the date and location where waste packages originate, and providing training on newly revised policy documents. Meanwhile, the causal investigation team continued its efforts and remains on schedule to out-brief senior leadership next week. Notably, the team reviewed CCP requirements as the impact LANL waste characterization processes.

Weapons Engineering Tritium Facility: On Monday, facility operations personnel discovered that a tritium room monitor had failed during the weekend due to loss of flow. They took the required safety basis actions and were able to restore operability to the unit; however, the unit failed again later that day. This was the same unit that had failed earlier this year (see 2/5/2021 report). Discussion at the fact-finding centered around whether the issue was associated with the gas supply or the monitor itself. Based on a suggestion from an engineer, facility personnel swapped the monitor with another unit from a different room that had multiple monitors. This approach allowed them to isolate the problem between monitor and gas supply. On Wednesday, the swapped monitor also alarmed. Facility personnel further investigated and found a regulator for the gas supply that was set below the expected pressure. Facility management is using this experience to emphasize more comprehensive troubleshooting when safety systems malfunction.

Legacy Facilities: On Thursday, N3B received EM Field Office unconditional approval of the evaluation of the safety of the situation for the TA-21-257 radioactive liquid waste treatment facility and associated industrial waste lines (see 9/18/2020 report).

Federal Oversight: Last month, the NNSA Field Office issued its corrective action plan to address the Chief of Defense Nuclear Safety's biennial review of nuclear safety performance (see 10/16/2020 report). Field office leadership concluded that the issues are all low risk in accordance with their issues management process. As a result, none of the issues required a causal analysis. Corrective actions are scheduled to be completed by May 2022.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 16, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 16, 2021

Transuranic Waste Management: On Thursday, Triad's causal investigation team out-briefed senior laboratory leadership and multiple leaders from NNSA Headquarters on the results of their assessment of the sparking event involving reactive titanium metal fines. The team identified two root causes: (1) the programmatic operations group responsible for the welding activity did not recognize that welding titanium in an inert glovebox could result in the generation of potentially pyrophoric fume condensates and (2) neither Triad waste management nor Central Characterization Project processes rejected the prohibited reactive titanium metal fines from the transuranic waste stream. The team expects to release its full report next week with additional details, including a comprehensive barrier analysis and an event and causal factors tree. In our opinion, the second root cause and the associated contributing causes presented by the team demonstrate flaws in the corrective actions taken to enhance the acceptable knowledge program following the 2014 radiological release event at the Waste Isolation Pilot Plant.

Area G: This week, N3B and Triad personnel completed two shipments of legacy transuranic waste from the RANT Shipping Facility to the Waste Isolation Pilot Plant. Given the ongoing investigation on the titanium sparking event and the need for corrective actions, the Carlsbad Field Office has allocated Area G with all near-term planned shipments from LANL.

Flanged Tritium Waste Containers (FTWC): Triad and N3B personnel continue to work on corrective actions from last fall's federal readiness assessment associated with activities to vent and disposition the FTWCs with potentially flammable headspace conditions that are stored in a shed at Area G (see 1/29/2021 report). They are currently working to submit required safety basis changes, develop a case to conduct the activity under the limited operational envelope at Area G, and receive necessary regulatory approvals from the State of New Mexico. Given recent EM Field Office review and approval cycle times and the fact that Triad personnel will need to conduct additional practice and demonstrate those activities for DOE personnel, it will be challenging for Triad to conduct this important risk reduction activity prior to the start of the monsoon season. The radioactive decay of tritium increases FTWC pressures meaning that the continued delays increase the likelihood of an unplanned release to the environment.

Transuranic Waste–Safety Basis: On Tuesday, the NNSA Field Office rejected the three evaluations of the safety of the situation (ESS) related to spent ion exchange resins in waste containers associated with the Plutonium Facility, Chemistry and Metallurgy Research building, and the Transuranic Waste Facility (see 2/5/2021 report). The field office's rejection noted that Triad's supporting calculation does not provide an adequate basis to justify the conclusion that a small volume of unrinsed resin should be allowable in waste containers because it would not create a potential over-pressurization hazard. The rejection also noted that the evaluations do not identify procedures that render resins non-reactive through rinsing or cementation as safety controls. For the ESS specific to the Transuranic Waste Facility, the field office also noted that there are no controls associated with safely moving a container out of the facility that is noncompliant with the resin requirements—which is currently a required safety basis action.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 23, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 23, 2021

Safety Basis: In March, N3B declared a potential inadequacy of the safety analysis (PISA) at Area G because the safety basis had dismissed helicopter crashes as insignificant without a site-specific analysis (see 3/26/2021 report). In early April, N3B concluded the PISA constituted a positive unreviewed safety question (USQ) based on affirmative answers to four of the seven evaluation questions. Triad facilities use a variety of approaches to analyze helicopter crashes. The RANT Shipping Facility, which is adjacent to Area G, also does not evaluate helicopter crashes in the calculations supporting its safety basis. After receiving information from N3B about its PISA, Triad did not enter its New Information process to formally evaluate whether any of its facilities warranted entry into the PISA process for this issue. On Tuesday, Triad safety basis personnel briefed NNSA Field Office personnel on their arguments for not formally evaluating this matter. The field office requested Triad provide a written explanation of its analysis.

On a related note, last month the Facility Representative for the EM Field Office issued N3B a finding against DOE guidance associated with the PISA process. The finding cited: N3B did not make multiple PISA determinations in the expected timeframe of “hours to days;” and noted that documentation associated with multiple PISA determinations included more analysis than the expected “go/no-go” for this step in the process. We note that Triad safety basis personnel have a demonstrated record of these same practices.

Plutonium Facility–Construction Safety: Triad management paused backshift construction activities after two injuries last week: (1) a worker suffered a broken hand when a wind gust closed an unsecured transportainer door that smashed into the hand and (2) a worker received lacerations to the hand from an inadvertent actuation of a saw during practice downsizing operations in a glovebag in a non-radiological area. Fact-finding personnel discussed several concerns including: improper emergency notifications and associated conflicting direction on notifications; the need for additional onsite support personnel during backshift operations; the lack of drills and exercises to ensure readiness of the backshift for emergency events; and consideration of abnormal operating procedures to protect personnel working outside of the facility during high-wind conditions. Triad management is reviewing and individually releasing work packages for the backshift. We note that neither the NNSA Field Office nor the local NNSA Acquisition and Project Management Office have routine federal presence on the backshift.

Emergency Management: On Monday, the NNSA Field Office directed Triad to create a plan of action within 45 days to address the recurrence of improper emergency notifications. To support its argument, the field office cited seven instances of improper notifications since February 2020. The two construction safety injuries discussed above were not included in the tally.

Area G: On Wednesday, EM rejected N3B’s justification for continued operations associated with flammable gas sampling (see 1/8/2021 report). The rejection letter from the field office commits to provide detailed written comments to N3B no later than May 6, 2021. On Thursday, EM Headquarters and Field Office personnel discussed with N3B their concerns with the submittal. Flammable gas sampling operations have been suspended since January 2020.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 30, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 30, 2021

Plutonium Facility–Infrastructure: On Tuesday, the Deputy Secretary of Energy approved the Critical Decision 1 milestone (Approve Alternative Selection and Cost Range) for the Los Alamos Plutonium Pit Production Project. The Critical Decision 2 milestone (Approve Performance Baseline) is expected in 2023, and overall project completion is projected for 2027–2028. Triad also announced the creation of a new Associate Laboratory Directorate for Plutonium Infrastructure. This organization will be responsible for preparing the Plutonium Facility to meet its enduring programmatic missions through the execution of a multitude of efforts including: the pit production project, remaining subprojects from the Chemistry and Metallurgy Research Replacement Project, phase 3 of the Technical Area 55 Reinvestment Project, and other infrastructure efforts executed through programmatic funding.

Area G: Last week, N3B personnel identified two new potential inadequacies of the safety analysis (PISA). Personnel developing a modern documented safety analysis for the facility identified an inconsistency between the guidance in DOE-STD-5506-2007, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*, and the construction classification of waste storage domes. The current safety basis considers the uncredited domes and Permacons to be light construction—meaning that if they collapsed, falling structural pieces will not damage waste containers and result in a release of radioactive material. The PISA notes that steel support trusses in some of the domes and Permacons are significantly heavier than the aluminum framework and may not be appropriately considered as light construction. A similar question came up two years ago following heavy snowfall which damaged some of the domes, but did not lead to a PISA (see 1/11/2019 report).

On Friday, N3B declared another PISA related to an inconsistency between DOE-STD-5506 and the current safety basis. The safety basis states that sympathetic deflagrations of additional waste containers can be prevented by not stacking containers and does not consider lateral as opposed to vertical sympathetic deflagrations. There are currently eight unvented containers, most of which contain cemented waste, stored aboveground at Area G. The containers are currently segregated in a restricted work zone and N3B is evaluating the storage situation. Container venting capability is not currently active at Area G; however, six of the unvented containers are 110-gallon drums that do not fit in the existing venting apparatus.

Federal Oversight: Mr. Pete Rodrik arrived this week to begin performing duties as the interim Manager of the NNSA Field Office. Later this summer, Mr. Ted Wyka will assume the permanent Manager position. Two new individuals also commenced their roles as Deputy Manager for Technical Operations and Deputy Manager for Business, Security, and Missions. As a result of these advancements and one departure, currently three of the four middle management positions in Technical Operations are vacant or being filled by individuals on temporary details.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 7, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: J.W. Plaue and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 7, 2021

DNFSB Staff Activity: Next Monday, J.W. Plaue will temporarily cease resident inspector duties to begin a detail as the acting Associate Technical Director for the newly formed Nuclear Facility Infrastructure and Projects group.

Weapons Engineering Tritium Facility: Last Friday, facility personnel noted that the closure mechanism for a fire door failed. This door is part of the facility structure, a safety class design feature. Engineering personnel evaluated the door and initially concluded it could still serve its safety function while secured with rubber door stops. Further evaluation concluded that the preventive maintenance performed last year to support the in-service inspection of the door was improperly completed. Facility personnel have declared a violation of the technical safety requirements and are planning to repair or replace the closure mechanism. Nuclear safety personnel have entered the New Information process to determine whether the existing configuration of the door provides the same fire rating as its tested configuration.

Emergency Management: On Wednesday, a team from the DOE Office of Enterprise Assessments in-briefed its upcoming assessment of the effectiveness of Triad and the NNSA Field Office in managing and maintaining emergency preparedness capability. The team plans to complete its primary interactions with LANL by the end of June with a final report expected in August.

Infrastructure: On Monday, Triad safety basis management transmitted to the NNSA Field Office for approval a major modification determination performed in support of a proposed project to replace an inoperable ventilation system exhaust fan in an inactive wing of the Chemistry and Metallurgy Research building with a externally-placed modular unit. This project will also serve as a demonstration of a key approach to transitioning other wings to an improved state of system reliability while awaiting final disposition. Of the six criteria provided in DOE-STD-1189-2016 for major modification determinations, Triad personnel concluded that the project tripped a single criterion associated with a hazard that is not previously evaluated in the safety basis. This hazard was associated with ventilation system maintenance performed outside. Triad personnel plan to develop new hazard scenarios for the ventilation system but expect they will not derive any new, or modifications to existing, credited safety systems.

Area G: N3B personnel commenced an Implementation Verification Review to validate adequate implementation of the compensatory measures documented in the consolidated standing order addressing 21 potential inadequacies of the safety analysis for the Area G safety basis (see 3/26/2021 report). Part of the review included a walkdown of storage areas to validate that pipe overpack containers with greater than 80 plutonium-239 equivalent curies and drums with the potential for energetic chemical reactions, as discussed in DNFSB/TECH-46, were segregated in their approved locations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 14, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending May 14, 2021

Transuranic Waste Management: Last Friday, Triad released LA-UR-21-24378, *Analysis of an Unexpected Reaction Observed During Drumout Activities, Feb. 26, 2021*, their final report for the investigation into the titanium fines event (see 4/16/2021 report). The report provides numerous recommendations to address the two identified root causes. Key recommendations for the root cause that the hazard of the reactive metal fines was not recognized include: ensuring potential pyrophoric hazards associated with inert gloveboxes are captured in work control documents, developing and implementing passivation criteria for material coming out of inert gloveboxes, and improving change control processes to re-evaluate hazards following changes such as scale-up or process modification. Recommendations for the second root cause that existing processes did not reject the prohibited material from the waste stream include: establishing a formal process for flowing down requirements from Central Characterization Project documents into Triad work control documents, requiring completion of chemical compatibility evaluations as discussed in DNFSB-TECH-46, and ensuring Acceptable Knowledge documentation accurately represents the nature of the process.

Safety Basis: On Wednesday, the NNSA Field Office approved a revision to the Triad Unreviewed Safety Question (USQ) process that addresses comments from the original submittal (see 11/20/2020 report). The Field Office provided one condition of approval. They requested that the procedure be revised such that the New Information process is indicated as being a part of the USQ process. They noted that the separation between the processes in the current revision is inconsistent with the DOE implementation guide for USQs. They further noted that entering the New Information process is an entry condition for the Potential Inadequacy of the Safety Analysis (PISA) process. As such, timeframes associated with the USQ process should start with entry into the New Information process. The Board's July 10, 2020 letter on complex-wide implementation of the PISA process also highlighted that DOE site contractors, including Triad, often take time to evaluate new information before entering their formal processes which could further extend the time a facility may be in an unsafe condition.

Area G–Safety Basis: Last Monday, the Environmental Management Field Office and Headquarters responded to N3B's most recent revision of their Safety Basis Strategy for upgrading the Area G safety basis to a modern DOE-STD-3009-2014 compliant document while maintaining safe current operations under the existing safety basis (see 3/19/2021 report). The letter provided several comments on the strategy but requested that the comments be used to inform N3B's safety basis development efforts instead of submitting a revision or formal comment response.

Readiness: This week, Triad submitted its third quarter startup notification report to the NNSA Field Office. Also this week, N3B received approval of its first and second quarter startup notification reports from the EM Field Office. Notable changes include shifting the project startup date for elevating the Radiological Laboratory Utility Office Building to a hazard category-3 nuclear facility out nine months to April 2022 and continued delays in venting the Flanged Tritium Waste Containers at Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 21, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending May 21, 2021

Area G–Safety Basis: On Monday, the Environmental Management Field Office and Headquarters approved the consolidated Evaluation of the Safety of the Situation (ESS) covering 18 of the current potential inadequacies of the safety analysis (see 3/26/2021 report). The Safety Evaluation Report included no conditions of approval. However, it did note a programmatic concern with application of the Unreviewed Safety Question process. N3B already responded to that concern in a March letter outlining their approach to adjudicating open safety basis issues.

On-Site Transportation: On Wednesday, Triad responded to the NNSA Field Office’s conditional approval and submitted a revised ESS addressing pyrophoric hazards in the Transportation Safety Document (see 2/12/2021 report). The revised ESS removes the previous allowance in a standing order to ship potentially pyrophoric materials in a pipe overpack container. It proposes to add a new packaging control to the Transportation Safety Document and Technical Safety Requirements. The packaging control will allow shipments of less than 50 grams of pyrophoric material using a pipe overpack container or SAVY-4000 container inside a Department of Transportation 7A drum.

Waste Characterization Reduction and Repackaging Facility (WCRRF): On Tuesday, the NNSA Field Office conditionally approved Triad’s request for a temporary exemption from the DOE Order 420.1C requirement to comply with NPFA 13 sprinkler installation requirements. The glovebox enclosure in WCRRF contains several sprinkler heads that are not installed per code. Triad sought the exemption to decontaminate the enclosure prior to fully evaluating the sprinkler system. NNSA’s three conditions of approval were: to include the exemption in the next annual update of the facility’s Fire Hazards Analysis, the approval expires one year after decontamination efforts are complete, and annually report to the field office on the status of correct actions. WCRRF is an aging facility that is currently in cold standby but is one option to restore size reduction capabilities on site (see 10/9/2020 report).

Transuranic Waste Facility (TWF): Late last month, TWF personnel completed converting their dry pipe fire suppression system from using nitrogen to dry air. This eliminated an asphyxiation hazard in the waste storage buildings and the need for oxygen monitoring (see 11/22/2019 report).

Federal Oversight: On Thursday, the DOE Office of Enterprise Assessments issued their final report on the results of their remote assessment of the Triad Nuclear Criticality Safety Program (see 2/5/2021 report). Overall, they concluded that the program has improved since the 2013 Director’s pause and that the NNSA Field Office has been providing comprehensive oversight. The one finding from the report was that criticality safety analysts authoring and reviewing criticality safety evaluations are not always ensuring compliance with analysis and documentation requirements defined in DOE-STD-3007. The report noted that approximately one third of the evaluations reviewed were noncompliant. There were several supporting deficiencies related to documentation and referencing of bases, references, and models in analyses. The team is planning a second assessment focused on control implementation and conduct of operations within the next year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 28, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending May 28, 2021

DNFSB Staff Activity: On Wednesday, members of the Board's staff conducted a teleconference with Triad and NNSA Field Office personnel to discuss the results of their review of the Onsite Transportation Safety Document (see 3/19/2021 report).

Transuranic Waste Facility (TWF): On Tuesday, Triad submitted to the NNSA Field Office for approval a revised TWF safety basis. Last month, NNSA rejected a previous revision of this submittal which addresses issues with firewater pump acceptance curves (see 8/28/2020 report). Last October, Triad re-performed field tests of the firewater pump to establish a new performance baseline. The Fire Suppression System was elevated to safety-significant as a major contributor to defense-in-depth in a 2018 revision of the TWF Documented Safety Analysis. However, resolving the pump curve issues has delayed full implementation of said designation.

Transuranic Waste Management: A review team sponsored by NNSA's Office of Safety, Infrastructure, and Operations was onsite this week completing a review of transuranic waste needs to support production of 30 pits per year. The review scope is focused on optimizing the processes to compliantly prepare newly generated transuranic waste drums for shipment to the Waste Isolation Pilot Plant (WIPP) rather than looking at existing inventories. The team expects to complete their final report next month.

N3B completed two transuranic waste shipments to WIPP last week and one this week through Triad's RANT Shipping Facility. Given the additional controls and restrictions associated with the safety basis issues at Area G, and material at risk limitations at RANT, N3B will have a challenge in the near term building additional shipments from their current population of WIPP certified drums. Mobile loading at Area G, the alternative to shipping through RANT, is currently restricted due to a prohibition on crane usage at Area G as a compensatory measure to a potential inadequacy of the safety analysis. N3B and EM-LA are working to resolve safety basis issues and ramp up operations in a compliant manner.

Safety Basis: Earlier this month, the NNSA Field Office issued their review plan for the planned upgrade of the Plutonium Facility safety basis using DOE-STD-3009-2014. This safety basis update will include a new accident analysis using modern methodologies for key safety inputs such as the leak path factor, atmospheric dispersion modeling, and fire hazards analysis. Triad plans to submit the new safety basis in March 2022. The field office's review plan identifies additional subject matter expert support from other DOE organizations but does not yet identify a reviewer for the MELCOR code calculations that will be used to develop a new facility leak path factor. NNSA plans to update their review plan as additional resources are identified.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 4, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending June 4, 2021

Area G–Safety Basis: Last Thursday, N3B transmitted to the EM Field Office and EM Headquarters for approval a revised Justification for Continued Operations (JCO) for the Potential Inadequacy of the Safety Analysis (PISA) related to headspace flammable gas sampling (see 1/31/2020 report). EM personnel rejected a previous revision of this JCO (see 4/23/2021). The revised JCO attempts to address the EM concerns, and continues to propose a new Specific Administrative Control during flammable gas sampling that requires the filter vent cover to be removed within 10 hours. A supporting calculation estimates that it would take at least 22.5 hours to reach the lower flammability limit in a bounding drum with the vent covered.

Last Thursday, N3B also transmitted an Evaluation of the Safety of the Situation (ESS) for the PISA on horizontal sympathetic deflagrations for transuranic waste drums (see 4/30/2021 report). The eight unvented drums currently stored in Area G are not horizontally distanced from each other. The ESS adds a compensatory measure to limit the total material at risk (MAR) of the unvented drums. The eight drums together constitute less than 80 plutonium equivalent curies and so long as no additional unvented drums are added to the location, the consequences are protected as moderate. N3B will also prepare a JCO.

Also last Thursday, N3B transmitted a draft Chapter 3: Hazard and Accident Analysis and Control Selection for their new safety basis that will be developed per the modern DOE Standard 3009-2014 and informed by the developing revision to DOE Standard 5506.

Last Friday, N3B transmitted to the EM Field office and EM Headquarters for approval the ESS for the PISA on dome construction classification (see 4/30/2021 report). Of the three impacted domes, one does not currently store transuranic waste. All three have been restricted from receiving additional waste drums, however waste is not being moved out of the other two domes due to lack of space and a desire to minimize handling of drums with high MAR or potential chemical incompatibilities. N3B is preparing a JCO for this ESS as well.

Weapons Engineering Tritium Facility (WETF): Triad personnel concluded that the damaged fire door that was not properly latching represented a positive unreviewed safety question (see 5/7/2021 report). The condition was discovered on May 4, the PISA was declared on May 18, and the positive unreviewed safety question determination was made on May 28.

Emergency Management: On Thursday, Triad transmitted their response to the NNSA Field Office letter requesting a plan of action to address issues with improper emergency notifications (see 4/23/2021 report). The proposed plan of action includes a series of corrective actions to standardize emergency reporting requirements, improve emergency notification resources, and communicate leadership expectations for notifications. Many actions including rollout of new notification training have been completed already. Completion of all corrective actions is planned by the end of February 2022 with an effectiveness review to be performed in the same timeframe.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 11, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending June 11, 2021

Plutonium Facility–Glovebox Safety: On Monday, a worker in a plutonium machining area discovered contamination on their personal protective equipment while performing a survey upon exiting the glovebox gloves. There was no skin contamination or evidence of an uptake. Further evaluation determined that the over-gloves used to protect from substantial sharps hazards had a breach in the internal Kevlar layer. The outer goatskin layer was visibly worn, but the breach was not obvious from an external inspection. This type of over-glove was introduced in the facility in 2018 and has so far been performing well for allowing dexterity while providing additional protection. Facility personnel plan to evaluate additional inspections and lifetime tracking of these gloves.

Following the glovebox glove breach and uptakes last June (see 8/7/2020, 6/12/2020 reports), Triad performed an investigation and implemented several corrective actions including new practices for exiting glovebox gloves to detect breaches earlier and reduce their impact to others in the room. These practices were initially implemented via a standing order and were later rolled into the training requirements for glovebox workers. The training does not currently address inspection expectations when working in over-gloves as in the above event. During recent observations of glovebox work in the Plutonium Facility, the Resident Inspector has not observed rigorous compliance with the current requirement for a visual inspection of glovebox gloves prior to removing one's hands on every glovebox glove exit. Compliance with the long-standing requirement to survey one's hands following removal from glovebox gloves remains strong, however compliance with the new timing expectation of said survey, prior to securing the gloves, is mixed.

Transuranic Waste Management: Last Wednesday, Triad issued the Corrective Action Plan for the energetic event during a waste drumout activity (see 3/5/2021, 5/14/2021 reports). All corrective actions are expected to be completed this year. Of note, the corrective actions include one to develop process reviews that will include the process operators, waste packaging personnel, and representatives from the WIPP Central Characterization Program. The reviews will identify process inputs and outputs to support development of operations-specific Chemical Compatibility Evaluations and accurate Acceptable Knowledge Reports. The reviews are also intended to ensure that Chemical Compatibility Evaluations account for comingled streams and will support Safety Basis personnel in developing a systematic approach to analyze and control potential incompatible material hazards.

Plutonium Facility–Criticality Safety: On Thursday, Triad nuclear criticality safety personnel issued a revised memo that provides a new basis for the conclusion that a criticality accident resulting from leakage of fissile solutions from aqueous chloride process areas to a non-safe geometry in the basement was not credible (see 1/15, 1/8/2021 reports). The new memo notes that due to non-seismically qualified gloveboxes and the potential for cracks to form in the floor, fissile solution could potentially leak into the basement. However, given the location of the boxes where a leak could occur and the pathways to an unfavorable geometry in the basement (e.g., a sump), the memo concludes that it would be incredible for the maximum possible volume of leaked solution to accumulate into a critical geometry.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 18, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending June 18, 2021

Transuranic Waste Management: Last Thursday, workers identified a transuranic waste drum on an outdoor storage pad with a corroded drum filter. They promptly tagged and segregated the drum, and later moved it indoors to the basement of the Plutonium Facility. The drum primarily contains glovebox gloves from heat source plutonium operations. Filter corrosion was observed two years ago from drums containing the same type of gloves used in heat source operations (see 5/24/2019 report). Unlike the previous event, facility personnel declared the drum inoperable due to the degraded filter. The resident inspector believes that is the appropriate decision for heavily corroded drum filters, where their ability to provide a filtered vent path is not readily discernable through a visual inspection. The more modern Transuranic Waste Facility safety basis includes more explicit statements about filter integrity for drum operability than the Plutonium Facility safety basis. Triad plans to analyze the filter to determine the cause of the corrosion.

Area G–Safety Basis: Last Friday, Environmental Management Headquarters and Field Office personnel unconditionally approved the Justification for Continued Operations (JCO) for the potential inadequacy of the safety analysis for headspace flammable gas sampling of transuranic waste drums (see 6/4/2021, 1/31/2020 reports). DOE noted they expect the JCO to be implemented within 90 days. Due to inclusion of a new credited hazard control in the JCO, N3B is planning an Implementation Verification Review.

Plutonium Facility–Conduct of Operations: Housekeeping and management of low-level and other combustible waste in the basement of the Plutonium Facility has been a continuing challenge. The increased pace of construction work to support the pit production mission has correspondingly increased waste generation. During basement walkdowns, the resident inspector has noted numerous plastic bags filled with garbage accumulating. Of note, several undated plastic bags filled with cardboard framed air filters have been staged for the past month. An informal marking on one bag notes that these filters have no waste acceptance form and are of questionable provenance. There is also no transient combustible permit associated with the bags. Facility management does have a project to improve housekeeping in the basement. On a positive note, during the last plant inventory, the amount of combustible waste in the basement was significantly lower than normally observed.

On Site Transportation: Last Tuesday, Triad submitted to the NNSA Field Office for approval an addendum to the Transportation Safety Document to allow shipping of potentially pyrophoric material in accordance with the proposal outlined in a recent Evaluation of the Safety of the Situation (see 5/21/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 25, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending June 25, 2021

Federal Oversight: The resident inspector met with Mr. Ted Wyka who became the manager of the NNSA Field Office on Monday. He replaces Mr. Pete Rodrik who served two months as the interim Field Office Manager.

Plutonium Facility–Criticality Safety: On Monday, workers inadvertently moved water resistant containers with salt residue materials into a glovebox where that material type was not allowed per the criticality safety posting. They moved these materials out of a dropbox to move in a higher mass item while maintaining compliance with its mass limits. Promptly after they moved the containers, while performing checks, they identified the error and responded appropriately. This was an analyzed upset condition in the criticality safety evaluation for the receiving glovebox. The upset condition was recovered later in the week. Criticality Safety personnel plan to evaluate whether the criticality safety evaluation and posting for the receiving glovebox should be revised to allow inclusion of this type of material. They also plan to evaluate increasing the mass limit for the dropbox the materials were moved from.

Chemistry and Metallurgy Research Building (CMR)–Safety Basis: On Monday, Triad personnel declared a Potential Inadequacy of the Safety Analysis (PISA) for the analysis of wildfire hazards in the CMR yard. The safety basis states that plume lofted burning embers from wildfires of any size cannot impact containers stored in the CMR yard. Triad safety analysts noted that the wildfire analysis calculation does not support that conclusion for the entire yard, but only for one sheltered area of the yard. Since the safety basis analyzes other potential types of fires that can impact containers in the yard and identifies existing credited and non-credited controls, Triad is not adding any compensatory measures to address this PISA.

Area G–Safety Basis: Last Friday, N3B submitted to the Environmental Management Field Office and Headquarters a revised Evaluation of the Safety of the Situation (ESS) for the PISA related to DNFSB TECH-46 and potentially energetic drums. The new revision is intended to resolve DOE’s comments on the previous revision which was rejected (see 1/22/2021, 4/2/2021 reports). It includes detailed tables of waste containers subject to operational restrictions following extent of condition reviews of the entire population of above ground containers looking for potential chemical incompatibilities or unknown contents.

Plutonium Facility–Infrastructure: On Tuesday, the NNSA Field Office and the Federal Project Director unconditionally approved the Safety Design Strategy for the Chemistry and Metallurgy Research Replacement Plutonium Facility Equipment Installation Phase 2 subproject. The majority of the scope in this project does not directly impact the safety basis of the Plutonium Facility, however construction to support an expanded access portal for the Plutonium Facility will impact the safety class missile barriers. The approval letter notes that the safety function of the barrier must be maintained during all phases of work.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 2, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 2, 2021

DNFSB Staff Activity: Staff members J. Jarvis, P. Migliorini, J. Plaue, and S. Seprish were on site this week for a review of Critical Decision 1 (Approve Alternative Selection and Cost Range) of the Los Alamos Plutonium Pit Production Project (LAP4). Staff member R. Kazban supported the review remotely. The onsite team also walked down the Plutonium Facility and Technical Area 21 and held discussions with N3B and Environmental Management Field Office personnel regarding the current state of Area G operations within safety basis constraints.

Plutonium Facility–Infrastructure: The resident inspector and headquarters staff members walked down the Plutonium Facility to better understand the current pit production flowsheet and infrastructure improvements related to LAP4. The team noted the challenge of maintaining current production work while construction efforts to add and upgrade equipment is in progress. While the construction work occurs primarily on the backshift, scaffolding and other equipment increases congestion in the process rooms.

Chemistry and Metallurgy Research Building (CMR)–Radiological Protection: On June 16th, a radiological control technician surveying out of a high contamination area/airborne radioactivity area in the Wing 5 basement discovered contamination on their personal protective equipment (PPE). Further surveys identified skin contamination on the back of the ankle and personal clothing contamination at the pant cuffs. The individual was successfully decontaminated. The PPE requirements for this area included shoe covers that do not overlap with coveralls and are not required to be taped. That is a standard practice at the laboratory. As a corrective action, Triad personnel are planning to supply personnel at CMR with PPE used at the Plutonium Facility including anti-contamination socks and bands to secure pant legs. The area where the individual was working is subject to leaks from an industrial waste line and is the most contaminated area in the facility. Repairs to leaking flanges and decontamination of the room are planned for later in the summer.

Legacy Facilities: The resident inspector and headquarters staff members walked through Technical Area 21 with N3B and Environmental Management Field Office personnel and discussed the plans to perform additional characterization for TA-21-257 and the underground industrial waste lines (see 4/9/2021 report). In May, N3B submitted to the field office for approval a Justification for Continued Operations to allow these characterization activities.

Safety Basis: On Tuesday, Triad submitted to the NNSA Field Office for approval a revision to their proposed protocol and input parameters for dispersion analysis (see 2/26/2021 report). The revision is intended to address technical comments from the Field Office provided on the previous February submittal. Upon approval by the Field Office, this will be a key input to the upgrade of the Plutonium Facility safety basis to DOE-STD-3009-2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 2, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 2, 2021

DNFSB Staff Activity: Staff members J. Jarvis, P. Migliorini, J. Plaue, and S. Seprish were on site this week for a review of Critical Decision 1 (Approve Alternative Selection and Cost Range) of the Los Alamos Plutonium Pit Production Project (LAP4). Staff member R. Kazban supported the review remotely. The onsite team also walked down the Plutonium Facility and Technical Area 21 and held discussions with N3B and Environmental Management Field Office personnel regarding the current state of Area G operations within safety basis constraints.

Plutonium Facility–Infrastructure: The resident inspector and headquarters staff members walked down the Plutonium Facility to better understand the current pit production flowsheet and infrastructure improvements related to LAP4. The team noted the challenge of maintaining current production work while construction efforts to add and upgrade equipment is in progress. While the construction work occurs primarily on the backshift, scaffolding and other equipment increases congestion in the process rooms.

Chemistry and Metallurgy Research Building (CMR)–Radiological Protection: On June 16th, a radiological control technician surveying out of a high contamination area/airborne radioactivity area in the Wing 5 basement discovered contamination on their personal protective equipment (PPE). Further surveys identified skin contamination on the back of the ankle and personal clothing contamination at the pant cuffs. The individual was successfully decontaminated. The PPE requirements for this area included shoe covers that do not overlap with coveralls and are not required to be taped. That is a standard practice at the laboratory. As a corrective action, Triad personnel are planning to supply personnel at CMR with PPE used at the Plutonium Facility including anti-contamination socks and bands to secure pant legs. The area where the individual was working is subject to leaks from an industrial waste line and is the most contaminated area in the facility. Upon approval by the Field Office, this will be a key input to the upgrade of the Plutonium Facility safety basis to DOE-STD-3009-2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 9, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 9, 2021

Area G: N3B personnel continue their efforts to address transuranic waste containers with potential reactivity hazards as described in the revised Evaluation of the Safety of the Situation related to DNFSB-TECH-46 that was recently submitted to the Environmental Management Field Office (see 6/25/2021 report). The initial sets of containers identified as potentially reactive were moved into a single layer in the Dome 375 Permacon (see 2/12/2021 report). As N3B performed an extent of condition, they identified more containers of potential concern, and determined through additional review that some previously identified containers did not constitute a concern. There are currently 60 containers subject to operational restrictions due to potential reactivity. Fifteen of them are segregated in the Dome 375 Permacon and the rest remain in their original storage domes as N3B and the Field Office later determined it would be more prudent to avoid moving potentially reactive containers. For the drums that were not moved, N3B recently completed a posting effort to help assure compliance with operational restrictions. The current restrictions are that the containers shall not be moved, there is a marked buffer zone established around each container of potential concern, and intrusive operations are prohibited within the buffer zone.

The resident inspector has noted during walkdowns that control of vegetation in Area G has improved significantly this growing season following corrective actions from a 2019 Technical Safety Requirements violation (see 12/20/2019 and 6/5/2020 reports).

Plutonium Facility–Operations: While restarting control systems following a variable frequency drive upgrade for the ventilation system on Saturday June 26, Triad personnel discovered problems with the Facility Control System (FCS). The FCS is a safety-significant support system that controls and monitors the safety functions of the ventilation system. They determined the system was inoperable per the Technical Safety Requirements but were able to restore it to operability later that day. On the next Tuesday, Triad personnel identified additional issues with the FCS, declared it inoperable, and entered the associated limiting condition of operation. Replacement of an optical communications module resolved the issues with the system and, following additional monitoring of the system, facility personnel exited the limiting condition of operation and declared the FCS operable. The communications module has been installed for approximately seven years. The modules are currently scheduled to be replaced every eight years per the manufacturer's recommendations and spares are available. Facility personnel are evaluating their replacement and maintenance cycles as well as what level of system evaluation should occur following system errors.

Plutonium Facility–Radiological Safety: Last Tuesday, while performing an orderly exit of their area due to the FCS outage described above, an operator discovered contamination on a personal protective equipment glove. The cause was a glovebox glove breach. There was no skin contamination. The individual had been cutting open a 3013 can of plutonium feed, an activity with many potential sharps and pinch points. However, they were using overgloves and there was no evidence of damage to the overglove.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 16, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 16, 2021

Emergency Management: On Monday, a 4.2 magnitude earthquake and several smaller events occurred approximately 50 km northwest of the laboratory. Onsite personnel felt the event, and facility personnel performed inspections which concluded there was no damage. A seismic cutoff valve for the natural gas feed into TA-55 did actuate during the event.

On Tuesday, the NNSA Field Office conditionally approved Triad's April request for an extension of the suspension of certain requirements from DOE Order 151.1D, *Comprehensive Emergency Management System*, as a result of the COVID-19 response. Triad noted they would be unable to meet many of the order's requirements for FY2021 largely due to limiting in-person drills. While NNSA agreed to continue the suspension of requirements, they noted that due to increasing vaccination, the risk profile for conducting more in-person drills and exercises is far lower now than when the suspension of requirements per secretarial memo was enacted last October. Therefore, NNSA provided two conditions of approval. First, they asked that Triad develop a prioritized list of facilities to begin conducting in-person drills and exercises prior to the end of the fiscal year. Second, they stated that Triad should begin meeting all order requirements at the start of FY2022.

Transuranic Waste Management: Triad has resumed regular shipping of their transuranic waste to the Waste Isolation Pilot Plant. NNSA owned shipments were paused following the February reactive event involving titanium fines. Last week, there were two shipments from the RANT Shipping Facility which included a mix of NNSA and EM owned containers. There were also two shipments of NNSA owned containers from the RANT Shipping Facility this week.

Chemistry and Metallurgy Research Building (CMR)–Infrastructure: On Tuesday, the NNSA Field Office concurred with Triad's determination that installation of a supplemental ventilation skid to replace a failed ventilation fan in the inactive Wing 3 of CMR does not constitute a major modification (see 5/7/2021 report).

Transuranic Waste Facility (TWF): On Wednesday, the NNSA Field Office unconditionally approved the revised safety basis for TWF that addresses performance of the fire pumps (see 5/28/2021 report). The approval noted that the new revision addressed all NNSA comments on a previous version and requested implementation within 60 days. Full implementation is the last step to get the fire suppression system elevated to safety-significant, as originally documented in a 2018 safety basis revision.

Plutonium Facility–Conduct of Operations: The resident inspector and Triad personnel walked down portions of the Plutonium Facility to observe current housekeeping and combustible loading conditions. Conditions were not appreciably different compared to last month (see 6/18/2021 report). While facility personnel have removed some of the combustible items that had been lingering in the basement, the overall amount of waste bags in that area was slightly higher. Triad management is accelerating their efforts to improve waste removal and housekeeping in the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 23, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 23, 2021

DNFSB Staff Activity: Staff member L. Lin was on site this week for resident inspector training in preparation for an assignment at the Savannah River Site. Members of the DNFSB headquarters staff called into the virtual Los Alamos National Laboratory Master Asset Plan Deep Dive held this week by the NNSA's Office of Safety, Infrastructure, and Operations.

Plutonium Facility–Operations: On Monday, there was a spill of over 200 gallons of water in the Plutonium Facility. Following refilling of a seal water tank, a worker did not close one valve, and another spring-closed valve did not fully shut, resulting in water flow. The water moved into a ventilation header where it drained out of an inactive glovebox. An alarm in the Operations Center was not acted on as personnel thought it was an expected alarm during the maintenance evolution. The water spread contamination to the floors of adjacent rooms and into the basement. No individuals were contaminated or injured during the event. Triad personnel are drying and decontaminating the impacted rooms. They also entered the New Information process to evaluate whether water ingress into gloveboxes through the ventilation system could result in an unanalyzed criticality scenario.

Plutonium Facility–Construction: Last Thursday, a continuous air monitor (CAM) alarmed inside a tent while construction workers were separating internally contaminated piping from a glovebox slated for removal. CAM alarms positioned in the room outside of the tent did not alarm. All the workers were in respiratory protection, and none were contaminated. During the fact finding this week, participants noted that having point source ventilation located an appropriate distance from the cut would likely have helped capture contamination. There was also a discussion of the challenges of performing equipment removals where active facility assets are in the same room as construction work (see 7/2/2021 report).

Area G: Last Thursday, N3B personnel discovered that a monthly Technical Safety Requirements surveillance of thermal separation distances had not been performed. The thermal separations are established to reduce the likelihood of fire propagation between defined areas where material at risk is present. A line in a reference table used while performing the surveillance was inadvertently deleted in March 2020. Additional revisions had been made since then without the error being caught. Furthermore, the version in document control was two revisions out of date. A causal analysis of this event is planned. All separation distances in the impacted area are currently in compliance.

On Thursday, the Environmental Management Field Office and Headquarters approved the Evaluation of the Safety of the Situation (ESS) for the PISA related to DNFSB TECH-46 and potentially energetic drums (see 6/25/2021). They provided two directed changes. First, they directed N3B to revise one of the existing compensatory measures in the submittal to identify additional physical barrier types to protect waste containers of concern from forklift impacts. Second, they directed that N3B install jersey barriers to prevent forklift impacts to stacked shielding adjacent to drums of concern. On Monday, Environmental Management unconditionally approved the ESSes for dome construction classification and horizontal sympathetic drum deflagrations (see 6/4/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 30, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending July 30, 2021

DNFSB Staff Activity: On Thursday, members of the DNFSB staff held a call with NNSA Field Office and Headquarters personnel to discuss the response to DNFSB-TECH-46. On Tuesday, staff members held a call with NNSA Field Office personnel to support a review of DOE directives in NNSA's management and operation contract for the laboratory.

Plutonium Facility: On Wednesday, Triad personnel concluded that the water overflow in the Plutonium Facility last week (see 7/23/2021 report) represents an unanalyzed water ingress mechanism for criticality scenarios in gloveboxes and therefore constitutes a potential inadequacy of the safety analysis (PISA). The PISA is currently specific to the criticality hazard from water interaction. The resident inspector notes that a steam pressurization event is another potential hazard from unintended ingress of water. The existing Plutonium Facility safety basis includes a steam over-pressurization event from cooling water entering furnaces or calciners in gloveboxes. Water ingress from the ventilation system could be another mechanism for this event which may need different controls than the existing scenario.

Facility personnel are continuing recovery from the overflow event. Two of the impacted rooms have been decontaminated and released back to operations. The others remain in progress.

Last Tuesday, the NNSA Field Office approved a safety basis addendum supporting changes to storage of heat source plutonium items in fire rated safes. There is a new material-at-risk limit for the safes, which are now specifically credited as safety class. In their approval, NNSA directed Triad to resolve several comments in a future revision of the safety basis. The comments included a request to revise one of the hazards analysis events and to clarify language regarding maximum internal temperatures.

Emergency Management: On Tuesday, Triad conducted an operations-based emergency drill in Technical Area 11, a high explosives area. The scenario involved a wildland fire initiated by a lightning strike. Field play included deployment of Los Alamos Fire Department wildland division resources. The NNSA Field Office recently requested that Triad resume in-person emergency drills and exercises (see 7/16/2021 report).

RANT Shipping Facility: Last Wednesday, the NNSA Field Office unconditionally approved a page change to the safety basis for the RANT Shipping Facility. The change modifies the term "outer drums" to the more generic "outer TRU waste container." This will allow the RANT Shipping Facility to compliantly handle Ten Drum Overpacks and Standard Waste Boxes in addition to drums.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 6, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending August 6, 2021

DNFSB Staff Activity: On Thursday, DNFSB staff members held a closeout call with Triad and NNSA Field Office personnel to review the staff's observations from their review of the Critical Decision 1 (Approve Alternative Selection and Cost Range) of the Los Alamos Plutonium Pit Production Project (LAP4).

Transuranic Waste Facility (TWF): On Wednesday, a lightning strike damaged the fire protection system at TWF. Following the storm, Triad personnel evaluated the system due to alarms that actuated. They discovered that the control panels for both fire water pumps were damaged by the strike. Implementation of the new safety basis that elevates the fire suppression system to safety-significant is in progress but not complete. Therefore, the new limiting condition of operation associated with the fire pumps is not yet applicable (see 7/16/2021 report). Facility personnel placed TWF into warm standby and instituted a fire watch. They are beginning procurements to replace the damaged components since spares were not on hand. Implementation of the new safety basis will be delayed due to this event.

Plutonium Facility–Safety Basis: Triad personnel concluded that the recent potential inadequacy of the safety analysis (PISA) associated with the water overflow in the Plutonium Facility constituted a positive unreviewed safety question (USQ) (see 7/30/2021 report). While the PISA was specific to unanalyzed criticality safety scenarios, the USQ is more expansive and also notes that this previously unanalyzed source of water may also be a new initiator for other hazard scenarios including steam overpressurization and contamination spreads.

Area G–Safety Basis: Last Friday, N3B submitted to the Environmental Management Field Office and Headquarters for approval the Justification for Continued Operations (JCO) for the PISA related to DNFSB TECH-46 and potentially energetic drums (see 7/23/2021 report). The JCO notes that upon further evaluation, 27 of the 60 containers identified as potentially reactive do not pose a reactivity hazard and no longer need supplemental controls. For the remaining containers of concern, the JCO removes the previous prohibition on operations with these containers and would allow limited doublepacking and movement under new controls such as vehicle spotting, lift plans, restriction of other activities, and combustible control. DOE personnel are evaluating the submittal.

Weapons Engineering Tritium Facility (WETF): On Friday, Triad submitted to the NNSA Field Office for approval a safety basis addendum to support upcoming plutonium coupon studies at WETF (see 3/12/2021 report). The amount of plutonium handled in WETF will be limited to protect the calculated low consequences and ensure that criticality is not credible. The submittal also identifies several defense in depth controls including a robust container. Last Thursday, Triad submitted to the NNSA Field Office for approval another safety basis addendum that changes the limiting oxidant concentration for the safety-significant oxygen monitoring system from 5.0% to 4.6% to match the current national consensus code (see 11/27/2020 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 13, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending August 13, 2021

DNFSB Staff Activity: On Tuesday, staff members held a call with Environmental Management Field Office personnel to support a review of DOE directives in the Legacy Cleanup Contract.

Plutonium Facility–Criticality Safety: Last Friday, the NNSA Field Office responded to Triad’s memo regarding the potential for fissile solutions to leak into the basement of the Plutonium Facility (see 6/11/2021 report). NNSA concurred with the memo’s conclusion that it is not credible for a criticality event to result from the leakage scenario. However, they noted that the analysis supporting this conclusion was incomplete and requested it be revised to better support the overall conclusion. For example, the current analysis only addresses fixed collection points in the basement and does not include other potential collection points such as buckets. NNSA personnel performed a walkdown of aqueous processing rooms and vertically adjacent basement locations with Triad engineering and criticality safety personnel three weeks ago as part of their evaluation of Triad’s conclusions.

Area G: Following completion of an implementation verification review, N3B and Central Characterization Project personnel have resumed flammable gas measurements to support certifying transuranic waste drums for shipment to the Waste Isolation Pilot Plant. The measurements must be performed compliant with the recently approved Justification for Continued Operations for the activity (see 6/18/2021 report) and all other current restrictions at Area G in place from the numerous safety basis issues. This activity had been paused since the beginning of 2020 (see 1/31/2020 report).

Chemistry and Metallurgy Research Building (CMR)–Deactivation and Decommissioning: Last week during a walkdown, facility industrial hygiene personnel discovered that a subcontractor removed a chemical hood from Wing 3 that had not been sampled for perchlorates. Perchlorate sampling is part of a specific administrative control (SAC) to prevent explosions of residual perchlorates in the ventilation system. The subcontractor removed the hood two weeks ago as part of their equipment removal scope. They did use wet methods during the removal which the SAC would have required for sampling results above a threshold level. Facility management determined that this event constituted a violation of the Technical Safety Requirements. They also noted other issues surrounding this event including inappropriate work release, a lack of clarity in the language of the SAC and its implementing procedure, and informal tracking of sampling activities and results. Invasive work by the subcontractor is currently paused while corrective actions are developed and implemented. Planned actions include additional rigor in documenting locations where perchlorate sampling has been completed, development of a labeling system for simple visual identification of sampled locations, and inclusion of a hold point in the subcontractor work documents to verify perchlorate sampling has been completed and is within specified limits.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 20, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending August 20, 2021

Plutonium Facility–Readiness: Last week continuing into this week, an independent contractor team performed a readiness assessment for the Isotope Fuels Impact Tester (IFIT) in the Plutonium Facility. The system has not been used since the end of 2019 so it is going through the formal review process prior to restarting hot operations. The cold impact test using a fuel clad containing no nuclear material was also observed by members of the federal team, which will complete their readiness review following closeout of actions from the contractor readiness team. At their outbrief, the contractor team identified four pre-start and one post-start finding and concluded that the IFIT process could be restarted safely upon resolution of the prestart findings. They also provided a positive observation on the cleanliness and housekeeping of the IFIT room.

Weapons Engineering Tritium Facility (WETF): Last week, WETF personnel completed all required surveillances and started using new digital tritium monitors to support real time tritium monitoring as part of the safety-significant Tritium Monitoring System. The installation and testing of these new monitors was a multi-year upgrade project to increase system reliability.

On Wednesday, the NNSA Field Office concurred with Triad’s conclusion that the upcoming plutonium coupon study at WETF does not constitute a major modification to the facility (see 8/6/2021 report).

Area G: Last Thursday, N3B personnel declared a violation of the technical safety requirements (TSR) after they discovered that they had not completely performed two quarterly surveillances in the TSR that verify waste storage area dimensions and separation distances. The engineering drawing supporting the surveillance procedure had an error in its designation for Dome 375 so the field verification of conditions in that area could not be verified against requirements. A similar error occurred last month involving thermal separation distances (see 7/23/2021 report). Facility management authorized an extension of the completion time for the surveillance requirements while the drawings and procedures are corrected. N3B personnel are also performing a walkdown of all drawings used to support TSR surveillances.

Site Infrastructure: On Monday, there was a power outage to portions of the laboratory due to a utility pole fire and a circuit breaker relay opening. The only nuclear facility impacted was the RANT Shipping Facility, which lost power for approximately two hours.

Federal Oversight: On Monday, Mr. Michael Mikolanis became the new manager of the Environmental Management Field Office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 27, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending August 27, 2021

Transuranic Waste Management: Last Friday, N3B and Central Characterization Project personnel completed a cold mockup demonstration of transuranic waste mobile loading operations. Mobile loading has not taken place at Area G since last October. The demonstration activity took place in a parking lot outside of the Area G facility boundary. Mobile cranes are currently prohibited within Area G, regardless of whether material-at-risk is present, due to current operational restrictions that address safety basis issues (see 2/26/2021 report). The intent of the demonstration was to maintain proficiency for the activity while it cannot be performed normally. It proceeded without incident other than a missing step in a procedure which was identified and corrected through N3B's immediate procedure change process.

Triad has not performed mobile loading at Technical Area 55 since last November. They plan to exercise the activity in October before a full year has elapsed so that they would not have to perform a readiness review per DOE directives.

Transuranic Waste Facility (TWF): On Tuesday evening after restoring operability of the fire suppression system, TWF personnel ended the one-hour fire watch that had been in place following damage to fire protection systems from a lightning strike earlier in the month (see 8/6/2021 report). They replaced the damaged fire pump controllers and brought in the vendor to troubleshoot the generator. The replacement components do not meet the quality assurance requirements for the future safety-significant designation of the system. Parts meeting those requirements have been ordered. Implementation of the new safety basis will be delayed pending receipt and installation of those parts and testing of the system.

Plutonium Facility–Conduct of Operations: A corporate team from one of Triad's integrated subcontractors performed a review this week and last week of conduct of operations at Technical Area 55. They briefed the results of their review to Triad and NNSA Field Office personnel on Tuesday. The review team had no findings and concluded that the current state of conduct of operations was adequate to perform work safely. However, they noted that Triad needs additional qualified personnel and improved rigor in conduct of operations to perform work effectively. The final report from the review including its recommendations for improvements is expected in mid-September.

Plutonium Facility–Criticality Safety: On Wednesday, Triad submitted to the NNSA Field Office for concurrence the recovery plans to restore negative pressure chilled water systems to service following the overflow event in one system last month (see 7/23/2021 report). The recovery plans include providing administrative verifications intended to prevent overfilling the systems during refill and restart until engineered controls are proposed, evaluated, and implemented. NNSA is evaluating the submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 3, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending September 3, 2021

Area G: On Wednesday, Environmental Management Field Office and Headquarters personnel conditionally approved four Justifications for Continued Operations including the one pertaining to DNFSB TECH-46 and potentially energetic drums (see 8/6/2021 report). The approval letter included two conditions of approval and nine directed changes for the four submittals. The requested changes primarily relate to the details of combustible controls.

On Sunday morning during a post-weather event walkdown, facility personnel discovered one of the poles supporting the catenary lightning protection system around Dome 48 had fallen onto the dome. No waste containers were impacted. There was minor structural damage to the dome frame and a new tear in the fabric. The dome was already scheduled to be reskinned for existing fabric degradation. On Sunday afternoon, facility management authorized immediate actions outside of the facility's safety basis in order to remove the pole using equipment containing liquid fuel beyond current limits. They successfully removed the pole without incident and removed all equipment. The lightning protection system is not formally credited in the safety basis, and its operability is currently degraded. Facility personnel are evaluating repair options to the system and to Dome 48.

Radioactive Laboratory Utility Office Building (RLUOB): Triad personnel completed an Implementation Verification Review (IVR) for the upgrade of RLUOB to a Hazard Category 3 nuclear facility to be known as PF-400. The team identified two findings: one related to filter replacement frequency and the other regarding material at risk controls for hallways.

Transuranic Waste Management: An extent of condition review following the RLUOB's IVR team's questions on the Specific Administrative Control (SAC) prohibiting polysaccharides and concentrated nitric acid identified five transuranic waste drums at the Chemistry and Metallurgy Research Building (CMR) that may contain a prohibited mixture. Both facilities have the same prohibition on concentrated nitric acid and polysaccharides. While further evaluation concluded there was no immediate concern, the question highlights challenges in compliantly loading waste drums. CMR and RLUOB generate waste drums over time where individual bags of waste are evaluated and then combined into a single drum. As written, the facility SACs totally prohibit the presence of concentrated nitric acid and polysaccharides in the same drum with no allowance for trivial quantities. The waste packaging requirements procedure has a more limited prohibition, and individual loading procedures do not note the SAC. The procedures also do not provide guidance on evaluating combinations from different bags in the same waste container.

Emergency Management: On Wednesday, Technical Area 55 personnel held a coached tabletop training drill. The scenario was a criticality event in the Plutonium Facility. Drill participants identified several items for follow-up including assessing communications capabilities in the alternative Operations Center. Facility personnel ordinarily perform a required annual field drill and facility evacuation for a criticality event. This was not performed in Fiscal Year 2020 due to COVID, so the last field performance was in October 2019. The field drill for Fiscal Year 2021 is planned later in September.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 10, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending September 10, 2021

DNFSB Staff Activity: On Wednesday, DNFSB staff members held a call with Triad and NNSA Field Office Personnel to discuss the staff's observations from their review of the combustible trailer formerly parked adjacent to an outside transuranic waste storage pad at the Plutonium Facility (see 2/12/2021 report). While the trailer was moved away from the location adjacent to waste drums by facility personnel, the staff believes its ordinary combustible hazard is not treated appropriately in the safety basis which focuses on combustible liquids.

Federal Oversight: On Wednesday, the Environmental Management Field Office issued its corrective action plan to address the findings and management concerns from the EM Chief of Nuclear Safety's review of nuclear safety functions at the Field Office (see 7/17/2020 report). Key corrective actions developed from a causal analysis of the issues include: completing development of a compliant nuclear safety basis review and approval procedure; and training and mentoring nuclear safety staff on the expectations and discipline required in the review and approval of safety basis submittals.

Plutonium Facility–Safety Basis: Last Thursday, Triad submitted to the NNSA Field Office for approval an Evaluation of the Safety of the Situation (ESS) for a recent spill in the Plutonium Facility (see 8/6/2021 report). The proposed operational restrictions stem from those already in place from Triad's recovery memo for this event (see 8/20/2021 report). They will remain in place until a Justification for Continued Operations changes them or a permanent engineered solution is developed.

Plutonium Facility–Radiological Safety: Last Tuesday, a worker discovered contamination on their hand when using a hand and foot monitor upon exiting a laboratory room. Radiological control personnel responded and were able to successfully decontaminate the individual. Facility personnel are evaluating the best approach to personal protective equipment usage for the activity involved.

Chemistry and Metallurgy Research Building (CMR): On Tuesday, the NNSA Field Office unconditionally approved the ESS for wildfire impacts on waste containers stored in the CMR yard (see 6/25/2021 report). The ESS acknowledges the previously unanalyzed hazard and describes existing controls that address it including the design of certain containers, the material-at-risk management specific administrative control for the yard, and the material-at-risk inventory control.

Also on Tuesday, Triad submitted to the NNSA Field Office for approval a safety basis addendum addressing the planned outdoor ventilation skid to support Wing 3 (see 5/7/2021 report). The changes identify new events that can impact the system due to its outdoor location and adjust the existing material-at-risk inventory control to address the externally mounted filter.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 17, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending September 17, 2021

Plutonium Facility–Criticality Safety: On Monday, a Plutonium Facility worker was reviewing a database to determine options for a future nuclear material movement. They noted that the recorded mass of material in a glovebox appeared higher than the posted criticality safety limit and reported the concern. Facility and criticality safety personnel responded and found that the amount of nuclear material in the glovebox exceeded the limit on the criticality safety posting. Criticality safety personnel determined the overmass was bounded by the analysis in the criticality safety evaluation and the condition was currently safe and stable. The glovebox has been posted out of service until the condition is resolved. Further review of the event determined that the workers who moved the material into the glovebox did not fully understand the language on the criticality safety posting. The posting was updated last year and the limits on material type masses included the new logical connector “with” instead of the more routinely encountered “and” or “or.” The term “with” is not yet formally defined in the criticality safety command media for Technical Area 55. The posting does include a table of example masses for material type combinations to help explain the intent of the new language. Triad personnel are evaluating the best language to define this type of mass limit which adds value to several operations that inherently create a change in material form, but is not yet trained on or widely understood. This event also showed the potential for error due to the tremendous number of material moves being performed. Congestion in many process rooms has reached the point where it often takes several moves to get other items out of the way to support movement of a part while complying with mass limits in each location.

Safety Basis: On Thursday, the NNSA Field Office transmitted a letter to Triad directing they provide schedules and implementation plans for implementing the newly revised DOE-STD-5506-2021, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*. For the Plutonium Facility, they requested implementation be coordinated with the current upgrade of the safety basis to DOE-STD-3009-2014. For the other nuclear facilities, they requested recommendations as to whether to implement DOE-STD-5506-2021 promptly or to defer to when the safety bases for those facilities are upgraded to DOE-STD-3009-2014.

Emergency Management: On Wednesday, Triad personnel performed the annual criticality evacuation drill for the Plutonium Facility. This was the first field performance of the drill since October 2019. There was a tabletop drill earlier this month and an e-mail response based ‘virtual drill’ in December 2019 (see 9/3/2021 report). The scenario for the field drill was a criticality event in a laboratory room with three casualties in the immediate area and four others receiving an elevated dose in an adjacent hallway.

Weapons Engineering Tritium Facility (WETF): On Wednesday, the NNSA Field Office unconditionally approved the safety basis addendum to support plutonium coupon studies at WETF (see 8/6/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 24, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending September 24, 2021

DNFSB Staff Activity: This week, members of the Board's staff held separate teleconferences with NNSA Field Office and Environmental Management (EM) Field Office personnel to discuss the staff's observations on its review of federal oversight.

Area G: On Monday, N3B transmitted to the EM Field Office for approval the annual update to the existing Area G safety basis, which is a Basis for Interim Operations rather than a more modern Documented Safety Analysis. In July, the EM Field Office and EM Headquarters rejected a previous submittal and directed that N3B submit a revised document that incorporated the Justification for Continued Operations related to headspace gas sampling (see 6/18/2021 report) and the safety analysis and credited hazard controls for the Flanged Tritium Waste Container venting activity (see 4/16/2021 report). The new revision includes other changes to address EM review comments such as noting activities (e.g., drum venting and retrieval from trenches) that will not be performed until a modern safety basis is developed. EM personnel are evaluating the revised submittal.

On Wednesday, N3B management paused all vehicle usage due to a series of vehicle incidents at their sites. One impact occurred Tuesday in Area G where a vehicle impacted a jersey barrier outside of a waste storage dome. The impact barrier was not one of the credited safety-class vehicle barriers to protect high-risk locations. An engineering incident discovered no positional change or damage to the barrier following the impact. N3B previously paused work due to vehicle concerns in January (see 1/29/2021 report). Management is evaluating whether corrective actions from that timeframe remain effective.

Plutonium Facility–Safety Basis: On Thursday, the NNSA Field Office transmitted a letter to Triad requesting a resubmittal of the Evaluation of the Safety of the Situation (ESS) related to the July overflow of water in the Plutonium Facility (see 9/10/2021 report). NNSA provided six comments that needed to be addressed in a revised ESS. Those comments include requesting that the ESS provide: an evaluation for potential water entry into all systems that vent to the Zone 1 ventilation system, a full consideration of overflow paths from both active and inactive chilled water and wet vacuum systems, and a clear discussion of future deliverables to address the problem including any engineering modifications or safety submittals. The Field Office requested a response by October 1, 2021.

Safety Basis: Last Tuesday, Triad transmitted to the NNSA Field Office a revision of their Unreviewed Safety Question (USQ) process intended to address the condition of approval from the May approval of the revised process (see 5/14/2021 report). The resubmittal notes that the New Information process is 'associated with' rather than 'separate from' the USQ process in response to the condition of approval that directed the procedure be revised to note that the New Information Process is a part of the USQ process. NNSA is evaluating whether the changes address their concern with the previous submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 1, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: P. Migliorini, Acting Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending October 1, 2021

DNFSB Staff Activity: P. Migliorini was onsite performing resident inspector duties. While onsite, the acting resident inspector performed walkdowns of Area G and the Plutonium Facility.

On Wednesday, a staff team held a remote interaction with Triad and NNSA Field Office personnel to discuss the ongoing upgrade to the Plutonium Facility leak path factor methodology (see 8/28/2020, 2/26/2021, and 5/28/2021 reports). The leak path factor is used to quantify the building's ability to confine radioactive materials during an accident scenario and is particularly important for the evaluation basis earthquake event that the active confinement ventilation system is not credited to survive. The upgraded leak path factor methodology is a key supporting analysis for the new DOE Standard 3009-2014 compliant safety basis that Triad plans to submit for approval in March 2022.

Plutonium Facility–Infrastructure: Last week, Triad submitted to the NNSA Field Office for concurrence a major modification determination for the Plutonium Facility Equipment Installation Phase 2 (PEI2) subproject. PEI2 will install new gloveboxes and equipment in the Plutonium Facility to provide enduring analytical chemistry and materials characterization capabilities that support plutonium pit production and other plutonium missions. Triad safety basis analysts determined that while PEI2 may introduce process changes, the changes do not generate hazards outside of the existing Plutonium Facility safety basis. Accordingly, Triad safety basis concluded that PEI2 is not a major modification to the existing facility. Triad plans to revise the project safety design strategy to reflect the negative major modification determination.

Area G: On Thursday, N3B transmitted to the Environmental Management Field Office an interim draft of a DOE Standard 3009-2014 compliant safety basis for Area G. This submittal is intended to meet one of the performance-based incentives for the fiscal year 2021 Los Alamos Legacy Cleanup Contract. The interim draft safety basis includes placeholders for important aspects that still need to be developed, such as mapping safety controls to specific hazard scenarios and finalizing performance criteria for safety controls. N3B plans to submit the final draft safety basis in February 2022. Following implementation, this modern safety basis will replace the outdated basis for interim operation.

On Thursday, the acting resident inspector walked down the domes that currently house the transuranic waste containers with potentially reactive materials that are associated with DNFSB TECH-46. The containers are protected from direct impacts by robust barriers (e.g., stacked and banded metal pallets or standard waste boxes) and from fire hazards by administrative controls. Once the approved justification for continued operation (see 9/3/21 report) is implemented, 12 containers will remain in their current location and 21 containers will be moved to Dome 33, which has a non-credited fire suppression system, until remediation or additional historical information can demonstrate that they do not contain reactive materials.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 8, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending October 8, 2021

Plutonium Facility–Criticality Safety: Over the past month, facility personnel have discovered and reported several instances where extraneous materials such as construction or radiological control supplies were stored on or around nuclear material safes in the basement. Controls listed on the criticality safety postings vary by safe, but many include a requirement to keep an area of six inches around the safe clear. Following one such discovery in September, personnel added operator aids to the safes to provide additional clarity to facility residents that materials are not allowed close to certain safes. So far, all these instances where the spacing control was violated have not included enough reflective materials to approach the analyzed condition for neutron reflection around the safes. On Wednesday, the resident inspector and an NNSA facility representative observed portions of a Triad walkdown of basement safe conditions. At the time, one safe had a welding curtain propped against it, and several had miscellaneous items sitting on their tops. Facility personnel are working on methods to prevent these occurrences. This is a challenge given the rapid increase of staffing in the facility especially of construction and craft forces who are not trained on criticality safety postings to the same level as fissile material handlers. In the near term, facility management plans to mark areas where no material is allowed with painted no storage zones on the floor and rope them off. Longer term, they are evaluating engineered controls such as a physical cage around safes to help ensure compliance with the spacing requirement. Additional training and lessons learned, especially for personnel who are not fissile material handlers is also planned.

Plutonium Facility–Safety Basis: Last Friday, Triad submitted to the NNSA Field Office for approval a revision to the safety basis for the Plutonium Facility. This revision includes a reanalysis of the seismic accident, reapportionment of material at risk, and a downgrade of the seismic power shutoff system from safety-class to other hazard control (see Board Letter 6/9/2021). The seismic accident change includes the removal of three specific post-seismic fire initiation locations with molten plutonium. As all gloveboxes containing molten plutonium have been seismically upgraded, they are no longer considered a credible fire initiation source. A randomly initiated post-seismic fire location remains in the analysis. With this reduction in post-seismic fire consequences, the locations of material at risk have been reapportioned to support the facility mission. The seismic power shutoff system, an active system, now has its credited safety function being performed by the passive system of seismically credited glovebox stands that reduce the likelihood of heat producing equipment from spilling even if powered.

Flanged Tritium Waste Containers (FTWCs): N3B recently submitted the annual update to the Area G safety basis that covers FTWC venting activities (see 9/24/2021 report). Approval and implementation of this safety basis is expected before the end of the year and is a key prerequisite for Triad personnel to perform the venting activities. This week, Triad personnel resumed practice for the venting activity at the mockup area in Technical Area 49. They have also procured a new portable generator with a smaller fuel capacity in order to ensure compliance with the liquid fuel limits at Area G. Another activity that must be completed prior to commencing the actual venting activity is a demonstration for the federal readiness assessment team given the gap between assessment and performance (see 11/13/2020 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 15, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending October 15, 2021

Area G: On Monday, a four member team commenced an Implementation Verification Review for four recently approved Justifications for Continued Operations (JCO) that apply to a variety of topics including potentially energetic drums, sealed sources, mobile crane and forklift operations, and fire events (see 9/3/2021 report). Implementing this set of JCOs adds 44 new specific administrative controls. This week the team conducted numerous personnel interviews, observed field conditions, and assessed performance of new surveillances. The review is expected to be completed next week.

On Wednesday, N3B personnel performed a full mockup demonstration of transuranic waste activities in the Building 412 contamination enclosure. Drum liner and repackaging activities have not been performed in Building 412 for almost a year due to safety basis issues. This mockup activity was intended to demonstrate continued proficiency in performing this activity, similar to the mobile loading demonstration in August (see 8/27/2021 report).

Flanged Tritium Waste Containers (FTWCs): Last Friday, Triad entered their new information process to determine the safety basis implications of additional decay time from the date assumed in a supporting pressure calculation. Given the decay rate of tritium, the new calculated pressure may be higher and impact standoff distances or other controls to protect workers from FTWC over pressurization or deflagration. This affects three Triad safety basis documents for venting FTWCs at Area G, transporting FTWCs from Area G to the Weapons Engineering Tritium Facility (WETF), and storing FTWCs at WETF. The N3B-owned safety basis annual update that addresses FTWC venting at Area G has not been approved and implemented yet. N3B personnel determined that their current controls on storage are not impacted, and are awaiting the results of Triad's evaluation to see what changes may need to be incorporated in the recently submitted annual update.

Radioactive Laboratory Utility Office Building (RLUOB): Last Thursday, Triad transmitted to the NNSA Field Office their major modification determination for equipment installation in RLUOB supporting its transition to a hazard category 3 nuclear facility. They concluded that the installations do not constitute a major modification. The determination notes that the equipment being installed is for processes that are already described in the hazard category 3 safety basis and will not introduce new hazards.

Chemistry and Metallurgy Research Building (CMR)–Infrastructure: On Tuesday, the NNSA Field Office unconditionally approved the safety basis addendum for the planned outdoor ventilation skid that will replace the capabilities of a failed fan within the currently inactive Wing 3 (see 9/10/2021 report). Facility personnel have started developing work documents to perform the installation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 22, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending October 22, 2021

Plutonium Facility: On Tuesday, Triad personnel declared a violation of the Technical Safety Requirements (TSR) for the Plutonium Facility due to a breach of a confinement boundary without entering the appropriate limiting condition for operation (LCO). Workers have been installing pressure and velocity measurement instruments in the ventilation system to collect data for future upgrades. The installation involves opening ports in ductwork which breaches the credited confinement boundary. They performed several of these installations starting last week without entering the LCO before a review of logs identified the issue. The controlling work document for the installation notes it breaches a confinement boundary and has a hold point to inform the operations center of the potential for TSR impact although it does not explicitly state that the appropriate LCO must be entered prior to breaching the system. Miscommunication between operations center personnel and the crew performing the work resulted in a failure to recognize the need for LCO entry. Following discovery of the error, facility personnel measured differential pressures and verified the confinement boundary was intact. Facility management is evaluating their work control processes to find opportunities for improved work package review and release to avoid this type of error in the future.

Last week, following decontamination efforts, facility workers identified a steady drip of liquid from the wet vacuum system involved in the July overflow event (see 7/23/2021 report). The system resides in a room posted as a high contamination area/airborne radioactivity area. The exact source of the liquid is not currently known, although it was postulated that the source is related to the overflow event and may be holdup in the system. Swipes of the area indicate that it is highly contaminated consistent with other sampling related to the overflow event. The impacts of this liquid of questionable provenance will be assessed in the continued development of the Evaluation of the Safety of the Situation and upcoming modifications to the system (see 9/24/2021 report).

Area G: On Wednesday, the Implementation Verification Review team for four recently approved Justifications for Continued Operations (JCO) briefed their results to Environmental Management and N3B personnel (see 10/3/2021 report). They identified eleven pre-implementation findings, two post-implementation findings, nine observations, and two noteworthy practices. Several of the findings involve management of hydraulic oil as a potentially combustible liquid. One noteworthy practice involved the use of flashcards to train the workforce on the numerous new controls. The resident inspect concurs that this was a noteworthy practice as he frequently observed that most workers had their cards on hand and frequently reviewed them or quizzed each other.

Emergency Management: On Tuesday, the NNSA Field Office sponsored a wildfire workshop. Field Office, Triad, and Los Alamos Fire Department personnel discussed impacts and lessons learned from previous major wildfires impacting the laboratory and surrounding communities. They also described current prevention and preparedness activities including fuel mitigation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 29, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending October 29, 2021

Plutonium Facility: On Thursday, the NNSA Field Office conditionally approved a safety basis addendum for the Plutonium Facility pertaining to missile barriers to protect confinement doors (see 6/25/2021 report). The addendum uses an adjacent structure as credited protection from wind borne missiles for both confinement doors on one side of the building. Previously, this approach had only been taken for one of the doors. The NNSA approval included two conditions of approval and three directed changes. The conditions of approval were to add a discussion of the impacts of indirect natural phenomena hazard events and to include an in-service inspection of the structure acting as a safety-class missile barrier in the Technical Safety Requirements.

Transuranic Waste Management: This week, Triad personnel performed a transuranic waste mobile loading activity in Technical Area 55. They received and unloaded TRUPACTs with standard waste boxes from Sandia National Laboratory containing items from plutonium experiments performed there. These will later be moved to Area G for storage and eventual certification to be disposed of as transuranic waste at the Waste Isolation Pilot Plant (WIPP). The TRUPACTs were then reloaded with Triad-owned transuranic waste to ship to WIPP.

Area G: On Thursday, N3B personnel conducted an operations-based emergency management drill in Dome 231. The scenario was a fire during glovebag operations within the Dome 231 Perma-Con. Between the reduction in field drills due to COVID-19 and new hiring, this was the first field drill for approximately one third of the participants. Preparations for startup of glovebag operations were put on hold due to the safety basis issues at Area G following the contractor readiness assessment last year (see 12/11/2020 report). With implementation of the fixes to the safety basis in process, N3B personnel are resuming preparations to restart glovebag operations and other paused activities such as Corrugated Metal Pipe retrieval. Given the substantial time since the contractor readiness assessment, the Environmental Field Office directed that N3B reperform an appropriately scoped contractor readiness review prior to DOE performing the Federal readiness review.

Two weeks ago, N3B submitted to the Environmental Management Field Office for approval a Justification for Continued Operations (JCO) to address movement of unvented transuranic waste drums. The JCO stems from two potential inadequacies of the safety analysis: one from February pertaining to an inappropriate control during unvented drum movement (see 2/19/2021 report) and the other from April about horizontal sympathetic deflagrations of unvented drums (see 4/30/2021 report). The JCO proposes a series of interim controls for movement of unvented drums including using a critical lift plan. There are no new controls proposed for sympathetic deflagrations as they conclude that a horizontal sympathetic deflagration is bounded by an existing design basis accident.

Radiological Laboratory Utility Office Building (RLUOB): The NNSA Field Office concurred with Triad's conclusion that equipment installation in RLUOB supporting its transition to a hazard category 3 nuclear facility does not constitute a major modification (see 10/15/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 5, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending November 5, 2021

Plutonium Facility–Infrastructure: The resident inspector joined Triad personnel to observe off-shift deactivation and decommissioning and construction activities supporting the 30 pit per year mission. Of note, Triad personnel have begun planning for the removal of a more challenging glovebox than other recent removals that have been disconnected, wrapped, and removed without significant issues. Given its size and weight, this box will likely require some in-situ size reduction in an actively used processing room. Triad is currently evaluating several options for performing the activity while controlling contamination and meeting other requirements. Triad is also actively removing equipment and concrete pads in the basement to clear space in what remains a congested location. This process generates a substantial volume of low-level waste. Keeping up with waste generation remains a challenge in the facility. Waste removal activities were in progress Wednesday morning and personnel were actively loading a waste box with bags of concrete debris.

Plutonium Facility–Safety Basis: Last week, Triad submitted to the NNSA Field Office both another extension request for the current Evaluation of the Safety of the Situation (ESS) for overpressurization of sealed sources in the Plutonium Facility and a new revision to the ESS. The current ESS has been in place since December 2019 and stems from an August 2019 potential inadequacy of the safety analysis (see 9/20/2019 report). The new revision attempts to address concerns from the NNSA Field Office. It includes additional justification for the choices of airborne release fractions/respirable fractions and a limiting condition for operation for application of new multiplication factors for analysis of materials releases.

Radioactive Liquid Waste Treatment Facility (RLWTF): Over the past month, there have been three air-hose disconnects during doffing of powered air purifying respirators (PAPR) at RLWTF. These incidents have all been for the same job involving almost two hundred total respirator entries into a containment tent. Facility personnel leveraged the DOE Operating Experience system and noted their issues appears similar to a problem at the Y-12 National Security Complex in 2019. They believe that extra attention to properly taping up the respirators and formally documenting that in work instructions will resolve the issue. The activity is paused until corrective actions are incorporated into work practices.

Radiological Laboratory Utility Office Building (RLUOB): The NNSA Field Office conditionally approved an equivalency to DOE-STD-1066, *Fire Protection*, for HEPA filter deluge systems in RLUOB. The facility currently includes such a system, however Triad proposed removing it per the provision in the DOE standard that allows for a technically justified alternative approach. They are using a computational fluid dynamics model to demonstrate that dilution air is sufficient to keep filter temperatures below requirements in lieu of the deluge system. NNSA's approval letter includes five conditions of approval largely related to assuring formal control of the modeling assumptions and other facility conditions related to the equivalency.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 12, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending November 12, 2021

Transuranic Waste Management–Safety Basis: On Tuesday, Triad personnel entered their new information process to re-evaluate the safety basis implications of transuranic waste containers with nitric acid and polysaccharides at the Plutonium Facility, the Transuranic Waste Facility (TWF), the Chemistry and Metallurgy Research Building (CMR), and the RANT Shipping Facility. This was in response to the Board’s September 8, 2021 letter regarding the technical basis for the Carlsbad Field Office accepting such waste at the Waste Isolation Pilot Plant. They had concluded that such mixtures were acceptable and no longer a reactivity hazard if they have been aged for a sufficient amount of time. Triad has previously evaluated this issue and is re-evaluating it in light of the Board’s letter. Triad currently has specific administrative controls at CMR and the Plutonium Facility that prohibit waste containers from containing polysaccharides and greater than 12 molar nitric acid. The Radiological Laboratory Utility Office Building also includes such a prohibition in its safety basis to support future Hazard Category 3 operations. TWF and RANT have broader specific administrative controls prohibiting them from receiving potentially reactive waste drums as defined in the waste acceptance criteria for the Waste Isolation Pilot Plant.

Plutonium Facility–Operations: Last week one of the trolley cables failed in the Plutonium Facility. The trolleys are a critical piece of infrastructure that support movement of materials between gloveboxes and rooms without the need for bagging materials out. Facility personnel were testing the system following an upgrade to the trolley controller. After raising the bucket, the cable snapped, and the bucket fell to the floor of the drop box. There were no injuries or damage to glovebox gloves as no workers had their hands in the box, and all glovebox gloves were secured outside. Initial inspections indicated no damage to the glovebox. The trolley bucket is damaged, although it is not currently known whether this is from the fall. Facility personnel are evaluating the failure mechanism and planning for replacement of the failed components.

Radiological Laboratory Utility Office Building (RLUOB): On Monday, an eighteen-member team including several independent personnel from non-Triad organizations commenced the Management Self-Assessment for upgrading RLUOB to a Hazard Category 3 nuclear facility to be known as PF-400. The team expects to issue their final report in December. Following completion of this self-assessment, there will be additional readiness reviews including a contractor operational readiness review currently planned for late February 2022 and a Federal operational readiness review in early May 2022 to support a late June upgrade to Hazard Category 3.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 19, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending November 19, 2021

Transuranic Waste Facility (TWF): On Monday, TWF personnel identified that they had not completed three required monthly surveillances supporting compliance with the facility's Technical Safety Requirements (TSR) within the required timeframe. The surveillances involved verifying compliance with requirements on outdoor combustibles, outdoor equipment, and banding of drums on the third tier of stacked arrays. Soon after discovering the issue, facility personnel performed the surveillances with satisfactory results. The performance delay was within the 25% extension that is allowed by the TSR. Facility management is evaluating means to prevent recurrence of missed TSR surveillances including improving surveillance scheduling processes.

Weapons Engineering Tritium Facility (WETF): Off shift early on Monday, the fire department and facility duty officer responded to a fire alarm at WETF. They discovered the alarm was due to water flow and found evidence that the flow had come from a fire riser drain. They reset the system after sweeping the facility. A few hours later, the system alarmed again. This time, the responders found active flow from the drain. To evaluate and repair the system, the facility entered the limiting condition for operation for the safety significant wet-pipe fire sprinkler system being inoperable which initially requires a fire watch. Spare parts to repair the system were on hand, and it has been repaired. The leak appeared to be the result of a missing bolt in the alarm check valve. Further investigation to determine if the bolt is held up in the system is planned.

Plutonium Facility–Safety Basis: Last week, Triad submitted to the NNSA Field Office for approval the Evaluation of the Safety of the Situation and Justification for Continued Operations (ESS/JCO) pertaining to the potential inadequacy of the safety analysis and positive unreviewed safety question that stemmed from the July overflow event (see 8/6/2021 report). The submittal includes an extent of condition evaluation to determine what other systems could pose a risk of an overflow event. Operational restrictions on these systems remain in place and are elevated to TSR-level through the proposed ESS/JCO.

Area G: On Thursday, N3B personnel performed another operations-based emergency drill for glovebag operations in the Dome 231 Perma-Con (see 10/29/2021 report). The scenario involved a medical emergency for a worker performing transuranic waste operations in the glovebag. The participants exercised practices for balancing radiological control and a medical emergency within an airborne radiation area. One key item uncovered during the drill was that the automated external defibrillator the participants obtained had not been surveilled and needed a new battery.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 26, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending November 26, 2021

Plutonium Facility–Safety Basis: Triad is developing a safety basis addendum to support a future campaign for receipt and processing of additional heat source plutonium materials in the Plutonium Facility. The nature of this activity will result in mitigated public dose consequences from a post-seismic fire event that are expected to exceed the 25 rem TED evaluation guideline from DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*. NNSA Headquarters and Field Office personnel are preparing to use the process described in DOE-STD-1104-2016, *Review and Approval of Nuclear Facility Safety Basis and Safety Design Basis Documents*, for review, approval, and risk acceptance of this activity. The NNSA Field Office Manager will make the recommendation for approval of the addendum to the cognizant NNSA Program Secretarial Officer who will serve as the safety basis approval authority, with concurrence from the NNSA Central Technical Authority.

Area G: Last week and on Monday, N3B personnel executed the movement of several problematic containers associated with the recently approved and implemented justifications for continued operations (see 10/15/2021 report). In total, N3B personnel moved 24 containers from Domes 48, 49, and 375 to Dome 33. Of note, 21 containers contain waste with the potential for energetic chemical reactions and are associated with DNFSB TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*. Three of these containers also have contents with high fissile gram equivalents. The other three containers moved were pipe overpack containers with material-at-risk greater than 80 plutonium-239 equivalent curies. Facility personnel briefed the work crew last Thursday afternoon to explain why the drums were being moved, review the applicable controls from the justifications for continued operations, and review criticality safety requirements. The work commenced on Friday, continued through Saturday, and completed on Monday. The activity proceeded smoothly according to the planned sequence of moves with one exception due to an error in the waste tracking software.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): On Tuesday, Triad submitted to the NNSA Field Office for concurrence a safety basis strategy for developing a new documented safety analysis to operate WCRRF as a hazard category 3 nuclear facility. WCRRF is currently a hazard category 2 nuclear facility and has been in cold standby for approximately three years. The new mission for WCRRF will be to size-reduce large metal objects (e.g., gloveboxes removed from the Plutonium Facility) and repackage them as either transuranic or low-level waste. The safety basis strategy notes that material-at-risk in the facility will be limited such that unmitigated dose consequences due to a building collapse and fire will not exceed the thresholds for identifying safety class or safety significant controls. While the facility will not have any credited safety controls, the safety basis strategy identifies existing hazard controls (e.g., fire suppression system, ventilation system, lightning protection system) and notes that Triad is evaluating options for performing size reduction activities in a radiological protection enclosure (e.g., the existing glovebox enclosure, a Perma-Con, or containment tent). Triad plans to submit a draft safety basis in August 2022.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 3, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending December 3, 2021

DNFSB Staff Activity: On Tuesday, a staff team held a remote interaction with Triad and NNSA Field Office personnel to discuss the staff's observations from its review of the ongoing upgrade to the Plutonium Facility leak path factor methodology (see 10/1/2021 report).

Plutonium Facility–Safety Basis: On Tuesday, Triad submitted to the NNSA Field Office for approval the safety basis addendum supporting receipt of large shipments of heat source plutonium (see 11/26/2021 report). The addendum would allow an increase to material-at-risk limits as this activity will exceed the current first floor and glovebox limits until repackaged in credited containers. The mitigated public dose due to the bounding post-seismic fire accident is estimated to be a range from 83 to 378 rem because there is substantial uncertainty regarding the leak path factor that can be appropriately applied to the scenario. The increased doses are applicable during the time when the new material is not in credited containers. As this exceeds the DOE evaluation guideline of 25 rem to the public, Triad is requesting that NNSA accept the risk involved with performing this mission. The addendum includes an attachment outlining how Triad addressed the evaluation criteria from DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*, for existing facilities with greater than 25 rem mitigated doses. This includes a discussion of potential controls and why they were unable to be used and credited to further reduce mitigated dose. NNSA has established a headquarters and field office safety basis review team to evaluate the submittal.

Last week, the NNSA Field Office unconditionally approved the revision to the Plutonium Facility safety basis that includes reanalysis of the post-seismic fire accident and downgrade of the seismic power shutoff system, which has known vulnerabilities in meeting the requirements for a credited safety class system (see 10/8/2021 report). The approval letter noted that Triad should evaluate known upcoming changes to the safety basis prior to implementation and if a future change would require re-implementing the seismic power shutoff system as a credited control, they should consider retaining it as a credited system. It is not currently proposed as a control for the heat source plutonium addendum described above.

Area G–Safety Basis: Last week, the Environmental Management Field Office transmitted to N3B a letter directing they revise the safety basis strategy for developing a modern Area G safety basis to incorporate DOE comments on the previous revision (see 3/19, 5/14/2021 reports).

Transuranic Waste Management: Triad personnel have completed their re-evaluations of the safety basis implications of transuranic waste containers with nitric acid and polysaccharides at the Plutonium Facility, the Transuranic Waste Facility, the Chemistry and Metallurgy Research Building (CMR), and the RANT Shipping Facility (see 11/12/2021 report). They concluded that the only facility with a potential inadequacy in the safety analysis is the RANT shipping facility as it can receive waste from locations without existing Specific Administrative Controls prohibiting such waste as TA-55 and CMR do. Triad is establishing operational restrictions on nitric/polysaccharide waste at RANT and concluded that the potential inadequacy in the safety analysis constitutes a positive unreviewed safety question.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 10, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending December 10, 2021

DNFSB Staff Activity: Staff members W. Dumayas, P. Migliorini, P. Natividad, and J. Plaue were on site to perform a review of construction quality lessons learned for fire protection features from the Radiological Laboratory Utility Office Building and the Transuranic Waste Facility. The staff toured both facilities as part of the review and also went to the Weapons Engineering Tritium Facility, the Emergency Operations Center, and joined DOE Environmental Management headquarters personnel at Area G.

Area G–Safety Basis: Last week, Environmental Management Field Office and headquarters personnel conditionally approved the annual update to the Area G safety basis (see 9/24/2021 report). The three conditions of approval were: to evaluate fixed and rotary wing aircraft crashes to address issues stemming from the potential inadequacy of the safety analysis early this year and update the safety basis per the results of said analysis (see 3/26/2021 report), enter a written agreement between N3B and Triad to maintain a 1500-foot helicopter standoff distance from Area G, and a prohibition on venting and handling activities for the Flanged Tritium Waste Containers until revised calculations are completed and incorporated into approved and implemented safety basis documents.

The Environmental Management Chief of Nuclear Safety and members of their staff were on site along with members of the contractor’s reachback team supporting development of a modern safety basis for Area G (see 12/3/2021 report). The Board’s staff joined them on a full walkthrough of Area G. Focus areas of the walkdown included: current and planned waste operations including upcoming corrugated metal pipe and glovebag activities; desired approaches for control implementation from the workforce to complete their mission effectively; and the current condition of the facility following implementation of the four Justifications for Continued Operations and the movement of many drums of concern to Dome 33 (see 11/26/2021 report).

Transuranic Waste Management: Triad personnel briefed the NNSA Field Office on their recommendation for re-establishing the capability to remediate oversized, non-compliant waste containers or difficult waste streams including treatment, repackaging, or removal of prohibited items. They recommended using the Waste Characterization, Reduction, and Repackaging Facility (WCRRF) under a new hazard category 3 safety basis (see 11/26/2021 report). Other options considered included: working with N3B to perform the work at Area G, performing the work in the Plutonium Facility, using the Chemistry and Metallurgy Research Building, building a new nuclear facility, or transporting items offsite for treatment. NNSA is evaluating Triad’s recommendation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 17, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending December 17, 2021

DNFSB Staff Activity: On Monday, Triad personnel remotely briefed members of the Board's staff on the interim risk assessment results for the Plutonium Facility Seismic Performance Reassessment Project. The interim risk results suggest that the facility will be able to meet seismic design category 3. Triad is proposing to wait for the updated site probabilistic seismic hazard analysis to be completed before performing a reduced-scope final risk assessment. The final risk assessment is expected to be completed within two years.

Severe Weather: On Wednesday, the laboratory and surrounding region experienced a severe weather event with high winds and wintry precipitation. Unstable electrical power and outages occurred throughout the laboratory. The main impacts to nuclear facilities were power losses at Area G where two utility poles came down, the Weapons Engineering Tritium Facility, and the RANT Shipping Facility. The Emergency Operations Center also lost power and ran on its backup generators. All nuclear facilities, the Emergency Operations Center, and most other laboratory buildings had power restored by the end of Wednesday.

Federal Oversight: On Thursday, NNSA Headquarters personnel and a supporting contractor briefed Triad on the Safety, Analytics, Forecasting, Evaluation, and Reporting (SAFER) effort. SAFER is a software tool for collecting, managing, and viewing data from numerous input sources. NNSA has started populating the tool at sites across the complex to assist in their oversight. At the laboratory, NNSA is currently focusing on populating the tool in the functional areas of fire protection, maintenance, electrical safety, radiation protection, and safety basis. NNSA intends for Triad to be the first management and operating contractor to pilot using the tool to aid data management on the contractor side.

Plutonium Facility–Safety Basis: Last week Triad responded to the NNSA Field Office's request for an impact assessment for incorporating DOE-STD-5506-2021, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*, into the modern TA-55 safety basis under development (see 9/17/2021 report). Their new schedule estimates an impact that delays final submittal of the new safety basis from November 2022 to January 2023. Other factors had shifted planned submittal from March 2022 to November 2022.

Emergency Management: The NNSA Field Office transmitted to Triad the assessment report on emergency preparedness capabilities at the lab from the DOE Office of Enterprise Assessments. They requested Triad provide a corrective action plan to address the findings in the report. The assessment covers the five year period from October 2015 through September 2020. The first finding was that Triad has not established or maintained an adequate site-level exercise program to validate all its emergency response capabilities for identified hazards. Many of the capabilities that have not been demonstrated recently involve interface with other organizations such as regional hospitals. The second finding was that Triad has not self-identified an accurate status on the readiness and effectiveness of its response capabilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 24, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending December 24, 2021

Plutonium Facility–Safety Basis: The NNSA Field Office responded to Triad’s latest revision of the Evaluation of the Safety of the Situation (ESS) for overpressurization of sealed sources in the Plutonium Facility (see 11/5/2021 report). They noted that they will not approve the ESS until provided comments are addressed. Notable comments from the field office included: concern with the application of multiplication factors to material release events, and several related to reliance on combustible loading controls from the fire protection program.

Last week, NNSA Office of Safety and Field Office personnel informally provided Triad with initial comments on the safety basis addendum supporting the receipt of large shipments of heat source plutonium (see 12/3/2021 report). Topics include: the consistency of the safety basis document with the specifications and test report for the containment vessel; compliance with DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*; and interface with the ESS discussed above. NNSA requested to discuss these comments with Triad early next year.

Radiological Laboratory Utility Office Building (RLUOB)/PF-400: Triad submitted to the NNSA Field Office for approval a revision to the hazard category 3 safety basis for PF-400 and a revised safety design strategy. The revised safety basis is intended to address issues from the recent Implementation Verification Review (see 9/3/2021 report).

Chemistry and Metallurgy Research Building (CMR): Last week, a radiological control technician discovered contamination in a radiologically uncontrolled area of CMR during a routine survey. They controlled the location and contacted personnel who may have walked through the area. They cleaned the area and verified that there was no further contamination spread. Analysis of the contamination found that it was americium-241 which was not an expected isotope for that portion of the facility. Facility personnel are attempting to determine the provenance of the contamination and are evaluating their routine survey requirements for uncontrolled areas. The evaluation will also be informed by the shift in activities in some wings to more invasive deactivation and decommissioning. This contamination was discovered outside of a wing undergoing equipment removal.

Federal Oversight: NNSA Field Office staff showed the resident inspector some of the current capabilities for using the Safety, Analytics, Forecasting, Evaluation, and Reporting (SAFER) software tool for facility oversight (see 12/17/2021 report). Available information varies widely by module as the system is still being built and populated with relevant data.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 31, 2021

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending December 31, 2021

Year in Review: A summary of the key developments of 2021.

- The pace of work in the Plutonium Facility continued to increase, especially construction work on the backshift when many of the equipment removals and upgrades to support the 30 pit per year mission take place. Triad is working to support a large influx of workers including providing the substantial training and conduct of operations mentoring needed to work safely and effectively in a nuclear facility.
- This marked the first year for comingled shipments of NNSA managed and Environmental Management transuranic waste from the RANT Shipping Facility. Comingling shipments allows for more efficient building of payloads. Despite safety basis issues at Area G and the titanium event at the Plutonium Facility, Triad and N3B completed more than fifty shipments to the Waste Isolation Pilot Plant this calendar year. These shipments included more than a thousand waste containers and exceeded the generation rate of transuranic waste at the lab.
- N3B curtailed transuranic waste operations at Area G following the identification of several potential inadequacies of the safety analysis. Many of these were discovered through a detailed extent of condition review of the current safety basis directed by the Environmental Management Field Office. N3B personnel have been addressing the weaknesses in the current safety basis and have re-established much of their mission work under controls from a series of Justifications for Continued Operations. Meanwhile, a modern safety basis for Area G is still under development.
- Triad and N3B both experienced challenges addressing potentially reactive transuranic waste containers as discussed in DNFSB-TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*. By the end of the year N3B had identified the set of containers they were most concerned about in terms of potential reactivity and are managing them under new controls. Triad experienced an unexpected titanium powder sparking while loading a waste drum in the Plutonium Facility and performed a causal investigation which generated many corrective actions to improve waste generation and handling.
- The multi-year effort to establish the fire suppression system at the Transuranic Waste Facility as safety-significant continued with the approval of a new safety basis. Implementation is planned to be completed in January 2022.
- Triad continued efforts to transition the Radioactive Laboratory Utility Office Building to a Hazard Category 3 nuclear facility to be known as PF-400. This year they performed an Implementation Verification Review of the new safety basis and commenced a Management Self Assessment to support federal and contractor Operational Readiness Reviews next year.
- Progress on venting the Flanged Tritium Waste Containers stored at Area G stalled this year partly due to the safety basis issues at Area G and permitting delays.
- Both the Environmental Management and the NNSA Field offices again welcomed new site managers in 2021.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 7, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for Week Ending January 7, 2022

Area G–Safety Basis: Last month, the Environmental Management Field Office and Headquarters personnel approved N3B’s Justification for Continued Operations (JCO) for the potential inadequacies of the safety analysis (PISA) related to unvented transuranic waste drums movements and horizontal sympathetic deflagrations in unvented drums (see 10/29/2021 report). While there were no conditions of approval or directed changes in the Safety Evaluation Report, the transmittal letter formally noted that the duration of the JCO will not exceed one year rather than being in place until a modern safety basis for Area G is approved and implemented. This is the fifth and final JCO developed to address the 23 PISAs identified against the Area G safety basis in 2020 and early 2021.

Emergency Management: The NNSA Field Office approved Triad’s annual Emergency Readiness Assurance Plan and submitted it to NNSA Headquarters. This year, the plan discusses some of the challenges to emergency management due to the COVID-19 pandemic and the relief granted by DOE to many requirements during the pandemic. Also of note, fiscal year 2021 was the final year in the five-year implementation process of DOE Order 151.1D, *Comprehensive Emergency Management System*, at the site. Once the NNSA Field Office approves a few remaining Emergency Management Planning Assessments which are currently under review, implementation will be complete.

Federal Oversight: The Resident Inspector joined the NNSA Site Manager and other Field Office personnel in a tour of the Weapons Engineering Tritium Facility (WETF). Key topics addressed during the visit included disposition of Flanged Tritium Waste Containers (FTWCs), and the upcoming Plutonium Coupon Studies (see 8/6/2021 report). WETF currently stores two potentially pressurized FTWCs that are slated for venting; one FTWC in this category was vented and unloaded in 2019. The facility also has two FTWCs that are not potentially pressurized but are overloaded and must have their contents split and distributed to additional containers prior to shipment offsite as waste. The four potentially pressurized FTWCs at Area G are planned to be vented there, then transported to WETF in spring of this year. For the Plutonium Coupon Studies, WETF personnel discussed the new safety basis controls and showed the location of the filter in the tubing manifold that is intended to protect WETF tritium systems from inadvertent plutonium contamination.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 14, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 14, 2022

DNFSB Staff Activity: J. Plaue completed his headquarters assignment and returned to regularly assigned duties as a Resident Inspector.

Plutonium Facility–Glovebox Safety: Last Friday, an airborne release of radioactive material occurred in a laboratory room while workers were executing a repack, consolidate, and discard activity. Specifically, a worker finished sizing a legacy container of nuclear material for a new overpack, withdrew their arms from the glovebox, and detected contamination during standard monitoring. Moments later, continuous air monitors sounded, and all six workers evacuated the room according to procedure. Radiological control technicians responded and identified contamination on areas of the personal protective equipment, face, and heads of two workers—they were subsequently successfully decontaminated. However, nasal swabs indicated potential radiological intakes of one of the contaminated workers, as well as two other workers who were in the room. All six workers were placed on special bioassay. Yesterday, the NNSA Cognizant Secretarial Officer for Safety appointed a formal Accident Investigation Board in accordance with DOE Order 225.1b, *Accident Investigations*. This decision was based on the NNSA’s determination that the potential exposure levels exceed the investigation criterion of a confirmed monitoring result indicating an intake of two or more times the annual limit on intake. Because bioassay results are not yet available, the confirmed monitoring result was based on the concentrations of airborne radioactive material detected by air monitoring equipment.

Plutonium Facility–Safety Basis: The NNSA Field Office formally responded to Triad’s submittal of a combined justification for continued operations/evaluation of the safety of the situation pertaining to the potential inadequacy of the safety analysis resulting from the July overflow event (see 11/19/2021 report). NNSA directed that Triad resubmit the document after addressing numerous review comments.

Area G: On Monday, a five-member contractor team commenced a readiness assessment for resumption of drill and drain and glovebag operations in the Dome 231 Permacon. These activities underwent a contractor readiness assessment in late 2020; however, safety basis issues at Area G curtailed nuclear operations prior to the completion of the federal readiness assessment. As a result, the Environmental Management Field Office directed N3B to perform a new readiness assessment scoped to account for the previous review prior to an upcoming federal assessment. This week’s review included cold performance demonstrations of both drill and drain operations and glovebag operations, which included two operational drills and one emergency drill. On Thursday, DOE Environmental Management personnel noted that there was a discrepancy between the actual review team leader and the leader designated in the approved plan of action. The field office and N3B are adjudicating the situation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 21, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 21, 2022

Plutonium Facility–Glovebox Safety: On Wednesday, a five-member federal Accident Investigation Board commenced its review of the contamination event and potential intake of radioactive material by a worker that occurred on January 7, 2022. Following Triad’s decontamination efforts, board members walked down the laboratory room associated with the incident. They also conducted interviews and received a briefing from Triad’s internal dosimetry team.

Transuranic Waste Facility: On Thursday, Triad declared full implementation of two safety basis changes. One change was related to flammable gas sampling, and the other was the upgrade of the fire suppression system to safety significant. Upgrading the fire suppression system has involved substantial effort since the facility became operational in 2017 (see 9/6/2017 report).

Weapons Engineering Tritium Facility: A Triad team performed an implementation verification review for the safety basis changes supporting upcoming plutonium coupon studies. The team noted four findings in their outbrief and expressed a general concern outside of safety basis implementation with bringing plutonium into the facility given the substantially different radiological hazard compared to tritium.

Radioactive Liquid Waste Treatment Facility–Readiness: Triad’s Joint Evaluation Team met this week to evaluate readiness needs for the resumption of transuranic waste drumming operations. This operation has not been performed since 2014. The hazard category 3 facility is approaching material-at-risk limits which can best be reduced by resuming the drum cementation process. Facility personnel proposed that this was an expansion of existing capability, however the Joint Evaluation Team concluded that it was a restart and should undergo a readiness assessment.

Nuclear Criticality Safety: On Wednesday, the NNSA Field Office concurred with Triad’s revision to the program improvement plan. Focus areas for this fiscal year include: continued development of standardized criticality safety requirements documents; completion of the 86 fissile material operations remaining in the backlog; and full implementation of a new holdup database. On Thursday, Triad requested a variance to the requirement to conduct annual fissionable material operational reviews citing onsite staffing impacts from COVID-19. They specifically requested an extension of the frequency from 12 to 15 months for 79 fissionable material operations with due dates between January 15, 2022 and February 25, 2022.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 28, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending January 28, 2022

DNFSB Staff Activity: J. Flora was on-site to observe activities of the federal Accident Investigation Board. This week, the Accident Investigation Board continued interviews and observed a glove change demonstration in a cold training facility. On Wednesday, the staff held a teleconference with N3B and Environmental Management personnel to discuss the current safety posture of Area G until a modern safety basis is developed and implemented. On Thursday, the staff held a teleconference with NNSA Field Office personnel as part of a complex-wide review of DOE's review and approval of safety basis documents.

Weapons Engineering Tritium Facility: Last Friday, an operator incorrectly implemented a procedure for a gas transfer resulting in the rupture of a safety-significant pressure disk. No tritium was released from the system. Facility management took corrective actions with the operator and more broadly to reinforce proper use of the facility control system. Facility management concluded this event does not meet DOE reporting criteria. In the opinion of the resident inspectors, this event meets reporting criteria for the actuation of a safety-significant component because it resulted from the actual unsafe condition of too much pressure in a segment of the line.

Plutonium Facility–Infrastructure: Last month, Triad issued the tenth revision of the project execution strategy that guides improvement activities necessary to achieve further reductions of the mitigated consequences from postulated accidents to support enduring operations (see 1/15/2021 report). Achievements for last fiscal year include completion of the design for a facility control system replacement, continued progress on fire barriers, and completion of 13 fire hazard evaluations for gloveboxes. Focus areas for this fiscal year include completing modification to fire barriers and structural upgrades necessary to eliminate seismic equipment interactions for the bleed-off ventilation system.

The resident inspectors' review of the document identified that the schedule slipped for several out-year projects including those focused on the ventilation and fire suppression systems. We also noted the approach for achieving a more robust active confinement ventilation system is to replace aging ventilation fans with new equipment that meets performance category 3 seismic criteria, replace the obsolete facility control system, and install a new diesel electric generator and secondary uninterruptible power supply. Of significance, the resident inspectors note that equipping these fans with safety-class electrical power and controls no longer appears to be planned. The need for DOE to provide clarity on the planned end-state of the ventilation system, the schedule for achieving that end-state, and how the system will be credited in the facility safety basis was the subject of the Board's letter dated November 24, 2021.

Area G–Safety Basis: Last Friday, N3B transmitted a revised annual update for the Area G safety basis to the Environmental Management Field Office. The revision is intended to address the field office's condition of approval related to Flanged Tritium Waste Containers (see 12/10/2021 report).

Federal Oversight: On Monday, the NNSA Facility Representative for the Transuranic Waste Facility, RANT Shipping Facility, Radioactive Liquid Waste Treatment Facility, and Waste Characterization, Reduction, and Repackaging Facility completed final qualifications following a walkdown of the Transuranic Waste Facility with the NNSA Field Office Manager.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 4, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 4, 2022

DNFSB Staff Activity: Members of the DNFSB staff held a closeout teleconference with personnel from both field offices and DOE headquarters to discuss the results of the staff's complex-wide review of the process to update and implement DOE directives in contracts.

Plutonium Facility–Glovebox Safety: This week, the Accident Investigation Board covering the January 7, 2022, radioactive material intake event continued interviews with Triad and NNSA Field Office personnel.

On Tuesday, facility personnel conducted fact-findings concerning two recent potential glovebox glove breaches. In one event, a worker was lapping small pieces of plutonium metal and upon exiting the glovebox, identified contamination on his personal protective equipment glove. Glove specialists were unable to identify a breach in the glovebox glove or a potential source of the breach in the operation. In the other event, a worker supporting pyrochemical processing operations similarly detected contamination on his personal protective equipment glove upon exiting the glovebox. Unlike the other event, responding radiological control technicians identified contamination on the worker's face. They were able to successfully decontaminate the worker and there were no indications of an intake. In this case, the work crew and glove specialists identified a likely pinching mechanism associated with manually moving an automatic transfer device that was inoperable. Management took an action to expedite repair of this transfer device. More broadly, workers in both cases indicated compliance weaknesses with the required techniques for exiting gloves. Facility management implemented this technique in August 2020 as a corrective action from the June 2020 glove breach and intake event involving heat-source plutonium. Facility management took an action to include continuing training on the technique, which maximizes confinement in the event of a breach. Also of note, attendees discussed the need to accelerate plans to re-establish capabilities to better examine potentially failed gloves.

Plutonium Facility–Operations: This week, Triad management commenced operations in the facility 24 hours a day, seven days a week. In the near-term, night shift activity will be similar type and tempo as to what was previously performed on the backshift. Longer term, they expect night shift activity to significantly ramp-up in tempo and complexity.

Area G–Safety Basis: Last Friday, N3B submitted for approval a revised Unreviewed Safety Question (USQ) procedure to the Environmental Management Field Office. The field office rejected N3B's previous major revision to the current procedure in 2020 and requested clarification of the procedure's applicability to less than hazard category 3 facilities that may have been miscategorized and the process for requesting extensions. The new procedure provides time limits of three working days from discovering new information to making a determination of a potential inadequacy of the safety analysis and a subsequent limit of five working days to make a USQ determination—a substantial improvement in timeliness requirements from the current procedure.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 11, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 11, 2022

Weapons Engineering Tritium Facility: On Tuesday, the tritium stack monitor alarmed resulting in a facility evacuation in accordance with procedure. At the time, no programmatic activities were in progress and only three individuals were in the facility. Personnel in the area reported to designated shelter-in-place locations and facility command obtained positive accountability. Monitors showed no evidence of an ongoing tritium release either inside or outside of the facility. Further analysis of the stack monitor data concluded the event released a small quantity of tritium (approximately 0.1 curie). Facility personnel are investigating the cause of the release. Facility and emergency management personnel conducted a hotwash to evaluate their response to the event and develop improvements. Key items discussed during the hotwash included: two individuals responded to the event scene before it had been cleared for safety; the need to revisit the appropriate setpoint for facility evacuation due to a stack monitor alarm; and alarm panel communications with the Emergency Operations Support Center.

Transuranic Waste Management: Earlier this month, Triad received approval from the Carlsbad Field Office to resume packaging and shipping transuranic waste originating from gloveboxes with inert or semi-inert atmospheres. The approval is predicated on completing the corrective actions from the titanium event (see 5/14/2021 report), continued use of a compensatory measure to ensure such waste is opened and observed in an air environment, and committing to the near-term completion of a Generator Site Technical Review. Key remaining corrective actions include: developing a plan and schedule to implement chemical compatibility evaluations for evaluation against the safety basis; revising a requirements document to adjust terminology, ensure integration, and incorporate lessons learned; and revise waste management training.

Plutonium Facility–Safety Basis: Last Friday, Triad submitted to the NNSA Field Office for approval a revised version of the combined justification for continued operations/evaluation of the safety of the situation pertaining to the potential inadequacy of the safety analysis resulting from the July 2021 overflow event. The revision is intended to address NNSA’s comments on topics such as clarifying the requirements for the water filling specific administrative control and ensuring that control level designations are consistent with the consequences in the hazard evaluation (see 1/14/2022 report).

Last week, the NNSA Field Office formally transmitted to Triad the review comments on the safety basis addendum supporting receipt of large shipments of heat source plutonium (see 12/24/2021 report). They directed that Triad revise the safety basis addendum to incorporate changes resulting from comment resolution.

Onsite Transportation: Triad submitted to the NNSA Field Office for approval a revision to the technical safety requirements for onsite transportation that incorporates an increase in the limit for heat source plutonium in a package from 10 grams to 25 grams which was previously approved through an evaluation of the safety of the situation and a safety basis addendum.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 18, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 18, 2022

Plutonium Facility–Infrastructure: Heat-source plutonium (HS-Pu) operations are among the highest risk in the facility due to the material’s high radioactivity and dispersible material forms. During the past few years, Triad personnel have made progress analyzing the seismic performance of HS-Pu gloveboxes following the updated seismic hazard from 2007. Their current analyses indicate that only about 10 HS-Pu gloveboxes meet the required seismic performance, meaning that more than 50 gloveboxes are now known to be deficient. The NNSA approved safety basis acknowledges the potential for gloveboxes to be seismically deficient and commits to analyze and upgrade gloveboxes on a risk-based priority. NNSA and Triad are upgrading and replacing about a hundred gloveboxes to support pit manufacturing, analytical capabilities, and surplus plutonium disposition. There are currently no funded plans associated with upgrading or replacing HS-Pu gloveboxes.

Plutonium Facility–Readiness: On Wednesday, Triad managers met to evaluate whether a formal readiness review is necessary for the proposed startup of a new HS-Pu bench-scale recovery line. The new line occupies the gloveboxes associated with the full-scale scrap recovery line that never became operational after challenges completing a readiness review (see 7/8/2005 report). The new line will house a second open vessel and furnace operation, like the existing bench-scale operation, to produce purified HS-Pu oxide through comminution, dissolution, precipitation, and calcination. The new line will also repurpose some of the fixed vessels from the defunct full-scale line to support new capabilities to store and process waste filtrate solutions. Filtrate processing is currently conducted in a different location and is dependent on the use of many plastic carboys to store solutions awaiting processing. Given that these carboys have leaked in the past (see 6/8/2018 report)—moving to the engineered vessels represents an improvement. Triad engineering personnel are currently evaluating whether these gloveboxes meet required seismic performance. Triad managers concluded that this startup will not require a formal readiness review because it meets local criteria for an expansion of an existing capability.

Plutonium Facility–Operations: Facility personnel held a fact-finding meeting to evaluate an event where drums of transuranic waste were staged too close to inactive areas containing holdup of special nuclear material contrary to the criticality safety posting for drums. Last fall, following the start of holdup measurements in this area to support future equipment removal, facility personnel identified that their current processes have weaknesses for tracking material at risk in inactive areas. Until a process is put in place, compliance with criticality safety limits and material at risk limits will continue to be a challenge for facility workers.

Radiological Laboratory Utility Office Building (RLUOB)/PF-400: A contractor team completed an operational readiness review for the upgrade of RLUOB to a hazard category 3 nuclear facility to be known as PF-400. They identified four prestart and three post-start findings during their review. A federal operational readiness review is planned for May following completion of corrective actions from this review.

Area G–Readiness: N3B and Environmental Management Field Office personnel held an event investigation meeting to evaluate the commencement of the contractor readiness assessment for resumption of drill and drain and glovebag operations in the Dome 231 Permacon with an inaccurate approved Plan of Action (see 1/14/2022 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 25, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending February 25, 2022

Chemistry and Metallurgy Research Building: Subcontractor personnel recently commenced more invasive decontamination and decommissioning activities such as glovebox removal. Last week, during removal of the first glovebox, a continuous air monitor alarmed. The work crew, who were wearing respiratory protection, evacuated the room. Responding radiological control technicians found contamination on the personal protective equipment of several individuals. They found no skin contamination, no evidence of any uptakes, but areas of substantial contamination in the room and adjacent areas. The air monitor alarmed shortly after subcontractor personnel removed and replaced a plug from the glovebox to drain possible oil holdup. At the fact-finding, personnel discussed several areas in need of improvements. Most prominently, the group discussed the need to ensure ventilation systems are configured optimally for the work. In this case, subcontractor personnel had placed plastic sheeting around the room that may have obstructed ventilation exhaust intakes. Additionally, ventilation draw on the glovebox being removed may not have been maximized. A second prominent topic of discussion involved improved planning and controls for breaching contaminated systems. In this case, subcontractor personnel breached the glovebox confinement without the aid of a glovebag, local task exhaust, or continuous monitoring by a radiological control technician. Other areas discussed included improving housekeeping and ensuring correct anti-contamination clothing for potential hazards such as contaminated oil.

Sigma Facility: On Wednesday evening, facility personnel noticed smoke and evacuated the building after pulling the fire alarm. The two people present evacuated without issues. The Los Alamos County Fire Department responded and extinguished a smoking piece of equipment in a radiological area with one fire extinguisher followed by water for cooling. No contamination was released by the fire. Researchers reported finishing an experiment with the piece of equipment about an hour before the event without any apparent issues. The fire department is investigating the cause of the incident.

Federal Oversight: On Wednesday, a six-person team led by an individual from the NNSA Production Office commenced an assessment of conduct of operations in the Plutonium Facility. The primary purpose of the assessment is to evaluate the effectiveness of Triad's corrective actions from several negative events that occurred last year (see 4/2/2021 and 7/23/2021 reports), as well as overall compliance with requirements for conduct of operations. NNSA is also using this assessment as part of a broader effort to ensure enhanced and sustainable formality of operations at all its sites after a recent review indicated that there has not been a measurable reduction in events during the past 10 years despite numerous corrective actions. The team is expected to complete their onsite observations by March 18, 2022.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 4, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plae, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 4, 2022

DNFSB Staff Activity: A. Hutain was onsite to observe activities by the NNSA team reviewing conduct of operations at the Plutonium Facility.

Weapons Engineering Tritium Facility: On Tuesday, facility management was notified that an operator made various unapproved deviations from a use every time procedure while loading a Hydride Transport Vessel. The operator could not follow the approved procedure as written because of the configuration of the system following last month's actuation of a safety significant rupture disk (see 1/28/2022 report) and believed he had verbal permission to make the changes. Facility management confirmed the safety of the tritium gas handling system and the loaded vessel. Given this was the second conduct of operations even in about six weeks, they also plan several other corrective actions including conducting a causal analysis and holding a conduct of operations refresher session.

Engineering: Last week, Triad submitted to the NNSA Field Office for awareness its plan to update the site's probabilistic seismic hazards assessment (PSHA). DOE Order 420.1C, *Facility Safety*, requires contractors to review natural phenomena hazards (NPH) at least every 10 years. In 2014, the previous LANL contractor completed a review of NPH and set a milestone to complete a revision of the PSHA by September 1, 2019. The current PSHA for the LANL site was completed in 2009. Since then, LANL contractors have completed a number of studies to reduce uncertainties in the seismic model, most notably they have obtained additional valuable geotechnical data associated with the LANL site. As a result, Triad concluded a PSHA update is necessary and noted that their current schedule calls for completion by the end of fiscal year 2025.

Plutonium Facility–Glovebox Safety: Last Thursday, while an operator was lifting a vessel out of a furnace well, the lifting tool disengaged from the vessel and impacted the inside of the glovebox window causing a crack. Operators responded to the event as if it was a glovebreach as there is no specific training for responding to a cracked window. There was no evidence of any contamination spread from the cracked window and engineers consider the glovebox fully operable. The window is currently taped up awaiting replacement. One planned corrective action is to develop and train to a response procedure for cracked windows. This and several similar activities involve challenging ergonomics of hand lifting a heavy vessel in glovebox gloves. Attempts to introduce mechanical lifting aids for similar activities have not been met with success.

Area G–Readiness: A nine-member federal team commenced a readiness assessment for resumption of drill and drain and glovebag operations in the Dome 231 Permacon.

PF-400–Readiness: The contractor's operational readiness review team issued their final report for the upgrade of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility to be known as PF-400. The four prestart findings include the need to identify the full scope of needed maintenance activities and the need to include the full set of necessary activities in the startup plan. The three post-start findings include an unprotected material-at-risk assumption in the safety basis and the need to fully implement vital safety system and system health reporting processes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 11, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 11, 2022

DNFSB Staff Activity: On Tuesday, staff members conducted a teleconference with personnel from the Idaho National Laboratory, the DOE Idaho Operations Office, the NNSA Headquarters, and the NNSA Los Alamos Field Office. They discussed contingencies associated with the campaign to ship heat-source plutonium to the Plutonium Facility in quantities that exceed the current safety basis limits (see 11/26/2021 report). Of note, DOE/NNSA stated that they have no contingencies should the plan to ship this material to LANL be foreclosed for any reason.

Plutonium Facility–Operations: Last Wednesday, after a question from a resident inspector, operations personnel assessed waste drums staged near a pencil tank and declared a potential process deviation. At a fact-finding held on Tuesday, facility personnel confirmed that three drums violated a criticality safety requirement because they were too close to pencil tanks that have recently been determined to contain fissionable material. This is the third time this issue has recently occurred in this room (see 2/18/2022 report). Fact-finding participants confirmed previous concerns about posting inactive equipment locations that have been determined to contain holdup. After a revitalization of the holdup measurement program, there are currently about 30 of these locations across the facility. Participants also discussed broader concerns with the imprecision in the language of a criticality safety limit that specifies a standoff from “any other fissionable materials,” since this could be interpreted to include minor contamination.

Plutonium Facility–Glovebox Safety: On Wednesday, facility personnel conducted two fact-findings for recent glovebox glove breaches. In the first event, after moving tools a worker observed a breach while inspecting gloves prior to removing their arms. This is the best time to catch a breach and the subsequent response worked as intended without any release of radioactive contamination to the room. In the second event, a worker felt a pinch while releasing a tool from a holding bar, did not observe a glove breach upon inspection, but identified contamination on their inner gloves while surveying immediately upon removing their arms. This is the second-best time to catch a breach and contamination spread was also avoided. Glovebox safety personnel recommended that both activities use protective overgloves in the future. For the second event, they also recommended that line management select a more frequent glovebox glove change periodicity as the glove was on year 7 of the 10-year default service life.

Last year, glovebox safety personnel identified 19 glove failures or breaches in the facility. While this represents an improvement from about 2.5 glove failures per month experienced in earlier years, glovebox safety personnel recognize that improvements are still needed, particularly as the amount of work in the facility increases. They have started several initiatives including developing improved metrics, deploying an in-service leak testing device for glovebox gloves, refining procedures and training related to gloves, and applying additional scrutiny of selection of glove change frequencies.

Plutonium Facility–Safety Basis: On Tuesday, the NNSA Field Office approved a revised version of the combined justification for continued operations/evaluation of the safety of the situation pertaining to the July 2021 overflow event (see 2/11/2022 report). The field office directed two changes in the wording of Specific Administrative Controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 18, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 18, 2022

DNFSB Staff Activity: Staff members M. Dunlevy and P. Migliorini were on site for a review of the current safety posture of Area G under multiple Justifications for Continued Operations developed to address the 23 potential inadequacies of the safety analysis (PISA) identified against the Area G safety basis in 2020 and early 2021. M. Sautman was on site for familiarization and to evaluate resident inspector performance. M. Randby was on site for familiarization.

Area G–Safety Basis: Last week, N3B personnel declared a PISA against the Area G safety basis following questions raised by the federal team assessing readiness of drill and drain and glovebag operations. The PISA concluded that a safety basis reference did not support a conclusion regarding hydrogen accumulation in closed plastic containers with lids. This PISA further determined that the technical basis was incorrect for two exemptions from a technical safety requirement specific administrative control for Sort, Segregate, Size Reduction, and Repackaging activities. N3B is generating a shift order to communicate any compensatory measures and has determined that this is an unreviewed safety question.

Plutonium Facility–Infrastructure: On Tuesday, the NNSA Administrator responded to the reporting requirement from the Board’s letter dated November 24, 2021. The Board requested a written report that describes DOE’s strategy for the Plutonium Facility confinement ventilation system, the planned end-state of the ventilation system, the schedule for achieving that end-state, and how the system will be credited in the facility safety basis. NNSA’s response states that it will pursue upgrades to achieve a more robust ventilation system but will not achieve a safety class active confinement ventilation system at the Plutonium Facility. This path forward represents a change in strategy from what NNSA personnel briefed the Board in February 2020, where they described the future control strategy as including safety class active confinement ventilation.

Plutonium Facility–Materials Processing: There were two events last week involving processing of materials stored at the Plutonium Facility. In the first event, a portable continuous air monitor alarmed during introduction of a legacy item into a glovebox line through an open front hood for eventual disposal as waste. Responding radiological control technicians found no contamination on the workers or evidence of any uptake. They discovered contamination on the floor in front of the hood which has been cleaned. Facility personnel are evaluating other containers in this feed stream to determine if additional planning is needed to prevent issues during future processing of similar containers.

The other event involved materials to be processed to plutonium oxide in a muffle furnace. Upon opening the can workers discovered an oily sludge of questionable provenance. The work crew paused and reported the event. During the response, the workers placed the solid items into a water-resistant container per direction from criticality safety personnel. Further recovery actions are in progress for the container with sludge residue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 25, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending March 25, 2022

DNFSB Staff Activity: Staff members F. Bamdad, P. Migliorini, and R. Oberreuter were onsite for a review of the safety basis addendum supporting the upcoming receipt of large shipments of heat source plutonium. They also held a meeting to discuss the technical basis behind a fire protection equivalency at the Radiological Laboratory Utility Office Building. Another staff team held a virtual meeting with site personnel to discuss decontamination and decommissioning activities at the Plutonium Facility and the Chemistry and Metallurgy Research building to support an upcoming staff review.

Transuranic Waste Management: Last Friday, personnel at the Waste Isolation Pilot Plant (WIPP) identified that a transuranic waste drum from Los Alamos had been emplaced in the repository without having received a flammable gas analysis. WIPP certification personnel at Los Alamos are required to perform this analysis to comply with shipping requirements. WIPP management paused receipts of drums from Los Alamos while they evaluate the event. Locally, Triad personnel have entered their new information process to evaluate the safety basis implications of having a drum without flammable gas analysis in the RANT Shipping Facility, the Transuranic Waste Facility, and the Transportation Safety Document.

Plutonium Facility–Nuclear Criticality Safety: This week, personnel in the pyrochemistry room implemented a pilot for a new glovebox combustible loading program. The new program limits the amount of fixed and transient combustibles within a glovebox to an amount that would limit a fire to less than 100 kilowatts. Triad analysts determined that a fire within a glovebox of less than 100 kilowatts would be of insufficient energy to activate nearby over-head fire sprinkler heads. This allows criticality analysts to limit the amount of flooding they must analyze when this combustible limit is implemented in a seismically qualified glovebox without any other viable sources of liquid-ingress. In order to implement this new control, operations personnel have developed operator aids posted at the glovebox location. The aids include photographs of the inside of the glovebox with the baseline level of allowed combustibles. During their morning inspections to release work, area controllers compare the as-found condition against the baseline. If conditions exceed the baseline, they declare a potential process deviation and work cannot be performed.

The pilot includes two gloveboxes and facility personnel will evaluate this approach in about a month. If found to be workable and effective, the resident inspectors note that a similar approach could be applied to control housekeeping and combustible loading issues in other gloveboxes such as those with increased hazards like heat-source plutonium. While improvements have been made in the past year, maintaining good glovebox housekeeping continues to need management attention. Notably, the combined waste accumulation in all approved staging locations often challenges the limit of 55 gallons for a single room.

Onsite Transportation: The NNSA Field Office unconditionally approved the revision to the technical safety requirements for onsite transportation allowing an increase in the amount of heat source plutonium in packages (see 2/11/2022 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 1, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 1, 2022

Plutonium Facility–Infrastructure: On Tuesday evening, facility personnel shut down the ventilation system for the north half of the facility because of malfunctioning damper actuators. As a result, all normal mission activities in the north half were terminated. Maintenance personnel were able to restore the system by Thursday evening. Repair efforts were hindered by insufficient spare parts. The affected portion of the facility also experienced several continuous air monitor alarms during the ventilation outage. On Thursday, facility personnel declared the instrument air system, which supports the ventilation system, degraded but operable following issues with an air dryer.

In a letter to the Board dated March 15, 2022, the NNSA Administrator stated that they are no longer pursuing a safety class active confinement system (see 3/18/2022 report). The resident inspectors note that both the actuators and the instrument air system that failed would have required upgrades to support the previous documented plans to achieve a safety class system. NNSA’s letter now lists these upgrades as open, meaning that no plans exist for upgrades.

Plutonium Facility–Safety Basis: On Monday, NNSA Headquarters conditionally approved the safety basis addendum associated with the receipt of large quantities of heat source plutonium (see 11/26/2021 report). The conditions of approval, required by April 29, 2022, involve addressing outstanding comments on the addendum and wording changes to a technical safety requirement. In approving this addendum, NNSA Headquarters accepted an “exigent condition” where there is no viable control strategy to meet DOE’s evaluation guideline for postulated consequences to the public. In this case, NNSA accepted bounding mitigated consequences to the public that range from 490 to 3,175 rem depending on the amount of radioactive material assumed to leak out of the building structure following a post-seismic fire. NNSA deemed the risk acceptable based on the conservatism in the analysis, the low likelihood that the accident occurs, and the limited number of shipments. The primary controls credited to protect the public are the shipping containers (which must be received by May 2024 before certifications expire) and the seismic power shutoff system (which has an acknowledged deficiency and cannot prevent all fire ignition sources following an earthquake). Work associated for this activity will be primarily performed in four gloveboxes where only one of the gloveboxes meets minimum seismic requirements.

Transuranic Waste Management: On Wednesday, Triad sent the NNSA Field Office a progress report on actions associated with an inadequacy with the safety analyses they declared in December 2020 for three nuclear facilities following issuance of DNFSB-TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*. The report notes that they plan to resubmit an evaluation of the safety of the situation by the end of July 2022—about a year after N3B received approval on its evaluation for Area G (see 7/23/2021 report). The report also notes that an extent-of-condition review to complete chemical compatibility analyses for activities in the Plutonium Facility should be completed by the end of fiscal year 2022. The report justifies the schedule delays due to ongoing research effort to study the reactivity of anion exchange resins. Meanwhile, the resident inspectors note that NNSA has yet to develop a defensible general solution for determining a *de minimis* amount of incompatible chemical mixtures.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 8, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 8, 2022

Radiation Protection: On Tuesday, Triad personnel briefed the NNSA Field Office leadership on efforts to manage worker radiation doses. The most recent DOE annual radiation exposure report shows Los Alamos leads all sites with the highest collective worker dose and an upward trend, consistent with an expanding mission. Triad explained that most of this dose comes from workers in the Plutonium Facility, particularly the groups that work with heat-source plutonium, support legacy material repackaging, manufacture new pits, conduct surveillance work on old pits, and support construction and maintenance. They further explained their dose management processes and various action levels. Triad sets their administrative control level at 2,000 mrem and their action level to perform a management review at 1,000 mrem. These values are considerably higher than other sites. For example, the Savannah River Site and the Lawrence Livermore National Laboratory both perform plutonium work and use 500 mrem as their administrative control level. Triad justified these higher levels based on historical information for the type of work performed in the Plutonium Facility. They further asserted that their As Low As Reasonably Achievable program was effective and compliant. Notably, Triad discussed additional reviews of established operations, since most dose review processes focus on operations that are new or modified.

Plutonium Facility– Infrastructure: Last Friday, the NNSA Field Office approved the third revision of the safety design strategy for the Los Alamos Plutonium Pit Production Project. This revision separates out activities into those needed to achieve a base capability to produce 30 pits per year and those needed to achieve that rate reliably. It also increases the material-at-risk for the solvent extraction process. The approved safety design strategy continues to indicate planned upgrades to achieve a safety class active confinement ventilation system contrary to NNSA’s recent response to the Board (see 4/1/2022 report).

On Monday, Triad personnel conducted a fact-finding on last week’s ventilation system failure. Due to obsolescence, there are no working spare actuators on hand. Of the two damper actuators that failed, facility personnel restored one through manual stroking and replaced the other through cannibalization of damaged spares and inactive actuators installed in the facility. System engineering personnel believe they can maintain functionality of the damper actuators through continued scavenging of unused or damaged components until replacements are installed. A new model of actuator will be installed as soon as possible and was already undergoing testing and commercial grade dedication at the time of the failures.

Area G: Last Wednesday, N3B management declared a nuclear criticality safety infraction after personnel conducting an annual review determined a waste container was non-compliant with spacing requirements. Their criticality analysts determined the configuration was safe and would be allowed under an approved evaluation that is not yet implemented. Because containers involved have uncertain potential for an energetic chemical reaction, N3B management conservatively decided to leave the configuration in-place and accelerate implementation of the new evaluation. N3B management also requested additional review to determine why the existing limit did not get incorporated into the applicable procedure and posting.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 15, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 15, 2022

DNFSB Staff Activity: Members of the DNFSB staff held a closeout teleconference with personnel from the Environmental Management Field Office and N3B to discuss the results of the staff's review of the current safety posture of Area G (see 3/18/2022 report).

Plutonium Facility–Infrastructure: Last month, facility engineers determined that the gloveboxes for the new heat-source plutonium recovery line meet seismic performance requirements after revising their calculation to account for the installed anchors (see report dated 2/18/2022). This glovebox line is essential to increasing the throughput necessary to support the eventual processing of the shipments of large quantities of heat-source plutonium expected to meet launch requirements for the National Aeronautics and Space Administration (see report dated 4/1/2022). Workers continue to finalize modifications to the glovebox line. The new line will rely on a portable vacuum pump because of long-term availability and reliability issues with the house wet vacuum system that supports this area of the facility. NNSA does not have a schedule or funding to refurbish that system. Notably, the portable vacuum pumps typically provide a service life of about six months and then become a challenge to remove from the glovebox environment and dispose as transuranic waste.

Plutonium Facility–Worker Safety: Last Thursday, a worker felt a poke on a finger while performing decontamination activities in one of the material management rooms. Radiological control technicians responded and found no detectable contamination on the finger to include a subsequent wound count. The worker indicated that he identified a strand of wire embedded in the floor paint that may have been the source of the puncture. At the fact-finding on Tuesday, facility personnel discussed improvements for decontamination activities including the use of more puncture resistant gloves. They also discussed potential origins of the wire strand. Tamper indicating devices and radiological condition tags both use braided wire and are ubiquitous in the facility. In particular, workers routinely cut the tamper devices inside and outside of gloveboxes, which are known to unravel and generate sharp strands. In response, management directed a learning team to identify any near-term improvements to working with the tamper devices and longer-term efforts to investigate whether the braided wire could be substituted with a safer material.

Transuranic Waste Management: Last month, the NNSA Field Office directed Triad to develop a plan and schedule to establish size reduction capabilities for oversized transuranic waste using the Waste Characterization, Reduction, and Repackaging Facility (WCRRF) as a hazard category 3 nuclear facility. Triad does not possess this capability, which is needed to support removal of more than 150 legacy gloveboxes and some pieces of large, contaminated equipment from the Plutonium Facility as part of upgrades for pit manufacturing. NNSA previously planned to establish modern and enduring capabilities for size reduction and container remediation as part of the original mission the Transuranic Waste Facility, but they eliminated the scope as a cost saving measure. The 1980's vintage WCRRF will require a new safety basis, substantial corrective maintenance, and readiness reviews before operations can begin. The NNSA Field Office also directed Triad to evaluate establishing capabilities for other size reduction processes inside the yard at the Plutonium Facility and for shipping larger-size waste boxes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 22, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 22, 2022

DNFSB Activity: On Wednesday, the Board members received a briefing from Triad and NNSA Field Office personnel on their actions to improve the safety of transuranic waste operations. This updated DOE's response dated March 30, 2021, to DNFSB-TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*, with information regarding corrective actions from the titanium sparking event and other current initiatives for chemical compatibility evaluations for transuranic waste.

On Tuesday, members of the Board's staff conducted a closeout teleconference with NNSA Field Office and Triad personnel to discuss the results of the staff's review of the receipt and repackaging of large amounts of heat source plutonium at the Plutonium Facility (see 3/25/2022 report).

Plutonium Facility–Accident Investigation: On Tuesday, the Federal Accident Investigation Board briefed the NNSA Field Office on the results of its investigation into the contamination spread and potential uptake of radioactive material by a worker in January (see 1/21/2022 report). The final investigation report will be issued following a briefing to the NNSA Administrator.

Plutonium Facility–Conduct of Operations: A worker manipulated a valve and inadvertently drained the negative pressure chilled water system. This was in the same room where the wet vacuum system overflowed from a valving error last year and the performance errors were similar (see 7/23/2021 report). Facility management has directed that work activities in the pump room will be overseen by a senior supervisory watch as a corrective action. The chilled water system cannot be refilled and used until the justification for continued operations related to last year's overflow event is implemented, which is expected next week (see 3/11/2022 report).

Readiness: Triad and N3B are entering a period of increased readiness activities, including:

- A federal operational readiness review for the startup of PF-400, planned to commence in May. This is the upgrade of the Radiological Laboratory Utility Office Building to a hazard category 3 nuclear facility.
- A federal readiness review to support startup of plutonium coupon experiments in the Weapons Engineering Tritium Facility, planned for the summer.
- A federal readiness review to support restart of aqueous nitrate operations in the Plutonium Facility, planned for the fall.
- A contractor readiness assessment for corrugated metal pipe retrieval and federal readiness assessments for size reduction of the corrugated metal pipes and venting of the Flanged Tritium Waste Containers at Area G, all planned for the summer.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 29, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending April 29, 2022

Wildland Fire: Last Friday, during an epic high wind event, a fire of unknown origin started west of the laboratory in the Jemez Mountains. The fire, designated the Cerro Pelado Fire, has since grown to more than 7,000 acres and is approximately 10 miles from the laboratory. Much of the land between the active fire and the lab is filled with burn scars from the 2011 Las Conchas fire. Triad Emergency Management personnel are monitoring the situation and plan to activate the Emergency Operations Center if conditions deteriorate indicating a threat to laboratory property. Currently, the main impact to laboratory operations is degraded air quality.

Plutonium Facility–Infrastructure: On Thursday, Triad personnel successfully removed an unused glovebox from a laboratory room in the Plutonium Facility. The box had never been used, and all radiological swipes were clean. It was removed without incident. The box is currently staged in the basement awaiting clearance to be removed from the facility. Once removed, it will be repurposed for training personnel in deactivation and decommissioning activities.

Emergency Management: Last week, during a planned chemical cleanup activity at the Technical Area 48 Radiochemistry Facility, workers identified an unsealed bottle of uninhibited tetrahydrofuran, a peroxide-forming chemical. Workers did not observe any visible crystal formation; however, they tested the bottle with test strips and determined it contained peroxides. They segregated the bottle in the corner of fume hood behind a blast shield and informed the hazardous materials team. The team responded and performed a controlled destruction of the reagent bottle in a containment vessel without incident.

Federal Oversight: Recently, the NNSA Field Office leadership has made a concerted effort to increase oversight staffing to support pit production and other priority mission increases at the laboratory. They recently hired individuals to fill roles as facility representatives, nuclear safety specialists, and maintenance managers. They are working to get these new staff fully qualified for their roles. In the past two weeks, three individuals completed final oral boards: one facility representative for the Los Alamos Neutron Science Center, one facility representative for the Science and Technology Operations facilities, and one maintenance manager who will focus on nuclear facilities other than the Plutonium Facility.

The Environmental Management Field Office leadership is also working to increase staffing and recently hired a nuclear safety specialist. Their direct field oversight, which has four authorized positions for facility representatives, is currently staffed at one fully qualified facility representative and one facility representative in training. Two technical assist contractors provide support to the federal personnel.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 6, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 6, 2022

Plutonium Facility–Infrastructure: Last week, an NNSA team conducted a technical independent project review of the Los Alamos Plutonium Pit Production Project (LAP4). At the exit brief, the review team provided an overall conclusion that nuclear safety is being successfully integrated into the design, and qualified personnel are engaged in the project. They provided 9 recommendations, which are concerns that, in the team’s opinion, need to be addressed. Of particular note, the team recommended that LANL demonstrate that the confinement approach results in a “very high assurance” of the confinement of radioactive material and consistency with facility safety basis documents by December 2, 2022.

On Friday, Triad transmitted to the NNSA Field Office for approval an update to the safety design strategy for LAP4. This update reflects the elimination of the goal to achieve a safety class active confinement system for the facility (see 4/1/2022 report). The strategy discusses meeting confinement requirements through the safety significant ventilation system and the safety class passive confinement identified in the safety basis. The strategy asserts that the leak path factor calculations supporting the passive confinement approach have withstood “a tremendous number of technical evaluations...” Contrary to this assertion, the Board provided extensive critique of the leak path factor calculations in November 2019 via Tech Report 44, *Los Alamos National Laboratory Plutonium Facility Leak Path Factor Methodology*. In response, NNSA and Triad committed to develop a new calculation; however, Triad has experienced delays developing the new calculation and the schedule for completion is uncertain.

Transuranic Waste Management: On Wednesday, the NNSA Field Office noted its concurrence with Triad’s proposed impacts for implementing DOE Standard 5506-2021, *Preparation of Safety Basis Documents for Transuranic (TRU) Waste Facilities*, for the safety bases for the Transuranic Waste Facility and the RANT Shipping Facility. Triad concluded that some types of additional safety controls would have lesser programmatic impacts, but there would be costs associated with development and implementation of new controls. They noted completion of the analysis would allow for a better understanding of the programmatic impacts.

Wildland Fire: The Cerro Pelado Fire continues burning in land west of the laboratory and has impacted more than 32,000 acres. Much of the fire is currently active in the blackened region from the 2011 Las Conchas Fire. On Monday, the LANL Emergency Operations Center entered monitoring mode as the fire moved closer to the site boundary. Triad Emergency Management personnel and the NNSA Field Office have established criteria for moving the laboratory to a maximum telework status and for suspending onsite operations. The fire is currently approximately 5 miles from the site boundary. Fire crews have been performing tactical backburn operations to limit fire spread toward the laboratory. Additionally, Triad personnel have aggressively pursued fuel mitigation efforts near the Weapons Engineering Tritium Facility, which is the closest nuclear facility to the fire. N3B requested Triad perform additional mitigation on the south side of Technical Area 54 to increase defensible space around the storage of transuranic waste drums in the domes at Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 13, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 13, 2022

DNFSB Staff Activity: A. Boussouf commenced duties as the third resident inspector assigned to LANL

Wildland Fire: The Cerro Pelado wildfire remains active west of the laboratory and grew to more than 45,000 acres. Spread in the direction of the laboratory has been relatively slow over the past week. Last weekend, the fire crossed the decision point for the laboratory to move to a maximum telework posture, which became effective Monday morning. The Emergency Operations Center also moved from monitoring mode to a partial activation.

Radiological Laboratory Utility Office Building (RLUOB)/PF-400: A federal team completed an operational readiness review for the upgrade of RLUOB to a hazard category 3 nuclear facility. On Wednesday, they briefed NA-LA Field Office and Triad personnel on the initial findings. They presented eight findings for Triad and two for the Field Office. Notable findings for Triad include: the issues management system does not effectively resolve moderate and high significance issues, the fire protection program has not been effectively implemented to address some elements for a hazard category 3 facility, and the maintenance program does not currently meet the requirements for a hazard category 3 facility. The findings for the field office were that they do not have a baseline oversight plan for the facility and that they do not have sufficient qualified oversight staff to support the transition to hazard category 3 operations.

Plutonium Facility–Infrastructure: Last weekend, the NNSA Field Office conditionally approved a longstanding LANL contractor exemption request from 2015 regarding areas underneath gloveboxes that cannot receive coverage from the automatic fire suppression sprinklers mounted on the ceiling contrary to standards required by DOE Order 420.1C, *Facility Safety*. LANL proposed placing fencing around new or modified gloveboxes to eliminate the common practice of placing combustibles under the gloveboxes. We note that this fencing is highly effective, but Triad has no plans to expand installation to the large number of existing gloveboxes. To compensate, one of NNSA's conditions of approval included improving a number of elements of the transient combustible loading program, including developing a process to evaluate combustibles underneath gloveboxes.

On Tuesday, Triad personnel briefed NNSA headquarters on the Plutonium Facility Seismic Performance Reassessment Project (see 12/17/2021 report). NNSA accepted Triad's proposed alternative to fully document and peer review the interim risk results while placing the full seismic performance reassessment on hold until the updated probabilistic seismic hazards assessment is completed, which is currently anticipated in 2025. The interim risk results currently show performance for all limit states governed by horizontal motions are well below the target performance goals. Mean performance for limit states driven by vertical ground motion are below the target performance goals. However, in some conservative sensitivity studies, limit states driven by vertical ground motion approach and exceed the target performance goals.

Transuranic Waste Management: Last Friday, the NNSA Field Office directed Triad to develop a safety design strategy and address elements of DOE-STD-1189-2016, *Integration of Safety into the Design Process*, for its plan to develop a new safety basis supporting size reduction and limited waste container remediation activities at the Waste Characterization, Reduction, and Repackaging Facility operated as a hazard category 3 nuclear facility (see 4/15/2022 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 20, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 20, 2022

Wildland Fire: The Cerro Pelado wildfire west of the laboratory did not grow significantly last week and is now more than 70 % contained. On Tuesday, given the decreased threat to laboratory property, Triad downgraded staffing levels for the Emergency Operations Center and laboratory personnel returned from maximum telework status. Given the dry conditions of fuels in the area, wildland fire experts remain concerned about a new fire start and have placed additional fire restrictions on laboratory property and the surrounding area.

Weapons Engineering Tritium Facility: Last week during the monthly surveillance for the safety-significant Oxygen Monitoring System, facility personnel identified problems with monitors in two gloveboxes and determined they were inoperable. Further evaluation found a white deposit on these detectors, and an extent of condition on other detectors in the plant found no other white deposits. Facility personnel cleaned the white deposit and reperformed the surveillance, which restored the function of the detectors. The system has been restored to service, and the facility's investigation continues including communications with the detector manufacturer.

Plutonium Facility–Infrastructure: Last week on the backshift, workers decontaminating a glovebox slated for removal identified contamination on their personal protective equipment indicative of a glove breach. There were no issues with the workers' response to the event, and no evidence of skin contamination or any airborne radioactive material. The work crew was conducting a first use of a new decontamination solution, which is expected to be used in many other boxes. Deactivation and decommissioning activities continue to ramp up at the Plutonium Facility. Following this event, facility management is recommending evaluating changing glovebox gloves to 20 mil thickness prior to in-box decontamination activities to provide an optimal balance of durability and dexterity. The gloves involved in the event were 15 mil thickness and had been in contact with equipment inside the glovebox.

Plutonium Facility–Readiness: Earlier this month, facility management determined that no readiness activities, including a management self-assessment or subject matter expert checklist reviews, are necessary for the upcoming campaign to process large quantities of heat-source plutonium. The screening worksheet acknowledges the activity will involve larger quantities of radioactive material but notes that this change has been approved in the safety basis with procedural controls. Given the overall determination, Triad's joint readiness evaluation team will not be considering this activity. The NNSA Field Office is reviewing the matter.

Area G–Readiness: A contractor team commenced the readiness assessment for retrieval of Corrugated Metal Pipes (CMP) in Area G. Size reduction and packaging of the CMPs into standard waste boxes for disposal as transuranic waste is not part of the scope of this review and will be assessed at a later date. This week, the team performed interviews, observed an emergency preparedness drill, and watched a field demonstration for uncovering the CMPs with an excavator which included an operational drill. The review will continue next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 27, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending May 27, 2022

DNFSB Staff Activity: On Wednesday, the Board's staff held a call with DOE and N3B personnel to discuss the proposed atmospheric dispersion protocol that will support the new DOE Standard 3009-2014 compliant documented safety analysis under development for Area G.

Weapons Engineering Tritium Facility: Last Wednesday, there was a procedure execution error during a first time use validation using helium as a surrogate gas for tritium. A worker inadvertently opened a cap in the tritium gas handling system instead of opening a valve. The individual noticed the error immediately and tightened the cap, but helium was released into a glovebox. Tritium levels in the box increased but remained below alarm setpoints. This is the third procedure error at the facility since the beginning of the year (see 1/28/2022, 3/4/2022 reports). Facility management suspended gas transfers and is performing an extent of condition on the tritium gas handling system to look for other caps that could be inadvertently loosened. The tritium gas handling system will remain out of service until it is leak tested.

Radiological Laboratory Utility Office Building/PF-400: The resident inspectors walked down portions of the facility with Triad engineering personnel to further discuss the modeling assumptions used in the calculation justifying the equivalency to remove the HEPA filter deluge system (see 11/5/2021, 3/5/2022 reports).

Plutonium Facility–Emergency Management: Last Wednesday, there was an emergency medical response to the Plutonium Facility due to a head injury in the basement. Facility personnel later held a fact-finding meeting to discuss the incident and the response. One key item that emerged was that this was the first medical response to the facility following the disbanding of the Medical Response Team (MRT). The MRT was a volunteer group of personnel who maintained a level of first responder training to promptly respond to injuries in the protected area. They usually moved patients out of the facility to meet the fire department outside of some security or radiological boundaries to improve response time. Training and communications of this change is incomplete, which led to some communications errors during this response. Also, the Building Emergency Plan update reflecting this change is still in approval.

On Thursday, Triad personnel conducted a tabletop drill to train on emergency response actions associated with a criticality accident at the Plutonium Facility. In the scenario, four individuals were adjacent to the accident and needed emergency medical attention. One key item discussed at length during the tabletop was the medical response including integrating medical needs with security and radiological requirements, and the capabilities of the local hospital to deal with four potentially contaminated patients at once.

Area G–Readiness: A contractor team finished its readiness assessment for retrieval of the Corrugated Metal Pipes (CMP) and briefed DOE and N3B on their initial findings. The team had three pre-start findings and six post-start findings. Key findings included: procedure compliance is not at the expected level of performance; the five CMPs with higher dose rates were not addressed as part of reviews to minimize dose; and the event investigation meetings held to evaluate two events during demonstrations did not include all the actions described in the company policy for learning from events.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 3, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 3, 2022

Plutonium Facility–Accident Investigation: On Tuesday, the NNSA Cognizant Secretarial Officer for Safety signed out the report from the accident investigation associated with the January 7, 2022, radioactive material release and uptake event (see 4/22/2022 report). The report notes that subsequent bioassay monitoring of the exposed individuals revealed radiation doses that did not exceed the criteria for a formal Accident Investigation Board; however, NNSA personnel continued to review the event to obtain lessons learned and document them in an Incident Review Report. The report identified the overall direct cause as an incorrectly configured ventilation lineup that isolated the glovebox from ventilation and allowed radioactive material to leak from a degraded gasket on an unused sample port. The report provides 27 conclusions resulting in 9 judgements of need. Some of the weaknesses identified include: insufficient configuration management of gloveboxes; lack of protocols to ensure procedures reflect actual equipment configurations; overreliance on the skill of the worker; confusion on roles and responsibilities with respect to glovebox ownership; and inadequate control of hazards from glovebox appurtenances.

On the last point, the report notes that there is no systematic process in place to monitor appurtenances, many of which use gaskets that degrade and are often run to failure. These appurtenances constitute part of the physical confinement boundary provided by the glovebox safety system. Gloveboxes are required to maintain confinement even under loss of ventilation. In this event, the glovebox failed to perform its safety function. The resident inspectors note that since 2011, facility personnel have been monitoring and planning to address about 40 appurtenances with questionable seals, including 4 of the same design that failed in this event. Facility personnel are also monitoring flexible boots on another 8 gloveboxes, including one that recently developed a hole. In our opinion, the tendency to consider these safety significant confinement boundaries as operable despite components with questionable integrity creates a mindset that impedes timely permanent fixes.

Transuranic Waste Management: On Thursday, the NNSA Field Office noted its concurrence with Triad's impact assessment and proposed plan for updating the safety basis for the Plutonium Facility to include DOE Standard 5506-2021, *Preparation of Safety Basis Documents for Transuranic (TRU) Waste Facilities*. Triad plans to incorporate implementation of Standard 5506-2021 into the project execution plan for the larger effort to upgrade the Plutonium Facility safety basis to a DOE Standard 3009-2021 compliant product. The field office previously concurred on plans for the Transuranic Waste Facility and the RANT Shipping Facility (see 5/6/2022 report).

Area G: On Thursday, the EM Field Office unconditionally approved the evaluation of the safety of the situation (ESS) for the potential inadequacy of the safety analysis related to hydrogen accumulation in closed plastic transuranic waste containers with lids (see 3/18/2022 report). The ESS contains one compensatory measure, which prevents opening any of these types of containers with potential hydrogen accumulation. This will replace the immediate operational restriction that prohibited any transuranic waste container made of plastic or with a plastic lid from being included in a waste processing plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 10, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussof, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 10, 2022

Chemistry and Metallurgy Research Building: The resident inspectors joined members of the Los Alamos County Fire Department and Triad emergency management personnel for a familiarization tour of the facility. The tour covered building access, facility layout, fire alarm panels, and facility command for emergency response. Fire department personnel annually tour the high hazard facilities onsite to maintain awareness of facility conditions to support emergency response. The tour was cut short due to a fire alarm in an adjacent facility. A binder left on a furnace in the Materials Science Laboratory started smoking.

Fire Protection: Earlier this year, Triad completed a management assessment of spurious and inadvertent fire protection system alarms during the prior three-year period. During this period, the laboratory experienced approximately 100 false alarms per year that required a fire department response. Approximately 25 percent of these alarms were caused by maintenance or construction work near detection devices. The assessment identified seven opportunities for improvement with recommended actions and two noteworthy practices. Recommendations included: issuing formal event notifications and further evaluating spurious alarms, allocating funding for the replacement or additional maintenance of fire suppression systems, and adjusting work planning and control processes to reduce maintenance and construction impacts. One of the noteworthy practices is that Triad utilities personnel are in the process of installing water filling stations in lieu of hydrants for non-firewater uses such as dust suppression.

Area G–Operations: The resident inspectors observed Central Characterization Project personnel performing flammable gas measurement of transuranic waste drums in Area G using the new control set from the Justification for Continued Operations (see 8/13/2021 report). No issues were noted; the spatula-like tool that blocks the drum vent during sampling was in place for only the brief period of time needed to pull the gas sample (seconds to minutes). The new control limits the time the drum vent is blocked to ten hours or less.

Emergency Management: The NNSA Field Office completed an assessment of Triad's Emergency Management program focused on the Emergency Response Organization, termination and recovery, and readiness assurance. The assessment identified one finding related to maintaining training records for Incident Response Commanders. Triad had previously identified this issue in an assessment of their training program, and corrective actions have been developed and are being worked.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 17, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 17, 2022

Transuranic Waste Management: A. Boussouf remotely supported a DNFSB staff review of the process Waste Isolation Pilot Plant personnel use to certify transuranic waste for disposal using the Waste Acceptance Criteria. The team reviewed the certification process and walked through examples of the waste stream container review and approval specific to Los Alamos as well as other DOE waste generator sites.

Plutonium Facility–Accident Investigation: The NNSA Field Office formally transmitted the Incident Review Report for the January contamination event at the Plutonium Facility to Triad (see 6/3/2022 report). The field office requested Triad provide a corrective action plan for review and approval within 30 days that addresses all of the judgements of need from the report.

Federal Oversight–Conduct of Operations: The NNSA team that reviewed conduct of operations at the Plutonium Facility provided an outbrief to Triad personnel and field office management describing the conclusions of their assessment (see 2/25/2022 report). The field office requested the assessment earlier this year in response to concerns about conduct of operations following events last year such as the vault water bath and wet vacuum overflow events (see 4/2/2021, 7/23/2021 reports). The assessment team concluded that operations at the Plutonium Facility are substantially compliant with the requirements in DOE Order 422.1 *Conduct of Operations*, but that a high level of formality of operations is needed to support 24/7 operations for the pit production mission. They noted several issues including: weaknesses in control of equipment and system status, use of uncontrolled operator aids, and a need for improvement in training for maintenance and construction workers. The team also provided positive observations including: the recent investments in training for the expanding workforce, increased hiring and deployment of conduct of operations mentors, and implementation of oral board qualifications for working persons in charge. The team’s recommendations included: continued improvement of training especially for maintenance and construction personnel, better use of the conduct of operations mentors, and improvement to activity level work planning and control.

Area G–Safety Basis: N3B continues its efforts to develop a modern DOE-STD-3009-2014 compliant safety basis for Area G. This week, they briefed the EM Field Office manager on their progress developing an atmospheric dispersion protocol, a key input to the safety basis. Initial results are showing an increase in consequences to the public due to the methods used in the new protocol; however, N3B continues to evaluate the appropriate level of conservatism to include in this and other safety basis calculations. They plan to formally submit the completed protocol to the EM Field Office later this year for review and approval.

Wildland Fire: The Cerro Pelado wildfire west of the laboratory is now 100% contained. The Los Alamos Emergency Operations Center exited monitoring mode. Stage III fire restrictions remain in effect for the laboratory and surrounding areas.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 24, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 24, 2022

DNFSB Staff Activity: After nine years at LANL and four years at Lawrence Livermore National Laboratory, J. Plaue completed his service in the field and will be returning to DNFSB Headquarters (see 11/8/2013 report).

Flanged Tritium Waste Containers (FTWC): On Thursday, the resident inspectors observed Triad personnel resume practice for FTWC venting operations for the first time since last year. The rehearsal at TA-49 included a mock-up and walkthrough of steps for venting the FTWCs stored at Area G, and use of the remote vehicle for moving the FTWCs from the Area G storage sheds to a transport vehicle for shipment to the Weapons Engineering Tritium Facility. The rehearsal identified areas to improve the venting and loading activity.

Area G–Safety Basis: On Tuesday, the Environmental Management Field Office approved a revised safety basis for Area G. The approval included one directed change to adjust the wording of the specific administrative control for depressurization of FTWC headspace gas to ensure consistency with the Technical Safety Requirement definition. The Field Office confirmed that this version of the safety basis resolves one of the three conditions of approval from the Field Office’s conditional approval of the previous revision (see 12/10/2021 report). It incorporates revised calculations for FTWC pressurization and will allow venting to proceed. The two conditions of approval related to aircraft crash analysis remain open.

Plutonium Facility–Radiological Control: Last Wednesday, a contamination monitor detected a small particle of contamination on the arm of a Plutonium Facility worker. The particle was not detected on exit surveys from the glovebox and the lab room, but was caught at the hand and foot monitors at the facility exit. Facility personnel later held a fact-finding meeting to discuss the incident and the response. They noted that particles are especially challenging to detect and plan to reinforce the importance of having multiple layers of monitoring prior to exiting the facility.

Wildland Fire: On Thursday, Triad lowered fire restrictions on laboratory property from Stage III to Stage II. The surrounding region including Los Alamos County, Forest Service, and National Park Service also lowered fire restrictions on their land. Recent monsoonal rain events have increased moisture levels and lowered the wildland fire risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 1, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 1, 2022

Area G: Last Friday, the Environmental Management Field Office provided authorization for N3B to restart drill and drain operations at the Dome 231 Permacon in Area G. They did not authorize resumption of glovebag activities in the same location. The field office requested N3B submit revised procedures for the glovebag work and is withholding approval until they evaluate the submitted documents. N3B commenced deliberate hot operations for drill and drain this week; these operations have proceeded without incident.

On Monday, a worker in a tool crib turned on a heater which started sparking and smoking. The worker called 911 and notified personnel working in other parts of the building to evacuate. The fire department responded promptly. There was no fire and there is no material at risk in this building. The resident inspectors observed that a fire alarm pull station in the area was not readily accessible as it was behind a padlocked gate that had been added in the building. N3B engineering is evaluating corrective measures to fix this code compliance issue.

Chemistry and Metallurgy Research Building (CMR): Last Wednesday, two workers in CMR alarmed radiological monitors due to contamination on their personal protective equipment. There was no skin contamination or evidence of an uptake. Further evaluation found that there was a contamination spread originating from a laboratory room in Wing 7. The likely source of the contamination was a fume hood with internal contamination levels well above the threshold for routine decontamination. Radiological control technicians found contamination on the floor immediately outside of this hood which then was further spread to other laboratory rooms and the corridor through routine custodial activities. Air monitoring equipment in this room showed elevated readings which did not reach alarm levels but did exceed thresholds for evaluation by radiological control personnel. Facility personnel noted that this lab room and the fume hood were not subject to routine radiological surveys and plan to correct that and do a wider evaluation of routine survey locations. The last measurement of the face velocity for the hood was satisfactory, but on the low end so another corrective action is to retest the flow and increase it if possible. Custodial practices in radiological areas have evolved over time so those will also be reevaluated. Decontamination efforts are in progress.

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office conditionally approved the annual update to the Plutonium Facility’s safety basis. In April, the Field Office requested a resubmittal of the annual update to address review comments. In this week’s approval, the field office noted that all of their comments were adequately resolved other than one related to fire suppression system performance criteria. The condition of approval is to update the fire system performance criteria with respect to ongoing fire pump upgrade activities no later than the next annual update.

Weapons Engineering Tritium Facility (WETF): During a management self-assessment to prepare for startup of plutonium coupon studies at WETF, assessors identified that some accidents involving the test cell assembly when connected to the tritium gas handling system were only analyzing plutonium and not tritium. Safety basis personnel determined this constituted a positive unreviewed safety question and are recalculating consequences using both tritium and plutonium to see if there will be any impact on control selection.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 8, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 8, 2022

Transuranic Waste Management: In response to the titanium powder flash event of 2020 and DNFSB-TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*, Triad developed a new procedure for developing and using chemical compatibility evaluations (CCE) for processes that generate transuranic waste. Using this procedure, Triad's acceptable knowledge specialists have started systematically reevaluating the approximately 50 processes that have the potential to generate transuranic waste at the Chemistry and Metallurgy Research Building (CMR) and the Plutonium Facility. A key new feature of the process is integration with the safety basis organization to inform them of any changes to CCEs. So far, Triad has evaluated four waste generating processes and entered the new information process to evaluate safety basis impacts of these processes for CMR, the Transuranic Waste Facility, and the Plutonium Facility. On Tuesday, Triad briefed the NNSA Field Office on its progress implementing this approach.

Legacy Facilities: Last Thursday, the Environmental Management Field Office unconditionally approved N3B's revised Justification for Continued Operations (JCO) that allows characterization work for Building 21-257 and the industrial waste lines in TA-21 (see 7/2/2021 report). The previous JCO had reached its termination date, and EM approved this revision to extend the JCO to the end of September. This will provide additional time to support closure of the potential inadequacy of the safety analysis pertaining to the potential for exceedance of hazard category 3 material quantities (see 8/14/2020 report).

Plutonium Facility–Readiness: The NNSA Field Office approved Triad's quarterly startup notification report. In their approval they noted that the planned campaign to harvest large quantities of heat source plutonium material was screened out of the readiness process (see 5/20/2022 report). Triad considers the activity sufficiently similar to current activities. However, the field office determined this should be considered a new activity and directed that Triad include the activity in the next startup notification report with the requirement to conduct a limited scope checklist federal readiness assessment concurrent with a contractor readiness assessment.

Plutonium Facility–Infrastructure: Last Thursday, Triad submitted to the NNSA Field Office for approval a revised draft Preliminary Documented Safety Analysis (PDSA) for facility modifications associated with a subproject for the Los Alamos Plutonium Pit Production Project (LAP4). This revision is intended to address the majority of the field office's comments on the previous submittal. Triad proposed to resolve the remaining items, including completion of fire hazards evaluations for new gloveboxes, in the final PDSA.

Plutonium Facility–Radiological Control: Last Wednesday, a contamination monitor detected a small particle of contamination on the hand of a Plutonium Facility worker. The particle was not detected on exit surveys from the immediate work location and upon exiting the basement, but was caught at the hand and foot monitors at the facility exit similar to another recent contamination event (see 6/24/2022 report). Facility personnel later held a fact-finding meeting to discuss the incident and the response. They noted that a re-evaluation of personal protective equipment and monitoring practices would be performed. This incident again reinforces the importance of having multiple layers of monitoring prior to exiting the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 15, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 15, 2022

DNFSB Activity: DNFSB Vice Chair T. Summers was onsite this week accompanied by staff members A. Hutain, and M. Sautman. The Vice Chair visited the Plutonium Facility, Area G, Technical Area 21, the Chemistry and Metallurgy Research Building, The Dual Axis Radiographic Hydrodynamic Test Facility, the Waste Characterization Reduction and Repackaging Facility, the RANT Shipping Facility, the Weapons Engineering Tritium Facility, and the Emergency Operations Center. He also observed the annual emergency exercise and met with senior management from Triad, N3B, and both field offices. On Wednesday evening, he spoke offsite with local stakeholder groups to discuss their concerns with site operations.

Emergency Management: On Wednesday, Triad conducted the annual full-participation evaluated emergency management exercise. The scenario was a criticality accident in the Plutonium Facility with two workers near the event needing transport to the hospital and two workers in an adjacent room with lesser medical needs. Triad and NNSA personnel are evaluating the exercise performance.

Plutonium Facility–Infrastructure: Triad personnel upgraded the site public address system (SPAS) at the Plutonium Facility due to approaching obsolescence. The SPAS provides credited emergency paging capability and sounds emergency evacuation and fire alarms. It has a safety-significant function supporting the audible alarm for the criticality alarm system. During the final portions of the upgrade, the Plutonium Facility was in standby mode which restricts operations with material at risk. Switchover to the new system was completed this week, and the facility returned to normal operations mode.

Plutonium Facility–Accident Investigation: On Friday, Triad transmitted to the NNSA Field Office for approval their corrective action plan from the Incident Review of the January contamination event at the Plutonium Facility (see 6/3/2022 report). The plan states that responsible personnel and due dates for the corrective actions will be defined by August 2022. Key actions include re-evaluating the 2011 extent of condition on glovebox penetrations, revising command media and training to ensure better understanding of who is the owner of a glovebox, and improved training on the different types of ventilation used for gloveboxes.

Radioactive Laboratory Utility Office Building (RLUOB)/PF-400: Triad personnel transmitted to the NNSA Field Office for approval the corrective action plan and causal analysis from the federal operational readiness review supporting the transition of RLUOB to a hazard category 3 nuclear facility to be known as PF-400.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 22, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 22, 2022

Plutonium Facility–Safety Basis: On Wednesday, Triad transmitted to the NNSA Field Office, for information, an updated project execution plan for upgrading the Plutonium Facility’s safety basis to meet DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis* (see 7/19/2019 report). The updated plan includes using transuranic waste hazard evaluation methods per DOE-STD-5506-2021, *Preparation of Safety Basis Documents for Transuranic (TRU) Waste Facilities* and adding the updated waste stream chemical compatibility evaluation process (see 7/8/2022 report). The contractor’s new safety basis submission date is May 25, 2023. The NNSA Field Office is evaluating the plan and how to manage future changes.

Plutonium Facility–Material at Risk: Facility personnel recently started a long-term effort to reduce excess material at risk in heat source plutonium laboratory areas. There are numerous containers with assorted materials stored in gloveboxes and the surrounding workspace. Personnel are starting by evaluating which materials need to be archived in the vault and which can be recycled as feed. There are many safety benefits to this activity, including improved ergonomics, reduced worker dose, and reduced material at risk.

Chemistry and Metallurgy Research Building (CMR): Last week, the decontamination and decommissioning subcontractor resumed higher hazard work in Wing 3 using improved practices for airborne and surface contamination control developed following the contamination event during a glovebox removal earlier this year (see 2/25/2022 report). Last Thursday, workers were decontaminating an area where a vacuum pump had been moved and were also disconnecting gloveboxes and hoods in the same room. The workers performing the decontamination had contamination detected on their personal protective equipment. While doffing and exiting the room, the continuous air monitor (CAM) alarmed. The workers were in respiratory protection and exited safely with no skin contamination or evidence of an uptake. The contamination did not spread into the hallway and remained in the laboratory room. In response to this event, facility and subcontractor personnel plan to retrain individuals on CAM alarm response, evaluate doffing practices including the potential use of fixative, and evaluate installing remote monitoring of CAMs as they currently only have local readouts in the laboratory rooms.

Area G–Safety Basis: Last Monday, N3B transmitted a letter to the Environmental Management Field Office for Approval requesting to extend the expiration date of four Justifications for Continued Operations (JCO) set to expire on 9/2/2022 (see 10/15/2021 report). These are the JCOs associated with 1) material at risk in pipe overpack containers, sealed sources, and Building 412; 2) mobile crane and forklift operations; 3) potentially energetic waste drums as discussed in DNFSB-TECH-46; and 4) multiple fire and seismic scenarios. As the new documented safety analysis is not expected to be completed until January next year, N3B requested an extension of the JCOs until February next year. In addition to the expiration extension, the request includes a change to the first JCO to allow for movement and removal of legacy sealed sources and a change to the third JCO to update the list of drums of potential concern. Environmental Management personnel are evaluating the request and the appropriate extension timeframe to match the expected approval of the updated safety basis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 29, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 29, 2022

Plutonium Facility–Infrastructure: The resident inspector joined facility management and the NNSA facility representatives on a walkdown of the Plutonium Facility. One purpose was to see the progress on installing new trolley controllers. The previous controllers had obsolete parts that were becoming difficult to procure even through non-traditional sources. The modern system will also provide additional capabilities for more efficient trolley operations.

The Plutonium Facility's credited diesel firewater pumps are being upgraded, partly due to issues procuring obsolete parts. One pumphouse has been upgraded and is slated to come online next month. The other will be replaced this year. This upgrade will provide improved pump performance and access to spare parts which will reduce system downtime. In addition, this modern pump design will be more familiar to a changing maintenance workforce that may lack experience with fifty-year-old pump designs.

Plutonium Facility–Conduct of Operations: During the above walkdown, the resident inspector noted that housekeeping in the basement, especially transient combustible loading, was greatly improved from previous observations (see 6/18/2021 report). Facility personnel have procured new metal boxes for staging combustible waste bags. They are also installing a tool crib to reduce the number of toolboxes cluttering the basement.

Last Friday, the NNSA field office formally transmitted to Triad the final assessment report from the NNSA Team that reviewed conduct of operations at the Plutonium Facility. The assessment team looked strategically at conduct of operations implementation. Though all objectives and criteria were considered met, the report identified several weaknesses (see 6/17/2022 report). The field office has requested a corrective action plan addressing these issues within 30 days.

Flanged Tritium Waste Containers (FTWC)–Readiness: The federal readiness assessment for venting FTWCs stored at Area G occurred in November 2020 (see 11/13/2020 report). Given timing uncertainties for closing out issues from the readiness reviews and the constraints on performing the actual activity, the readiness team recommended that an additional field proficiency demonstration be performed for them prior to startup if there was a substantial delay. On Thursday, the EM field office manager transmitted a memorandum to the startup authorization authority at EM headquarters documenting an approach consistent with this recommendation from two years ago. The proposed approach states that NNSA and EM field office personnel do not believe that reperforming a full readiness assessment is needed given the current state of the personnel, procedures, and equipment. Instead, they will perform an additional formal proficiency demonstration. The letter also notes that continued delays in venting the FTWCs at Area G will increase the risk to the workers performing venting as pressures may increase. Meanwhile, Triad personnel performed additional rehearsals with mockup FTWCs at TA-49 this week in preparation for the upcoming proficiency demonstration and actual operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 24, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, D. Gutowski, and J. Plaue, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending June 24, 2022

DNFSB Staff Activity: After nine years at LANL and four years at Lawrence Livermore National Laboratory, J. Plaue completed his service in the field and will be returning to DNFSB Headquarters (see 11/8/2013 report).

Flanged Tritium Waste Containers (FTWC): On Thursday, the resident inspectors observed Triad personnel resume practice for FTWC venting operations for the first time since last year. The rehearsal at TA-49 included a mock-up and walkthrough of steps for venting the FTWCs stored at Area G, and use of the remote vehicle for moving the FTWCs from the Area G storage sheds to a transport vehicle for shipment to the Weapons Engineering Tritium Facility. The rehearsal identified areas to improve the venting and loading activity.

Area G–Safety Basis: On Tuesday, the Environmental Management Field Office approved a revised safety basis for Area G. The approval included one directed change to adjust the wording of the specific administrative control for depressurization of FTWC headspace gas to ensure consistency with the Technical Safety Requirement definition. The Field Office confirmed that this version of the safety basis resolves one of the three conditions of approval from the Field Office’s conditional approval of the previous revision (see 12/10/2021 report). It incorporates revised calculations for FTWC pressurization and will allow venting to proceed. The two conditions of approval related to aircraft crash analysis remain open.

Plutonium Facility–Radiological Control: Last Wednesday, a contamination monitor detected a small particle of contamination on the arm of a Plutonium Facility worker. The particle was not detected on exit surveys from the glovebox and the lab room, but was caught at the hand and foot monitors at the facility exit. Facility personnel later held a fact-finding meeting to discuss the incident and the response. They noted that particles are especially challenging to detect and plan to reinforce the importance of having multiple layers of monitoring prior to exiting the facility.

Wildland Fire: On Thursday, Triad lowered fire restrictions on laboratory property from Stage III to Stage II. The surrounding region including Los Alamos County, Forest Service, and National Park Service also lowered fire restrictions on their land. Recent monsoonal rain events have increased moisture levels and lowered the wildland fire risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 1, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 1, 2022

Area G: Last Friday, the Environmental Management Field Office provided authorization for N3B to restart drill and drain operations at the Dome 231 Permacon in Area G. They did not authorize resumption of glovebag activities in the same location. The field office requested N3B submit revised procedures for the glovebag work and is withholding approval until they evaluate the submitted documents. N3B commenced deliberate hot operations for drill and drain this week; these operations have proceeded without incident.

On Monday, a worker in a tool crib turned on a heater which started sparking and smoking. The worker called 911 and notified personnel working in other parts of the building to evacuate. The fire department responded promptly. There was no fire and there is no material at risk in this building. The resident inspectors observed that a fire alarm pull station in the area was not readily accessible as it was behind a padlocked gate that had been added in the building. N3B engineering is evaluating corrective measures to fix this code compliance issue.

Chemistry and Metallurgy Research Building (CMR): Last Wednesday, two workers in CMR alarmed radiological monitors due to contamination on their personal protective equipment. There was no skin contamination or evidence of an uptake. Further evaluation found that there was a contamination spread originating from a laboratory room in Wing 7. The likely source of the contamination was a fume hood with internal contamination levels well above the threshold for routine decontamination. Radiological control technicians found contamination on the floor immediately outside of this hood which then was further spread to other laboratory rooms and the corridor through routine custodial activities. Air monitoring equipment in this room showed elevated readings which did not reach alarm levels but did exceed thresholds for evaluation by radiological control personnel. Facility personnel noted that this lab room and the fume hood were not subject to routine radiological surveys and plan to correct that and do a wider evaluation of routine survey locations. The last measurement of the face velocity for the hood was satisfactory, but on the low end so another corrective action is to retest the flow and increase it if possible. Custodial practices in radiological areas have evolved over time so those will also be reevaluated. Decontamination efforts are in progress.

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office conditionally approved the annual update to the Plutonium Facility’s safety basis. In April, the Field Office requested a resubmittal of the annual update to address review comments. In this week’s approval, the field office noted that all of their comments were adequately resolved other than one related to fire suppression system performance criteria. The condition of approval is to update the fire system performance criteria with respect to ongoing fire pump upgrade activities no later than the next annual update.

Weapons Engineering Tritium Facility (WETF): During a management self-assessment to prepare for startup of plutonium coupon studies at WETF, assessors identified that some accidents involving the test cell assembly when connected to the tritium gas handling system were only analyzing plutonium and not tritium. Safety basis personnel determined this constituted a positive unreviewed safety question and are recalculating consequences using both tritium and plutonium to see if there will be any impact on control selection.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 8, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 8, 2022

Transuranic Waste Management: In response to the titanium powder flash event of 2020 and DNFSB-TECH-46, *Potential Energetic Chemical Reaction Events Involving Transuranic Waste at Los Alamos National Laboratory*, Triad developed a new procedure for developing and using chemical compatibility evaluations (CCE) for processes that generate transuranic waste. Using this procedure, Triad's acceptable knowledge specialists have started systematically reevaluating the approximately 50 processes that have the potential to generate transuranic waste at the Chemistry and Metallurgy Research Building (CMR) and the Plutonium Facility. A key new feature of the process is integration with the safety basis organization to inform them of any changes to CCEs. So far, Triad has evaluated four waste generating processes and entered the new information process to evaluate safety basis impacts of these processes for CMR, the Transuranic Waste Facility, and the Plutonium Facility. On Tuesday, Triad briefed the NNSA Field Office on its progress implementing this approach.

Legacy Facilities: Last Thursday, the Environmental Management Field Office unconditionally approved N3B's revised Justification for Continued Operations (JCO) that allows characterization work for Building 21-257 and the industrial waste lines in TA-21 (see 7/2/2021 report). The previous JCO had reached its termination date, and EM approved this revision to extend the JCO to the end of September. This will provide additional time to support closure of the potential inadequacy of the safety analysis pertaining to the potential for exceedance of hazard category 3 material quantities (see 8/14/2020 report).

Plutonium Facility–Readiness: The NNSA Field Office approved Triad's quarterly startup notification report. In their approval they noted that the planned campaign to harvest large quantities of heat source plutonium material was screened out of the readiness process (see 5/20/2022 report). Triad considers the activity sufficiently similar to current activities. However, the field office determined this should be considered a new activity and directed that Triad include the activity in the next startup notification report with the requirement to conduct a limited scope checklist federal readiness assessment concurrent with a contractor readiness assessment.

Plutonium Facility–Infrastructure: Last Thursday, Triad submitted to the NNSA Field Office for approval a revised draft Preliminary Documented Safety Analysis (PDSA) for facility modifications associated with a subproject for the Los Alamos Plutonium Pit Production Project (LAP4). This revision is intended to address the majority of the field office's comments on the previous submittal. Triad proposed to resolve the remaining items, including completion of fire hazards evaluations for new gloveboxes, in the final PDSA.

Plutonium Facility–Radiological Control: Last Wednesday, a contamination monitor detected a small particle of contamination on the hand of a Plutonium Facility worker. The particle was not detected on exit surveys from the immediate work location and upon exiting the basement, but was caught at the hand and foot monitors at the facility exit similar to another recent contamination event (see 6/24/2022 report). Facility personnel later held a fact-finding meeting to discuss the incident and the response. They noted that a re-evaluation of personal protective equipment and monitoring practices would be performed. This incident again reinforces the importance of having multiple layers of monitoring prior to exiting the facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 15, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 15, 2022

DNFSB Activity: DNFSB Vice Chair T. Summers was onsite this week accompanied by staff members A. Hutain, and M. Sautman. The Vice Chair visited the Plutonium Facility, Area G, Technical Area 21, the Chemistry and Metallurgy Research Building, The Dual Axis Radiographic Hydrodynamic Test Facility, the Waste Characterization Reduction and Repackaging Facility, the RANT Shipping Facility, the Weapons Engineering Tritium Facility, and the Emergency Operations Center. He also observed the annual emergency exercise and met with senior management from Triad, N3B, and both field offices. On Wednesday evening, he spoke offsite with local stakeholder groups to discuss their concerns with site operations.

Emergency Management: On Wednesday, Triad conducted the annual full-participation evaluated emergency management exercise. The scenario was a criticality accident in the Plutonium Facility with two workers near the event needing transport to the hospital and two workers in an adjacent room with lesser medical needs. Triad and NNSA personnel are evaluating the exercise performance.

Plutonium Facility–Infrastructure: Triad personnel upgraded the site public address system (SPAS) at the Plutonium Facility due to approaching obsolescence. The SPAS provides credited emergency paging capability and sounds emergency evacuation and fire alarms. It has a safety-significant function supporting the audible alarm for the criticality alarm system. During the final portions of the upgrade, the Plutonium Facility was in standby mode which restricts operations with material at risk. Switchover to the new system was completed this week, and the facility returned to normal operations mode.

Plutonium Facility–Accident Investigation: On Friday, Triad transmitted to the NNSA Field Office for approval their corrective action plan from the Incident Review of the January contamination event at the Plutonium Facility (see 6/3/2022 report). The plan states that responsible personnel and due dates for the corrective actions will be defined by August 2022. Key actions include re-evaluating the 2011 extent of condition on glovebox penetrations, revising command media and training to ensure better understanding of who is the owner of a glovebox, and improved training on the different types of ventilation used for gloveboxes.

Radioactive Laboratory Utility Office Building (RLUOB)/PF-400: Triad personnel transmitted to the NNSA Field Office for approval the corrective action plan and causal analysis from the federal operational readiness review supporting the transition of RLUOB to a hazard category 3 nuclear facility to be known as PF-400.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 22, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 22, 2022

Plutonium Facility–Safety Basis: On Wednesday, Triad transmitted to the NNSA Field Office, for information, an updated project execution plan for upgrading the Plutonium Facility’s safety basis to meet DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis* (see 7/19/2019 report). The updated plan includes using transuranic waste hazard evaluation methods per DOE-STD-5506-2021, *Preparation of Safety Basis Documents for Transuranic (TRU) Waste Facilities* and adding the updated waste stream chemical compatibility evaluation process (see 7/8/2022 report). The contractor’s new safety basis submission date is May 25, 2023. The NNSA Field Office is evaluating the plan and how to manage future changes.

Plutonium Facility–Material at Risk: Facility personnel recently started a long-term effort to reduce excess material at risk in heat source plutonium laboratory areas. There are numerous containers with assorted materials stored in gloveboxes and the surrounding workspace. Personnel are starting by evaluating which materials need to be archived in the vault and which can be recycled as feed. There are many safety benefits to this activity, including improved ergonomics, reduced worker dose, and reduced material at risk.

Chemistry and Metallurgy Research Building (CMR): Last week, the decontamination and decommissioning subcontractor resumed higher hazard work in Wing 3 using improved practices for airborne and surface contamination control developed following the contamination event during a glovebox removal earlier this year (see 2/25/2022 report). Last Thursday, workers were decontaminating an area where a vacuum pump had been moved and were also disconnecting gloveboxes and hoods in the same room. The workers performing the decontamination had contamination detected on their personal protective equipment. While doffing and exiting the room, the continuous air monitor (CAM) alarmed. The workers were in respiratory protection and exited safely with no skin contamination or evidence of an uptake. The contamination did not spread into the hallway and remained in the laboratory room. In response to this event, facility and subcontractor personnel plan to retrain individuals on CAM alarm response, evaluate doffing practices including the potential use of fixative, and evaluate installing remote monitoring of CAMs as they currently only have local readouts in the laboratory rooms.

Area G–Safety Basis: Last Monday, N3B transmitted a letter to the Environmental Management Field Office for Approval requesting to extend the expiration date of four Justifications for Continued Operations (JCO) set to expire on 9/2/2022 (see 10/15/2021 report). These are the JCOs associated with 1) material at risk in pipe overpack containers, sealed sources, and Building 412; 2) mobile crane and forklift operations; 3) potentially energetic waste drums as discussed in DNFSB-TECH-46; and 4) multiple fire and seismic scenarios. As the new documented safety analysis is not expected to be completed until January next year, N3B requested an extension of the JCOs until February next year. In addition to the expiration extension, the request includes a change to the first JCO to allow for movement and removal of legacy sealed sources and a change to the third JCO to update the list of drums of potential concern. Environmental Management personnel are evaluating the request and the appropriate extension timeframe to match the expected approval of the updated safety basis.

July 29, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending July 29, 2022

Plutonium Facility–Infrastructure: The resident inspector joined facility management and the NNSA facility representatives on a walkdown of the Plutonium Facility. One purpose was to see the progress on installing new trolley controllers. The previous controllers had obsolete parts that were becoming difficult to procure even through non-traditional sources. The modern system will also provide additional capabilities for more efficient trolley operations.

The Plutonium Facility’s credited diesel firewater pumps are being upgraded, partly due to issues procuring obsolete parts. One pumphouse has been upgraded and is slated to come online next month. The other will be replaced this year. This upgrade will provide improved pump performance and access to spare parts which will reduce system downtime. In addition, this modern pump design will be more familiar to a changing maintenance workforce that may lack experience with fifty-year-old pump designs.

Plutonium Facility–Conduct of Operations: During the above walkdown, the resident inspector noted that housekeeping in the basement, especially transient combustible loading, was greatly improved from previous observations (see 6/18/2021 report). Facility personnel have procured new metal boxes for staging combustible waste bags. They are also installing a tool crib to reduce the number of toolboxes cluttering the basement.

Last Friday, the NNSA field office formally transmitted to Triad the final assessment report from the NNSA Team that reviewed conduct of operations at the Plutonium Facility. The assessment team looked strategically at conduct of operations implementation. Though all objectives and criteria were considered met, the report identified several weaknesses (see 6/17/2022 report). The field office has requested a corrective action plan addressing these issues within 30 days.

Flanged Tritium Waste Containers (FTWC)–Readiness: The federal readiness assessment for venting FTWCs stored at Area G occurred in November 2020 (see 11/13/2020 report). Given timing uncertainties for closing out issues from the readiness reviews and the constraints on performing the actual activity, the readiness team recommended that an additional field proficiency demonstration be performed for them prior to startup if there was a substantial delay. On Thursday, the EM field office manager transmitted a memorandum to the startup authorization authority at EM headquarters documenting an approach consistent with this recommendation from two years ago. The proposed approach states that NNSA and EM field office personnel do not believe that reperforming a full readiness assessment is needed given the current state of the personnel, procedures, and equipment. Instead, they will perform an additional formal proficiency demonstration. The letter also notes that continued delays in venting the FTWCs at Area G will increase the risk to the workers performing venting as pressures may increase. Meanwhile, Triad personnel performed additional rehearsals with mockup FTWCs at TA-49 this week in preparation for the upcoming proficiency demonstration and actual operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 5, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 5, 2022

Plutonium Facility–Transuranic Waste Management: On Thursday, facility personnel held a fact-finding meeting to evaluate an event where potential transuranic waste from a demolition activity was inadvertently staged in a low-level waste bag. Following the discovery of this discrepancy, the area was roped off to restrict access. Fact-finding participants noted that the proper waste disposal process was not adequately relayed to maintenance workers. Facility personnel also acknowledged that their current work planning processes have weaknesses in identifying material at risk during demolition activities and integrating waste planning. They plan to improve their work planning processes to address these weaknesses.

Plutonium Facility–Infrastructure: Facility personnel continue their efforts to replace the chlorine gas system in the Plutonium Facility (see 1/17/2020 report). The old system has been removed, but the new one is not operational yet. The original mass flow controllers for the new system had too large a flow range for accurate control so new ones had to be purchased and installed. There were also issues with material compatibility for sealants in the system. Programmatic personnel are preparing to go through readiness with the new system and are performing procedure walkthroughs using the new human machine interface, however until the new system is pressure tested, they cannot do a high-fidelity cold run using inert gas.

Electrical Power Interruptions: The site experienced two power interruption events last week that impacted nuclear facilities. During the first one, the Plutonium Facility experienced a brief power dip likely due to lightning. The backup diesel generators activated promptly so all safety systems remained functional. The second event over the weekend was far more widespread as a lightning strike caused a transformer to trip at the TA-5 substation. All loads from that transformer were lost as a tie circuit breaker failed to close automatically. Workers restored power after several hours by manually closing that breaker to shift the loads to another transformer. Impacted nuclear facilities that lost power included Area G, the RANT Shipping Facility, and the Transuranic Waste Facility (TWF). The Plutonium Facility did not lose power, however ancillary facilities at TA-55 did. As there were a tremendous number of alarms coming in with the widespread power losses, some notifications to on call duty officers for facilities that were unmanned at the time such as TWF and RANT were delayed for several hours. The diesel generators at TWF activated properly but did not automatically deactivate once power was restored. Facility personnel are troubleshooting the system.

Area G: This week, N3B and Central Characterization Project personnel performed transuranic waste mobile loading operations for the first time since October 2020 (see 8/27/2021 report). Fourteen drums and eight standard waste boxes were successfully loaded for shipment to the Waste Isolation Pilot Plant. Some of these containers did not meet the requirements for indoor shipping through RANT and required mobile loading. The activity was completed within the one-year timeframe for maintaining readiness.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 12, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 12, 2022

DNFSB Staff Activity: F. Harshman, one of the Board's resident inspectors at Y-12, was onsite this week to benchmark oversight approaches for nuclear facilities. Among other activities, the guest resident inspector visited the Plutonium Facility, Sigma, and the Chemistry and Metallurgy Research Building.

Plutonium Facility–Glovebox Safety: This week, facility personnel held three fact-finding meetings to evaluate three events where workers discovered glove breaches. The first event involved a Plutonium Facility worker performing a non-approved glovebox leak evaluation method. The method involved adding a second glove around the suspect glove. Though this method confirmed the presence of two separate glove leaks, one glove fixed to another is not an approved configuration and combustible loading limits within the boxes were exceeded. Facility personnel are evaluating standardizing the leak detection method used and formalizing a procedure to implement a similar detection approach to the unauthorized one used.

For the second and third events, glovebox workers detected contamination on their personal protective equipment during monitoring immediately after exiting their gloves. In all three instances, there was no detectable skin contamination or contamination spread, the impacted gloves were replaced, and the rooms were returned to normal operations.

Plutonium Facility–Safety Basis: Last Friday, the NNSA field office formally concurred with Triad's latest revision to the project execution plan for upgrading the Plutonium Facility's safety basis to meet DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis* (see 7/22/2022 report). The approval letter requested monthly status reports discussing potential schedule risks and tracking project milestones.

Flanged Tritium Waste Containers (FTWC): On Monday, Triad personnel who are trained to perform the venting activity of FTWCs stored at Area G visited the storage location with N3B personnel. One purpose of the visit was to refamiliarize the Triad personnel with emergency response actions and assembly area locations at Area G. Another was to plan equipment siting locations to remain compliant with the new controls in the Area G safety basis.

Nuclear Environmental Sites: The Environmental Management Field Office unconditionally approved the annual update to the safety basis for nuclear environmental sites. One significant change in this update was to adjust the periodicity of in-service inspections to every thirty days. The inspections visually look for degradation of the sites. Previously, there were two inspections: one annually and one after significant events. Determining what constituted a significant event caused compliance challenges (see 8/21/2020 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 19, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 19, 2022

DNFSB Staff Activity: Members of the Board's staff held a virtual meeting with Triad and NNSA Field Office Personnel as part of a review of the site-wide atmospheric dispersion protocol.

Plutonium Facility–Fire Protection: On Monday, facility personnel held a fact-finding meeting to evaluate an incident last week where facility workers accidentally struck firewater piping with equipment causing a leak. The workers notified the appropriate facility personnel, and the leak was isolated promptly. Approximately 10 gallons of firewater was discharged. Maintenance personnel replaced the impacted piping, and the fire suppression system came back online the same evening. During the meeting, participants noted that this section of piping showed evidence of having been previously struck. Facility personnel are evaluating the adequacy of low clearance postings in low clearance areas with the potential for impacts to the fire suppression system.

Plutonium Facility–Glovebox Safety: On Tuesday, a glovebox glove and support ring disconnected and pushed into the glovebox while a worker was entering the gloves. The impacted worker and other personnel responded appropriately. Radiation control technicians detected substantial contamination on the worker's coveralls. There was no detectable skin contamination or evidence of an uptake. There were also no elevated airborne readings or any detectible spread of contamination into the room. There were two similar events two years ago where a worker pushed a glove and support ring into a box (see 9/25/2020, 7/24/2020 reports). Those events occurred with oval gloveports where this week's event was a round gloveport from the same manufacturer. While the cause of this separation is still under evaluation, it does not appear that excessive force at an angle was a factor as in the previous events. There have been no recurrences of oval gloveport separations following implementation of corrective actions from those events. Facility personnel are now evaluating how to safely perform this non-routine gloveport replacement using appropriate controls.

Radiation Protection: Last Thursday, workers at the Los Alamos Neutron Science Center (LANSCE) were performing repairs due to a vacuum issue. They were performing work on a valve outside of a posted high radiation area. The valve had not been surveyed as part of establishing the high radiation area, and a radiological control technician found it had a high dose rate after the work was in progress. The workers who had been in that room had their dosimeters read, and four workers received elevated exposures with the maximum dose being greater than 500 millirem over the course of the shift. Facility personnel paused work in that area pending further evaluation of radiological control practices.

Area G: On Wednesday, the Environmental Management Field Office authorized startup of corrugated metal pipe retrieval at Area G. N3B anticipates commencing next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 26, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending August 26, 2022

DNFSB Staff Activity: A. Boussouf provided support to the acting resident inspector at Pantex.

Transuranic Waste Facility (TWF): Last Thursday, there was a violation of the Technical Safety Requirements at TWF. Workers began moving drums in a waste storage building that was in warm standby mode (waste is present, but only limited operations are allowed) rather than in operations mode as required for moving waste drums. The building had stayed in warm standby mode due to maintenance being performed on the fire suppression system. Due to errors in communications, the facility mode was not recognized. As soon as they discovered the unallowed work, facility personnel paused the drum movements and ensured all waste was in safe condition. Facility management is evaluating means to improve communications and work release processes to prevent this type of error occurring in the future.

Work Planning and Control: Last Thursday, electrical safety officers paused work in a building adjacent to the Radioactive Liquid Waste Treatment Facility. Electricians, including vendor personnel were working on installation of radio frequency welders. The electrical safety officers noted that shorting jumpers were not installed on the capacitor bank to ensure that they were discharged. The work instructions for this task did not identify this hazard. Facility management plans to rework the instructions for this activity following a new planning walkdown with renewed attention to the scope, hazards, and controls. They also plan to reinforce rules regarding vendor participation in potentially hazardous activities. Longer term, there is an existing effort to evaluate work planning and control processes at the laboratory.

Plutonium Facility–Criticality Safety: Last Tuesday, a can containing fissile material was moved without an appropriate engineered spacer present as required. Responding personnel determined the condition was safe and allowed an immediate in the field correction to add a spacer. In the follow-up fact-finding meeting for the event, personnel noted that field correction may not have been allowable in this situation and the infraction level is being re-evaluated.

Area G: On Wednesday, N3B personnel performed an emergency response drill as part of the management self-assessment for startup of size reduction operations of corrugated metal pipes. The scenario involved a rigging failure in the Dome 375 Permacon with the winch hook disconnecting from the bag holding the corrugated metal pipe while it is being advanced to the cutting shear. The hook then struck the winch operator in the chest. Players in the drill noted this was a realistic scenario as it involved one of the more challenging movements during the planned operation. One key item identified during the drill was the need to improve radiological control practices during casualties in contamination areas.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): On Tuesday, Triad submitted to the NNSA Field Office for approval a safety design strategy for restart of WCRRF as a hazard category 3 nuclear facility (see 5/13/2022 report). The strategy relies heavily on an inventory control to constrain accident consequences.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 2, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 2, 2022

DNFSB Staff Activity: M. Bradisse and M. Dunlevy were on site this week. They met with Environmental Management Field Office and N3B personnel to prepare for the Board's planned public hearing in November. They provided resident inspector augmentation including observations of mobile loading of transuranic waste at Technical Area 55, metal production activities in the plutonium facility, mockup practice for corrugated metal pipe size reduction at Area G, and drill and drain activities at Area G. A headquarters staff team held a follow-up call with Triad and NNSA Field Office personnel to complete the discussion on atmospheric dispersion (see 8/19/2022 report).

Plutonium Facility–Decontamination and Decommissioning: Facility personnel held a fact-finding meeting to evaluate a Tuesday event where facility workers discovered unexpected contamination. A leak was identified around two glovebox window seals while performing decontamination activities. The facility workers paused work and notified appropriate personnel. Meeting personnel noted that future decontamination work would include pre-job surveys for contamination around gaskets and removable glovebox surfaces.

Plutonium Facility–Transuranic Waste Management: On Wednesday, the staff observed transuranic waste mobile loading operations in Technical Area 55. The crew successfully loaded twenty-one pipe overpack containers into TRUPACTs for shipment to the Waste Isolation Pilot Plant. This infrequently performed activity was completed within the one-year timeframe for maintaining readiness (see 10/29/2021 report).

Plutonium Facility–Infrastructure: Facility personnel held a fact-finding meeting to evaluate an event where eighteen dropbox fire dampers unexpectedly closed during troubleshooting of a ground fault within the system. Facility personnel are working to locate the ground fault and conducting an investigation to determine the cause of the unexpected fire damper response. All eighteen fire dampers are back in service following replacement of actuated components.

Emergency Management: On Wednesday, there was an emergency preparedness training drill at the Transuranic Waste Facility. The scenario involved a fire in an electric forklift during a drum movement which caused one of the drums to deflagrate, lose its lid and release material. The forklift driver was also injured during their evacuation from the vehicle but remained ambulatory. The scenario used real meteorological conditions which led to several movements of personnel as wind conditions shifted and protective actions needed to be adjusted.

Federal Oversight: The DOE Office of Enterprise Assessments completed an assessment of specific administrative controls at the Weapons Engineering Tritium Facility. The review identified three deficiencies, one opportunity for improvement, and four positives. One deficiency was that a programmatic administrative control was used instead of a specific administrative control to protect an over-pressurization assumption in the accident analysis. One positive observation was that the plans and rehearsals for the flanged tritium waste container activity are thorough and extensive.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 9, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 9, 2022

Plutonium Facility–Infrastructure: Last Wednesday shortly after midnight, the ventilation in the Plutonium Facility experienced a loss of differential pressure. Facility personnel entered the appropriate limiting condition for operation, restricted access to the facility, and began troubleshooting efforts. They were able to restore the pressures through manual control and allowed normal access to the south half of the facility by late morning. The northern wings remained restricted as personnel continued troubleshooting efforts. This failure had many similarities to an event at the end of March (see 4/1/2022 report). In that case, damper actuators failed. In this case, the problem was with the positioners that control the damper actuators. The probable cause of the failure was water accumulation in the Instrument Air System. Personnel replaced the broken positioners with components that were installed in the plant but are no longer in use. Full access to the facility was restored by Wednesday evening. The Instrument Air System has a drying train to ensure only dry air is present. However, there were multiple issues with the drying system. One of the heat exchangers that condenses and removes water had its chilled water supply shut off for an indeterminate period. The valve for that system is normally not readily accessible; however, there is currently substantial scaffolding in the area allowing access. A moisture analyzer on the system was also out of commission. Now that ventilation is restored, facility personnel are working on an extent of condition review to evaluate water accumulation and potential component damage in other areas. They are also working to restore the drying system for instrument air and reinforce training to assure valves are not repositioned inappropriately.

On Thursday, Triad transmitted an exemption request related to seismic qualification for portions of the ventilation system to the NNSA Field Office for approval. The request specifically notes that not all components in the safety-significant system meet performance category 2 requirements for seismic hazards. The request states that these portions of the ventilation system were not upgraded during past efforts due to high cost and low safety benefit. This ductwork provides a worker safety function and is not part of the confinement boundary that is intended to protect the public during a larger performance category 3 event.

Flanged Tritium Waste Containers (FTWC): This week, Triad personnel demonstrated FTWC venting and handling activities for federal assessors per a 2020 federal readiness assessment recommendation (see 11/13/2020 report). Environmental Management personnel were present throughout the evolution and will provide their observations to the startup authorization authority. The demonstration included the use of a new, four-legged, canine-inspired robot replacing a human spotter during the lifting and moving of FTWC containers with the remote vehicle.

Area G: On Thursday, N3B personnel commenced retrieval of corrugated metal pipes (CMP) from their burial pit. Following retrieval of the CMPs, they will be sheared into segments that can fit into standard waste boxes for shipment to the Waste Isolation Pilot Plant for disposal. This week, N3B personnel also completed a management self-assessment to prepare for upcoming formal readiness reviews to support the startup of this size reduction activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 16, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 16, 2022

DNFSB Staff Activity: Staff members M. Bradisse, K. Deutsch, D. Grover, T. Koshy, P. Natividad, J. Plaue, and R. Wu were on site to gather information to support the Board's upcoming public hearing. They held meetings with NNSA Site Office and Triad personnel to discuss safety systems and safety management programs at the Plutonium Facility and how those will be able to support the pit production mission. They also walked down the Plutonium Facility with an emphasis on safety systems and any upgrades to said systems.

Area G: Last Thursday, which was the first day of corrugated metal pipe (CMP) retrieval activities, a worker experienced heat related illness. Other workers aided the individual, moved them from the excavation area, rehydrated them, and requested a medical response. N3B management paused CMP retrieval operations and held two fact-finding meetings related to this event. There were many factors leading to the incident. Temperature monitoring was outside, and there was none inside the much hotter excavator cab. The air conditioning in the excavator cab has been broken for some time, but this was not recognized by all individuals at the work site. There were several unexpected conditions found as the excavation commenced including additional frameworks buried with the CMPs and a damaged end cap on the first CMP. Workers appropriately paused and evaluated each of these anomalies; however, this led to an extended amount of time without any hydration breaks. On Tuesday morning, N3B paused all field activities in Area G with the exception of required safety and compliance activities while they evaluate corrective actions from this heat illness incident. The pause remains in effect.

Plutonium Facility–Radiological Control: Late last month, there was a continuous air monitor alarm during bagout activities at the Plutonium Facility. The workers were bagging out heavy glovebox door assemblies including counterweights when a bag failed. All of the workers were in respirators, and there was no evidence of an intake or any skin contaminations. Facility personnel are evaluating bagout techniques to avoid further incidents with heavy objects being removed from glovebox lines. Options under evaluation include stricter limits on the number of items in a bag, use of thicker bags, or loading to a waste drum rather than doing bagouts. There will be many more of these assemblies in the waste stream as the facility is moving towards a new type of glovebox door design. A frayed cable connecting the counterweight to the door was the culprit for an injection intake in 2018 (see 2/8/2019 report). Following that event, facility personnel replaced aging cables and placed additional crimps around their ends to reduce the puncture hazard. The new door design being installed eliminates the cables entirely.

Plutonium Facility–Criticality Safety: On Wednesday, the NNSA Field Office concurred with Triad's latest memo regarding criticality safety in the basement of the Plutonium Facility. The memo documents the basis for why leakage of fissile solutions from aqueous processing laboratories on the first floor and subsequent formation of a critical geometry in the basement is not credible during a seismic event (see 8/13/2021 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 23, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 23, 2022

Area G: On Tuesday, N3B management authorized resumption of field activities in Area G with the exception of corrugated metal pipe retrieval (see 9/16/2022 report). During the pause, facility personnel held safety briefings and reviewed procedures to assure that job hazards were all fully identified and integrated. Authorized work resumed deliberately under senior supervisory watches. The job hazards for corrugated metal pipe retrieval are still under evaluation.

Plutonium Facility–Decontamination and Decommissioning (D&D): There were two recent issues identified during D&D activities in a laboratory room that is being repurposed. Both events involved a hood that is being decontaminated. Glove changes and decontamination activities in this hood led to non-compliance with transient combustible controls and work control practices for activities during material inventory. The hood has no allowance for transient combustibles, meaning any items such as gloves or waste bags must be removed or containerized unless attended. Glovebox gloves from the changeout and waste from decontamination were left in the hood. Access to this room is currently restricted due to radiological concerns with the waste bag. Fact finding meetings this week related to these events identified several areas for improvement. Many different organizations are involved in D&D, and the communications between them to ensure that all requirements are met was a major item noted for improvement. Also, glovebox/hood ownership remains a concern similar to an issue identified in the accident investigation earlier this year (see 6/3, 7/15/2022 reports).

Plutonium Facility–Conduct of Operations: On Wednesday, facility personnel held a fact-finding meeting to investigate a lockout tagout (LOTO) procedure violation after facility workers discovered a damaged circuit breaker lockout pin. Participants identified several concerns: 1) poor key-keeping practices, 2) locks being used by other than the authorized worker, 3) evidence of tampering with a locking mechanism, and 4) workers unfamiliar with site LOTO policies and practices. Facility management paused work on the impacted project pending re-training of workers on LOTO policies and procedures, and completion of an extent of condition.

Fire Protection: Last week, the NNSA Los Alamos Field Office approved the 2021 *Los Alamos National Laboratory Baseline Needs Assessment for Fire Protection and Emergency Response* with three conditions of approval. The updated assessment includes the current DOE-Los Alamos County Cooperative Agreement for fire department emergency services, contract adoption of DOE Order 420.1C Chg. 3, *Facility Safety*, and changes since the last assessment. The report describes the poor condition of two of the county's fire stations and includes a discussion on plans for replacement. The field office's conditions of approval are 1) the development of a conceptual staffing plan for upcoming fire station replacements within six months, 2) the closure of NNSA review comments in the next revision of the document, and 3) an explanation of the technical need and justification for recently procured firefighting robots in the next revision.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 30, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending September 30, 2022

Transuranic Waste Facility (TWF): Last Thursday, as part of an extent of condition review of work release from a previous event, TWF personnel identified another violation of the facility's Technical Safety Requirements related to work allowed during different facility modes (see 8/26/2022 report). Flammable gas analysis had been performed in a building in cold standby mode. The Technical Safety Requirements only allow that activity to be performed at a location in warm standby or operations mode. Facility management is evaluating whether flammable gas analysis can be separated from flammable gas sampling and be an authorized activity for cold standby.

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF management declared a violation of the facility's Technical Safety Requirements. They identified that in-service inspections for two safety-class tritium containment vessels were not performed within the required five-year periodicity. Facility personnel identified these vessels as due for inspection during a recent walkdown, but the incorrect due dates were placed on facility status boards. Facility personnel completed the inspections soon after the discrepancy was discovered. The results were satisfactory. Facility management is planning to adjust their procedure for status board updates to help prevent recurrence of a similar event.

Plutonium Facility–Fire Protection: On Wednesday, the resident inspector accompanied facility personnel on a management observation verification walkdown focused on chemical inventory control including storage in flammable cabinets. During the walkdown, the resident inspector noted that a suspended leak diaper, installed due to a prior spill (see 7/23/2021 report), was in excess of obstruction limits defined by the National Fire Protection Association. This diaper could impede the discharge pattern of several sprinklers in the basement. Facility management is evaluating how to fix this non-compliance. The members of the walkdown also opened flammable liquid storage cabinets in the basement to observe internal conditions and storage practices.

Radioactive Liquid Waste Treatment Facility (RLWTF): A seven member contractor team commenced a readiness assessment to support resumption of transuranic waste drumming operations activities at RLWTF. These activities have not been performed since 2014 (see 1/21/2022 report) when the Waste Isolation Pilot Plant was shut down after an accident. The process needs to resume to support stabilization of the transuranic fraction of liquid waste coming from the Plutonium Facility.

Area G: The Environmental Management Field Office authorized startup of glovebag operations in Dome 231 following their review of N3B's revised procedures (see 7/1/2022). Actual performance of this activity is not starting immediately as personnel are focusing on drill and drain activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 7, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 7, 2022

Radioactive Liquid Waste Treatment Facility (RLWTF): The contractor team assessing readiness to restart transuranic waste drumming operations at RLWTF completed their review and briefed facility management on their preliminary findings. The draft report identified seven pre-start findings and one post-start finding. Key findings included: the preventive maintenance program is not effectively implemented, several defense-in-depth controls in the safety basis are not implemented in accordance with the facility engineering processes manual, and the facility did not demonstrate effective, integrated procedural command and control for the full scope of drum tumbling operations. The team recommended the operation could restart following issuance of the final report closure of the pre-start findings.

Last Tuesday, during excavation work to support the Transuranic Liquid Waste project, an excavation subcontractor contacted and damaged an effluent line for the new Low-Level Liquid Waste Facility. The proposed cause for the strike on this line, whose location had been identified through potholing, was distraction due to other unexpected conditions in the excavation area. The damaged line has never been used to transport radioactive liquid waste as the Low-Level Liquid Waste Facility has not commenced hot operations yet. RLWTF management paused work on the excavation activities pending corrective actions by the subcontractor. Other lines within this excavation area are in use and radioactively contaminated. While evaluating this event, personnel noted that some of the unexpected conditions were due to installations associated with the Low-Level Liquid Waste Facility not using standard practices associated with the placement of test stations and marking new buried lines.

Plutonium Facility–Criticality Safety: On Thursday, facility personnel held a fact-finding meeting to discuss weighing practices during waste bag-out operations where a gross weight measurement is taken on top of a fissionable material transport cart. This long-standing weighing method is not defined in the criticality safety evaluation or the posting for the carts. Waste bag-outs in locations that rely on this method are paused until further review.

Weapons Engineering Tritium Facility (WETF): The NNSA Field Office unconditionally approved the safety basis addendum supporting plutonium coupon studies at WETF. This revision to the addendum resolved the issue regarding analyzing accident consequences for both tritium and plutonium identified during the management self-assessment (see 7/1/2022 report).

Emergency Management: Last week, the NNSA Field Office concurred that Triad successfully closed all corrective actions to address the 2019 Office of Inspector General report that identified weaknesses in pre-incident planning. One action taken by Triad is creating a Pre-Incident Plan Program integrated with the Geographic Information System, which incorporates critical facility information including, floor plans, fire alarm panels, fire detection systems, as well as a visual based document for quick access to critical information.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 14, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 14, 2022

N3B–Electrical Safety: On Thursday, N3B management stopped all work in their facilities with the exception of minimal safety and environmental compliance activities. This stop work was due to concerns with formality of operations. The Environmental Management Field Office is currently finalizing a conduct of operations assessment focused on electrical and lockout tagout practices. Field Office personnel have communicated preliminary concerns regarding training deficiencies and a lack of knowledge among electrical workers. In response, N3B personnel began self-assessing their electrical practices. This led to management pausing all electrical and lockout tagout activities, then stopping those activities, then stopping all work other than minimum safety and compliance tasks. While work is curtailed, N3B management is reinstating the senior management review process for releasing any work beyond that needed for minimum safety or compliance. They used this process in 2021 when activities were curtailed due to copious safety basis issues.

Plutonium Facility–Electrical Safety: While bagging out waste items, facility personnel discovered two potentially energized capacitors. They paused and reported the discovery. The exact provenance of the capacitors is not known, but they likely came from a blending machine that was size reduced earlier in the year. If the capacitors were fully charged, their stored energy would have exceeded the threshold for a hazardous energy source. Facility personnel have since discharged the capacitors to a safe condition. Transuranic waste specialists are determining whether any adsorbent is needed for the mineral oil in the capacitors. Proposed corrective actions to prevent recurrence of a similar event include additional emphasis on the use of equipment specifications during work planning for size reduction and another round of training on capacitor safety especially for personnel working with transuranic waste.

Plutonium Facility–Criticality Safety: While moving an item into a storage carousel in a glovebox, workers discovered that one of the storage locations was not latched shut per requirements, and the latch was not functional. They paused and reported the discovery. The identified condition violated the criticality safety posting for the glovebox, which forbids non-functional latching mechanisms and staging of items outside of a secured storage location. The non-compliant condition has been resolved, and facility personnel are evaluating better documentation of the expected criticality safety requirements for this box. Personnel who use the storage carousel also noted that its software control system is not reliable. They have provided this information along with a recommendation for a manual movement system to the Los Alamos Plutonium Pit Production Project, which will be installing several more storage carousel boxes of this type.

Onsite Transportation: On Wednesday, the NNSA Field Office requested that Triad provide an impact assessment for proposed compensatory measures to increase the safety of onsite shipments of nuclear material. NNSA provided a series of potential compensatory measures that could strengthen the existing controls in the onsite transportation safety document. Options for compensatory measures included: tying material at risk limits in shipments to packaging configuration, restricting or eliminating the use of wooden pallets, and strengthening pre-transfer checks for hazards along the route.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 21, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussof and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 21, 2022

DNFSB Staff Activity: The Resident Inspectors were in Washington, D.C. to brief the Board and attend meetings. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 28, 2022

MEMORANDUM FOR: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending October 28, 2022

DNFSB Staff Activity: Staff member R. Jackson was onsite to attend a workshop on the Plutonium Facility Seismic Performance Reassessment Project. Staff member Y. Li attended remotely.

Plutonium Facility–Fire Protection: The resident inspectors accompanied facility management on their weekly management observation verification walk-through and suggested evaluating fire barrier features as part of the walk-through. During this activity, a resident inspector identified an unsealed penetration through a credited fire barrier between one of the laboratories and the basement. The hole had been drilled as part of a construction activity; however, the required firestop seal was not promptly installed. Facility engineering personnel had previously identified this penetration and submitted a service request to have a temporary three-hour fireproof seal installed. Facility management is following up on why this temporary seal has not been installed and whether the permanent seal can be installed expeditiously.

Plutonium Facility–Infrastructure: Last week, Triad submitted the revised Preliminary Documented Safety Analysis for the Los Alamos Plutonium Pit Production Project (LAP4) to the NNSA Field Office for approval. This revision is intended to address previous comments from the Field Office and to incorporate details from the final design (see 7/8/2022 report). This week, the NNSA Field Office approved Revision 4 of the Safety Design Strategy for LAP4 which has no major changes.

Last week, the NNSA Field Office approved a temporary modification to the Plutonium Facility's safety basis to support the upgrade of the Facility Control System (FCS). The FCS is a safety-significant system that supports operation of the facility's ventilation system. It also supports other facility systems such as the criticality alarm system and fire suppression system, but these functions are not credited safety functions. The current FCS was installed in 1996 and obtaining obsolescent parts is becoming a challenge. The first three phases of the FCS upgrade could be performed while the facility was in a limited operations mode. The final two phases, which involve commissioning, testing, and surveillances of the new system, will be performed in operations mode under the new temporary modification. The modification revises the limiting condition of operation for ventilation system operability to allow additional flexibility in operating the facility without a fully functional FCS during the transition. The approval included one directed change to clarify that the temporary modification only applies during phases four and five of the upgrade following the completion of phase three, in which the new FCS is connected.

Emergency Management: On Tuesday, there was an emergency preparedness training drill at the Chemistry and Metallurgy Research Building. The scenario involved a worker who was manipulating a pallet of transuranic waste drums falling off a loading dock with the drums. The worker received a compound fracture while a drum lost its lid and spilled some of its contents. The injured worker and one other were contaminated. Drill participants noted many potential improvements during their hotwash following the conclusion of the activity. Field drills at nuclear facilities were infrequent during the pestilence (see 7/16/2021 report). Meanwhile there has been tremendous staffing growth and turnover such that many personnel have never participated in emergency preparedness drills or are in new roles with different responsibilities during emergency events.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 4, 2022

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending November 4, 2022

Staff Activity: Members of the Board's staff participated in a virtual briefing with the Board, DOE/NNSA Headquarters, and the Los Alamos Field Office to discuss DOE's response to the January 6, 2022 letter addressing concerns with the adequacy of LANL's Transportation Safety Document and the onsite transportation safe harbors in 10 CFR 830.

Plutonium Facility–Infrastructure: This week, facility personnel held a meeting to discuss concerns with scaffolding. Workers had discovered several quality issues on a scaffold that had been erected and released for work. During the meeting, participants noted that the pre-job inspection process is not well defined, and that workers rely on skill of the craft rather than written criteria when releasing an erected scaffold for work. Given the large number of ongoing construction activities, facility personnel plan to re-evaluate the scaffold inspection criteria and are considering increased use of an existing checklist for each pre-job inspection.

N3B–Stop Work: Last week, N3B released several activities that had been previously stopped (see 10/14/22 report). The resumed activities included transuranic waste container movements to support mining, characterization, remediation, and shipping, as well as the central characterization program's performance demonstrations. In addition, transfers for weight certification, nondestructive assay/examination, and shipments to the RANT facility were resumed.

This week, N3B resumed shipping mixed low level waste, repackaging waste liner from one of the domes, and overpacking waste containers. Currently, corrugated metal pipe retrieval, drill and drain, dome reskinning, and activities requiring lockout tagout are still stopped.

Safety Basis: On Tuesday, Triad transmitted its methodology for calculating leak path factor and atmospheric dispersion to the NNSA Field Office for review and concurrence. This methodology will be part of the mitigated accident analysis in the new TA55 Documented Safety Analysis (DSA) being developed using DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*. The new methodology couples the leak path factor and atmospheric dispersion factor. In addition, the analysis would increase the wind direction resolution from 8 points to 16 points and provide more granularity at lower wind speeds.

On Wednesday, the NNSA Field Office approved the Technical Area (TA) 55-DSA-2020-R1 Addendum 4, and the TA55-TSR-2020-R2, Technical Safety Requirements (TSRs) with no conditions of approval or direction. The addendum addressed changes to equipment in the Plutonium Facility to accommodate activities currently performed in the Chemistry and Metallurgy Research Building. This will require adding gloveboxes and equipment for multiple processes including dry powder handling, material characterization and analytical chemistry, machining, casting and molten operations, and primary confinement.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 11, 2022

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending November 11, 2022

Plutonium Facility–Emergency Response: Last Wednesday, the newly installed chlorine delivery system was brought online and used for the first time (see 8/5/2022 report). The system was then shut down, valves were isolated, and chlorine lines were purged without incident. Approximately six hours later during the night shift, chlorine was detected in the chlorine cylinder cabinet with a peak concentration of 0.7 parts per million. A responding worker also reported smelling chlorine in a laboratory room. The facility operations center contacted the emergency operations support center who issued a shelter in place order for surrounding buildings. Initially, personnel believed that residual chlorine in the line may have leaked, triggering the alarm. On Monday, a fact-finding meeting was held to discuss the event. Participants identified several issues: the local alarm readout provided conflicting information regarding the location of the potential leak while the readout in the operations center had the correct information, the detection system does not communicate real-time chlorine concentrations to the operations center, and there were miscommunications between different responding organizations in providing meteorological data. After the meeting, facility personnel concluded that the likely cause of the alarm was due to transient vehicle exhaust fumes from nearby idling vehicles rather than a chlorine leak as there was no evidence of any pressure changes in the system.

Radiological Laboratory Utility Office Building (RLUOB)/PF-400: The NNSA Field Office, with support from an independent NNSA Headquarters and NNSA Sandia review team, approved the revised corrective action plan to address findings from the federal readiness assessment to startup RLUOB as a hazard category 3 nuclear facility to be known as PF-400. Field Office personnel provided copious commentary on the original corrective action plan and causal analysis (see 7/15/2022 report). In general, their commentary focused on corrective actions not being specific enough or obviously flowing from the causal analysis. The revised documents adequately addressed these concerns.

Emergency Management: The NNSA Field Office approved the contractor's corrective action plan to address two of the issues from the annual emergency exercise (see 7/15/2022 report). These two issues tied directly to the operations of a defense nuclear facility (the Plutonium Facility) and thus required a formal corrective action plan. The first finding was that the initial operational emergency notification form identified the wrong community location for protective action recommendations. Corrective actions included enhanced means to correct errors and new data validation processes to assure accuracy prior to issuance. The second finding was that workers in the Plutonium Facility did not all exit from the closest facility exit point. Corrective actions included revising evacuation maps and enhancing emergency training for facility workers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 18, 2022

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending November 18, 2022

Board Activity: On Wednesday, the Board held a public hearing in Santa Fe, New Mexico. The hearing included four sessions. The first gathered information from a panel of Office of Environmental Management and N3B personnel on the status of the activities performed by the Department of Energy's Office of Environmental Management at the Area G transuranic waste management facility. The session also included a public comment period. The second and third sessions involved NNSA and Triad personnel discussing the production activities to be conducted in the Plutonium Facility, the nuclear safety risks the NNSA has accepted, and the state of planned safety improvements to safety system infrastructure and safety programs at the facility. The fourth session took additional commentary from members of the public.

On Tuesday, the Board members and accompanying staff were onsite. They held meetings with Triad, N3B, NNSA, and Environmental Management personnel and toured the Plutonium Facility. The tour included several laboratory rooms supporting the pit production mission, transuranic waste movement, and the americium separation process. They also looked at safety systems including fire suppression system upgrades, the ventilation system, and the uninterruptible power supply system.

While in New Mexico, the Board members also spoke with members of local stakeholder groups.

N3B–Stop Work: N3B management has reviewed and released all work other than electrical and lockout/tagout activities (see 11/4/2022 report). At Area G, drill and drain activities in the Dome 231 Permacon have resumed following their release. Retrieval of corrugated metal pipes is also now released, and workers performed a mockup activity this week in preparation for resuming hot operations.

Plutonium Facility–Criticality Safety: On Tuesday, facility workers discovered a non-compliance with the mass requirements from the criticality safety posting for a safe in a laboratory room. The workers paused and reported the discovery. The safe has drawers that are partitioned into two sections, and the mass limits for criticality safety apply to each location. Two items were in one section and exceeded the mass limit. The day prior, workers were rearranging items in the safe to support non-destructive assay activities and inadvertently moved the two items into the noncompliant configuration. This over-mass condition is bounded by the upset scenarios in the criticality safety analysis for the safe. Workers restored the safe into compliance and returned it to operations. In order to prevent recurrence of similar events, facility personnel are evaluating corrective actions including driving consistency between the location definitions for criticality safety and material accountability.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 25, 2022

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending November 25, 2022

Plutonium Facility–Safety Basis: Last Thursday, Triad submitted to the NNSA Field Office for review draft portions of the new safety basis under development for the Plutonium Facility. This submittal included the site characteristics and site description as well as their planned methodologies for performing the hazard analysis. The project execution plan for updating the safety basis includes a commitment for Triad to periodically share key documents with the Field Office staff. The purpose of this sharing is to inform the Field Office of the approaches Triad is making with the new safety basis before the Field Office begins their review of the final submission.

Last Wednesday, the NNSA Field Office approved the Preliminary Documented Safety Analysis (DSA) for the Los Alamos Plutonium Pit Production Project 30 Base (LAP4 30B) with no conditions of approval or directed changes.

Weapons Engineering Tritium Facility (WETF): The resident inspector was accompanied by WETF operations management on a walkdown of the facility. The focus of the walkdown was to observe the general condition of passive fire protection features, such as fire walls, fire doors, and fire dampers. The current DSA and Technical Safety Requirements for the facility require that certain interior walls be maintained as 1-hour fire rated walls, separating the tritium processing, handling, and storage areas. Overall, the resident inspector noted that these systems appeared robust, well maintained, and in good working order. Some areas for improvement were identified and discussed with facility personnel, specifically in the labeling and tracking of penetration seals, as well as acceptable ways of filling open holes in fire doors.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 2, 2022

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending December 2, 2022

Staff Activity: Staff members W. Dumayas and R. Jackson were at the University of Nevada, Reno to observe testing of cast iron fittings. These fittings are expected to be the most vulnerable components of the Plutonium Facility's fire protection system during seismic loads. Additional analysis will help determine their expected performance during a seismic event and whether any upgrades are needed.

Los Alamos Neutron Science Center (LANSCE)–Emergency Response: On Monday morning, a fire broke out in a computer numerical control (CNC) machine at a non-radiological LANSCE machine shop. A machine shop employee extinguished the fire, the equipment was shut down and the building was evacuated. The Los Alamos fire department responded to the scene and released the facility soon thereafter. The following morning, facility personnel held a fact-finding meeting to discuss the incident. Meeting participants noted that the CNC machine had likely sent a spark into accumulated aluminum shavings, acrylic shavings, and possibly lubricating oils. The operator's account of the incident identified that they first attempted to extinguish the flames with a pressurized air hose, followed by use of liquid coolant, and finally, successfully extinguished the flames with a nearby dry chemical fire extinguisher. Meeting participants noted that fire was not a hazard identified in the controlling work documents and questioned housekeeping practices as large amounts of excess machined shavings had been allowed to accumulate in the assembly. The resident inspectors visited the machine shop and noted that the CNC machine where the fire occurred had a substantial quantity of thin shavings inside its enclosure, in addition to two large combustible containers filled with shavings adjacent to where the fire occurred. Facility management noted that a more stringent cleaning regimen is under evaluation.

Plutonium Facility–Conduct of Operations: Two weeks ago, a construction worker found a damaged locking device for lockout/tagout with an intact lock in a toolbox in the basement. The worker turned it in to the facility's operations center. There is no obvious damage to the system the lock had been installed on. This week, facility personnel held a fact-finding meeting to evaluate the event. The worker who placed the lock has not been with the laboratory since early 2022, and there is no conclusive determination of when and how the locking device was intentionally removed without authorization. This is the second recent instance of unauthorized removal and damage of locking devices at the Plutonium Facility (see 9/23/2022 report). Lockout/tagout training has been ramping up with additional in-person training to support the growing workforce, to return to normal practices following the reduction of in-person classes during the pandemic, and as a corrective action from the September incident.

Plutonium Facility–Safety Basis: On Thursday, Triad submitted the revised temporary modification to the Plutonium Facility's safety basis to support the upgrade of the Facility Control System. The revision addresses the NNSA Field Office's directed change to clarify the applicability of the temporary modification from their approval of the previous revision (see 10/28/2022 report).

Area G–Stop Work: Electrical and lockout/tagout work are now released to be performed at Area G (see 11/18/2022 report). Said work must be performed under the oversight of a senior supervisory watch. N3B's senior management review process remains in place for any emergent work activities that have not been reviewed and released yet.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 9, 2022

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending December 9, 2022

Staff Activity: Staff members C. Beaty, J. Heath, and L. Lin were onsite this week for an initial visit to support a review of decontamination and decommissioning (D&D) at the Plutonium Facility and the Chemistry and Metallurgy Research Building.

Plutonium Facility–Fire Protection: On Thursday, the resident inspectors identified approximately 40 flammable gas cylinders staged outside of the Plutonium Facility in a configuration that violated the minimum separation distance from oxygen cylinders. The resident inspectors notified facility operations management of the issue. The improper staging of flammable cylinders outside of the Plutonium Facility has been a recurring issue; the resident inspectors identified a similar non-compliance on the other side of the facility in July which has been resolved.

Plutonium Facility–Criticality Safety: On Thursday, workers identified that some units of one model of water-resistant containers used to store nuclear material in the Plutonium Facility had lids that were not secure even after proper closure. They informed criticality safety personnel as this type of container is widely used in areas where the criticality safety evaluation requires water resistant containers or containers that remain closed while in transit. Further inspection of units of this container model suggested that the poor closure may be specific to a large batch of recently purchased containers that have minor differences from previous purchase batches evident on visual inspection; there is no obvious visual distinction between functional and non-functional containers within the same batch. Facility personnel are inspecting containers in use and restricting procurement and distribution of new containers while they determine whether there was a specification change or procurement error with these containers.

Plutonium Facility–D&D: On Tuesday, the resident inspectors and staff review team observed a cold mockup demonstration for the removal, downsizing, and disposal of criticality-safe geometry cylindrical tanks (pencil tanks). The demonstration involved the cutting of metal piping of a similar material and geometry inside a glovebag. Triad D&D personnel shared lessons learned from their mockup activities, discussed hoisting logistics, and the planned safety protocols for the activity. Pencil tank D&D in the Plutonium Facility is scheduled to start in 2023.

Chemistry and Metallurgy Research Building (CMR)–D&D: Glovebox removal activities in CMR are not being performed this fiscal year. In August, transuranic waste management personnel expressed concerns with the planned strategy to package gloveboxes with lower activity items from the same rooms to be disposed of as low-level waste. They considered that there was a substantial likelihood that some containers could exceed limits for transuranic waste and would then have to be opened and repackaged. Waste management personnel are currently preparing acceptable knowledge documentation for waste generation from glovebox D&D at CMR. Once that is complete, the approach to resuming glovebox removal will be developed. Meanwhile, the D&D subcontractor is performing lower risk low-level waste removal activities in CMR.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 16, 2022

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending December 16, 2022

Onsite Transportation: Last Friday, Triad submitted their response to the NNSA Field Office regarding incorporating compensatory measures to increase the safety of onsite shipment of nuclear material while DOE reevaluates its approach for developing transportation safety documents complex-wide (see 10/14/2022 report). The Field Office's letter included a copious list of potential compensatory measures to evaluate for feasibility and impact. Triad's response stated that they completed an evaluation of potential compensatory measures and concluded that, in their opinion, they already perform such actions as part of normal transportation activities. Therefore, the response stated that the only change needed is to elevate such items into the controls in the Transportation Safety Document. The Field Office is evaluating the response.

N3B–Stop Work: Last Thursday, N3B management stopped work on all hoisting and rigging activities. While following up on questions from a DOE Headquarters assessment, N3B personnel determined that their program was not compliant with the DOE standard on hoisting and rigging. N3B personnel are currently reviewing job hazard analyses for activities using hoisting and rigging and performing a review of their program.

Plutonium Facility–Criticality Safety: On Thursday, facility personnel held a fact-finding meeting to discuss a Tuesday incident where glovebox workers introduced an item into a glovebox exceeding the mass limit on the criticality safety posting. Meeting participants noted there was a miscommunication when switching one glovebox worker with another who then assumed the glovebox contained no fissile material. Also, another worker transferring material from the intro hood into the glovebox line accidentally touched the receiving glove and their personal protective equipment was contaminated. Criticality safety personnel determined this was an analyzed upset condition, and workers restored the glovebox into compliance and returned it to operations. In order to prevent recurrence of similar events, facility personnel are evaluating corrective actions including splitting up cold entries from special nuclear material entries, using more senior persons in charge for jobs, and treating this entire glovebox train as one area for future moves.

Emergency Management: On Thursday, there was an emergency preparedness training drill at the emergency operations center. This served as a proficiency drill for several new emergency response organization personnel. The scenario involved a flanged tritium waste container (FTWC) transport vehicle accident caused by the driver taking an evasive maneuver to avoid a herd of elk in the road. The truck flipped over, and the contents of the FTWC were released into the atmosphere. The driver of the vehicle suffered injuries, including lacerations and a broken arm, and two elk were killed. Participants identified potential improvements including ensuring the proper identification of affected facilities for shelter-in-place actions (two were missed) and performing accountability of N3B personnel in the vicinity of the accident location.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 23, 2022

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending December 23, 2022

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): Last Monday, the NNSA Field Office conditionally approved a revised safety design strategy that supports the restart of WCRRF as a hazard category 3 facility (see 8/26/2022 report). The Field Office provided eight directed changes in their approval. These changes included the following requirements: to perform a baseline functionality assessment on selected systems, submit selected codes of record for every design change, and evaluate previously approved exemptions to safety standards at the facility.

Plutonium Facility–Radiological Control: Last Wednesday, while performing maintenance on a glovebox oxygen monitoring system, a worker noticed a breach in one of their glovebox gloves. A responding radiological control technician found contamination on the worker's personal protective equipment. On Monday, a fact finding was held to discuss the incident. During the meeting, participants noted that a furnace in proximity to the oxygen monitoring system was on during this maintenance evolution. Work control documents for this activity did not include the hazards associated with working near an operating furnace, and the worker had not donned overgloves as normally required when working near a hot furnace. Facility personnel are considering several corrective actions, including updating work planning documents to include furnace hazards, limiting the scope of maintenance activities when a furnace is on, and providing additional operator aids to indicate the status of the furnace.

Criticality Safety: On Tuesday, the NNSA Field Office unconditionally approved a revision to Triad's Criticality Safety Program. The main change in this revision is a substantial increase in the de minimis values of nuclear material below which activities do not need a formal criticality safety evaluation. For example, the new program documentation has a de minimis value of 25 grams of plutonium compared to the previous value of one gram. NNSA personnel identified no concerns with the technical basis behind this change during their review.

Transuranic Waste Facility (TWF)–Safety Basis: Triad submitted a revised TWF safety basis to the NNSA Field Office for approval. One significant change in the revision is a corrective action from the violation of the technical safety requirements related to flammable gas sampling and analysis being performed in an unauthorized facility mode earlier in the year (see 9/30/2022 report). The new revision splits flammable gas sampling and analysis into two separate activities and allows the analysis of samples to be performed in all facility modes as material at risk is not present during analysis. Flammable gas sampling still must be done in warm standby or operations mode. Another significant change was to the limiting condition for operation when the electric fire pumps are inoperable. This change was due to damage caused by a lightning strike, which took significant time to repair (see 8/6, 8/27/2021 reports). The new revision proposes allowing 90 days to restore a pump to operability and adds in a fire watch and opening a valve to the domestic water supply, which should allow sprinklers to activate at reduced pressure while the pumps are inoperable. The previous time to restore operability was 7 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 30, 2022

MEMORANDUM FOR: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for Week Ending December 30, 2022

Year in Review: A summary of the key developments of 2022.

- The DNFSB Los Alamos Office welcomed a new resident inspector, A. Boussouf, and marked the departure of J. Plaue, who returned to headquarters.
- The Board held a public hearing in Santa Fe to explore the safety posture at the Plutonium Facility and transuranic waste operations at Area G.
- NNSA accepted a safety basis to support receipt of large quantities of heat source plutonium at the Plutonium Facility with an “exigent condition” where worst-case consequences exceed DOE’s evaluation guideline for postulated consequences to the public.
- In May, the Emergency Operations Center partially activated in response to the Cerro Pelado wildfire west of the laboratory. The fire was contained in June without any significant impact to the laboratory.
- Both Triad and N3B continued regular shipments of transuranic waste containers primarily through shared use of the RANT Shipping Facility. Shipments of transuranic waste exceeded generation for the year.
- N3B performed work at Area G under several Justifications of Continued Operations while they continue developing a modern safety basis. Drill and Drain, Glovebag, and Corrugated Metal Pipe retrieval activities all went through readiness reviews in preparation for restart.
- In the fall, N3B management implemented a stop work to address safety concerns with conduct of operations, especially electrical safety and lockout/tagout. Work resumed following management review and corrective actions. In December, N3B management stopped work on all hoisting and rigging activities. These remain halted.
- Decontamination and Decommissioning activities at the Chemistry and Metallurgy Research Building increased early in the calendar year as the first glovebox removals commenced. Glovebox removals are not funded in fiscal year 2023 so current activities are limited to low-level waste removal.
- The transition of the Radioactive Laboratory Utility Office Building to a Hazard Category 3 nuclear facility to be known as PF-400 neared completion as Federal and Contractor Operational Readiness reviews occurred in May and February respectively.
- NNSA made the decision to restart the Waste Characterization, Reduction, and Repackaging Facility as a hazard category 3 nuclear facility to establish size reduction capabilities for oversized transuranic waste items. Safety basis development to support this transition also commenced this year.
- The team who will vent the Flanged Tritium Waste Containers stored at Area G performed a proficiency demonstration for federal assessors in the summer. Commencement of venting is awaiting permitting.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 6, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending January 6, 2023

Plutonium Facility–Infrastructure: Last month, Triad completed the annual revision of the TA-55 Project Execution Strategy (PES) (see 1/28/2022 report). The PES outlines the strategy, estimated cost ranges, general scope, high-level schedule, and potential funding sources to be used to complete a set of upgrades, modifications, and maintenance activities at the Plutonium Facility. For last fiscal year, the PES highlighted key accomplishments including: completion of the chlorine system upgrades which included a new chlorine gas delivery system and chlorine gas detection system; closure of several issues identified as part of the ongoing seismic evaluation efforts, such as duct seams, were resolved through calculation or further evaluation of code; and completion of seismic analyses for 38 gloveboxes.

For this fiscal year, the PES recommends actions including the completion of: a fire dynamic simulator model of a lab room fire across the corridor, in addition to a 2-hr test of a mock PF-4 corridor coated with intumescent fire barrier paint; construction and commissioning of the new facility control system (FCS); seismic testing of fire suppression system piping components; the design for the instrument air system upgrades; a prioritized schedule of gloveboxes to be analyzed in support of the seismic program and evaluations for six groups of them; and a prioritized list of fire hazard evaluations to be analyzed with seven to be completed.

Plutonium Facility–Operations: Beginning two weeks ago, facility personnel experienced multiple problems with the FCS. The FCS has a safety-significant function supporting the ventilation system and has other non-credited functions including monitoring radiation detection systems, monitoring fire systems, and interfacing with the paging system. Facility personnel repaired the first issue with the FCS by replacing a communications module. They resolved a second issue about a week later with a server swap and restart. Following a third incident, facility management kept the facility in limited operations mode and the FCS formally inoperable after the successful initial repair until more detailed troubleshooting and repairs could be completed. Those activities continued this week. The FCS is now operable, and the facility is in normal operations mode. The FCS is an aging system, and there is a current project in place to replace its safety-significant function. The existing system will remain largely in place to perform its other functions following completion of the new system. The new system is installed, and several outages to support swapping over to it are planned over the next few months.

Area G–Safety Basis: On Sunday, the Environmental Management Field Office conditionally approved the latest revision of the Area G basis for interim operations and unconditionally approved an addendum supporting corrugated metal pipe (CMP) size reduction. The approval documentation included one new condition of approval to include new calculations and standoff distances to support eventual Flanged Tritium Waste Container venting. Internal pressure of these containers steadily increases due to tritium decay, and the field office directed a similar evaluation last year. Two other conditions of approval remain from last year and are related to 1) helicopter crash standoff distances, and 2) the re-evaluation of the frequency of combined fixed wing aircraft and helicopter crashes with results incorporated into the modern documented safety analysis under development to replace the current basis for interim operations. Work is ongoing to close the remaining condition of approvals. A contractor readiness assessment to support startup of that activity is planned for later this month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 13, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending January 13, 2023

Staff Activity: R. Eul was onsite to observe the assist visit from the Criticality Safety Support Group.

Criticality Safety: A six-member team from the Criticality Safety Support Group (CSSG) was onsite to perform an assist visit. The NNSA Field Office requested the CSSG review the nuclear criticality safety program as implemented at the Plutonium Facility to evaluate the program's ability to support the no less than 30 pit per year production mission. The tasking asked the review to include: looking at criticality safety limits at the plutonium facility to enhance operational flexibility; recovery from deviations and infractions; the roles, responsibilities, authorities, and accountability within the nuclear criticality safety program; and adjudication of differing technical opinions. The team split into three groups focusing on: the pit process flow and field observations; the development of criticality safety evaluation documents and controls; and line management support of nuclear criticality safety. The team briefed field office and Triad management on their initial observations at the end of the week and plan to develop recommendations and issue a final report by the end of March.

Plutonium Facility–Operations: On Monday, a grit paper disk auto-ignited while a worker was transferring it between gloveboxes. A small flame traveled along the path where the grinding surface had been in contact with plutonium and then self-extinguished. The involved worker paused the operation and contacted facility operations. Management subsequently paused all facility grinding, cutting, and polishing operations. A fact-finding meeting was held on Wednesday to discuss the event. Meeting personnel could not identify any change to the process which could cause a fire. However, plutonium fines have known pyrophoric properties. They noted that this is the first occurrence of a fire on a grinding disk in this frequent operation. Facility personnel are evaluating potential causes. Additionally, a breakdown in communication occurred as the fire department was not notified of the incident. Facility management is evaluating ways to ensure workers understand the importance of taking proper actions in response to fire including activating the dropbox fire alarm or pulling a manual pull station and calling 911.

On Monday, workers repackaging a legacy item for disposal observed a few seconds of 'sparking' while pouring material from a can into a tray. The reaction occurred in a glovebox and was limited to sparks with no visible flame. The workers paused and reported the incident. The material was a free-flowing powder of electrorefining salt and plutonium. The cause was likely luminous oxidation of plutonium metal powder in the air atmosphere of the glovebox; however, this was not expected given the age of the material and its packaging conditions. The material was originally processed under an inert atmosphere; however, it was not packaged under inert conditions. As a corrective action from the 2021 titanium event (see 5/14/2021 report), Triad developed procedures to address moving materials from inert to air boxes. In response to this event, personnel are developing a path forward for safely repackaging this material and are evaluating feed lists to determine if additional controls are needed for similar materials slated to be repackaged for disposal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 20, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending January 20, 2023

Staff Activity: On Friday, a DNFSB headquarters team held a call with NNSA Field Office and DOE headquarters personnel to discuss the proposed methodology of coupling leak path factor and atmospheric dispersion. The proposed methodology will support the upcoming safety basis upgrade for the Plutonium Facility (see 11/4/2022 report).

Area G–Readiness: On Monday, a twelve-member contractor team commenced a readiness assessment to initiate Corrugated Metal Pipe (CMP) size reduction operations in Dome 375. Non-CMP size reduction operations were last performed at that location in May 2014, and nuclear operations other than the movement and storage of waste containers have not been performed in the dome since November 2017. Readiness for retrieval of CMPs was evaluated separately in May 2022 (see 05/20/2022 report).

The scope of this review includes winching the CMP along roller conveyors into cell 1 of the Dome 375 Perma-Con; winching the CMP along roller conveyors into cell 2, the main size reduction area; cutting one 4-ft section of the CMP with hydraulic shears; loading the 4-ft cut section into a standard waste box; and securing and moving the waste box to a staging area inside of Dome 375. This week, the team performed interviews with operations and support personnel. The review will continue next week with observations of an operational drill and field demonstrations.

Plutonium Facility–Decontamination and Decommissioning: Last Friday, workers preparing a glovebox line for removal prior to replacement identified an unexpected condition. When they moved a hand press in the box for size reduction, they discovered a deposit of unknown material that had accumulated under the press. Following consultation with a manager in the area, they paused work and made the appropriate notifications. There was no sparking or other evidence of a chemical reaction when the material was disturbed. The glovebox has not been used in decades and historical processes were under an inert atmosphere. The box currently has an air atmosphere. Prior to performing this activity, workers had removed all known nuclear material from the box, which was posted as containing no special nuclear material. The box remains out of service while facility personnel determine the nature of the material, whether it contains nuclear material, and how best to dispose of it as waste. Facility management is also evaluating adding additional contingencies to work documents to address conditions that are likely to occur during this type of work.

Weather Impacts: Snowfall impacted onsite operations at the laboratory resulting in a closure on Tuesday and a delayed start on Wednesday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 27, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending January 27, 2023

Staff Activity: D. Brown was on site.

Area G–Readiness: The contractor team continued its readiness assessment of corrugated metal pipe (CMP) size reduction activities in Dome 375. This week, N3B personnel demonstrated the loading, cutting, and packaging of a mockup CMP under chilly weather conditions requiring warm-up breaks to avoid cold stress. The demonstration included an operational drill where workers had to respond to the discovery of a tear in the bag holding the CMP. One of the assessors identified a lockout/tagout issue during the demonstration. The cutting shear is locked out when workers are cleaning the contamination control shroud surrounding it. While the worker performing the hands-on activity had a lock in place, the interface between the CMP cutting procedure and lockout/tagout documentation had weaknesses such that all lockout/tagout requirements were not completed properly. Facility management is developing corrective actions to resolve this discrepancy and prevent recurrence. The assessment team briefed the preliminary results of their review on Thursday and plan to finalize their report in February.

Area G–Emergency Management: As part of the readiness assessment, N3B personnel held an emergency preparedness drill. The scenario involved a process upset during CMP size reduction activities where the winch began to smoke. Workers appropriately identified the hazard, simulated use of a manual fire extinguisher, evacuated the Permacon and Dome, then met at the assembly area for accountability. During the drill critique participants identified potential areas for improvement. One idea was to considering adding additional assembly areas within the Area G fenceline to reduce travel time from work areas.

Area G–Safety Basis: N3B held a workshop to support development of a modern DOE-STD-3009-2014 compliant safety basis for Area G. Participants worked on topics such as atmospheric dispersion modeling, controls development, and expectations for safety management programs.

Emergency Management: On Wednesday, Triad held an emergency preparedness drill at the Emergency Operations Center. The scenario was a wildfire initiated by downed powerlines in Los Alamos Canyon at the northern edge of the site. The simulated conditions had the event occurring during high winds in May. The fire behavior in the scenario was challenging as flame height was too high for safe direct attack, and wind speeds were too high to deploy aerial resources. The nearest hazardous facilities to the event were Technical Area 21 and the Los Alamos Neutron Science Center. The fire's location also posed a risk to two of the limited evacuation routes out of Los Alamos County. In both reality and the drill scenario, fuel loading in Los Alamos Canyon is high as previous wildfires have not significantly impacted it. There are plans to perform fuel mitigation in the canyon later this year.

A team from the Office of Emergency Management Assessments (EA-33) in DOE's Office of Enterprise Assessments was on site as part of their assessment of the all-hazards planning basis for transuranic waste operations at the laboratory. The team expects to complete their review and issue a report in May. This is part of a complexwide assessment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 3, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending February 3, 2023

Area G–Stop Work: Last week, N3B personnel were working to resume excavation of corrugated metal pipes, which has been paused since last September due to a heat stress incident (see 9/16/2022 report). A facility representative from the Environmental Management Field Office paused resumption of activities due to questions on training, ladder requirements, snow removal, and the excavation slope. N3B management later formally stopped work after determining that the existing slope of the excavation was steeper than the slope on the drawings. The stop work remains in place while N3B personnel evaluate whether the existing slope is adequate for the soil conditions.

Plutonium Facility–Criticality Safety: On Monday, facility workers discovered a non-compliance with the mass requirements from the criticality safety posting for a safe in a laboratory room. This was the same safe involved in a similar event last year (see 11/18/2022 report). The workers paused and reported the discovery. A material move the week before was not completed properly with all mass checks such that a second item placed into the storage location exceeded the mass limit. This was an analyzed upset condition, and criticality safety personnel determined the condition was safe and stable. Access to the area was restricted until personnel completed recovery actions to restore compliance with the mass limit. Processing of special nuclear material in this room is paused with the exception of runs in progress that were completed per procedure to a stable condition. Corrective actions from this event include: prioritizing an incomplete corrective action from the November event to match the accountability and criticality safety locations for the safe, performing an extent of condition evaluation to determine if there are other locations with similar error traps where the criticality safety location is defined differently than accountability locations, and adding this event into the formal causal analysis in progress related to previous events.

Plutonium Facility–Infrastructure: Facility personnel are working on completing the installation of the new Facility Control System (FCS) (see 1/6/2023 report). Two weeks ago, facility personnel cut over portions of the new system to uninterruptible power supply power distribution panels. A delay due to issues with wire tracing left the FCS out of service for longer than anticipated, which delayed restoration of the facility to normal operations mode following the weekend work. This weekend, there will be another FCS outage to perform similar work. Facility personnel have taken photographs of wiring to alleviate similar wire tracing confusion during the upcoming cutover. A two-week outage is planned for the end of March to support the transition to the new FCS.

Onsite Transportation: On Monday, Triad provided a revised response to the NNSA Field Office regarding proposed compensatory measures to increase the safety of onsite transportation of nuclear materials while DOE reevaluates its approach to developing transportation safety documents (see 12/16/2022 report). The new response commits to implement a series of compensatory measures for high material-at-risk (MAR) onsite transfers of transuranic waste within sixty days. The response also states that non high MAR transfers will use existing controls, and there will be no high MAR transfers that are not transuranic waste until the transportation safety document is updated. A key compensatory measure is that the limit for high MAR transfers is dropping to 8.8 kg plutonium-239 equivalent from 20 kg plutonium-239 equivalent.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 10, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussof and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending February 10, 2023

Plutonium Facility–Infrastructure: Last Friday evening, as part of the on-going Facility Control System upgrade, facility personnel were working on a de-energized panel adjacent to an energized panel that had been installed two weeks prior (see 2/3/2023 report). An electrical worker identified a missing bushing on the energized panel, which should have been installed two weeks prior, and performed an out-of-scope repair. A live lead met the panel wall causing two breakers to trip, the local 120V as well as one in a 480V panel further upstream. On Monday, facility personnel held a fact-finding meeting that identified several potential corrective actions including: formalizing the turnover process from swing shift to night shift, performing an extent of condition review on training among electricians as this worker had not yet completed the required core electrical safety training, using flagged or marked panels to denote their energy status, and assembling a learning team to discuss the absence of voltage checks. The system impacts from this event prevented restoration of the facility to normal operations until Thursday evening.

On Monday, the NNSA Field Office concurred on the Fiscal Year 2023 Technical Area 55 Project Execution Strategy (see 1/6/2023 report). This is the first time the Field Office formally concurred on the strategy that documents planned upgrades, modifications, and maintenance at the Plutonium Facility. The concurrence letter notes that a key change for 2023 is removal of line item funding to support a safety-class active confinement ventilation system from the TA-55 Reinvestment Project III. This is inconsistent with a previous NNSA decision that removed said funding in 2016 (see 11/25/2016 report). In a 2020 briefing to the Board, NNSA again stated that the end state of facility would involve a seismically qualified safety-class active confinement ventilation system (see Exhibit 16 from DNFSB Public Hearing 11/16/2022). In a letter dated 3/15/2022, NNSA communicated to the Board the revised strategy for the active confinement ventilation system and NNSA and LANL discussed this strategy during the Public Hearing on 11/16/2022.

Chemistry and Metallurgy Research Building (CMR): Last week, CMR workers recognized that they failed to execute a required surveillance in August 2022. The requirement is to test open faced hoods handling nuclear material for adequate air flow biannually. During the surveillance evolution last week, a worker noticed three hoods were omitted from the work documentation. Upon further investigation, the workers determined that the surveillance had been skipped in February 2022 due to the room having an access restriction, and the three hoods were not included in subsequent work documentation for August 2022. All three hoods were tested and passed minimum air flows last week. On Monday, a fact-finding meeting was held to discuss the incident. Meeting personnel identified several potential corrective actions including updating the procedure to include fixed data (e.g., hood numbers and dimensions), evaluating a method to improve the tracking of surveillances through completion, and performing an extent of condition review to flag other surveillances that rely on previous paperwork to baseline current needs.

Area G–Stop Work: On Wednesday, N3B released the stop work on excavation of corrugated metal pipes (CMPs), and shortly thereafter, the Environmental Management Field Office released their pause (see 2/10/2023 report). N3B personnel completed and explained conducting a series of new soil penetrometer tests intended to justify that the existing slope of the excavation is acceptable for the soil characteristics. CMP retrieval has not yet resumed as personnel continue to validate that all training, maintenance, and other requirements are in place and documented.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 17, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending February 17, 2023

Board Activity: On Friday, the resident inspectors and staff member D. Bullen joined Vice Chair T. Summers on a tour of the Trinity Site with Sandia Field Office personnel, hosted by the Defense Threat Reduction Agency.

Staff Activity: M. Sautman was on site to evaluate resident inspector performance. R. Jackson and Y. Li attended a workshop in Los Alamos on the Plutonium Facility Seismic Performance Reassessment Project.

Plutonium Facility–Criticality Safety: Triad personnel identified two unanalyzed criticality safety scenarios for the vault in the Plutonium Facility. First, a new technical basis suggests that the previous 4” flooding depth due to fire sprinkler actuation in the vault is not defensible and new, higher numbers are more appropriate. The impact of this greater depth of moderator is under evaluation. The second scenario involves repackaging operations and the potential for open containers to fill with water if sprinklers actuate. While criticality safety personnel evaluate these scenarios, vault operations are limited. No overpacking or placement of containers on the floor is currently allowed.

Los Alamos Neutron Science Center (LANSCE)–Emergency Response: On Monday, a fire broke out in a non-radiological LANSCE building. An employee smelled smoke coming from a room where an ultrasonic cleaner, which heats and agitates ethanol, was being used. The employee extinguished the fire, called the emergency operations support center and 911, but did not activate the fire alarm pull station. The Los Alamos Fire Department responded to the scene, performed smoke venting, and released the facility soon thereafter. The following afternoon, facility personnel held a fact-finding meeting to discuss the incident. Meeting participants noted that the equipment had been left unattended and there was poor housekeeping in the area, which contributed to the fire spreading several feet across the lab table. The worker’s account was that 2-to-3-foot flames were present when they used the portable fire extinguisher. Facility management initiated a housekeeping pause in response to this event.

Readiness: Triad personnel started a self-assessment of their readiness to harvest containers containing high quantities of heat source plutonium that will exceed normal material at risk limits (see 4/1, 7/8/2022 reports). The assessment will continue next week, and concurrent contractor and federal readiness assessments will take place prior to startup.

A contractor team commenced their readiness assessment for plutonium coupon studies at the Weapons Engineering Tritium Facility. The review will continue into next week, and a federal readiness assessment will follow.

Transuranic Waste Facility (TWF)–Safety Basis: The NNSA Field Office transmitted a letter to Triad stating that the revision to the TWF safety basis is not approved, and that a new revision addressing field office comments should be provided (see 12/23/2022 report). Of note, the field office provided mandatory comments on the lengthy new completion times for limiting condition of operation actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 24, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending February 24, 2023

Staff Activity: D. Brown, M. Dunlevy, and P. Migliorini were on site to start their review of the enhanced chemical compatibility evaluation process for transuranic waste (see 7/8/2022 report). The team went to the analytical chemistry laboratory and the aqueous chloride room in the Plutonium Facility to better understand those processes in terms of the chemicals used and transuranic waste generated from them. D. Brown also observed Central Characterization Project activities on site.

Plutonium Facility–Readiness: A management self-assessment (MSA) team completed its review to assess the readiness to perform the upcoming campaign to process large quantities of heat-source plutonium (see 2/17/2023 report). On Thursday, the team briefed NNSA Field Office and Triad personnel on their initial results, which included five pre-start findings, two post-start findings, and four noteworthy practices. Pre-start findings included revising procedures, further analyzing hazards to ensure controls are integrated into the procedures, and adding specificity to the startup plan as called for by DOE Standard 3006, *Planning and Conducting Readiness Reviews*. The MSA team stated that the activity is ready to move to the contractor readiness assessment once the pre-start findings are completed. A federal readiness assessment will be completed concurrent with the contractor readiness assessment.

PF-400: Earlier this month, the NNSA Field Office authorized PF-400, the facility formerly known as the Radiological Laboratory Utility Office Building, to operate as a hazard category 3 nuclear facility. An independent review team from the local and Sandia NNSA Field Offices reviewed all pre-start corrective actions and concluded they had been satisfactorily completed. Initial operations will take place under an approved startup plan.

Environmental Management–Contractor Assurance: On Thursday, the Environmental Management Field Office issued the final report for a combined assessment of N3B’s contractor assurance system and the Field Office’s oversight activities. The assessment report lists fourteen opportunities for improvement leading to seventeen recommendations to improve processes. Recommendations included: better balancing of federal oversight activities between emerging issues and routine activities; improve risk-based oversight and refine metrics to better inform risk using guidance from the Energy Facility Contractors Group, other DOE sites, or industry best practices; and, provide effective tools to federal staff to consolidate the results of oversight efforts into defensible feedback to the contractor.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 3, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending March 3, 2023

Weapons Engineering Tritium Facility (WETF)–Readiness: The contractor readiness assessment team evaluating plutonium coupon study operations completed its review and briefed its initial results to facility management on Monday (see 2/17/2023 report). The team presented six pre-start findings. These included two related to emergency preparedness that identified issues with the operational drill program as well as with abnormal operating and alarm response procedures. A federal readiness assessment is planned prior to introducing plutonium to WETF.

Plutonium Facility–Transuranic Waste Management: Last month, transuranic waste management personnel identified that, in December, workers added absorbent to a waste drum without acceptable knowledge personnel present as required by the procedure for characterization and absorption of liquids. The drum went through the visual inspection and visual examination processes in January. Acceptable knowledge specialists discovered the error when they noticed they were missing data on the amount of absorbent added to the drum. Personnel involved in the event have several corrective actions planned to prevent recurrence and ensure drums are prepared properly for disposal at the Waste Isolation Pilot Plant (WIPP). These include assuring drums meets all WIPP Waste Acceptance Criteria, performing a major rewrite of the procedure for absorbing liquids including adding training and placekeeping requirements, and conducting training for both operations personnel and acceptable knowledge personnel.

Plutonium Facility–Criticality Safety: Vault activities are still impacted by the recently identified criticality safety concerns (see 2/17/2023 report). Three operational restrictions were eased this week. First, overpacking of non-fissionable materials is now allowed on the floor or on a transport cart. Second, overpacking of low mass fissionable containers and oxides are now authorized on a transport cart. Third, non-standard containers containing no fissionable material may be placed on the floor to support operations. All other restrictions on container placement remain in place.

Conduct of Operations: The Associate Laboratory Directorate for Weapons Production issued a new procedure for conducting fact-finding meetings to supplement the laboratory-wide institutional procedures on performance improvement and issues management. The new procedure includes a recommended timeline for holding fact-finding meetings more expeditiously after events.

Federal Oversight: On Tuesday, an NNSA Facility Representative for the Plutonium Facility completed final qualifications following a walkdown of the facility with the NNSA Field Office Manager. This brings the number of fully qualified Facility Representatives assigned full-time to the Plutonium Facility up to two. The Field Office has a large class of facility representative candidates in training who will be assigned to facilities as their training progresses.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 10, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending March 10, 2023

Staff Activity: W. Dumayas and R. Jackson were onsite as part of their review of the seismic testing of the fire suppression system (FSS) at the Plutonium Facility. The team met with facility management and engineering personnel to discuss test results and plans for future testing in Reno, Nevada, to characterize the performance of FSS cast iron fittings under simulated seismic loads (see 12/2/2022 report). The DNFSB headquarters staffers did two entries into the Plutonium Facility. First, a familiarization tour led by the resident inspectors that also included three NNSA fire protection personnel from the field office and the Chief of Defense Nuclear Safety's assessment team. The second entry was supported by Triad engineering personnel to walk down key aspects of the FSS including the pumphouses, risers, and piping with seismic support upgrades.

Plutonium Facility–Legacy Items: Last week, workers attempted to address a safe in a laboratory room with ongoing decontamination and decommissioning activities. Facility personnel were unable to identify the origin or organization responsible for the safe. Based on available information, they believed the safe was used for document storage only and executed the plan to drill open the safe to verify the nature of any contents. Upon opening the safe, workers discovered seven shielded material handling containers of questionable provenance, two of which were open and empty, and five closed. Additional personnel were called in to help determine the origin of these containers, including radiological control technicians, who surveyed them and did not detect any radioactivity beyond background from the shielded containers. Later, due to the uncertainty of the contents of the containers, facility personnel declared a potential process deviation and restricted access to the room. The fact-finding meeting for this event, held on Monday, was the first under the new process for Weapons Production facilities (see 3/3/2023 report).

Area G: N3B personnel resumed retrieval of corrugated metal pipes (CMP), which have not taken place since the heat stress incident last September (see 9/16/2022 report). A previous attempt to resume retrieval resulted in a stop work to address concerns from the Environmental Management field office, which have since been resolved (see 2/3, 2/10/2023). Last Wednesday, the team excavated one CMP from the burial pit. This Wednesday, they transported it to a staging pad where the CMPs will remain until size reduction activities are authorized. The work crew performed a post job review to evaluate potential improvements and plan to continue excavations next week.

Onsite Transportation: On Wednesday, the NNSA Field Office concurred with Triad's plan to update the Transportation Safety Document by June 2023 and implement compensatory measures until the update is complete and any new controls are implemented (see 2/3/2023 report).

Federal Oversight: A team led by NNSA's Chief of Defense Nuclear Safety was onsite this week as part of their 2023 review of the NNSA Los Alamos Field Office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 17, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending March 17, 2023

Plutonium Facility–Infrastructure: On Monday night, the cool down spray for a HEPA filter housing actuated. The operations center reported receiving a signal from a high temperature detector in the housing at the time of the cooldown spray system actuation. The Los Alamos Fire Department (LAFD) received notification via a water flow alarm. LAFD responded, cleared the basement, and found no evidence of a fire. LAFD reported four feet of water in the first stage of the housing, with no evidence of water leaking from under the access doors. Water eventually spread across the entire housing, settling to approximately 1.5 feet deep (estimated 4,700 gallons of water). Additionally, a substantial area of the basement was flooded with a few hundred gallons of water from overflow of the retard chamber on the fire riser supplying the housing. Initial attempts to isolate the release were delayed due to issues identifying local isolation valves and poor seating of a valve at the riser. The release was eventually stopped by closing the outdoor post indicator valve supplying the plenum cool down spray system. The cause of this system activation is still under investigation.

Basement floor water sampling revealed no contamination and cleanup is underway. Recovery efforts will include water sampling, draining, and processing through the Radioactive Liquid Waste Treatment Facility, and finally replacement and testing of new HEPA filters. The recovery timeline for this incident is expected to be on the order of weeks.

There was a similar inadvertent actuation of the deluge system protecting the PF-400 ventilation system in 2019 (see 6/14/2019 report). In 2021, the NNSA Field Office approved an equivalency to disconnect this system based on the results of a computational fluid dynamics simulation which is intended to demonstrate that the dilution of air during a fire is sufficient to keep filter temperatures below requirements in lieu of water for cooling (see 11/5/2021 report). Triad is considering requesting a similar equivalency to disconnect these systems for the Plutonium Facility (see Board letter 12/6/2022).

N3B–Area G Stop Work: Last Friday evening, following questions from the Environmental Management Field Office, N3B personnel paused work on the recently resumed excavation of Corrugated Metal Pipes (see 3/10/2023 report). On Saturday morning, N3B senior management elevated the pause to a stop work. The reason they stopped work was to verify compliance of the excavation with all applicable engineering standards and Occupational Safety and Health Administration requirements invoked by 10 CFR 851, *Worker Safety and Health Program*. There is currently no entry allowed into the excavation area.

Plutonium Facility–Readiness: Last week, a contractor team commenced the readiness assessment for restart of the Aqueous Nitrate Process at the Plutonium Facility. This is the last major process that has not resumed operations following the 2013 Director’s Pause. A limited operation of the cement fixation process, which is one of the aqueous nitrate operations, did take place in 2018 (see 9/14/2018 report). The above flooding event has impacted the ability for personnel to perform cold demonstrations for the assessment team and the readiness review is being extended to allow for review of the full suite of activities. Demonstrations are tentatively rescheduled for April 2023.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 24, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending March 24, 2023

Staff Activity: A. Kline, one of the Board's resident inspectors at the Savannah River Site, was on site to benchmark oversight approaches. M. Bradisse and R. Eul were on site providing additional support.

Plutonium Facility–Infrastructure: Facility personnel continued recovery efforts from the HEPA filter cool down spray actuation last week (see 3/17/2023 report). HEPA filter housing water sampling revealed no contamination, so the plan remains to drain remaining liquid and process it through the Radioactive Liquid Waste Treatment Facility. Triad entered the New Information process to determine any safety basis implications of this event. Access to the impacted wing of the facility is controlled by a standing order issued on Monday. The standing order specifies respiratory protection for entry into laboratory rooms and a room monitor with a radio stationed outside to communicate any changes in ventilation status between entry groups and Operations Center personnel.

Chemistry and Metallurgy Research Building (CMR): On Thursday, Triad submitted a revised temporary safety basis modification for CMR to support the third phase of activities to disposition americium bearing material from an offsite location (see 12/14/2018 report). These materials have been repackaged and characterized via gas sampling, imaging, and nondestructive assay. The next step is to unpack the inner containers for processing and final disposition of the material. Based on the characterization results, personnel determined there are no additional hazards beyond the radioactive material contained in inner containers. Therefore, the revised temporary modification proposes removing previous temporary controls and completing phase three activities under the controls currently established in the existing safety basis. The new temporary mod will be closed as soon as it is approved.

Federal Oversight: The staff and resident inspectors met with Environmental Management Field Office (EM-LA) personnel to discuss improvements in their oversight processes since the Board's August 17, 2022 letter communicating the results of a complexwide review of DOE safety oversight effectiveness. Since the data collection supporting that letter, EM-LA has hired additional federal and technical assistance contractor personnel into needed positions, revised a substantial fraction of their command media, and increased their level of oversight activities. EM-LA management is working to inculcate a culture of oversight into their staff and ensure that everyone recognizes their oversight responsibilities and is effective in their activities.

Area G–Safety Basis: N3B held another workshop to support development of a modern DOE-STD-3009-2014 compliant safety basis for Area G (see 1/27/2023 report). A resident inspector and staff members accompanied one of the workshop attendees from the DOE Chief of Nuclear Safety's Office and an EM-LA staff member on a visit to Area G. The primary purpose of the visit was to observe the implementation of controls in Dome 33 that support safe storage of potentially reactive drums and high fissile gram equivalent drums.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 31, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending March 31, 2023

Staff Activity: M. Bradisse, R. Eul, and B. Weathers were on site to review Triad's nuclear criticality safety program.

Chemistry and Metallurgy Research Building (CMR): This Wednesday, CMR personnel recognized that they failed to enter the appropriate limiting condition for operations (LCO) after they identified a degraded fire suppression sprinkler head during an annual surveillance of the safety-significant system the day before. The worker performing the surveillance notified operations and engineering personnel; however, the appropriate LCO was not entered, and this information did not go through the operability determination process until the following day. On Thursday, a fact-finding was held to discuss the incident. Meeting personnel identified several potential corrective actions including reviewing the associated work documents to ensure clarity and alignment with the facility technical safety requirements (TSRs), implementing more rigor in use-every-time procedures, and reviewing deficiencies identified during TSR surveillances daily.

Plutonium Facility–Infrastructure: Facility personnel continued recovery efforts from the HEPA filter cool down spray actuation (see 3/17/2023 report). Last Friday, workers began siphoning water from the flooded HEPA filter housing into one of the basement sumps. The following day, they added pumps to help speed up the process. Shortly thereafter, workers noticed that an adjoining sump began to overflow and paused work. Water sampling revealed contamination around the overflowed sump. On Monday, workers pumped down the overflowed sump and discovered a broken float. A recovery plan was implemented to clean and decontaminate the area which began Tuesday and continued through the week. On Wednesday, the HEPA filter housing draining activities resumed at a reduced flow rate and with additional personnel monitoring sump conditions: one stationed at receiving sump, one at the overflowed sump, and another on a rotational basis for the remaining facility sumps. Next week, facility personnel plan to commence HEPA filter replacement activities. Access to the impacted wing of the facility remains controlled by a standing order which specifies entry requirements (see 3/24/2023 report).

Plutonium Facility–Operations: Last week, Triad personnel performed a shot using the Isotope Fuels Impact Tester. During post-shot activities, the workers discovered contamination indicating a potential fuel clad breach. They followed the contingencies in their procedures and returned the equipment to a safe configuration. There was no detectable personnel contamination or any evidence of an uptake. Recovery activities to determine the condition of the fuel clad and restore the system are being planned under the standing order for infrequent or unusual work activities.

Federal Oversight: The NNSA Field Office held a qualifying oral board in criticality safety for a staff member. The candidate performed well. The Field Office brought in two federal criticality safety experts from other NNSA organizations to be members of the evaluation board. The Field Office currently has two personnel assigned to criticality safety oversight. The other individual completed their oral board in early February.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 7, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending April 7, 2023

Staff Activity: A headquarters staff team participated in a teleconference with DOE and N3B personnel to discuss the development of the atmospheric dispersion protocol planned for use with the new DOE Standard 3009-2014 compliant documented safety analysis under development for Area G.

Chemistry and Metallurgy Research Building (CMR): This Tuesday, CMR personnel held a fact-finding meeting to discuss an incident where a worker entered a restricted area without authorization or the proper personal protective equipment (PPE). The worker entered a filter tower to perform work and, upon realizing others in the area had different PPE, notified a radiological control technician in the area. The technician checked the worker for contamination and allowed them to leave the area. During the meeting, the worker noted they entered the area through a door from the attic, that the rope restriction was not installed across the entire entryway, and that they misunderstood the access restrictions in place. Radiological control personnel countered that the intent of the rope-style barrier should have been evident, the area was “red lit,” and appropriate postings were in place. Meeting personnel identified several potential corrective actions to prevent recurrence, including designating entrances from the attic to filter towers as non-normal entryways, evaluating radiological control barrier practices, and holding a lessons learned meeting for all CMR residents.

Plutonium Facility–Emergency Management: Facility personnel held a discussion-based emergency preparedness drill for the Plutonium Facility. The scenario was a chlorine leak inside of a laboratory room involving the chlorine system that was upgraded last year (see 11/11/2022 report).

Plutonium Facility–Infrastructure: Facility personnel continued recovery efforts from the HEPA filter cool down spray actuation (see 3/17/2023 report). This week, workers completed the installation of new HEPA filters across the affected housing. On Thursday evening, the photometer used for efficiency testing of the filters failed and no calibrated spares were readily available at the Plutonium Facility. On Friday, filter testing was completed using a calibrated photometer from CMR. Facility personnel are working directly with the photometer manufacturer to ensure additional calibrated spares are available. Next week, facility personnel plan to finalize HEPA filter testing and lift the standing order controlling access to the impacted wing of the facility (see 3/24/2023 report).

Area G–Readiness: A federal team performed a readiness assessment for size reduction of corrugated metal pipes. The team identified 9 pre-start findings, 4 post-start findings, and 11 deficiencies. Notable findings included open deficiencies in the fire hazard analysis pertaining to a new diesel fuel tank, the flow-down of operating requirements into procedures, and missing calibration for a pressure gauge on the hydraulic shear.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 14, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending April 14, 2023

Staff Activity: On Tuesday, a headquarters staff team held a call with Triad and NNSA Field Office personnel to continue interactions supporting their review of the enhanced chemical compatibility evaluation process for transuranic waste (see 2/24/2023 report). On Thursday, a different headquarters team held a call with Triad and NNSA Field Office personnel to start a review of glovebox glove integrity processes. And, on Friday, a third staff team held a remote interaction with Triad and NNSA Field Office personnel as part of a review of decontamination and decommissioning activities at the Plutonium Facility (see 12/9/2022 report).

Criticality Safety: On Wednesday, the NNSA Field Office formally transmitted to Triad the final report from the Criticality Safety Support Group's (CSSG) assist visit in January (see 1/13/2023 report). The letter acknowledges that Triad has already been acting on the CSSG's recommendations. Consequently, the letter requests that Triad formally transmit documentation from its issues management system regarding the status of those actions. Major changes already in progress include a reorganization of the Nuclear Criticality Safety division, which includes new leadership, a structure intended to better align with programmatic needs, and more senior technical positions including a chief engineer.

Plutonium Facility–Glovebox Safety: There have been three glovebox glove breaches in the past few weeks. In all cases, there was no skin contamination or evidence of an uptake, and the involved workers discovered the breaches immediately following contamination surveys upon exiting glovebox gloves. This week, facility personnel held a fact-finding meeting to discuss these breaches, evaluate whether there were any commonalities between the events, and develop actions to prevent recurrence. One event involved repetitive motion using a hand pump. Workers believed that caused undue wear on the glove, and efforts are in progress to replace the manual operation with an automated system. This is a relatively new activity, so personnel are also evaluating appropriate glove replacement timing as more data is gathered. Another event involved vigorous wire brushing of a part which is an infrequent activity. Evaluation of increased overglove usage and reinforcement of using tabs when taping items are potential corrective actions related to that breach.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): On Thursday, the NNSA Field Office unconditionally approved the latest Safety Design Strategy (SDS) for restarting WCRRF as a hazard category 3 nuclear facility. This revision addressed NNSA's directed changes from the previous version (see 12/23/2022 report). WCRRF was last operated as a hazard category 2 nuclear facility and will be restarted to support decontamination and size reduction of large items such as gloveboxes. The SDS proposes a strategy relying largely on limits on material at risk and does not expect credited engineered controls will be necessary. While efforts to develop a new safety basis for restart are in progress, the facility remains in cold standby under its existing hazard category 2 safety basis, which is an antiquated Basis for Interim Operations with an addendum to support addressing a drum of unknown contents currently in the WCRRF Glovebox Enclosure.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 21, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending April 21, 2023

Staff Activity: M. Bradisse was on site to observe the resumption of the contractor readiness assessment for restart of the Aqueous Nitrate Process at the Plutonium Facility. Field demonstrations for this assessment were rescheduled following the flooding event in the basement of the facility (see 3/17/2023 report). Facility personnel completed replacement of HEPA filters and restoration of ventilation in the impacted wing prior to the start of last week.

Plutonium Facility–Criticality Safety: Triad personnel identified a disconnect between criticality safety documentation and the safety basis regarding seismic qualification of nuclear material safes. A subset of safes in the facility are credited to remain upright during seismic events to prevent formation of a critical geometry. Safes required to perform this function are first identified in criticality safety analyses and then designated in the safety basis as a safety-significant control through a process defined in the site’s Criticality Safety Program. Triad personnel recently identified deficiencies in the documentation for one of the safes, and a subsequent extent of condition review in progress has identified several other safes with documentation issues. Triad personnel are working to ensure that all safes credited with this safety function have been identified and documented appropriately.

Plutonium Facility–Glovebox Safety: There were two glovebox glove breaches this week. Neither resulted in skin contamination or indication of any uptake. Workers identified one following a radiological survey performed immediately upon exiting the glovebox gloves, and the other was discovered following radiological monitoring at the laboratory room exit. Facility management is including further evaluation of these events into the ongoing evaluation of three other recent glovebox glove breaches (see 4/14/2023 report).

Area G–Safety Basis: On Tuesday, N3B transmitted their site-specific atmospheric dispersion protocol to the Environmental Management Field Office for approval (see 4/7/2023, 6/17/2022 reports). Key approaches used in this protocol include: use of the default χ/Q dispersion parameter for co-located worker consequences; use of plume buoyancy effects for some fire accident scenarios; and use of time-based plume meander correction for longer release durations. The Board’s staff plans to review how this new protocol will be used to establish dose consequences in the new safety basis under development for Area G.

PF-400–Electrical Safety: Last Thursday, electricians contacted an energized switch while torquing electrical components for equipment installation in PF-400. While no one was injured, the workers observed sparks. The work documentation for this task had recently been revised and no longer included a lockout/tagout for this scope of work. One of the immediate corrective actions from the event was to reinforce the need to perform zero energy checks by having a superintendent or higher observing the check. This requirement has also been put in place at the Plutonium Facility. Other corrective actions include a review of other electrical jobs in progress and an evaluation of work planning processes for revision of construction work packages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 28, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending April 28, 2023

DNFSB Staff Activity: The Resident Inspectors were in Washington, D.C. to brief the Board and attend meetings. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 5, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending May 5, 2023

Staff Activity: On Tuesday, a staff review team held a remote interaction with Triad and NNSA Field Office personnel supporting their continuing review of Triad's nuclear criticality safety program (see 3/31/2023 report).

Plutonium Facility–Readiness: Last week, a contractor team completed the readiness assessment for restart of the Aqueous Nitrate Process at the Plutonium Facility (see 4/21/2023 report). The team briefed NNSA Field Office and Triad personnel on their initial results, which included five pre-start findings and three post-start findings. One finding involved issues with procedures that cannot be performed as written, inadequate procedure validation, and inadequate subject matter expert review of procedures. Other findings included issues with operations records management, inadequate linkage of criticality safety parameters with the master equipment list, and an ineffectively closed pre-start finding previously identified during the management self-assessment.

Plutonium Facility–Safety Basis: Triad transmitted to the NNSA Field Office, for information, a major re-baseline of the project execution plan for upgrading the Plutonium Facility's safety basis to meet DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis* (see 7/22/2022, 7/19/2019 reports). The new plan now expects submittal of a completed safety basis to the field office for approval in the first quarter of fiscal year 2024. Triad also recently submitted to the NNSA Field Office, for concurrence, a revision to their methodology for calculating leak path factor and atmospheric dispersion. This methodology will support mitigated accident analysis in the safety basis under development.

Plutonium Facility–Emergency Response: On Tuesday, glovebox workers noticed sparking and a small fire while they were moving materials into a bag within a glovebox. The fire self-extinguished. Personnel in the room evacuated, made appropriate notifications, and the fire department responded. They found no evidence of continued thermal activity. As the response to this event was largely successful, facility personnel plan to issue a lessons learned to share this proper response to a fire. One corrective action from the event is to evaluate the positioning of dropbox manual fire alarm initiating devices as some are located too high for all employees to readily reach.

Plutonium Facility–Electrical Safety: Facility workers identified that wiring in the system that performs electrolytic decontamination of plutonium containers was degrading rapidly. The insulation was cracked, consistent with thermal damage. The system has been having issues with electrical components for several months and has undergone several component replacements including a power supply. These changes were not reviewed by electrical safety officers. Last month, when management became aware of the degradation, they paused the operation and requested a walkdown by electrical safety officers. The system is currently out of service while personnel work to identify the cause of the wire degradation and conduct repairs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 12, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending May 12, 2023

Staff Activity: N. Huntington and E. Tetteh were on site to attend a training course on DOE-STD-5506, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*, sponsored by the DOE Office of Environmental Management. A. Boussouf was at the Pantex Plant providing resident inspector coverage. Y. Li attended a meeting in Walnut Creek, CA regarding the update to the Los Alamos Probabilistic Seismic Hazard Analysis.

Area G–Emergency Response: On Monday, workers in Area G smelled a solvent-like odor in Dome 230 and later reported symptoms. Area G personnel entered their emergency response procedure, and the Los Alamos Fire Department and Triad Emergency Management personnel responded. Other than an initial miscommunication on dose rates, responders detected no abnormal chemical or radiological activity. Later in the week, N3B personnel developed a recovery plan to reenter Dome 230 and confirm that there was no evidence of a breached transuranic waste drum or other hazards. The plan included a slow entry while monitoring for chemical and radiological conditions. It included surveys of potentially reactive drums, designated locations in the dome, and a selection of other drums. They performed an initial dome entry on Thursday afternoon and found no abnormal chemical radiological readings. The dome is still restricted while more samples are being collected and analyzed.

Plutonium Facility–Criticality Safety: In April, Triad nuclear criticality safety personnel issued a revised technical basis for credible water accumulation in the vault due to fire sprinkler activation (see 2/17/2023, 3/3/2023 reports). The new calculations have a maximum flooding depth of 5.7’; the previous revision had 4’. Last week, Triad personnel suspended vault activities. Vault activities were already limited due to the previous revision of the water accumulation technical basis, and Triad personnel are evaluating whether current operational restrictions are adequate for the new flooding depth. Triad has been developing a process to address unknowns in nuclear criticality safety space similar to the unreviewed safety question process used for safety basis. This process is still under development, and this latest question regarding water depth in the vault was used as a pilot activity to support finalizing the process.

Plutonium Facility–Infrastructure: Last Friday, the Plutonium Facility entered standby mode, which curtails allowable work activities, to support two planned safety system upgrade activities. One is the cutover to the new Facility Control System. This process requires periodic securing of ventilation fans. The second upgrade activity involves the south fire riser, which will put part of the fire suppression system out of service.

Triad transmitted to the NNSA Field Office for formal review, the draft preliminary documented safety analysis (PDSA) for the Los Alamos Pit Production Project 30 reliable mission. The PDSA is based on the 30% design review and evaluates changes associated with the 30 reliable mission.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 19, 2023

TO: Christopher J. Roscetti, Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending May 19, 2023

Staff Activity: C. Beaty, M. Bradisse, and D. Bullen were on site to continue interactions with Triad and NNSA Field Office personnel supporting a staff review of Decontamination and Decommissioning (D&D) efforts at the Plutonium Facility and at the Chemistry and Metallurgy Research Building (CMR).

Plutonium Facility–Safety Basis: Triad submitted a temporary safety basis modification for the Plutonium Facility to the NNSA Field Office for approval. The temporary modification supports continued operation of specified gloveboxes during D&D activities. Removing gloveboxes can change the seismic performance of interconnected gloveboxes to below their requirements until new gloveboxes are installed. The temporary modification proposes identifying gloveboxes whose seismic performance will be degraded and treating them like existing gloveboxes that do not meet required seismic performance. There are no new proposed controls; the temporary modification instead identifies the existing compensatory measure of the seismic power shutdown system. Any of these gloveboxes that have criticality safety evaluations that rely on seismic performance to maintain geometry control will have to revise those evaluations.

Plutonium Facility–D&D: Last month, personnel performing a walkdown to support additional holdup measurements in a laboratory room undergoing D&D activities discovered four unlabeled metal containers in an out-of-service glovebox. An extent of condition review discovered several other containers of uncertain provenance in other gloveboxes in the room. Existing holdup measurements suggest that none of these containers contain significant quantities of nuclear material. Facility personnel plan to ensure a criticality safety evaluation is in place, change glovebox gloves, and perform other safety reviews before they can inspect and remove these containers. Meanwhile, personnel are continuing to develop processes for responding to the discovery of unexpected materials during D&D activities (see 1/20/2023 report).

Plutonium Facility–Infrastructure: The Plutonium Facility remains in standby mode to support upgrade activities (see 5/12/2023 report). The outage is expected to end at the beginning of the next work week when the facility will return to operations mode. Further testing of the new facility control system will be completed in standby mode over the next several weekends. As the new system is functional, but not fully operable per the definitions in the safety basis, the facility will enter operations mode under the conditions of the temporary modification to the safety basis that allows additional flexibility during commissioning of the new system (see 10/28/2022 report).

Chemistry and Metallurgy Research Building–D&D: Last month, the D&D subcontractor at CMR performing low-level waste removal completed their activities. Higher hazard D&D activities at CMR such as glovebox removals are still paused and are awaiting more characterization data. The current path forward is to develop a sampling and analysis plan to characterize gloveboxes in fiscal year 2024 which should support resumption of glovebox removals in fiscal year 2025 (see 12/9/2022 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 26, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussof and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending May 26, 2023

Staff Activity: On Monday, a headquarters team held a second remote interaction with Triad and NNSA Field Office personnel to continue the staff's review of glovebox glove integrity (see 4/14/2023 report).

Emergency Management: On Tuesday, the resident inspectors accompanied NNSA Field Office, Triad, and Los Alamos Fire Department personnel on a tour of the Los Alamos Medical Center Hospital decontamination unit and discussed their capabilities to receive and treat radiologically contaminated individuals.

Area G–Operations: Last Thursday, N3B personnel partially restored access to Dome 230, which was restricted following the emergency response event two weeks ago (see 5/11/2023 report). Continued radiological and chemical sampling activities following the event identified no unusual readings. Access to the dome is currently controlled with a daily shift order providing interim entry requirements while additional evaluations are performed. The shift order requires that industrial hygiene personnel survey Dome 230 to assess facility conditions at least once a day when work activities will be performed in the dome. It also requires that any workers entering the dome be accompanied by a qualified individual with industrial hygiene monitoring equipment. With access to Dome 230 partially restored, N3B personnel were able to complete moving all remaining waste containers identified as having the potential for energetic chemical reactions to Dome 33 (see 11/26/2021 report).

Last week N3B management released the stop work on excavation of corrugated metal pipes (CMPs) (see 3/17/2023). This week they completed excavation of one CMP and moved it to the staging pad for future size reduction. Closure of corrective actions from the federal readiness assessment for CMP size reduction operations are nearing completion, and facility personnel plan to commence size reduction this summer (see 4/7/2023).

Plutonium Facility–Safety Basis: The NNSA Field Office concurred on the revised Project Execution Plan for upgrading the Plutonium Facility's safety basis (see 5/5/2023 report).

Plutonium Facility–Infrastructure: The Plutonium Facility remained in limited operations mode this week (see 5/19/2023 report). Personnel completed the planned connection efforts for the new facility control system; however, fire riser work is still in progress.

Chemistry and Metallurgy Research Building–Safety Basis: The NNSA Field Office responded to Triad's submittal of the self-terminating temporary safety basis modification supporting the third phase of disposition activities for americium bearing material from offsite (see 3/24/2023 report). The Field Office did not approve the submittal and requested that Triad either update the existing safety basis or update the temporary modification to provide sufficient justification that the hazards associated with the activities are verified not to exist or can be remediated.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 2, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending June 2, 2023

Emergency Management: On Wednesday, the resident inspectors attended the annual wildland fire and forest management meeting with NNSA Field Office, Environmental Management Field Office, Triad, Los Alamos Fire Department, National Park Service, and U.S. Forest Service personnel. Due to higher than average moisture, the current wildland fire danger rating for the laboratory is low. The meeting concluded with a tour of a recently mitigated area showing current fuel reduction strategies, and a display of available wildland firefighting equipment, including a masticator, a brush truck, and a new lightweight water tender more capable of navigating fire access roads.

Plutonium Facility–Infrastructure: Triad submitted an update to the Safety Design Strategy for the Los Alamos Plutonium Pit Production Project (LAP4) to the NNSA field offices for approval. The document was revised to clarify the project’s approach to meeting glovebox line seismic performance criteria. This approach allows the release of glovebox enclosure installation packages without performing seismic cluster analyses across interconnected gloveboxes and instead completing them at a later date (see 5/19/2023 report).

The Plutonium Facility returned to normal operations mode following a three-week outage (see 5/26/2023 report). Personnel completed planned activities associated with three system upgrades to improve reliability: cutover to the new safety-significant facility control system; upgrades to the south fire riser, which is part of a safety-class system; and controller upgrades for the crosstown trolley, a non-safety system that is critical for efficiently moving materials within the facility. The facility control system and trolley work was completed without significant issues during the planned outage timeframe. The fire riser upgrade was a more challenging effort and took longer than expected, extending the outage. One key problem was successfully installing anchorages for fire water piping. There was also a lockout/tagout issue during fire riser work. Facility management held a hotwash this week to develop lessons learned to improve planning for and performance of future outages.

Plutonium Facility–Glovebox Safety: Weapons Production management is reinvigorating and expanding the glovebox and sharps program following recent glovebox glove events (see 4/21/2023 report). Their intent is to drive to zero preventable glove breaches by October 2023. In order to meet that goal, the new program owners have plans to increase staffing, expand forensic capabilities, and improve integration with conduct of operations mentors and causal analysts.

Onsite Transportation: Triad submitted to the NNSA Field Office for approval an update to the Transportation Safety Document and associated Technical Safety Requirements. The updated documents incorporate NNSA’s suggested compensatory measures within several new specific administrative controls as well as modifications of existing ones (see 3/10/2023 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 9, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending June 9, 2023

Staff Activity: Q. Boney attended a course on hazard analysis review sponsored by the National Training Center at the NNSA Field Office. A staff team held a remote meeting with Triad and NNSA Field Office personnel to discuss conclusions from the staff's review of Triad's atmospheric dispersion protocol that they developed to support modern safety bases compliant with DOE Standard 3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*.

Area G–Work Planning and Control: N3B and Central Characterization Project personnel are working to upgrade the high energy real-time radiography unit at Area G. Last Thursday, radiological control technicians reported concerns that subcontractor personnel had left the work area and Area G without having their tools surveyed out. There was no written requirement to survey tools, and the workers had not been in the area with radiological contamination from a historical spill. Further investigation of this concern identified a series of work planning weaknesses. The person in charge of the job should have been from N3B rather than the Central Characterization Project. The upgrade task was being performed using a generic maintenance radiological work permit. The subcontractor personnel did not meet the training requirements to work under said permit so at the pre-job briefing, the crew decided to work dismantlement of radiologically clean areas under the Facility Radiation Protection Requirements, the minimum basic radiological controls for entry into Area G, rather than under the radiological work permit as called out in the work documentation. This control change was not worked through standard practices and led to confusion on the radiological requirements for this portion of the job. The upgrade project is currently paused while facility personnel redevelop the work documentation for this task with appropriate radiological controls for the different tasks. N3B plans to perform a formal causal analysis on this event.

Plutonium Facility–Criticality Safety: Last Thursday, workers identified a container containing nuclear material that did not have an engineered spacer installed as required for the amount of material being moved. They recovered from the event, and the container is now compliant. This is the fifth event over the past two years where a spacer was missing when required. Facility management plan to evaluate these events for common causes to help prevent recurrence.

Plutonium Facility–Glovebox Safety: On Monday, workers completing a material breakout noticed a crack on a glovebox window. They exited the room under direction of a radiological control technician. There was no evidence of any airborne release or contamination spread; only the inner window of the double pane was cracked. The glovebox underwent an immediate operability analysis the day after the discovery, which determined it was operable as the crack does not impact the confinement function. The breakout activity is rather vigorous as it involves smashing a crucible with the pieces collected in a metal tray. Initial corrective actions include replacing the window, briefing new personnel on spatial awareness during breakouts, and having personnel from the glovebox and sharps program observe the next breakout activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 16, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending June 16, 2023

Transuranic Waste Facility (TWF): Last Thursday, TWF personnel discovered a missed Technical Safety Requirement (TSR) surveillance and entered the appropriate limiting condition for operation (LCO). Facility personnel were receiving drums containing sealed sources from Technical Area 55. Prior to receipt of drums in the shipping and receiving area, workers need to perform several TSR surveillances as described in the use-every-time attachment to a reference-use procedure for receipt. They did not perform the surveillance that verifies compliance with sealed source material-at-risk limits due to confusion with the receipt task description in the waste management tracking software. When the error was discovered, workers paused the activity, and entered the LCO. They performed the surveillance successfully a few hours later and exited the LCO. Initial corrective actions to prevent recurrence include modifying how the waste management software addresses receipts to reduce the chance of errors performing the surveillance using data from that database, and evaluating changes to procedures and forms used during receipts.

Plutonium Facility–Criticality Safety: Two weeks ago, workers in a laboratory room identified metal turnings of unknown provenance in a container labeled empty. They paused and reported the discovery per process. The amount of material-at-risk in the glovebox was still below criticality safety limits. A fact finding was later held to discuss the incident.

Area G: Environmental Management Field Office personnel paused retrieval of corrugated metal pipes (CMP) again. Upon questioning whether all workers had current training for silica hazards, it was discovered that not all of the radiological control technicians supporting the excavation activity had said training. The personnel are in respirators to protect from radiological hazards in the excavation, which will also protect against silica. N3B and Field Office personnel are working to lift the stop work and resume excavation. To date, N3B personnel have retrieved a total of four CMPs, one last September, and three following resumption this spring.

N3B and Central Characterization Project personnel completed mobile loading of two trailers of transuranic waste containers for shipment to the Waste Isolation Pilot Plant. Some of these containers did not meet the requirements for indoor shipping through RANT and required mobile loading. This infrequent activity was last performed at Area G in August 2022 (see 8/5/2022 report).

Sigma Facility: Last Thursday, a fire occurred while moving a metal component within a radiological area. The following week, facility personnel held a fact-finding meeting to discuss the incident. Meeting participants observed sparking near an acetone-soaked cloth used for cleaning, followed by ignition of the cloth. The workers immediately stepped away from the flaming cloth. One worker left to search for an extinguishing agent, while another worker extinguished the flames with a nearby cleaning agent. Facility personnel evacuated the facility and made notifications in accordance with approved procedures. Work in the area was paused pending a review of controls to mitigate similar hazards.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 23, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending June 23, 2023

Staff Activity: On Thursday, the resident inspectors met with the NNSA Associate Administrator for Environment, Safety, and Health and members of his staff, along with NNSA Field Office personnel, to discuss health and safety concerns at the Los Alamos National Laboratory. On Wednesday, a headquarters staff team held a remote interaction with Triad and NNSA Field Office personnel to support a complex-wide review of above and underground electrical power cables. On Thursday, a headquarters staff team held a remote interaction with Triad and NNSA Field Office personnel to provide initial conclusions from their review of seismic testing of Fire Suppression System fittings.

Plutonium Facility–Operations: Last Monday, facility personnel were heating a legacy item in a process furnace to burn off excess moisture or nitric species in preparation for disposition. Several hours later, workers noticed an abnormal amount of smoke emanating from the furnace, fogging of the glovebox windows, and elevated furnace temperatures. Workers actuated the emergency shutoff for the furnace and paused their work activities. The following day, operations personnel noticed evidence of a surface reaction on the stainless-steel glovebox internal walls as well as a glossy coating on the glovebox gloves. A fact-finding meeting was held to discuss the incident on Tuesday. Meeting participants noted that the item placed in the furnace may have had excessive residual moisture which was unapparent from external observation. Furnace activities remain paused pending chemical analysis of the glovebox interiors. Facility personnel plan to check for similar legacy materials slated for disposition to prevent recurrence.

Plutonium Facility–Readiness: This week, a contractor readiness assessment team and a federal readiness assessment team started their concurrent review of heat source plutonium harvesting planned at the Plutonium Facility (see 2/17/2023 report).

Plutonium Facility–Glovebox Safety: Last week there was one glovebox glove breach and one glovebox glove failure in the Plutonium Facility. The breach was in a heat source plutonium box where a worker felt airflow along their arm due to a substantial tear in the glove. They responded appropriately and remained in the glove while radiological control technicians arrived to assist. The source of the tear is still under evaluation. The other event was in a weapons grade box where an old, degraded glove developed a small crack upon use. Neither event resulted in skin contamination or any airborne alarms.

Area G–Safety Basis: Last Wednesday, the Environmental Management Field Office and Headquarters approved N3B’s site specific atmospheric dispersion protocol that will support the new Documented Safety Analysis under development (see 4/21/2023 report).

Federal Oversight: Last week, the NNSA Chief of Defense Nuclear Safety issued their report from their 2023 biennial assessment of the NNSA Field Office (see 3/10/2023 report). They reviewed ten functional areas and found that eight met expectations; one, emergency management, exceeded expectations; and one, conduct of operations/facility representative, did not meet expectations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 30, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending June 30, 2023

Staff Activity: J. Abrefah, M. Bradisse, F. Ruz-Nuglo, and E. Tetteh were on-site to continue their glovebox integrity review. Their visit included tours of a cold laboratory and the Plutonium Facility.

Plutonium Facility–Readiness: The contractor and federal readiness assessment teams completed their field activities and presented their initial findings regarding their parallel reviews of readiness to commence heat source plutonium harvesting. The contractor team provided six pre-start findings. The federal team concluded the contractor team performed adequately and mirrored the six contractor findings and added one additional pre-start and one post-start finding. The federal team will finalize its assessment following review of the final report from the contractor team. The most significant findings shared by the two review teams involved material-at-risk controls. There are inconsistencies on allowable material-at-risk within the safety basis supporting this activity, the implementing procedures, and the emergency planning hazards assessment.

Plutonium Facility–Emergency Management: On Wednesday, Triad personnel performed the annual criticality evacuation drill for the Plutonium Facility. The scenario for the field drill was a criticality event in a laboratory room where workers were transferring material-at-risk into a safe and observed a blue flash of light indicating a criticality event. The drill was initiated via sounding of the criticality alarm. The resident inspectors observed facility command actions from the PF-400 operations center as well as the Plutonium Facility evacuation, accountability, and radiation and contamination surveying of evacuees. One key lesson from the drill was that participants noted issues with the badge readers used for accountability, forcing a lengthier manual process.

Plutonium Facility–Decontamination and Decommissioning: Last week, workers were installing glovebags to support removal of solution tanks in an aqueous processing laboratory room. The general criticality safety requirements document for the facility requires that criticality safety personnel evaluate catchments that can collect liquid on a case-by-case basis to determine if a criticality safety evaluation is needed to perform the work safely. There is a specific evaluation for this activity that allows catchments, and the work documentation for this process included a hold point to consult with criticality safety personnel prior to installing the glovebags. Due to equipment issues, the work crew performed tasks in a different order, which later led to the crew skipping this hold point. While there was no immediate criticality safety concern from this event given limited potential for liquids, management is evaluating how to prevent future mistakes of this nature. Improvements include: enhancing consistency across all work requirements documents and improving pre-job briefings to ensure warnings and hold points are addressed before starting work.

Waste Characterization, Reduction, and Repackaging Facility: This week, the NNSA Field Office authorized Triad's request to commence design and modifications to the facility to support future Hazard Category 3 operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 7, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending July 7, 2023

Area G–Operations: Last week, the Environmental Management Field Office approved N3B’s corrective action plan from the federal readiness assessment for corrugated metal pipe (CMP) size reduction. They also authorized startup of the activity. N3B personnel commenced size reduction of CMPs last Thursday, completed one cut on a CMP, and packaged the resulting segment in a standard waste box. This week they completed cutting the first CMP. Each CMP gets four cuts resulting in five segments. Three of the segments were packaged, and the last two remain in the shear assembly in the Dome 375 Permacon. There have been no unexpected radiological conditions during the cutting activity. Meanwhile, retrieval of CMPs continues with seven total units retrieved and staged.

Technical Area 21–Decontamination and Decommissioning: Last Friday, N3B transmitted their quarterly startup notification report to the Environmental Management field office for approval. Last quarter, the field office requested that N3B provide a determination regarding whether readiness reviews would be required for activities at Building 21-257 or the nearby industrial waste lines. In response, this startup notification report included an assessment of initial characterization activities at 21-257 that concluded these sampling activities would not need any formal readiness reviews since they would be performed outside of safety basis controls as a less than hazard category 3 activity. A nuclear criticality safety determination for these activities concluded that they will remain subcritical for all normal and credible abnormal conditions.

Plutonium Facility–Safety Basis: On Monday, Safety Basis personnel entered the new information process to evaluate the discrepancies in material-at-risk limits identified during the readiness assessments for receipt of large heat source plutonium shipments (see 6/30/2023 report).

Plutonium Facility–Infrastructure: Last Monday, the NNSA field office and project office unconditionally approved the latest revision to the safety design strategy for the Los Alamos Plutonium Pit Production Project (LAP4) (see 6/2/2023 report).

Fire Protection: On Friday, the laboratory activated Stage 1 fire restrictions and increased their fire danger rating to very high. This increase was due to continued dry conditions on-site and in the surrounding area. Work restrictions are currently in-place to prohibit or limit certain activities, such as spark producing and shot/burn activities on laboratory property.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 14, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending July 14, 2023

Staff Activity: Headquarters staff members A. Hutain, P. Natividad, and E. Tetteh were on-site to observe the annual emergency preparedness exercise. Hanford resident inspector P. Meyer was on-site for the exercise and to compare resident inspector oversight approaches.

Emergency Management: On Wednesday, Triad conducted the annual full-participation evaluated emergency management exercise, coined TRIT-EX. The scenario was a process upset at the Weapons Engineering Tritium Facility leading to a fire and glovebox breach, releasing both tritium and plutonium. One worker near the event suffered burns and required transport to the hospital and another worker was transported to occupational medicine for behavioral health treatment. Exercise play emergency response actions included: fire department response, shelter-in-place, accountability, and monitoring for airborne radiological contamination. Triad and NNSA personnel are evaluating the exercise performance.

Plutonium Facility–Fire Protection: Last Thursday, the resident inspectors were observing conditions in the Plutonium Facility when one noted what appeared to be paint coating a concealed sprinkler cover plate. Foreign compounds applied to sprinkler components have the potential to impair their operability. They reported this observation to facility management who promptly sent personnel to evaluate the situation. Engineering personnel determined that the foreign material was a drywall compound and found the compound on several other sprinkler head covers. Management paused painting and drywall activities in the facility. The sprinklers are components of the safety-class fire suppression system. Operability evaluations concluded that the impacted sprinkler heads are operable but nonconforming. Facility personnel have spare covers and are planning to replace the impacted units. The pause on drywall and painting activities was lifted on Monday with additional restrictions on working too close to fire system components while physical solutions are under evaluation.

On Thursday, a resident inspector observed oxygen cylinders stored alongside fuel-gas cylinders in the compressed gas cylinder staging area outside of the Plutonium Facility. The storage array did not meet the minimum separation requirements between oxygen and fuel gases in accordance with National Fire Protection Association standards and Occupational Safety and Health Administration regulations. This is a recurring noncompliance that the resident inspectors have observed and reported to facility management (see 12/9/2022 report).

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Safety Basis: On Monday, Triad transmitted to the NNSA Field Office for approval a revised preliminary documented safety analysis (PDSA) to support resumption of operations as a hazard category 3 facility. NNSA did not approve the initial revision of the PDSA and this resubmittal is intended to resolve their review comments.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 21, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending July 21, 2023

Staff Activity: D. Brown was on site to observe personnel from the Waste Isolation Pilot Plant perform a generator site technical review on transuranic waste practices at the Plutonium Facility. The review was focused on corrective actions from the titanium sparking event (see 3/5/2021 report).

Plutonium Facility–Safety Basis: Safety Basis personnel concluded that the material-at-risk limit discrepancy identified during the readiness assessments for receipt of large heat-source plutonium shipments constitutes a potential inadequacy of the safety analysis (see 7/7/2023 report). As the process has not started yet, there are no needed actions to place the facility in a safe condition. If the activity is authorized, the more conservative of the discrepant mass limits will be used pending further analysis.

Plutonium Facility–Construction: Last Wednesday on the swing shift, construction personnel tied in a new glovebox to ventilation and the dry vacuum system. The next morning, dayshift personnel noticed that the glovebox had too much negative ventilation on it resulting in grossly distended glovebox gloves sucked into the box. The valves to the dry vacuum system were open while the damper to ventilation was closed. New glovebox tie-ins are currently an infrequent activity but will become more frequent as the facility continues construction efforts to support the pit production mission. The work documentation for the installation did not include hold points, and the workforce does not have much experience with this type of work. The valve alignment has been corrected, and activities in this box are paused until facility management confirms that the conditions are safe and stable. The glovebox gloves are degraded and will need to be replaced as will filters that were damaged by oil migration. Moving forward, facility and construction personnel plan to improve their work documentation for installation to better integrate with the glovebox installation checklist from glovebox installation engineering specifications.

Chemistry and Metallurgy Research Building (CMR): CMR personnel did not complete an annual in-service inspection of a passive safety-class design feature within the required periodicity and did not enter the grace period process to extend the allowable time to completion. The inspection was due last Wednesday. It consists of verifying that the vertical rise of walls providing credited fire protection separation between wings 3, 5, 7 and 9 are not degraded and have no new penetrations or modifications. Personnel realized the error last Friday and completed the inspection successfully this Monday. There are several existing practices at CMR to track required technical safety requirement surveillances including discussions of the status board during shift turnover, however these were not successfully used. Facility management is evaluating approaches to improve their tracking practices and ensure compliance with them.

Wildfire Hazards: On Wednesday, there were several lightning induced wildfire starts on land near the laboratory. Emergency operations personnel do not believe current conditions are likely to result in substantial fire growth or impact to laboratory facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 28, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending July 28, 2023

Staff Activity: M. Bradisse, R. Eul, D. Minnema, and B. Weathers were on site for another visit supporting their review of nuclear criticality safety (see 3/24/2023 report). Their visit included observations of a fissile material move and several fissionable material operation reviews in the Plutonium Facility.

Plutonium Facility–Safety Basis: On Thursday, facility management entered the limiting condition for operations pertaining to material-at-risk limits and directed all nuclear material on the first floor be placed in a safe configuration. Engineering personnel discovered an inconsistency with software version control on a tool used to track material-at-risk to ensure compliance with safety basis limits. While the software issues are being resolved, the compliance with limits is indeterminate, and the first floor of the facility is in limited operations mode.

Safety Basis personnel concluded that the material-at-risk limit discrepancy identified during the readiness assessments for the receipt of large heat-source plutonium shipments constitutes a positive unreviewed safety question (see 7/21/2023 report). The discrepancy has the potential to increase the consequences of an accident previously evaluated in the facility design basis and the consequences of a malfunction of equipment important to safety. Changes to the documented safety analysis and NNSA approval will be required prior to startup of this activity. As the safety basis addendum required NNSA headquarters to accept risk beyond DOE’s evaluation guideline for postulated consequences to the public, any adjustments to the safety basis should go through a similar review at the headquarters level (see 4/1/2022 report).

Plutonium Facility–Worker Safety: Senior management for Weapons Production and Plutonium Infrastructure are concerned by recent laboratory-wide negative trends in hazardous energy control events (see 2/10/2023, 4/21/2023, 6/2/2023 reports for examples in nuclear facilities). This week they started a series of briefings to all supervisory personnel who are charged with disseminating the content to their workforces by the end of August. The briefings provided a summary of recent hazardous energy events, plans for improving training, and planned changes to lockout/tagout procedures and policies. Management also discussed the importance of pausing work, their expectations for pre-job briefings when hazardous energy controls are required, and that zero energy checks for maintenance and construction tasks must have a superintendent or higher individual present to witness the check and verify the adequacy of the lockout/tagout in place.

Federal Oversight: The NNSA Field Office completed a staffing analysis of facility representative coverage for fiscal year 2023. The analysis gave a recommended staffing level of 19 full-time equivalent facility representatives including nine assigned to the Plutonium Facility. Current staffing is at 13 with three assigned to the Plutonium Facility. The field office continues with hiring efforts; however, this is limited by overall staffing caps.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 4, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending August 4, 2023

Staff Activity: H. Dacayanan was on site to attend the project review discussed below.

Plutonium Facility–Infrastructure: NNSA personnel were on site to perform a Technical Independent Project Review for the Los Alamos Plutonium Pit Production Project (see 5/6/2022). The team reviewed such nuclear safety topics as safety basis, nuclear criticality safety, and fire protection as well as scheduling and project management. The team is finalizing its conclusions and will brief them to NNSA and Triad management.

Plutonium Facility–Safety Basis: On Saturday morning, Plutonium Facility personnel exited the limiting condition for operations and returned to normal operations mode following resolution of the software version control issue for material at risk tracking on Friday evening (see 7/28/2023 report). Triad personnel believe the version error most likely came about due to the high workload of personnel who must address frequent software version changes. Another potential error contributor was the interface between testing and development organizations. Corrective actions are in progress to prevent further errors of this type.

The NNSA Field Office transmitted to Triad their comments from their review on the leak path factor and atmospheric dispersion methodology (see 5/5/2023 report). The revised methodology couples leak path factor and atmospheric dispersion to support the modern safety basis under development for the Plutonium Facility. The Field Office requested Triad submit a revised methodology incorporating all changes based on their comments within 45 days.

Plutonium Facility–Fire Protection: On Wednesday, facility management performed a walkdown to assess storage of compressed gas cylinders near the Plutonium Facility. This was part of an extent of condition review of cylinder storage at related facilities following issues identified with code compliance during the federal operational readiness review at PF-400. It also served to address frequent non-compliances with cylinder storage adjacent to the Plutonium Facility (see 7/14/2023, 12/9/2022 reports). During the walkdown, management identified several non-compliances including comingling of oxidizers and flammables, inconsistent labeling practices, and unsecured cylinders.

Emergency Management: Two weeks ago, there was a telephone service provider outage that affected most of New Mexico and impacted voice communications for Triad facilities laboratory-wide. The error originated at the provider's substation where telephone routing was corrupted, affecting landline telephone calls originating from the laboratory for approximately one and a half hours. As the telephone lines at the Emergency Operations Support Center (EOSC) were non-functional, site workers were notified to call 911 in the event of an emergency. Concurrent with this outage, the laboratory also experienced an unrelated network outage such that e-mail and messaging were not available. As a result, the EOSC relied on radio communications and cellular networks. Efforts to improve redundancy have been in progress since previous events of this type. These include providing backup contact information to Los Alamos County officials and facility operations center personnel as well as issuing and training personnel on the use of backup communications methods.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 11, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending August 11, 2023

Environmental Management–Safety Basis: N3B held another workshop to support development of a modern DOE-STD-3009-2014 compliant safety basis for Area G (see 03/24/2023 report). The workshop also included discussions for developing a Technical Area 21 safety basis to support sampling prior to decontamination and decommissioning. Several staff members from DOE Environmental Management Chief of Nuclear Safety’s office were onsite to attend the workshop. Meeting participants discussed proposed safety controls for the new Area G safety basis. A resident inspector accompanied workshop attendees on an Area G tour. One purpose of the tour was to observe the implementation of controls in Dome 33. Another was to observe flanged tritium waste container standoff distances which have now extended into the footprint of Dome 49 because of expected pressure increases over time due to tritium decay.

Transuranic Waste Facility (TWF): While restoring the system following performance of a surveillance on a channel of the safety-class seismic power cutoff switch, a fastening device sheared. Facility personnel determined this made the system inoperable and entered the appropriate limiting condition for operations. This requires all waste storage buildings at TWF be placed in warm standby, meaning transuranic waste drums may be stored but no other operations such as movements or gas sampling may be performed. Engineering personnel are evaluating how to restore the system to operability.

Plutonium Facility–Criticality Safety: Last week, workers moved a plutonium item into a dropbox with another item in it such that their combined masses exceeded criticality safety limits. The items were in water resistant containers with engineered spacers. When the workers recognized their error, they paused and made the appropriate notifications. The overmass was within the safe upset conditions analyzed in the criticality safety evaluation. Triad management is planning a causal analysis on this event and a comprehensive casual analysis reviewing overmass events in the past year to determine if common elements exist. Separately, efforts already in progress to improve the material move procedure to reduce the potential for human error are nearing completion.

Last week, workers disconnected a dropbox from adjacent gloveboxes to prepare for removal from the facility. However, this action rendered the seismic qualifications of the remaining gloveboxes indeterminate. One of those boxes had a criticality safety requirement to be seismically qualified. When personnel recognized this issue later in the week, they paused and made appropriate notifications. The non-compliant box has been placed out of service. It is also slated for removal, but still contains nuclear material. Corrective actions include evaluating the current seismic qualification of the non-compliant glovebox, evaluating integration process to assure glovebox removals recognize all requirements, and performing an extent of condition review of gloveboxes connected to those planned for removal to determine whether they could have a similar seismic non-compliance issue.

Plutonium Facility–Infrastructure: On Tuesday, the NNSA Project and Field Offices unconditionally approved the preliminary safety design report for the Los Alamos Plutonium Pit Production Project 30 reliable mission. Their approval included safety basis review comments that they requested be included in the future submittal of the final preliminary documented safety analysis at the final design stage.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 18, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending August 18, 2023

Staff Activity: Y. Li was on site to attend a Probabilistic Seismic Hazard Update workshop.

N3B–Training: Last week, Environmental Remediation personnel discovered discrepancies in the training qualifications for nuclear facility operations, supervisory, and management personnel. Given the indeterminate training status of required personnel, they stopped all field work in Technical Area 21 and the nuclear environmental sites. These qualification issues also apply to Area G where management paused work this Tuesday and then stopped work on Wednesday morning. All waste domes are currently in warm standby with only minimum safe operations authorized. N3B management is working to ensure that Area G has sufficient qualified personnel to meet minimum staffing requirements in the technical safety requirements and that all the nuclear sites have qualified operations management. They are also developing a matrix of personnel versus gaps with position requirements and working to fix training materials to ensure they cover all requirements from the approved qualification standard and the DOE training order.

Plutonium Facility–Radiological Safety: Last Friday, four continuous air monitors (CAM) alarmed in a laboratory room that processes heat source plutonium. Shortly after, CAMs in an adjacent room alarmed. Workers in the first room were not wearing respiratory protection and evacuated per response protocol; no one was present in the second room. The crew had been replacing glovebox spool doors with the new model that eliminates use of the braided wire cables that caused a puncture in 2018 (see 2/8/2019 report). There was no contamination detected on the individuals undergoing bioassay to determine if there was any uptake. The most likely cause of the airborne activity was a release from one of the spool pieces connecting to the dropbox where the workers were installing doors to adjacent gloveboxes. Both rooms are restricted while recovery efforts are in progress. Facility management paused work on all door replacements in the facility wing where the event occurred while corrective actions are developed.

Onsite Transportation: Last Thursday, the NNSA Field Office conditionally approved the latest revision to the Packaging and Transportation Safety Document and Technical Safety Requirements (see 6/2/2023 report). There were two conditions of approval. Both relate to addressing Field Office comments. One requires that specified comments be addressed no later than the 2023 annual update of the documents, and the other that remaining comments be addressed no later than the 2024 annual update with quarterly briefings on closure status.

Transuranic Waste Management–Safety Basis: Triad submitted to the NNSA Field Office for approval revisions to the longstanding evaluations of the safety of the situation (ESS) for potential hazards of nitric acid and anion exchange resin in transuranic waste drums for the Transuranic Waste Facility, the Chemistry and Metallurgy Research Building, and the Plutonium Facility (see 2/5/2021 report). The revisions state that experiments with anion exchange resins demonstrated no potential for rapid drum pressurization; thus, there is no unanalyzed event involving anion exchange resins in waste drums. The revised ESSs therefore request removal of compensatory measures and closure of the potential inadequacy of the safety analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 25, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending August 25, 2023

Staff Activity: M. Sautman gave a presentation on DNFSB activities in New Mexico to the Radioactive and Hazardous Materials Committee of the New Mexico State Legislature. Presentation materials can be found on the committee's website.

Weapons Engineering Tritium Facility (WETF)–Readiness: A federal team commenced a readiness assessment to evaluate startup of plutonium coupon studies at WETF (see 3/3/2023 report). This week, the team observed work demonstrations including an operational drill where a continuous air monitor alarmed due to plutonium, a new hazard of this activity. The review is expected to conclude next week.

Plutonium Facility–Radiological Safety: Last Tuesday, there was a contamination spread in a laboratory room. A worker requested radiological control technician (RCT) support to investigate an alarming survey monitor. The RCT confirmed contamination on the monitor and directed the large number of workers in the room to begin an orderly exit. Exit monitoring discovered several contaminated booties on workers. No workers had skin contamination in this event, and there was no evidence of airborne radioactivity. The cause of the contamination spread was traced to a breached glovebox glove. There was substantial contamination discovered around this glovebox during follow-up surveys. The room underwent decontamination and was released for work last Wednesday. The following day, in the same room, a worker performing administrative work at a computer alarmed a monitor upon exiting the room. RCTs discovered a hot particle on the skin of the individual's hand. Corrective actions in progress include an additional sharps walkdown of processes in this room, use of longer overgloves to protect the area of the glovebox glove that was damaged in the first incident, and a complete wipedown of the room.

Plutonium Facility–Safety Basis: On Monday, facility personnel entered an unplanned limiting condition for operations due to exceedance of material at risk (MAR) on a transuranic waste storage pad outside of the facility. Personnel were performing mobile loading of pipe overpack containers (POC) with high MAR that cannot be transported to the RANT Shipping Facility. While POCs have a damage ratio associated with them in the safety basis, on the waste pad, only the outermost container's damage ratio can be applied. Once the POCs were overpacked into standard waste boxes prior to being loaded into the TRUPACT, they lost their damage ratio and exceeded MAR limits on the pad. One TRUPACT was fully loaded and sealed for shipment to the Waste Isolation Pilot Plant prior to discovery of the MAR exceedance. The TRUPACT has a damage ratio of zero which exempts its MAR from the limits. The other standard waste boxes were opened and unloaded to restore compliance with the technical safety requirements. An approach to compliantly ship the remaining high MAR containers is being developed.

Transuranic Waste Facility (TWF)–Safety Basis: On Thursday, TWF personnel exited the limiting condition for operations regarding operability of one of the seismic power cutoff switches (see 8/11/2023 report). Engineering personnel completed an evaluation concluding that in the condition with the damaged fastener, the seismic switch is operable but degraded and can continue to perform its safety function. Efforts to fully repair or replace the degraded switch are in progress.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 1, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussof and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending September 1, 2023

Plutonium Facility–Safety Basis: Last Thursday, Triad submitted to the NNSA Field Office for approval an evaluation of the safety of the situation (ESS) pertaining to the recent positive unreviewed safety question for receipt and processing of large shipments of heat source plutonium (see 7/28/2023 report). The ESS maintains material at risk (MAR) restrictions using the lower of the two MAR limits discussed in the safety basis addendum supporting this activity. However, the ESS proposes that a revised addendum be submitted that analyzes the consequences from the higher of the two MAR limits and uses that as the limit for processing. As this change would increase doses to the public even further beyond the evaluation guideline, NNSA headquarters will need to approve the addendum in addition to the field office to accept that level of risk. The mitigated dose consequences to the public from this operation are already analyzed to range from 495-3175 rem depending on the leak path factor used (see Board Letter 8/11/2022). The Board’s staff expects the new addendum to show an increase upwards of 30 rem. This increase by itself exceeds the evaluation guideline of 25 rem.

Last Monday, Triad transmitted a revised atmospheric dispersion protocol to the NNSA Field Office for concurrence (see 8/4/2023 report). One change in this revision is discussion of an approach to use an alternative distance for collocated worker receptors for existing remote facilities.

Weapons Engineering Tritium Facility–Readiness: The federal team completed the readiness assessment for startup of plutonium coupon studies (see 8/25/2023 report) and briefed their conclusions to contractor personnel. They identified three pre-start findings one of which involved an ambiguity as to whether the technical safety requirements allow coupon operations to take place in standby mode.

N3B–Training: N3B personnel are continuing their efforts to resolve training issues and the stop work remains in place (see 8/18/2023 report). Minimum staffing at Area G has been compliant with the technical safety requirements since August 19th.

Area G–Safety Basis: Two Fridays ago, workers performing routine inspections in Area G observed a utilities pole swaying due to high wind. The workers notified facility management who contacted Triad utilities for support. Area G facility management authorized Triad to enter a combustible restrictive area with their utilities vehicle to assess the hazard and secure the utility pole. Though authorized, this entry introduced a larger quantity of fuel than analyzed in the safety basis, and a technical safety requirements violation was declared. This was an allowable action outside of the technical safety requirements as addressing the issue with the utility pole was necessary to protect workers, the public, or the environment from imminent and significant harm.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Safety Basis: Last Thursday, the NNSA Field Office conditionally approved a revised preliminary documented safety analysis that supports restart of WCRRF as a hazard category 3 facility (see 7/14/2023 report). The first condition of approval was to designate the lightning protection system, the fire detection and alarm system, and continuous air monitors as other hazard controls in the upcoming documented safety analysis for WCRRF restart. The other is to evaluate, update, and resubmit the three previously approved equivalencies from the safety design strategy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 8, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending September 8, 2023

Staff Activity: A staff team held a remote meeting with Triad and NNSA Field Office personnel to discuss initial conclusions from its review of the glovebox integrity (see 6/30/2023 report).

Plutonium Facility–Radiological Safety: Last Thursday, a worker alarmed the hand and foot monitor while exiting a laboratory room. Responding radiological technicians discovered contamination on the worker’s protective bootie. Further investigation of the room, which processes heat source plutonium, discovered contamination below a glovebox and flaky material that appeared to be corrosion products. Workers noted that it is not uncommon to spill liquids in that dropbox, as the caps for the carboys are often not fully sealed and are easily knocked over. There have also been instances of carboys leaking in gloveboxes (see 6/15/2018, 6/26/2019 reports). Workers taped the underside of the glovebox to control further flaking and contamination spread. The glovebox is posted out of service and the access to the room is restricted. Facility personnel are developing a room entry plan to gather more information, which will include collection of flaky material for chemical analysis. Engineering personnel will evaluate the integrity of the glovebox. Once additional data is collected to understand the condition of this glovebox, personnel plan to perform an extent of condition review of other gloveboxes with the potential for liquid spills and unexpected corrosion.

Plutonium Facility–Safety Basis: The contractor completed and submitted the revised safety basis addendum supporting the receipt of large quantities of heat source material (see 9/1/2023 report). The NNSA Field Office and headquarters are reviewing the submittal.

Work Planning and Control: Last Wednesday, personnel from a sub-tier construction contractor damaged the fence around a material disposal area. The workers were performing excavation work supporting the Transuranic Liquid Waste Project. They did not pause work and decided to repair the damaged fence. While replacement of this fence is part of this subcontractor’s scope, the fence repair they performed was not in their authorized scope of work for the day. During cutting activities for the repair, a small fire ignited in the vegetation in the material disposal area. The workers extinguished the fire with water and a fire extinguisher, made notifications to operations personnel, but did not call the fire department as required. Operations personnel called the fire department who did respond to verify the fire was fully extinguished. There was no hot work permit for this activity. Also, as the laboratory was under Stage II fire restrictions at the time, any hot work activities would have required review and approval by fire protection engineering personnel. Management paused the work until a training event could be held to reinforce the importance of pausing work, emergency notifications protocols, work scope definition, and content of prejob briefings.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Safety Basis: Last Friday, Triad submitted to the NNSA Field Office for approval a documented safety analysis that supports restart of the WCRRF as a hazard category 3 nuclear facility, downgraded from its original hazard category 2 designation. The submittal includes changes requested in the recent conditional approval of the preliminary documented safety analysis (see 9/1/2023 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 15, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending September 15, 2023

Staff Activity: M. Bradisse was on site this week providing resident inspector augmentation. Support activities included plutonium facility walkdowns, meetings with Environmental Management Field Office and N3B personnel, and attendance at fact findings.

Chemistry and Metallurgy Research Building (CMR): This week, facility personnel held a fact-finding meeting to discuss an individual who had entered radiological controlled areas in CMR without a dosimeter. The individual, a recently hired radiological control technician (RCT), finished the RCT training pipeline and was assigned to CMR starting on August 21. However, upon completion of training, the individual never received a dosimeter. Despite this, the individual proceeded to perform daily surveillances and other routine work on several occasions under an integrated work document, always in the company of other RCTs. On September 7, during preparation for a new work activity involving a radiological work permit, the individual self-identified that they had never received a dosimeter. Facility personnel have concluded that the individual likely did not receive any dose above background levels, based on the type of work conducted and the doses historically assigned to the other RCTs during such activities. The primary proposed corrective action was to task the radiation protection organization with reviewing the dosimetry assignment process and ensuring that newly qualified RCTs receive their dosimeters prior to starting work at their first assigned facility. Additionally, CMR facility personnel proposed reviewing onboarding processes to help ensure this situation does not occur in the future. Personnel at the meeting also discussed, but did not conclude, whether this event would be reportable per DOE O 232.2A, *Occurrence Reporting and Processing of Operations Information*.

N3B–Training: N3B personnel are continuing their efforts to resolve the training issues identified last month (see 8/18/2023 and 9/1/2023 reports). The organization has qualified sufficient personnel to perform surveillances to fulfill technical safety requirements and conduct corrugated metal pipe size reduction activities. To do this, N3B management reconstituted training records by cross referencing requirements from DOE O 426.2, *Personnel Selection, Training, Qualification, and Certification Requirements for DOE Nuclear Facilities*, with known existing qualifications for each individual performing this work, and then conducted remedial training as necessary. The stop work remains in place for other work activities. N3B management personnel have stated that the next priority activity needing qualified workers is glovebag operations, given near-term deadlines stemming from readiness activities nearly a year ago (see 9/20/2022 report).

When N3B took over its scope from the previous contractor in 2018, it retained relevant training and qualification programs. In 2020, N3B committed to instituting its own requalification program; however, this action was not satisfactorily completed, and key requirements from DOE O 426.2 were never properly implemented. N3B personnel are performing a causal analysis to determine how this occurred.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 22, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending September 22, 2023

Staff Activity: C. Beaty, M. Bradisse, D. Bullen, J. Heath, and L. Lin were on site this week as part of their review of decontamination and decommissioning activities at the Plutonium Facility (see 5/19/2023 report). During this visit, they observed the removal of a glovebox from the facility and placement into a waste container outside of the facility. They also walked down rooms with Plutonium Infrastructure personnel to observe current and planned equipment removal activities, contamination enclosure practices, and radiological control techniques. Additionally, they met with training personnel, radiological control management, waste management personnel, and work planners.

Plutonium Facility–Emergency Response: On Wednesday morning workers were performing an activity to split and dispose of legacy heat source plutonium material. The material was a process residue consisting of pyrolyzed cheesecloth with plutonium residue. It was packaged in an inner container bagged in a heavily degraded bagout bag placed in an outer container. As the workers opened the inner container in a glovebox and placed the material in a catch pan, they identified smoke, but no flames, coming from the material. The workers activated the dropbox fire alarm, exited the room, and contacted the operations center as required. The fire department responded and identified no anomalous heat signatures or other indications of an active fire and turned the scene back over to the facility. Meanwhile, other workers in the Plutonium Facility were directed to perform an orderly exit. Activities in the Plutonium Facility were restricted until Wednesday afternoon when the facility was released back to normal operations. Workers performed an observation of the material in question and identified no other anomalous behavior. They believe the smoking was caused by pieces of the degraded plastic bag falling on the thermally hot heat source plutonium residue. Work with this type of material is paused, and the glovebox where the event occurred is out of service until a recovery plan is developed. Facility personnel are developing corrective actions to help prevent future events with legacy materials. Facility and Emergency Management personnel are also developing actions to improve emergency response. One notable issue during the event was lack of attention to public address announcements.

Plutonium Facility–Infrastructure: Triad personnel recently submitted two safety basis documents supporting infrastructure upgrades to the NNSA Field Office for approval. Last Friday, they submitted a revised addendum for installation of a second seismically qualified uninterruptible power supply (UPS). The revision addressed a directed change from the Field Office to include surveillances of the criticality alarm system and site public address system following realignment of the UPS. This Wednesday, they submitted a temporary modification to the safety basis that would allow non-safety-credited process compressed air to feed the safety-significant instrument air system to provide a backup source of pressurized air while the instrument air system undergoes upgrades to improve reliability.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 29, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending September 29, 2023

Staff Activity: Staff from the Nuclear Regulatory Commission's Office of the Inspector General were on site Tuesday for site familiarization and oversight of the resident inspectors.

Plutonium Facility–Criticality Safety: Two months ago, workers removed containers from the vault for repackaging. Upon opening these containers in a glovebox last month, they discovered that the nuclear material items were surrounded by thick polymer shielding that was unanalyzed in the criticality safety evaluation for the glovebox. To recover from this criticality safety infraction, they closed the containers and sent them back to their original vault locations under the assumption that they their original storage conditions were compliant with criticality safety requirements. Two weeks ago, personnel identified that the thick shielding is unanalyzed in the criticality safety evaluations for the vault locations as well. The vault locations containing these items and adjacent locations are currently restricted. An extent of condition review has identified that there are likely more of these shielded containers in the vault and personnel are evaluating appropriate operational restrictions. Meanwhile, criticality safety personnel are working calculations to verify safe configurations when thick shielding is present and evaluating the process for recovering from criticality safety infractions to ensure that recovery from one event does not lead to another. Personnel are also working with the Offsite Source Recovery Program to see if these high-dose items that need shielding can be disposed of through that program with minimal processing and worker exposure.

Legacy Facilities: Last Friday, N3B submitted a new documented safety analysis (DSA) supporting activities at Technical Area 21 to the Environmental Management Field Office for approval. The DSA is intended to replace the justification for continued operations that has been in place for several years since sampling data suggested Building 21-257 and the buried Industrial Waste Lines may exceed inventory thresholds and be nuclear facilities. Work allowed under this DSA is limited to surveillance and maintenance, removal of debris, and limited sampling and characterization. The proposed controls include two specific administrative controls: an inventory control program to protect material at risk assumptions, and a limit on the length of industrial waste line that can be exposed.

Radioactive Liquid Waste Treatment Facility (RLWTF)–Emergency Management: On Tuesday, there was an emergency preparedness drill at the RLWTF. The scenario was a forklift backing into a chemical storage building causing a partial building collapse and a fuming nitric acid spill and plume. RLW personnel performed a controlled exit from radiologically controlled areas and sheltered in place until receiving direction from the Emergency Operations Center to evacuate. Construction subcontractors working on the Transuranic Liquid Waste project also participated in the drill and relocated to a shelter in place location then evacuated. Drill performance was largely positive; however, there was some confusion on wind directions based on instrumentation readouts compared to a windsock. Emergency management personnel are following up on this apparent discrepancy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 6, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending October 6, 2023

Plutonium Facility and Radioactive Liquid Waste Treatment Facility (RLWTF)–Tritium: Last week, Triad personnel determined that routine tritium releases from the Plutonium Facility’s stack had re-entered the facility due to atmospheric conditions. This same type of event happened on a much larger scale in January 2022 at the Savannah River Tritium Enterprise (see Board letter on tritium release event dated 8/11/2022). The first evidence of unusual tritium migration was in August when RLWTF started seeing elevated tritium readings in influent liquids. Readings remained in the nanocurie per liter range but were higher than normal which prompted action. In mid-September, further investigation determined the source of the tritium was the Plutonium Facility. Management paused all tritium activities in the Plutonium Facility last Monday. Triad personnel are still gathering information from this event and plan to hold a fact-finding meeting next week. Both facilities have entered the new information process to determine the safety basis implications of the unexpected tritium.

Plutonium Facility–Safety Basis: On Tuesday, Triad personnel met with NNSA Field Office and NNSA Environment, Safety, and Health (ESH) leadership to discuss the revised safety basis addendum for receipt and repackaging of large quantities of heat source plutonium (see 9/8/2023 report). NNSA ESH is the safety basis approval authority for this addendum given that the mitigated consequences during the bounding accident exceed the evaluation guideline for the public. NNSA ESH leadership has changed since the original approval and risk acceptance for this activity (see 4/1/2022 report). The meeting also included discussions on whether additional work could be performed at Idaho National Laboratory prior to shipment of this material to reduce risks at Los Alamos National Laboratory and on actions taken based on the Board’s letter dated August 11, 2022, regarding this activity.

Plutonium Facility–Glovebox Safety: On Monday, a glovebox worker using a measuring caliper saw visual evidence of a breach in one of their glovebox gloves. Responding radiological control personnel determined that there was indeed a glovebox breach. The impacted individual had contamination on a personal protective equipment glove, but no skin contamination. There was no evidence of an airborne contamination spread. During the response, there was a challenge locating respirator masks as the response cabinet closest to the event was depleted. The cause of the breach was the sharp caliper which is an alternative tool that was in use due to an electronic measurement device in the glovebox being out of service. Corrective actions under evaluation for this event include: evaluating the use of a different type of caliper, ensuring sufficient respirator masks are available for responses, reinforcing movement restrictions for workers involved in a suspected breach, and issuing a lessons learned report.

N3B–Training: N3B personnel are continuing their efforts to resolve the training issues identified in August (see 9/15/2023 reports). N3B is using a senior management review board to individually release specific activities while the overall stop work remains in place. So far at Area G, they have released offsite waste shipments, onsite material moves, technical safety requirements surveillances, and corrugated metal pipe cutting. All these activities have been performed since their release. This week Area G personnel moved waste to the RANT Shipping Facility and resumed corrugated metal pipe cutting. A root cause analysis for the training issues is in progress.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 13, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending October 13, 2023

N3B–Training: Last Friday, the causal analysis team investigating N3B’s training issues transmitted its report to the Environmental Management Field Office (see 10/6/2023 report). They found the root cause of the event to be that N3B did not ensure their training program: clearly provided instructions to implement all the requirements of DOE Order 426.2, *Personnel Selection, Training, Qualification, and Certification Requirements for DOE Nuclear Facilities*; was executable as intended; and was updated as changes occurred. The direct cause was that N3B did not have an adequately documented training or tracking method to meet requirements for qualifications and requalification for Contact-Handled Transuranic Waste and Environmental Remediation activities. Contributing causes were identified in the areas of staff retention, human performance, management, and communications. The team also provided seven recommendations, which included: revising the N3B qualification standards and training implementation matrix; improving the learning management system to show a clear, consistent, and verifiable qualification status for each individual; and performing an extent of condition to assess if similar inconsistencies are affecting other safety management programs.

Plutonium Facility–Infrastructure: The Plutonium Facility entered limited operations mode at the end of last week to perform a variety of equipment upgrades and repairs. One key activity was installation of new instrument air compressor equipment. The instrument air system is a safety-significant support system, and non-credited process air was used to keep the ventilation system operational during installation (see 9/22/2023 report). System health reporting on the instrument air system had identified that the compressors were approaching end of life. This week, the south side of the facility remained in limited operations mode to support fire suppression system work. On Thursday evening, the entire facility returned to limited operations mode to support electrical maintenance over the weekend.

Onsite Transportation: Last Thursday, Triad submitted to the NNSA Field Office for approval a revised version of the Transportation Safety Document and associated Technical Safety Requirements. This latest revision is the 2023 annual update of the document and is intended to address field office comments from its conditional approval of the previous revision (see 8/18/2023 report). Remaining field office comments will be addressed in the 2024 update.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): Efforts continue to restart WCRRF as a hazard category 3 nuclear facility. At the end of September, Triad provided the NNSA Field Office with a schedule to reconstitute the code of record for the facility. Triad now plans to have a final code of record to support startup by October 2024. Triad also provided NNSA with a safety basis addendum to the current hazard category 2 document that will authorize transition activities including decontamination of the Glovebox Enclosure and receipt and size reduction of uncontaminated large pieces of equipment, such as gloveboxes. Last week, Triad submitted an updated fire hazards analysis that is intended to address a condition of approval from NNSA’s approval of the preliminary documented safety analysis (see 9/1/2023 report). The document provides an updated status of all current equivalencies in the facility and a discussion of gaps from requirements. Two notable gaps leave the facility more vulnerable to exterior fires. There is one large section of the exterior stucco wall that has failed and is being repaired. Also, fire resistance properties of the exterior insulation finishing system led to a recommendation to restrict combustibles around the building.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 20, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending October 20, 2023

Plutonium Facility and Radioactive Liquid Waste Treatment Facility (RLWTF)–Tritium: Triad personnel held a fact-finding meeting to discuss the recent event involving tritium migration from the Plutonium Facility to RLWTF (see 10/6/2023 report). In addition to the atmospheric conditions that allowed tritium to reenter the Plutonium Facility through the building air intake, more tritium than usual was released during operations because the gas treatment system, a non-credited system that reduces the amount of tritium released up the stack, was not functioning properly. Released amounts were within permit limits. Safety basis personnel concluded that the event did not constitute a potential inadequacy of the safety analysis for either facility. In RLWTF, while the increase in tritium concentration exceeded the drinking water thresholds the facility uses as a limit, it was orders of magnitude lower than the amount of tritium analyzed in the safety basis. For the Plutonium Facility, while there was an acknowledgement that this scenario where material returned to the facility was not analyzed in the safety basis, the quantities were so small, they could be considered as contamination level and were covered in other hazard analysis scenarios. The resident inspectors believe it would be prudent to do a more thorough, bounding analysis of this type of scenario as part of the development of the new safety basis for the Plutonium Facility. Triad personnel are continuing to recover from the event and are actively decontaminating the inlet air dryers. They also plan to decontaminate the glovebox where the tritium work took place, repair and upgrade the gas treatment system, and rewrite procedures for tritium operations to include weather condition checks and other improvements.

Plutonium Facility–Infrastructure: NNSA’s Technical Independent Project Review team issued the final report for its review of a subproject of the Los Alamos Plutonium Pit Production Project (see 8/4/2023 report). The report concluded that the safety basis documentation is at an appropriate level of maturity for this stage of the project with an approved safety design strategy and a submitted preliminary documented safety analysis. The report had eight recommendations, three of which were within the technical scope. Those were: update the technical maturation plan to identify critical attributes of systems that need to be identified to support achievement of technical readiness level seven, complete an analysis of upset conditions within a glovebox that could result in fire and explosion hazards, and identify and implement actions to accelerate assessment of actual demands for utilities and balance of plant systems to determine if modifications/upgrades are required to ensure that final installed systems will fully support mission needs.

The Plutonium Facility exited its outage and returned to normal operations on Monday (see 10/13/2023 report). During the final stages of the outage, facility personnel replaced many of the sprinkler heads in one side of the basement to support the upcoming 50-year replacement cycle. They also completed planned high voltage electrical work.

Federal Oversight: The Environmental Management Field Office conducted training for all staff on oversight. This training was a corrective action stemming from an assessment of the N3B contractor assurance system and the Field Office’s oversight activities earlier this year (see 2/24/2023 report). The training covered the fundamentals of oversight including contractual requirements; executing oversight activities such as assessments and surveillances; and effective issue identification and communication. The Field Office is planning additional training on this topic.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 27, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending October 27, 2023

Emergency Management: On Tuesday, Triad personnel held a full-scale emergency exercise at the Los Alamos Neutron Science Center (LANSCE). The scenario started with an overhead crane dropping a load onto a shutter containing mercury contaminated with neutron activation products. This caused a large spill of mercury, and the adjacent workers were exposed. Soon after the spill, a large fire started, which provided energy to vaporize substantial amounts of mercury and form a significant plume. Exercise play included evacuations and shelters in place at LANSCE as well as a fire department and hazardous materials team response. N3B personnel also played in a limited capacity with a simulated evacuation of workers in Technical Area 21 and the canyons near LANSCE. Triad personnel are formally evaluating exercise performance with an emphasis on objectives related to corrective actions from previous exercises.

Plutonium Facility–Radiological Control: Last week, there were two skin contamination events in the same laboratory room. This room has a contamination control tent set up around a glovebox to support decontamination and decommissioning work. In the first event, a radiological control technician supporting a hot job in the tent surveyed out of the tent successfully but identified contamination on their hand during exit monitoring from the room at the hand and foot monitor. On the afternoon of the same day, a supervisor who was working outside of the same tent found contamination during a scan at the personnel contamination monitors on building exit after clearing the hand and foot monitors on room exit. Both individuals were successfully decontaminated, and there was no evidence of an airborne release in either event. While the exact source of the contamination for these events is indeterminate, facility personnel have several corrective actions to address potential causes. These include: modifying the process for doffing and surveying powered air purifying respirators, ensuring respirator storage cabinets are part of routine radiological monitoring, and evaluating personal protective equipment requirements for construction supervisors.

Plutonium Facility–Safety Basis: On Monday, the NNSA Field Office responded to Triad's request for concurrence on their latest revision of the atmospheric dispersion modeling protocol that will support the new safety basis for the Plutonium Facility (see 9/1/2023 report). The Field Office stated that Triad must revise the protocol within 45 days to address provided comments prior to obtaining concurrence. Key items the field office requested included: justification of the overall reduced conservatism in the proposed methodology from changes to plume meander, justification for not using the default dispersion parameter from DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*, to calculate co-located worker dose consequences, and clarification on remote facilities using a distance greater than 100 m for co-located worker consequences.

Transuranic Waste Facility (TWF): Two Saturdays ago, TWF personnel completed all repairs to the damaged seismic power cutoff switch and performed the quarterly functional check from technical safety requirements surveillance (see 8/25/2023 report). Following the successful surveillance, the system was declared fully operable.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 3, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: A. Boussouf and D. Gutowski, Resident Inspectors
SUBJECT: Los Alamos Activity Report for the Week Ending November 3, 2023

Staff Activity: A. Boussouf completed his assignment as a Los Alamos resident inspector. He will remain in New Mexico, but report to DNFSB headquarters supporting fire protection engineering needs complex wide. D. Brown was on site to observe personnel from the Waste Isolation Pilot Plant perform a generator site technical review on transuranic waste practices at Area G. The review covered corrugated metal pipe (CMP) activities.

Plutonium Facility–Decontamination and Decommissioning (D&D): A room owner reviewing a D&D work package to sign off on a hold point noticed that not all previous hold points had been signed. The in-progress package supported removal of a glovebox, and the unsigned hold points related to criticality safety and radiological control. Work on this glovebox is currently paused while D&D personnel are reviewing active work packages to identify other missed hold points. They have found many missed signatures and are trying to determine whether actions for hold points have not been completed or whether this is largely an error in documentation. Once this extent of condition is completed, Plutonium Infrastructure management plans to develop improvements to their work planning and control processes.

Plutonium Facility–Radiological Control: On Tuesday, a glovebox worker performing container repackaging detected contamination on their personal protective equipment (PPE) during monitoring immediately after exiting their glovebox gloves. Radiological control technicians responded and found a tear on the right thumb of the glovebox glove. While there was no skin contamination, and appropriate operator actions helped prevent further spread, the level of PPE contamination was quite high. Facility personnel are developing several potential corrective actions including evaluating different tools in the cold lab to reduce pinch and sharps hazards when handling similar container types.

Area G–Operations: While N3B remains in the overall stop work for training issues, major operations at Area G have all been released by senior management (see 10/6/2023 report). Retrieval and cutting of CMPs are progressing with 13 CMPs being fully cut and packaged into standard waste boxes while one CMP is partially cut as of Thursday afternoon. N3B personnel are planning to increase throughput by adding a staggered shift to CMP cutting.

Federal Oversight: On Wednesday, the NNSA Field Office transmitted to Triad its completed assessment of nuclear criticality safety integration into fissile material handler training. One driver for performing this assessment was the large number of new employees going through fissile material handler training. The assessment team identified nine findings and eight observations. Many of the findings relate to traceability of training and retraining requirements. The Field Office requested that Triad perform an extent of condition review of past fissile material handler and supervisor training to identify any deficient training or certification. Within 60 days, Triad must respond to the Field Office with information describing how findings from the assessment and any discoveries from the extent of condition review have been documented in the issues management system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 10, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending November 10, 2023

Plutonium Facility–Emergency Response: On Monday, there was a flash and a fire in a glovebox in the Plutonium Facility. Workers were pulverizing legacy material from 1983 for introduction into the aqueous chloride line. Upon activating the bonecrusher, there was a flash, followed by flames and smoke in the box. The workers immediately deactivated the equipment, activated dropbox fire alarms, and evacuated the room. All the continuous air monitors in the room alarmed, as did one in an adjacent room. Other workers in the facility performed a controlled egress to assembly areas outside the building. Los Alamos Fire Department personnel responded and found the fire was out when they made entry into the laboratory room where the event occurred. No workers were injured, contaminated, or showed any evidence of a radiological uptake. The likely cause of the energetic reaction was calcium metal contained in the feed material. Engineering personnel have determined that the glovebox is still maintaining negative pressure with respect to the laboratory room but have recommended replacing all filters and gloves as well as glovebox windows closest to the event. Access to the room is still restricted while Triad personnel develop a formal recovery plan. They also entered the New Information process to determine any safety basis implications from this event.

Plutonium Facility–Radiological Control: Management from operations, performance improvement, and radiological control organizations have started a new approach to learning from radiological events. While significant events will still be treated individually and have fact-finding meetings, the new approach involves management evaluating all radiological events over the past week and elevating topics to discuss further during fact-finding meetings, potentially with other similar events. This week, the first fact-finding meetings using this new approach were held. One covered a series of events during decontamination and decommissioning activities on a glovebox that had been used to process heat source plutonium in the past. Some of the events included continuous air monitor alarms, personal protective equipment contamination, and contamination found outside expected areas. Triad is planning to perform a causal analysis to evaluate this series of events to improved glovebox removal processes.

Transuranic Waste Management: This week and last week, Triad completed two mobile loading shipments from Technical Area 55. The shipments included several pipe overpack containers with large amounts of heat source plutonium. Personnel executed a series of moves in and out of the Plutonium Facility during packing these pipe overpacks into standard waste boxes and then into the TRUPACTs. This maintained compliance with all material at risk limits and avoided a repeat of the limit exceedance during the last mobile loading activity (8/25/2023). Longer term, safety basis personnel are developing a change to allow compliant shipping of higher material at risk items without resorting to a series of extra waste movements.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): Workers completed repairs to the exterior stucco of WCRRF this week (see 10/13/2023 report). This repair does not address the fire rating of the exterior walls. Therefore, the plan to implement a compensatory measure of restricting vehicles with a physical barrier to keep them at least 10 feet from the exterior walls remains in place.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 17, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending November 17, 2023

Staff Activity: M. Bradisse was on site this week providing resident inspector support. A. Boussouf was on site Thursday supporting Mr. Bradisse's visit.

Plutonium Facility–Glovebox Safety: On Monday, workers were preparing to package materials in a glovebox in a laboratory room. While attempting to open an empty container in the glovebox, a worker lost control of the container, which impacted the window between the glovebox gloves they were using. The impact cracked the inner laminated safety glass confinement window and shattered the outer leaded glass window used as radiation shielding. Because of the presence of glass shards, the worker chose to remain in the gloves while another worker sought assistance from radiation control personnel. Upon arrival, radiation control personnel surveyed the cracked window and the glass shards and discovered contamination. Surveys of the surrounding area showed no contamination spread outside the immediate vicinity of the glovebox, so workers were able to package the contaminated shards, affix tape to the cracked glovebox window, and release the room for work later that day. Nasal swabs of the worker in question indicated potential radiological intake, and that individual was placed on special bioassay. At the fact-finding meeting, participants noted that the worker did not use a prying tool to assist with opening the container. Using this tool is an encouraged practice, which workers are trained on, but it is not required. Participants also noted that there is no standard response for a glovebox window breach, like there is for a glovebox glove breach. Potential corrective actions from this event include clarification of the guidance, requirements, and training for pry tools, and clarification and documentation of the expected response to glovebox window breaches.

Plutonium Facility–Safety Basis: On Tuesday, Triad safety basis personnel briefed NNSA Field Office management on the preliminary results of a parametric study of leak path factor during certain accident conditions. The leak path factor describes the amount of radioactive material that escapes the building during accidents and is one of the factors used to calculate the potential dose consequences to members of the public following hypothetical accident scenarios. Once finalized, the results of this report will be used to inform the selection of appropriate leak path factor values for the new documented safety analysis for the Plutonium Facility, which is being developed per DOE-STD-3009-2014, *Preparation of Nonreactor Nuclear Facility Documented Safety Analysis*. For this study, Triad safety basis personnel created a computer model of the entire Plutonium Facility and simulated one of the current design basis accidents, a fire in a single laboratory room. They then perturbed several conditions, including: the specific room where the accident takes place, the amount of material at risk, the duration of material release, the cumulative time that outer confinement doors and inner laboratory room doors are open, the timing of when those doors are open, the activation of fire suppression systems, and the presence of active ventilation. Triad personnel stated that the preliminary values aligned with expectations and with leak path factor values used in the current documented safety analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 24, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending November 24, 2023

Staff Activity: D. Gutowski was offsite this week. M. Bradisse provided coverage remotely.

Area G–Stop Work: While performing an extent of condition review on operational record keeping practices for contact-handled transuranic waste operations at Area G, an N3B team discovered that records management was not in compliance with expectations laid out in the contractor’s policy. The team found that completed pre-job and post-job paperwork was of inconsistent quality and was not regularly undergoing a quality review process, that training and qualification paperwork for individuals performing work was difficult to trace, and that general understanding of expectations for records management was poor. Consequently, N3B management stopped work at Area G. This is the latest in a series of work stoppages at Area G related to deficiencies in paperwork, training, and qualification (see 11/4/2023 report). The team is finalizing a list of findings from the assessment and will develop corrective actions needed to resume work.

Plutonium Facility–Safety Basis: Last Wednesday, the NNSA Field Office approved the evaluation of the safety of the situation (ESS) pertaining to the positive unreviewed safety question for future mission work involving receipt and processing of large shipments of heat source plutonium (see 7/28, 9/1/2023 reports). However, the approval letter noted that the ESS’s operational restriction was vague since it did not clearly specify the affected area of the Plutonium Facility, or that Field Office concurrence would be required prior to introducing this heat source material into any glovebox. The approval therefore included one directed change to clarify these points.

The ESS resolves a discrepancy identified during readiness activities regarding the allowable material at risk (MAR) in a glovebox during these operations by proposing an operational restriction aligned with the lower of two potential MAR values. That lower MAR value corresponded to the dose consequences reported in the initial safety basis addendum. However, the ESS stated that a revised safety basis addendum would be submitted to allow the higher of the two MAR values. The revised addendum, submitted in early September, proposes a further increase in MAR, so it will also need to be approved by NNSA headquarters, as it will involve accepting additional risk to the public on top of the risk already accepted.

Plutonium Facility–Decontamination and Decommissioning: During a walkdown last week, the resident inspectors observed the conditions of an in-progress job to remove a large glovebox from the facility. This glovebox was large enough that it required multiple in-situ cuts to fit it through the laboratory doors. To perform this work, laboratory personnel erected a floor-to-ceiling contamination control tent, which allows the facility fire suppression system to maintain coverage within the tent. They performed the cuts with a method new to the Plutonium Facility. As of last week, the cuts have been performed, the portion of the glovebox to be removed has been wrapped and prepared for removal from the laboratory room, and the opening to the remaining glovebox line has been secured with a metal plate to maintain confinement. The resident inspectors also observed the condition of a smaller box in a different room that had recently been disconnected and was wrapped awaiting removal and identified a contamination control tent in the basement supporting a pump removal that was in disrepair.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 1, 2023

TO: Timothy J. Dwyer, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending December 1, 2023

Staff Activity: D. Gutowski was virtually in Washington, DC for the biannual ingathering of the resident inspectors to DNFSB headquarters. A. Boussouf was on site Tuesday and Wednesday providing support.

Area G–Work Planning and Control: On Tuesday, Area G management stopped work on corrugated metal pipe (CMP) retrieval and size reduction due to the identification of an issue with a procedure revision that removed a critical lift plan. Work was already stopped due to the training documentation issues identified two Thursdays ago (see 11/17/2023 report). As loads during size reduction activities can exceed 75% of the maximum rated capacity of lifting equipment, a critical lift plan is required per N3B policy. Several evolutions were completed with the revised procedure, and therefore without an associated critical lift plan. To lift this stop work, N3B management is evaluating either restoring the critical lift plan to the procedure or performing engineering work to eliminate the requirement for a plan for this activity. They are also evaluating whether the procedure development process is adequate and how to improve its effective use.

Plutonium Facility–Safety Basis: Last Monday, Triad personnel concluded that the pyrophoric event in a glovebox constituted a potential inadequacy of the safety analysis (see 11/10/2023 report). While the safety basis includes deflagration events for other processes and gloveboxes, there is no scenario specific to the size reduction process where the flash and fire occurred. Controls for those energetic events in other activities may not apply to this process.

Transuranic Waste Facility–Fire Protection: In early November, fire protection fitters reported water dripping from the fire department connection to one of the waste storage buildings. Further investigation determined that two ball drip check valves on the drain lines for the fire department connection were in the incorrect position. Triad personnel entered the New Information process to evaluate the safety basis impacts on the safety-significant fire suppression system. This Wednesday, safety basis personnel concluded that there was no potential inadequacy of the safety analysis primarily because the drain lines are not part of the safety-significant pressure boundary for the system.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): On Tuesday, the NNSA Field Office unconditionally approved a safety basis addendum to the current hazard category 2 WCRRF safety basis that supports activities to transition to a hazard category 3 facility. These activities include removal of existing contaminated equipment and practice evolutions for equipment downsizing. WCRRF will remain in cold standby for these activities and no new material at risk will be introduced. On Wednesday, the Field Office acknowledged Triad's plans for reconstituting the facility's code of record (see 10/13/2023 report).

Weather Impacts: A winter storm disrupted laboratory activities on Thursday and caused a delayed opening on Friday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 8, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending December 8, 2023

Plutonium Facility–Radiological Control: Last Tuesday, a worker alarmed the final set of hand and foot monitors prior to exiting the facility. Responding radiological control personnel identified skin contamination on the individual’s hand and successfully decontaminated them. The contamination was a particle, which are difficult to detect. The worker, wearing a labcoat and booties as personal protective equipment (PPE), had not been performing hands on work but was acting as an escort for carpenters performing preparatory activities for decontamination and decommissioning (D&D) in a laboratory room. During active D&D in this room, additional PPE is required, and the room is subsequently decontaminated to allow labcoat access. The room has had several contamination spreads and PPE contamination events over the past several weeks during active D&D and was the most likely source of the contamination. During this week’s fact-finding for this event, participants identified a broader training concern not directly related to the event. Facility specific contamination monitoring training is not being assigned until personnel meet all security requirements for unescorted access to the facility. Management is evaluating this issue to determine if personnel should take this training while still under escort.

On Monday, there were two related contamination events in the low-level waste area of the basement. The first event involved discovery of contamination on one worker’s PPE. During the next shift a new crew, supported by a radiological control technician, inspected the waste bags that were the probable source of the first contamination. They were unable to find any damage to the bags or contamination; however, three workers discovered PPE contamination during full body surveys, and a continuous air monitor alarmed as they exited the basement. No other personnel in the basement had any contamination detected on their PPE, but there was contamination detected on the low-level waste staging bins. Low-level waste staging, labeling, and bagging practices are under evaluation to help prevent recurrence of this type of event.

Plutonium Facility–Safety Basis: Last week, Triad personnel submitted a revised atmospheric dispersion modeling protocol that will support the new Plutonium Facility safety basis. The new revision is intended to address NNSA Field Office comments (see 10/27/2023 report). The revised protocol asserted that other conservative portions of the dose calculation justify reducing the conservatism of the proposed dispersion calculation. Triad quoted DOE Standard 3009-2014 regarding the use of an alternate dispersion parameter for calculating the co-located worker doses. Additionally, Triad stated that calculating a co-located worker dose to a worker that is not physically at 100 meters is excessively conservative. However, the resident inspector notes that DOE Standard 3009-2014 requires evaluating the co-located worker dose to a receptor at 100 m, unless no viable control strategy exists. In the protocol, Triad did not state which facilities lack a viable control strategy for the co-located worker. Triad said it would provide technical justification, including information on the viability of its control strategy, in facility-specific safety bases.

Area G–Safety Basis: N3B hosted a series of meetings this week to support development of the new DOE Standard 3009-2014 compliant documented safety analysis for Area G (see 8/11/2023 report). Efforts this week focused on development of implementable technical safety requirements and engaging the DOE Office of Environmental Management’s safety basis review team on the same topic.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 15, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending December 15, 2023

Staff Activity: M. Bradisse and R. Wu were on site providing resident inspector support. M. Bradisse also attended the training course *Safety Culture for Front Line Leaders* at the NNSA Field Office.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Radiological Control:

Last Wednesday, there was a skin contamination event at WCRRF. Personnel were working to remove legacy contaminated equipment from the glovebox enclosure, which is highly contaminated and has a legacy hydraulic oil spill. The workers were wearing two pairs of Tyvek coveralls and powered air purifying respirators. One of the workers who entered the enclosure alarmed monitoring equipment on exit after doffing his coveralls. Supporting radiological control technicians identified contamination on the individual's inner elbow. They were unable to successfully decontaminate the skin with the limited techniques allowed and available at WCRRF, so the worker was transported to Occupational Medicine where he was successfully decontaminated. Radiological control, operations, and industrial hygiene personnel plan to re-evaluate personal protective equipment requirements for this activity to better protect the workers from radiological hazards while avoiding heat stress issues.

Area G–Operations: Last week N3B lifted stop works specific to corrugated metal pipe activities and resumed those operations (see 12/1/2023 report).

N3B commenced a management self-assessment for startup of the Universal Drum Assay and Segregation System (UDASS). The UDASS is a new system under evaluation to obtain more accurate characterization of waste drums. As UDASS operations are largely similar to existing assay techniques, this is considered an expansion of existing capabilities, and no formal readiness assessment is planned. This week, the review team observed an operational demonstration and started interviews. The review is expected to conclude next week.

Plutonium Facility–Safety Basis: Last Wednesday, Triad personnel concluded that the energetic event in the bonecrusher constituted a positive unreviewed safety question (see 12/1/2023).

Chemistry and Metallurgy Research Building (CMR): Last Thursday, Triad submitted to the NNSA Field Office for approval a major modification determination for a potential new mission to size reduce mixed oxide fuel rods at CMR. These fuel rods have no defined use and are currently in shipping casks staged in the Plutonium Facility. The proposed project would be to ship the casks to CMR, open them, and size reduce the fuel rods in the Wing 9 Confinement Vessel Disposition enclosure prior to disposal as waste offsite. Triad concluded that this proposed mission would not constitute a major modification, but a safety basis addendum would be required.

Weather Impacts: A winter storm caused a laboratory closure on Thursday and a delayed opening on Friday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 22, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending December 22, 2023

Waste Characterization, Reduction, and Repackaging Facility (WCRRF)–Emergency

Preparedness: On Tuesday, Emergency Operations Center and WCRRF personnel performed an emergency preparedness drill. As WCRRF is undergoing preparations to restart as a hazard category 3 nuclear facility, the drill used the new emergency planning documents that are still under review by the NNSA Field Office as those reflect the hazards of the facility for its future mission. The scenario was a fire in a storage container adjacent to WCRRF. This event was then complicated by a personal medical condition at a shelter-in-place location and a contaminated individual.

Plutonium Facility–Emergency Response: Last Tuesday, a hazardous material (HAZMAT) team responded to the Plutonium Facility due to a low oxygen alarm. A portable oxygen meter was being used in a laboratory room to support functional testing of a newly installed glovebox. The glovebox is not yet fully connected to radiologically contaminated systems including ventilation and other gloveboxes. The glovebox contains an engineered fluid and a nitrogen powered pump. While the crew was working with the nitrogen system, the oxygen monitor alarmed. The crew exited the area and informed the Operations Center. HAZMAT personnel responded and measured unexpectedly high levels of volatile organic compounds and backed out. After replanning their entry to account for this additional hazard, the HAZMAT personnel reentered and closed all engineered fluid containers in the box. Work in the impacted wing of the facility was placed in a safe configuration, and personnel exited that wing until additional monitoring determined it was safe to return. The impacted box is currently cordoned off while recovery plans are in progress. Facility personnel are planning on improving communication regarding the location of portable monitoring equipment and revising the work document for functional testing of this glovebox to improve industrial hygiene controls.

Plutonium Facility–Emergency Preparedness: On Thursday, the NNSA Field Office conditionally approved a revised addendum to the Plutonium Facility Emergency Planning Hazards Assessment. This document supports the receipt and repackaging of large quantities of heat source plutonium. The addendum accounts for additional material at risk and this revision resolves a discrepancy in allowable material at risk values identified during readiness reviews (see 6/30/2023 report). The safety basis addendum revision supporting this larger material at risk limit is currently under review by a team led by NNSA Headquarters (see 9/8/2023 report).

Legacy Facilities–Safety Basis: On Monday, N3B resubmitted the safety basis for Technical Area 21 to the Environmental Management Field Office for approval. N3B withdrew its previous submittal (see 9/29/2023 report) to improve the documents. The revised submittal does not change the limited scope of work or the two specific administrative controls proposed in the original document.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 29, 2023

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending December 29, 2023

Year in Review: A summary of the key developments of 2023.

- A parallel federal and contractor readiness review took place to support the receipt and repackaging of large quantities of heat source plutonium in the Plutonium Facility. These reviews discovered discrepancies in the safety basis and emergency hazards planning assessment regarding the total amount of material at risk allowed. NNSA headquarters is evaluating a revised safety basis addendum that includes a higher amount of material.
- Triad continued to make upgrades at the Plutonium Facility. Major accomplishments this year included the commissioning of two new safety-class diesel fire pumps, commencement of the project to provide a separate fire water supply to non-seismically qualified buildings adjacent to the Plutonium Facility, and replacement of aging air compressors to support the safety-significant instrument air system.
- N3B identified a programmatic breakdown in their training program and instituted a stop work at Area G and Technical Area 21. Senior management has individually released the vast majority of individual work activities, but the training stop work remains in place.
- Corrugated metal pipe size reduction at Area G went through contractor and federal readiness assessments and commenced operations.
- N3B developed and the Environmental Management field office approved a new site-specific atmospheric dispersion protocol to support development of a safety basis compliant with the most current DOE standards for Area G. Triad has also developed an atmospheric dispersion protocol to support a modern safety basis for the Plutonium Facility. The NNSA Field Office is still reviewing Triad's proposed approach and has requested several modifications.
- The Radiological Laboratory Utility Office Building completed the transition to a Hazard Category 3 nuclear facility known as PF-400.
- Preparations to restart the Waste Characterization, Reduction, and Repacking Facility as a hazard category 3 nuclear facility continue. Workers have started entries into the highly contaminated glovebox enclosure to prepare it for future missions. The NNSA Field Office conditionally approved the new hazard category 3 safety basis. Readiness activities are planned for next year.
- DOE's Criticality Safety Support Group performed an assist visit in response to the NNSA Field Office's request to review Triad's criticality safety program. Triad has restructured its criticality safety division under new leadership in response to recommendations from the review.
- The Flanged Tritium Waste Containers stored at Area G are still awaiting venting. Updated pressure calculations and standoff distances have been developed to account for the steadily increasing internal pressures. These will be used to revise the safety basis addenda that will support venting.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 5, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending January 5, 2024

Area G–Safety Basis: On Tuesday, the Environmental Management Field Office and Headquarters approved the annual update to the Area G Basis for Interim Operations. Additionally, N3B submitted an extension request for the five Justifications for Continued Operations (JCOs) to February 28, 2025, which is currently undergoing DOE review for approval. The five JCOs have been in place since 2021 and cover a variety of topics from the numerous potential inadequacies of the safety analysis identified that year (see 9/3, 10/5, 10/29/2021 reports). DOE guidance recommends JCOs last no longer than 12 months, at which point they should be incorporated into the permanent facility safety basis. These JCO's have been extended to focus efforts on developing a modern documented safety analysis to serve as the safety basis for Area G. DOE's letter states that they are receptive to another extension on the condition that the JCOs will be incorporated into this new safety basis. The new safety basis is expected to be submitted for approval in March of this year with a goal of full implementation before the end of the fiscal year.

Plutonium Facility–Safety Basis: On Thursday, Triad safety basis personnel resubmitted a safety basis page change that would expand the types of allowable activities during limited operations mode at the Plutonium Facility. The driver for this change is to allow more flexibility for removing or installing equipment. Entry into limited operations mode is usually driven by incomplete functionality of credited safety systems (whether planned or unplanned) as defined in the facility's limiting conditions for operations. Therefore, only activities with limited risk are allowed. The NNSA Field Office did not approve the first version of this change last November. The Field Office expressed concerns in its response that there was not adequate detail regarding the justification for new types of activities and the specifics defining the risk threshold for those activities. The new submittal is intended to address these concerns.

Plutonium Facility–Readiness: At the end of last month, Triad requested the NNSA Field Office approve its corrective action plan from the contractor readiness assessment for resumption of aqueous nitrate operations (see 5/5/2023 report). Triad personnel performed causal analyses for each of the five pre-start and three post-start findings from the assessment to develop the suite of corrective actions. Actions affiliated with pre-start findings are either complete or scheduled for completion next week. NNSA personnel are reviewing these submittals and plan to start a federal readiness assessment at the end of January.

Continuous Improvement: The resident inspector met with the Triad Operational Performance Assurance manager to discuss initiatives to improve operations in the Weapons Production and Plutonium Infrastructure directorates.

Weather Impacts: A winter storm impacted laboratory operations with delayed openings on Thursday and Friday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 12, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending January 12, 2024

Staff Activity: Staff members P. Migliorini, S. Seprish, and S. Sircar were on site this week providing resident inspector augmentation and gaining perspective on plutonium operations to support design reviews of the Savannah River Plutonium Processing Facility. A. Boussof was on site Wednesday to support their visit.

Plutonium Facility–Radiological Protection: There were two skin contamination events in the Plutonium Facility last week. In one, an individual alarmed hand monitoring equipment while exiting a laboratory room. Follow-up surveys of this room discovered the likely source, a contaminated telephone. The other event involved a hot particle from a heat source room. Follow-up surveys of that room did not discover any contamination. Both individuals were successfully decontaminated. These events along with earlier lower magnitude contamination events are being looked at together to improve processes with the intent of reducing contamination events. Actions in progress include: additional surveys of items, such as telephones, that can be touched without gloves in radiological buffer areas; focused observations in the field by radiological control personnel to observe worker compliance with the facility radiation protection program; evaluating changes to that program especially for personal protective equipment requirements based on observations; and a common cause analysis for recent contamination events.

Plutonium Facility–Safety Basis: The resident inspector and a staff member joined two NNSA facility representatives to walk down the laboratory rooms that will be used for receipt and repackaging of large quantities of heat source plutonium (see 9/8/2023 report). The primary purpose was to provide the NNSA personnel with perspective and background on the safety improvement suggestions included in the Board's letter of August 11, 2022.

Plutonium Facility–Decontamination and Decommissioning (D&D): As part of the Los Alamos Plutonium Pit Production Project D&D efforts, Triad is draining and removing pencil tanks from the facility (see 12/9/2022 report). In December 2023, after installing a hot tap on a pencil tank, operations personnel noticed a small leak on the laboratory room floor. Operators adjusted the hot tap valve and installed a one gallon catch bag over the valve to prevent contamination spread. Criticality safety personnel were alerted and observed that the bag did not contain liquid, but the size exceeded the requirements in what they believed to be the criticality safety posting for the tank. Further investigation of this event determined that the hot tap installation noted above was performed on a tank that did not have an active criticality safety posting. This week, facility personnel held a fact-finding meeting to evaluate these events. Proposed corrective actions include performing fissile material operations reviews for all operations associated with tank removals and better contingency planning for hot tap leaks.

Area G–Operations: On Tuesday, N3B personnel identified that a corrugated metal pipe (CMP) evolution had been completed last week under an expired critical lift plan. Management paused CMP excavation. Workers must check this plan and other command media are valid before performing operations. In this instance, that check did not identify that the plan was expired. N3B plans to perform an extent of condition evaluation on lift plans and other documents to review expiration dates, revise their policy on developing critical lift plans, and evaluate whether this event has overlap with a previous critical lift plan issue (see 12/1/2023 report).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 19, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending January 19, 2024

Staff Activity: The Board's Executive Director of Operations, M. Buhler, accompanied by staff member P. Migliorini, was on site Tuesday and Wednesday for a familiarization visit. The visit started at the Chemistry and Metallurgy Research Building where Triad personnel led her through Wings 3, 5, and 9 while discussing current missions and risk reduction efforts. Senior leadership from the Environmental Management field office and N3B then led a tour of Area G which primarily covered the corrugated metal pipe excavation site and cutting activities in Dome 375. They also discussed organizational interfaces in the transuranic waste mission and the recent progress involving N3B training issues. Next was a visit to Triad's RANT Shipping Facility where Triad and N3B personnel discussed waste shipments and how they share the facility's capabilities. On Wednesday, Ms. Buhler went to Technical Area 55. Triad personnel discussed safe glovebox operations and training for the growing workforce in a cold lab. An exterior walk around the Plutonium Facility pointed out key safety systems such as fire pumps, instrument air, and the uninterruptible power supply. In the Plutonium Facility, the tour included entries into rooms associated with pit production, an overview of the heat source and plutonium disposition missions, and a visit to the basement focused on safety systems like the ventilation system. Ms. Buhler also met with both the NNSA and Environmental Management field office managers.

Plutonium Facility–Safety Basis: On Tuesday, the NNSA Field Office provided Triad with formal comments on a safety basis submittal that proposed limitations on fires inside certain gloveboxes to avoid the scenario where an internal glovebox fire actuates the fire suppression system, and damage to the glovebox allows water ingress and potential moderation of fissile material. This is a long-standing issue (see 3/21/2014 report) as many gloveboxes do not have criticality safety evaluations that account for flooding of the glovebox. These boxes must either be analyzed to show they are safe if moderated by flooding or flooding must be incredible.

Seismic Hazard Analysis: On Thursday, Triad personnel briefed NNSA Field Office and DOE headquarters subject matter experts on progress collecting data to support the new site probabilistic seismic hazard analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 26, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending January 26, 2024

Staff Activity: On Tuesday, the Board's staff held a remote factual accuracy meeting for a complex-wide review of electrical cable maintenance (see 6/23/2023 report).

Plutonium Facility–Infrastructure: At the end of last year, Triad issued the annual revision of the TA-55 Project Execution Strategy (PES) (see 1/6/2023 report). Key accomplishments in the last fiscal year highlighted in the latest PES include: completion of phase 2 seismic testing of cast-iron fire suppression system fittings, completion of six seismic cluster analyses for gloveboxes, and completion and commissioning of the new Facility Control System. Major activities planned for this fiscal year include: completing the construction of a new high pressure fire water feed for the non-seismic building separation project, completing the design for fan replacements for Zone 1 exhaust and Zone 2 bleed-off, completing six more seismic cluster analyses for gloveboxes, and completing the construction and commissioning of two instrument air system compressors.

Plutonium Facility–Safety Basis: This week, the NNSA Field Office transmitted to Triad its response on the leak path factor and atmospheric dispersion methodology. The field office did not concur with the revised methodology and directed Triad to use the currently approved one. The field office previously submitted comments regarding the justification for the overall reduced conservatism in the proposed calculation (see 10/27/2023 and 12/8/2023 report).

Plutonium Facility–Readiness: On Thursday, the NNSA Field Office approved the corrective action plan from the contractor readiness assessment for resumption of aqueous nitrate operations (see 1/5/2024 report). The federal readiness has been postponed due to an equipment issue identified this week.

Transuranic Waste Facility (TWF)–Criticality Safety: On Tuesday, Central Characterization Project (CCP) personnel were performing drum measurements at the High Efficiency Neutron Counter at TWF. Their initial measurements exceeded the 200 fissile gram equivalent criticality safety limit for three 55 gallon drums at TWF. Under their normal practice, CCP tags these drums to note the high initial reading, but does not report the values until they are validated through expert analysis and adjusted to account for instrument uncertainties. TWF operations personnel noted the tags and entered their criticality response process. The final validated value on all of these drums was below the 200 gram limit. Waste generator data from when the drums were originally received at TWF from Technical Area 55 also showed they were below the limit. Triad and CCP personnel plan to ensure that there is a consistent understanding of which types of data are appropriate to use for criticality safety compliance at TWF. There is an existing memorandum from the Nuclear Criticality Safety Division from 2011 that is referenced in the TWF criticality safety evaluation. This memorandum recommends using waste generator data for criticality safety compliance for transuranic waste operations in Area G as opposed to the practice at the time that initially used waste generator data then flipped to validated assay data from CCP.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 2, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending February 2, 2024

Staff Activity: M. Sautman was on site to evaluate resident inspector performance.

Plutonium Facility–Safety Basis: Last week, an NNSA facility representative questioned whether damage ratios were being appropriately applied when SAVY containers for nuclear material have hermetically sealed caps over their vents. These caps can be used to keep an inert environment in the container to protect the contents. SAVY containers have been tested in the uncapped configuration to provide a 1% damage ratio in specified fire and drop accident scenarios. However, the capped configuration has not been tested, and thus no damage ratio can be applied to a capped container. In many situations, these capped containers are being improperly credited with a damage ratio. Facility personnel entered the limiting condition for operations pertaining to container configuration in the room this was discovered in. Following resolution there, an extent of condition review found additional problems in other rooms leading to limiting condition for operations entries. All containers with caps are currently being evaluated to determine how they have been listed in the software that tracks nuclear material. In the long term, Triad is planning to implement software changes to ensure these types of containers are tracked properly and are not credited with damage ratios. Existing plans to test SAVY containers in the capped configuration to see if a damage ratio can be applied are on hold pending resource availability.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): Workers performing HEPA filter changes for the confinement ventilation system in WCRRF discovered that they were using the wrong model of filter. The new filters were not fitting properly into the housings, and after using more force than expected on several installs, the workers noted the discrepancy. Engineering personnel are evaluating whether the filter housings were damaged by the process of forcing in the incorrect filter model. The confinement ventilation system is credited as a safety-significant system in the current hazard category 2 safety basis, but is not required to be operational in cold standby mode, which is the current facility condition. The safety basis currently in development for the upcoming transition to hazard category 3 operation does not credit this system.

Area G–Operations: On Wednesday, the resident inspector and visiting staff member observed corrugated metal pipe size reduction activities in the Dome 375 Permacon. While performing rounds within the Permacon, a worker identified that one of the portable HEPA filter units was not operational. An examination of the power supply discovered a tripped breaker and thermal damage to a power cord. The work team appropriately paused work and made notifications.

Federal Oversight: Two individuals from the NNSA project management office went through final senior technical safety manager qualifications this week. Personnel from the NNSA field office acted as the qualifying officials. The field office has recently started developing alternative approaches to the traditional formal oral board approach for final qualifications. These involve a combination of discussion and field walkdown with more emphasis on the candidates volunteering knowledge rather than answering specific questions. The resident inspector and visiting staff member provided feedback on improving this approach.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 9, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending February 9, 2024

Staff Activity: M. Bradisse was on site providing resident inspector support. While on site, he attended fact-finding meetings, toured the Weapons Engineering Tritium Facility to discuss the safety implications of an upcoming mission, and made several entries into the Plutonium Facility.

Plutonium Facility–Decontamination and Decommissioning (D&D): Last Wednesday, Plutonium Infrastructure personnel discovered several issues in a room undergoing D&D activities. This room contains legacy gloveboxes, which workers are cleaning and preparing for eventual removal. Workers discovered that while some gloveboxes in the room had the correct version of the required criticality safety posting, other gloveboxes had a previous version that should have been replaced. Additionally, the workers discovered that two drums in the room had separate issues. The first drum had a specific criticality safety posting that meant it was not allowed in this room. The second drum had conflicting labels, such that it was marked as both as “empty” and “in progress” despite containing nuclear material. The workers also discovered discrepancies with material inventory printouts on several pencil tanks, which are staged for size reduction. At the fact finding, workers stated that, during one work evolution, they were running low on battery power for their respiratory equipment, which caused them to exit rapidly and miss the conflicting labels on the second drum. Corrective actions for this event include developing a lessons-learned document, and evaluating techniques for displaying criticality safety posting techniques to ensure such postings are replaced with current versions when necessary and avoid inadvertently introducing disallowed items into areas.

Last week in a different room, there was a continuous air monitor alarm in a contamination control tent supporting D&D work. There was no active D&D work occurring at the time; rather, personnel were smoke testing the tent to test for adequate ventilation flow. All personnel in the tent evacuated. Personnel in the laboratory room, but outside of the tent, also evacuated due to an announcement from the operations center. Further airflow measurements concluded that for large tents like this one, there can be a stagnant air layer that allows contamination to collect on elevated surfaces which can then be mobilized when the airflow changes. Additional filtered vents added near the top of this tent resolved this issue without the need for an additional air mover. This approach will be applied to future large tent installations. Another corrective action is to improve communications regarding the location of alarms to avoid unnecessary evacuations without radiological survey for personnel who are already one airspace away from the alarm. Unrelated to the airborne event, a management walkdown of this tent last week identified several housekeeping issues that were promptly resolved.

Federal Oversight: Last week, the NNSA Field Office transmitted to Triad an assessment of nuclear safety issues at the laboratory from the DOE Office of Enterprise Assessments (DOE-EA). The letter requested that Triad address the findings, deficiencies, and opportunities for improvement from the report. The report noted considerable improvement in issues management since the last DOE-EA assessment in 2019. It identified two findings related to persisting weaknesses: that Triad does not adequately identify items that do not meet requirements or need improvement, and that Triad does not adequately train and qualify its workforce on identifying and resolving issues. There were also several deficiencies and opportunities for improvement identified for Triad and one deficiency for the NNSA Field Office: that the field office has not performed assessments of the contractor assurance system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 16, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending February 16, 2024

Staff Activity: M. Bradisse was on site providing resident inspector support. E. McCullough was on site for familiarization with transuranic waste activities to support her role as the Board's cognizant engineer for the Waste Isolation Pilot Plant. This included visits to Area G, the RANT Shipping Facility, and the Plutonium Facility.

Plutonium Facility–Radiological Control: Last Wednesday, two workers were cleaning out containers used for ball-milled heat source plutonium. The process involves emptying the bulk contents into a catch pan and then using a wire brush to scrub out the remaining material from the inside. The first worker entered the gloves to demonstrate an action (without manipulating actual objects in the box) and then exited the gloves. That worker then performed a routine glove examination to check for damage and surveyed their hands for contamination on a nearby monitor. The second worker then entered the gloves and performed cleaning actions. When finished, they also performed the routine glove examination, did not note any issues, and exited. This time, however, the worker alarmed the hand monitor at the glovebox and called for radiological control personnel. The worker had contamination on the personal protective equipment on both hands and forearms but was successfully decontaminated. There was no skin contamination. Radiological control personnel later determined that the breach was due to cracking on the tip of the right thumb, which was the hand the employee used to hold the wire brush during cleaning. The glove will be sent for forensic analysis to help determine the cause of the breach. Photographs of the glove breach shared at the fact-finding meeting showed significant blackening, embrittlement, and some visible cracking, despite the glove being installed last November and having not been used for work until last week.

Plutonium Facility–Safety Basis: On Monday, the NNSA field office transmitted a letter to Triad that did not approve the revised safety basis addendum supporting receipt and repackaging of large quantities of heat source plutonium (see 10/6/2023 report). The field office provided a set of comments on the addendum and requested that Triad resubmit the addendum within 30 calendar days to address these comments. One key comment from NNSA stated that Triad should refine its safety analysis to better demonstrate the efficacy of its safety control strategy for glovebox fires.

Area G–Emergency Response: Last Friday, a worker in Dome 375 at Area G smelled and then saw smoke coming from an electrical outlet. They immediately notified the operations center who called the fire department and the Emergency Operations Support Center. The worker used a dry chemical extinguisher on the outlet before evacuating with other personnel to the assembly area. The fire department confirmed that there were no active heat sources. The cause of the event was a single circuit with two space heaters plugged in. The breaker did trip. N3B personnel are performing an extent of condition on space heater usage in domes. Heaters are used in winter to protect fire protection systems from freezing and to provide warming stations for workers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 23, 2024

TO: Katherine R. Herrera, Acting Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending February 23, 2024

Staff Activity: On Tuesday, a staff team held a remote interaction with personnel from both the NNSA Field and Project Management Offices to discuss federal review and approval of limited procurement and construction activities requests. This is part of a staff review that also includes capital asset projects at other NNSA sites.

Plutonium Facility–Readiness: A federal team commenced a readiness assessment to evaluate the aqueous nitrate process in the Plutonium Facility (see 1/26/2024 report). This process has been shut down since 2013 and is the last major processing operation in the facility that has not resumed since the 2013 director’s pause. A vigorous readiness assessment for the aqueous nitrate process is particularly important as the nature of aqueous processes presents criticality safety challenges that operations with primarily solid materials do not. This week, the team observed simulated field demonstrations of the ion exchange and calcination processes. They also performed numerous personnel interviews. The assessment will continue next week with additional field demonstrations and interviews.

Legacy Facilities: On Tuesday, the Environmental Management field office and headquarters conditionally approved the new hazard category 2 safety basis for 21-257 and the industrial waste lines in Technical Area 21 (see 12/22/2023 report). The one condition of approval was to ensure that the first annual update of the safety basis include a description of any industrial waste lines remaining east of 21-257. In August 2020, N3B declared a potential inadequacy of the safety analysis following sampling results that indicated that these facilities, which were being prepared for decontamination and decommissioning as radiological facilities, may have enough material at risk present to be nuclear facilities that need coverage by a documented safety analysis. The newly approved safety basis authorizes non-destructive assay, sampling, debris removal, surveillance, and maintenance. Further decontamination and decommissioning activities will be covered under a new safety basis to be developed based on sampling data obtained under this safety basis.

Area G–Criticality Safety: On Tuesday, N3B management paused corrugated metal pipe size reduction activities following a question as to whether use of water in a sprayer bottle was evaluated in the nuclear criticality safety evaluation. The criticality safety evaluation for this process evaluates a fully flooded condition, but there is no specific analysis of use of a spray bottle. The water spray is used to help control airborne radioactive contamination generated during the cutting process. Management released the pause on Thursday following an initial assessment from criticality safety personnel stating that use of water spray was acceptable. Longer term, criticality safety personnel are revising the criticality safety evaluation to include contamination control methods using water and proposed future usage of water with fixative. Criticality safety personnel will also perform the annual fissile material operations review of this process early.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 1, 2024

TO: Timothy J. Dwyer, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending March 1, 2024

Staff Activity: On Wednesday, a staff team held a remote interaction with personnel from Triad and the NNSA Field Office to discuss maintenance of safety related batteries. This is part of a multi-site staff review that also includes Lawrence Livermore National Laboratory and the Savannah River Site.

Plutonium Facility–Readiness: The federal readiness assessment for aqueous nitrate operations continued this week (see 2/23/2024 report). The team conducted additional personnel interviews and observed simulated evolutions for oxalate precipitation, evaporator operations, and dissolution. The oxalate precipitation demonstration included an operational drill involving a line plugged with solid oxalic acid. The one major sub-process not fully demonstrated during this assessment is the cementation process which creates cemented transuranic waste drums. That was included in the contractor readiness assessment last year and three waste drums were produced in 2018 under a limited safe and stable campaign (see 11/9/2018 report).

Plutonium Facility–Glovebox Safety: Two weeks ago, workers reported unusual degradation of their glovebox gloves; the gloves appear blistered. After further investigation, it appears that the degradation was caused by soft plastic tubing from recent procurements coming into contact with the gloves. Glovebox gloves are secured outside of boxes when not in use with clamps or are tied together to reduce time spent in the more degrading glovebox environment. Short segments of tubing are placed over the arms of the clamps to reduce the possibility of the metal clamps pinching and damaging the gloves. This technique has been in widespread use for years with no identified issues. Facility personnel are ensuring that all plastic tubes from recent batches are being removed from contact with glovebox gloves. Tubing from old procurements, where no issues have been identified, is still allowed, as is tying off the gloves. Chemical analysis is in progress to better determine what is causing this degradation. Personnel are also analyzing whether there is an impact to plastic waste bags.

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): Last week, facility personnel completed the removal of the lift table from the glovebox enclosure in WCRRF. This was a challenging, high-hazard activity in an airborne radioactivity area/high contamination area. Following the skin contamination event in December (see 12/15/2023 report), the outer layer of personal protective equipment was changed to a less permeable product. While this increased the heat stress challenges of the job, no other major radiological control events occurred during completion of the lift table removal. Personnel are continuing to clean the glovebox enclosure. They are also evaluating the best way to size reduce gloveboxes in the enclosure once WCRRF is restarted as a hazard category 3 facility.

PF-400: The resident inspector joined management on a routine safety walkdown of laboratory spaces in PF-400. Housekeeping and combustible control remain excellent in this facility compared to older nuclear facilities on site.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 8, 2024

TO: Timothy J. Dwyer, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending March 8, 2024

Staff Activity: M. Bradisse and M. Dunlevy were onsite providing resident inspector support. While onsite they met with safety basis personnel regarding proposed changes to allowable operations during limited operations mode at the Plutonium Facility, and with transuranic waste personnel to discuss changes to the enhanced chemical compatibility evaluation process. A staff team provided an outbrief to Triad and NNSA Field Office Personnel regarding the results of their review of the overall health of nuclear criticality safety programs at Los Alamos National Laboratory, the Savannah River Site, and the Y-12 National Security Complex.

Plutonium Facility–Readiness: Last Friday, the federal readiness assessment team reviewing restart of aqueous nitrate operations concluded its assessment activities and provided a briefing to site personnel regarding their preliminary conclusions (see 3/1/2024 report). They identified six prestart and eight poststart findings. The prestart findings related to criticality safety postings, approved waste processes for nitrated materials, and fire protection.

Area G–Radiological Control: On Wednesday, a radiological control technician identified contamination on a standard waste box (SWB) that had recently been moved into Dome 153. The SWB originated in the Dome 375 Permacon as part of corrugated metal pipe size reduction operations. Workers had not performed the required radiological surveys upon removing the SWB from the contamination area in the Permacon. The informal communications methods used during shift turnover appear to have been a major contributor to this omission. Facility personnel posted Dome 153 as a contamination area and performed additional surveys of that dome and other SWBs coming from Dome 375. They identified no additional contamination. As an immediate corrective action, radiological control personnel implemented a logbook to track surveys out of the contamination area.

Emergency Management: On Thursday, site personnel conducted an emergency preparedness drill at the Emergency Operations Center. The scenario was a lightning induced wildfire starting in Technical Area 14 near a high explosive firing site. Simulated meteorological conditions had the fire traveling north near underground potential release sites on a path leading to eventual collision with the high density of personnel and nuclear facilities in and around Technical Area 55. Key aspects of the drill included evaluating optimum evacuation timing for different parts of the laboratory, coordinating airspace usage for simulated airborne firefighting assets, and evaluating hazards from potential release sites for local and supplemental fire-fighting personnel.

Weapons Engineering Tritium Facility: On Tuesday, a valve failed to close during maintenance on a non-safety related air drier system. This led to a brief loss of operability of the safety-significant Tritium Monitoring System. Facility personnel entered the appropriate limiting condition for operation and performed all surveillances to confirm system operability and exit the condition. No personnel were performing tritium operations while the system was inoperable. Safety basis personnel entered the new information process for this event.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 15, 2024

TO: Timothy J. Dwyer, Technical Director
FROM: D. Gutowski, Resident Inspector
SUBJECT: Los Alamos Activity Report for the Week Ending March 15, 2024

Plutonium Facility–Operations: Last Thursday, workers accidentally placed a piece of equipment that had been removed from a laboratory room on the pressure plate for a decontamination shower. The shower actuated and water flowed until it overflowed the shower berm, migrated into a contaminated pump room, and started seeping through the walls and floors into adjacent rooms and the basement. The impacted locations were posted as contamination areas and are being decontaminated. There have been several other high impact inadvertent water flow events in the Plutonium Facility over the past few years (see 3/17/2023, 7/23/2021, 4/2/2021, 11/30/2018, 3/16/2018 reports).

Facility personnel determined that the newly installed glovebox that contains high levels of volatile organic compounds may be a flammability concern (see 12/22/2023 report). The box has been isolated since the hazardous materials response last year and may contain levels of organic vapors that would create a flammable atmosphere if mixed with air. Facility personnel are developing a recovery plan to safely connect the box to the ventilation system and purge the organic vapors. Meanwhile, safety basis personnel have entered the new information process to determine whether this condition is covered in the facility's safety basis.

Area G: Last Thursday, a radiological control technician (RCT) inadvertently removed radioactive survey smears from site. The smears were bagged, and the outer bags were surveyed prior to removal from the contamination area in the Dome 375 Permacon. Last Friday, another RCT called the first one to locate these smears for counting. They then realized the smears had been left in a vest pocket and removed from the site in a personally owned vehicle. DOE's Radiological Assistance Program team was activated to recover the material from offsite. They found that the smears remained in the bags and found no evidence of any contamination spread.

N3B personnel reviewing potentially energetic containers to support the new safety basis discovered that a standard waste box had been moved from Dome 33, where potentially reactive drums are segregated, to Dome 232 in April 2023. This standard waste box is listed in the Justification for Continued Operations (JCO) as requiring additional controls as it contains potentially reactive drums. N3B personnel determined that the move in April 2023 was done without complying with the additional controls in the JCO for moving potentially reactive containers. They have developed a plan to return the drum to Dome 33 using all required controls as soon as possible.

Plutonium Facility–Safety Basis: On Thursday, Triad submitted a revised safety basis addendum supporting receipt and packaging of large quantities of heat source plutonium to the NNSA Field Office. This revised addendum is intended to address recent comments from the field office (see 2/16/2024 report). If approved, this addendum will close out the current evaluation of the safety of the situation in place for these heat source rooms and support the planned receipt and repackaging activity.
