

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 10, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 10, 2001

This is the first DNFSB site rep report from Los Alamos. I reported aboard on Monday, August 6th. Also, DNFSB staff members Nichols and Von Holle were on site this week to attend the LANL energetics materials research review. The review, sponsored by LANL and several other organizations, provided useful insights for evaluating the conservatism that exists when using results of weapons response calculations.

TA-55 Emergency Exercise: On Tuesday, the site rep observed the annual emergency evacuation exercise in the Plutonium Handling and Processing Facility (TA-55). The exercise was also observed by LANL senior management at the Division and the Deputy Associate Laboratory Director levels and by two DOE facility reps. The scenario involved a recurring criticality due to simulated SNM rearrangement and sprinkler activation (controls exist to prevent this accident). The scenario also included (simulated) an unconscious, heart-attack victim and two contaminated individuals. For safety reasons, there were some artificialities. For example, PF-4 workers began to secure glovebox activities, frisk, and exit to the corridors 30 minutes before the alarm. This placed work in a safe condition and minimized the chance of contamination being carried outside the building.

Overall, the facility was proficient in their response, the exercise was well-controlled, and LANL self-identified several opportunities for improvement, such as: (1) issue tracking at the incident command post; (2) maintaining status and priority on the injured; and (3) minimizing cross contamination from PF-4 personnel. The site rep believes that higher priority should have been placed on evacuating the simulated victim. This was not a straight-forward decision because of the simulated radiation levels. Another area for improvement would be the presence of DOE subject matter experts at annual drills, such as this, that provide an opportunity to observe the facility making decisions in a high stress environment that affect safety, security, and the time it would take to restore facility operations if such an accident were to occur.

Weapons Engineering Tritium Facility (WETF): The staff continues to closely monitor DOE and LANL progress in improving the safety posture and the Authorization Basis for LANL tritium facilities, including resolution of issues raised in the Board's letter to DOE (3/29/01). This week, the staff (Bamdad, Jordan, Keilers, Nichols) discussed with DOE the current status of the recently submitted WETF Safety Analysis Report and Technical Safety Requirements. DOE plans to complete their review and provide comments to LANL by mid-September.

Accident prevention and mitigation in WETF is dependent on the building structure and several programs - particularly, the inventory control program, the combustible loading program, and the storage container program. Progress is being made. The roof has been seismically upgraded (PC-3). The vault racks will be upgraded to meet PC-3 requirements during the next 6 weeks. DOE and LANL also plan to upgrade the vault walls to meet a 2 hour fire rating and to transition to improved storage containers capable of withstanding higher temperatures. The staff has questions on the high reliance on administrative controls (e.g., programs) and the level of defense in depth for fires, especially in the interim before these upgrades are completed. The staff will continue to work with DOE and LANL to ensure an appropriate set of controls are identified and implemented.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 17, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 17, 2001

Staff members Jordan and McConnell were on site this week to help establish the site rep office.

Plutonium Handling and Processing Facility (TA-55): Early Monday morning, an off-site voltage fluctuation caused a complete loss of electrical power in TA-55. Essential lighting and instrumentation loads, including stack monitors, were immediately picked up by an uninterruptible power supply. Within 4 minutes, power to ventilation was restored by operator action. By design, this is not an automatic function in TA-55. During this period, normally occupied spaces were susceptible to possible air-flow reversal. Within about 3 hours, radcon personnel had confirmed there was no uncontrolled spread of contamination. Within 4 hours, normal operation was restored. Overall, it appears that operators responded per procedure, equipment functioned as designed, and there was no radioactive release to the environment. However, DOE and LANL review of the event concluded that robustness of the facility could be improved by automatically restoring power to ventilation, similar to that done in other nuclear facilities. This appears to be an improvement worth pursuing.

Improving Nuclear Facility Operations: Last week, BWXT Services issued a report on their 4-month evaluation of LANL strengths and weaknesses in nuclear facility operations and made recommendations for improvements. Overall, BWXT observed that LANL nuclear facilities are well managed in many respects, and that LANL is capable of identifying problems and developing appropriate solutions but frequently has difficulty instituting lasting change. The report also identified good practices and areas of excellence that are starting points to build overall improvement. The site rep understands that LANL is reviewing the report and recommendations.

Recommendations 94-1/2000-1: On Tuesday, LANL personnel provided a briefing on their current assessment of the 94-1 inventory, prioritization, stabilization processes, disposition options, and tentative schedules. This was a "shot-in-time," which supports DOE developing a response to the issues raised in the Board letter of March 23, 2001. The staff is planning further discussions with LANL in the coming weeks on the status of 94-1 planning and activities.

August 24, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending August 24, 2001

Plutonium Handling and Processing Facility (TA-55): On Wednesday, as part of a daily surveillance, TA-55 identified a high reading on a fixed head air sampler in one room, indicating an airborne release and uncontrolled spread of contamination. Access to the room was controlled pending resolution. Thirteen people have been requested to submit bio-assay samples to determine if they received an uptake. At this time, the source appears to be a mechanical seal on a glove-box vacuum pump. The facility is considering backfitting seal-less pumps as a long-term solution.

On Thursday, TA-55 moved several hundred TRU waste drums that were stored in a Butler building (PF-185) back into the hardened shell of the facility in order to comply with their authorization basis. This addressed concerns expressed by DOE on Wednesday that TA-55 was operating outside its authorization basis and that PF-185 had accumulated sufficient inventory to be categorized as a Hazard Category II facility, per DOE STD-1027.

It appears that, since at least 1998, PF-185 has been used for staging drums and waste containers before they are shipped out to Solid Waste Operations (TA-54). In June, while preparing a process hazards analysis (PrHA), LANL identified that these waste operations were anticipated in the current safety analysis report (1996) but relevant accidents were not addressed. PF-185 basically provides a weather-shield and airborne monitoring but little high wind, missile, or seismic protection. Many of the containers meet DOT Type A shipping requirements but are hypothesized to fail in a fire. As a result of the PrHA, TA-55 declared a Potentially Inadequate Safety Analysis (PISA) in June and implemented additional controls. In July, LANL informed DOE that a positive Unreviewed Safety Question Determination existed. Based on DOE concerns expressed to LANL this week, the facility chose to relocate the drums. This action restored operations to within the authorization basis.

Chemistry and Metallurgy Research Building (CMR): Last week, one of the DOE Facility Reps raised the question of whether the large number of ceiling tiles missing in the facility would adversely affect performance of the Safety Class fire suppression system. The ceiling tiles have been missing for several weeks to provide access for new cable runs and asbestos abatement. If a fire were to occur, the missing tiles would allow the heat layer to build up above the tiles, delaying sprinkler activation and possibly fire department response. On Tuesday, CMR management concluded that sprinkler system reliability was degraded. On Wednesday, LANL proposed and DOE approved a Justification for Continued Operation, through November, that involves posting a continuous fire watch in the affected sprinkler coverage area at all times while ceiling tiles are removed.

The site rep believes that the DOE Facility Representative should be credited for identifying the problem and the facility should be credited for following up. To prevent recurrence, it may be worthwhile for facility personnel (particularly system engineers and those preparing work packages) to receive additional training on when to enter LCO conditions, as well as on the authorization basis, the safety systems, and the assumptions made in the facility's safety analyses.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 31, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 31, 2001

Plutonium Handling and Processing Facility (TA-55): In a January 22nd letter to DOE-AL, the Board expressed concerns on the identification of quality requirements for the TA-55 Fire Protection Yard Main Replacement Project (FPYMRP) and on the need to complete this project without further delay. The project is intended to replace the TA-55 leaking fire water loop and make other upgrades that improve system reliability. Procuring the polyethylene piping and components is on the critical path. In early August, the Board's staff questioned the purchase order quality provisions. Following discussions with the staff this week, DOE and LANL agreed to revise and clarify both the purchase order and receipt inspection requirements to be more specific about the testing requirements and criteria, as well as test result traceability to material lot. DOE anticipates minimal impact on delivery. Next Friday, a DOE Energy Systems Acquisition Advisory Board (ESAAB) will review the project's preparations for start of construction (i.e., Critical Decision 3).

Radiochemistry Laboratory (TA-48): Last Friday, a TA-48 supervisor received Cm-244 alpha contamination on his shirt while performing an accountability inventory in the actinide research laboratory. The laboratory has a small actinide inventory stored in metal and glass cabinets in a controlled-access, radiological buffer area. The contamination was released from a torn zip-lock plastic bag containing a glass flask of Cm-244 solution with a glass stopper. The supervisor was wearing a lab coat, gloves, safety glasses, and booties. While the radiological consequences here were minimal (i.e., negative nasal smears, no airborne alarm, no skin contamination), it appears that a worker-safety review of this lab's material storage and handling practices would be worthwhile.

Chemistry and Metallurgy Research Building (CMR): On Tuesday, a maintenance worker skipped a hold point in a work procedure and removed 6 gages from service that are used to monitor differential pressure between the Wing 9 hot cells and the occupied space. An operator conducting daily rounds discovered the problem within an hour, but it was another 2 hours before the facility took appropriate actions, including terminating normal operations in Wing 9. Facility management has reported the event as a TSR violation and has stopped CMR upgrade work until a work package review is completed. The site rep believes that there are clear work control and training issues here, for both the operational and maintenance personnel. The facility is preparing a recovery plan.

Conduct of Operations: On March 15th, the DOE conduct of operations order (DOE O 5480.19) was added to the LANL contract. Implementation in key facilities is expected by the end of FY 02. The LANL Director has set an expectation that the quality of LANL operations match the quality of its science and technology. In July, LANL assigned responsibilities and identified the process requirements for verifying implementation. In mid-August, LANL submitted to DOE an implementation plan, identifying three essential components: (1) DOE approved documentation on requirement applicability and facility verification; (2) both institutional and facility actions to close gaps in implementation; and (3) a viable LANL self-assessment and continuous improvement process. During the next few weeks, DOE and LANL will be conducting joint training to assure starting this process with common expectations that are consistent with both the necessary formality of operations and the laboratory's fundamental research and development mission.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 7, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 7, 2001

Plutonium Handling and Processing Facility (TA-55): There is considerable DOE and LANL management attention directed now on the several hundred TRU waste containers that were stored in a Butler building (PF-185) and were relocated two weeks ago to within the hardened shell of the main processing building (PF-4). The site rep report of 8/24/01 discusses how this problem was discovered and the actions taken. While there are valid questions being asked on how this situation arose, the current priorities are unclear. The site rep believes that the priorities need to be quickly established considering both safety and operational needs. At this time, it appears appropriate from both these aspects to pursue safe and timely reduction of the waste backlog, as well as fixing the management processes to prevent recurrence of the backlog.

Work Controls: On Wednesday, DOE informed LANL that skill-of-the-craft (SOC) work is being done outside the LANL-approved work control process. LANL requirements define SOC tasks as discrete, defined work activities to be executed by either a qualified craftsman with the expertise to identify and control the hazards or by workers using a written procedure that specifies the hazards and associated controls. Under these conditions, LANL requires no separate, formal task hazard analysis. DOE observed that LANL had a Laboratory Implementation Requirement (LIR) for maintenance SOC work that was replaced in June with an expanded LIR, now applicable to all facility work. However, the latter has not yet been fully implemented, since checklists it requires to be used to document worker qualification have not yet been approved. DOE directed LANL to provide by Monday either a corrective action plan or evidence that all LANL SOC work has ceased.

Improving Performance on Technical Safety Requirements (TSRs): During the past year, LANL has been assessing TSR performance at nuclear facilities to meet a FY-01 contract provision. In December, LANL developed a review plan. Between January and May, a LANL review team investigated TSR-related occurrence reports issued since January 1999 from 19 nuclear facilities. The team also performed field observation and document reviews in 9 nuclear facilities. During the individual facility reviews, the team identified 22 strengths and 58 issues. In June and August, the team issued summary reports, identifying noteworthy practices and opportunities for improvement.

Overall, the LANL team appears to have conducted a thorough and objective appraisal. This week, LANL held a well-attended workshop on the findings. While there are many noteworthy practices, LANL identified that about half of the facilities assessed need improvements, such as more effective management oversight, better TSR document control, improved instrument calibration programs, better operating mode change controls, and more user-friendly and technically accurate surveillance procedures to which personnel are formally trained. The team also observed that the facilities generating the most issues were also generating the least number of occurrence reports. Between January 1999 and May 2001, only 5 of the 19 nuclear facilities submitted occurrence reports for authorization basis problems. If the facilities pursue these improvements, it is reasonable to expect in the near term that the number of occurrence reports will increase but the significance of the events should decrease. The LANL final report is due to DOE this month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 14, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 14, 2001

Security: This week, LANL implemented heightened security measures, which remain in effect.

Chemistry and Metallurgy Research Building (CMR): On Tuesday, CMR personnel reported elevated airborne monitoring results from one fixed head sampler, indicating an unanticipated airborne release into one room. The results were about 22 percent higher than the limit for continuous occupancy (i.e., 40 DAC-hours for a weekly sample). The facility is investigating the cause, and its followup actions appear to have been appropriate. No other contamination was found in subsequent surveys.

Work Controls: In response to a DOE request last week, LANL is limiting skill-of-the-craft (SOC) work to maintenance activities within the current LANL approved work control process and has submitted a plan for expanding use of the SOC approach within facilities by mid-FY02. Key elements of the plan include: completing development of worker qualification checklists; improving the Laboratory Implementation Requirement (LIR); piloting the expanded SOC approach at one facility (DX); incorporating lessons learned into the checklist and LIR; training facility management and supervisors; and verifying implementation during periodic management self-assessments.

While this plan appears to be well-structured, there have been many DOE occurrences involving jobs mis-categorized as "routine" and started as skill-of-the-craft without an adequate hazard analysis, leading to a facility upset. It would appear that expanded use of the SOC approach, if pursued, needs to be carefully considered and implemented at the individual facility and activity levels to avoid conditions conducive to initiating an accident.

Plutonium Handling and Storage Facility (TA-55): Last Friday, the DOE-AL Manager approved starting the construction phase (CD-3) of the Fire Protection Yard Main Replacement Project. The objective is to replace the existing safety significant system with a more reliable one that meets current codes and would remain operational after current design basis accidents (site rep weekly 8/31/01). Long-lead procurement (e.g., for piping) is underway; however, DOE has not yet authorized LANL to proceed, pending DOE review of relevant hazard analyses and performance of a readiness assessment on construction activities. Key milestones are completing construction of pump houses and tanks by mid-May 2002 and of underground piping by mid-July 2002.

Recommendation 2000-2: Board Recommendation 2000-2 addresses configuration management of vital safety systems. The DOE implementation plan includes commitments to develop a plan for a comprehensive fire safety review and to perform Phase II assessments of selected vital safety systems, including fire protection systems. Several DOE sites, including LANL, are pursuing completion of phase II fire protection assessments as part of the comprehensive review, which would be an efficient use of resources. This week, the DOE EH-led team performing the comprehensive reviews conducted a scoping visit and initial assessment at LANL. The full review is scheduled for October 15-26, with a final report expected in mid-November. Within the next few weeks, the team is expected to identify the specific facilities and systems that they will evaluate.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 21, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 21, 2001

Chemistry and Metallurgical Research Building (CMR): On Tuesday morning, a security checkpoint was set up at the CMR southeast gate and that gate was opened to provide access to the TA-3 Admin building parking lot. The CMR facility estimates that this has increased traffic flow around two sides of the CMR building by an order of magnitude, since the CMR southeast gate was previously closed to thru-traffic.

The site rep understands that neither the CMR facility management nor the DOE-LAAO operations or authorization basis staff were involved in the decision making process to reroute traffic inside the fence in close proximity to the CMR building – a Hazard Category 2 Nuclear Facility. Subsequent DOE and LANL reviews identified several new safety issues created by rerouting traffic.

On Thursday, the facility submitted and DOE approved a “backward looking,” unreviewed safety question (USQ) on the rerouted traffic. LANL identified the USQ as positive because of a new accident scenario and a new failure mode for a safety class system, created by the traffic rerouting. As a result of the backward looking USQ, LANL has taken compensatory measures to address these new safety issues.

While the compensatory measures taken appear to be adequate in the short-term, the site rep believes that the decision-making process followed was not unified and was not consistent with the principles of integrated safety management. Key decisions were made quickly with little involvement of the knowledgeable and responsible personnel, particularly for operations and safety. Key steps of the process, such as completing a USQ before the action, were skipped. The site rep acknowledges that there are times when senior management needs to make expeditious decisions. However, considering how quickly the safety review process was completed later in the week, it appears in hindsight that the correct process could have been expeditiously followed in this case.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 28, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 28, 2001

Plutonium Handling and Processing Facility (TA-55): In March 2000, a Pu-238 airborne release occurred from a TA-55 glovebox system, resulting in at least 7 of 8 workers in the room receiving confirmed intakes. The source was discovered to be a finger-tight compression fitting in a contaminated vacuum line. The line was disturbed by a technician troubleshooting a glovebox auxiliary system using skill-of-the-craft as work authorization. Contributing to the event was a ball valve in the vacuum line that had degraded teflon seats.

In July 2000, DOE issued a Type A accident investigation report on this event, which includes a list of causal factors and judgements of need. In September 2000, LANL provided a corrective action plan to address the DOE findings. At the facility level, the plan includes improving hazard analyses, work planning and controls, configuration management, and conduct of operations. At the institutional level, the desired improvements include glovebox quality assurance, communications (e.g., equipment status), defined roles and responsibilities, and the level of reliance on skill of the craft. Several of these have been discussed in recent site rep reports. Many of these involve ensuring that Integrated Safety Management is fully implemented.

During the last year, LANL has made progress on the above, including inspecting the integrity of the roughly 30,000 compression fittings in the facility. Discrepant gloveboxes and fittings have been or will be corrected on a risk-prioritized schedule. Other actions remaining include developing as-built configuration records for glovebox auxiliary systems; replacing the continuous air monitors (CAMS) to increase sensitivity by nearly an order of magnitude; and implementing a plan to inspect and replace degraded teflon components. The overall plan appears well-supported by DOE and LANL senior management. Within the next month, DOE expects to begin a review to validate many of the actions completed in the facility.

Weapons Engineering and Tritium Facility (WETF): Last Friday, DOE withheld approval of the updated authorization basis for WETF, consisting of the Final Safety Analysis Report (FSAR) and the Technical Safety Requirements (TSRs). During the comment resolution meeting last week, DOE, the facility itself, and an independent LANL review team each raised numerous questions on the safety analyses. LANL estimates that resolving the issues will cause a two month slip in operational readiness reviews for new WETF systems required for consolidation of LANL tritium operations. The site rep believes that the dependence on administrative controls and the level of defense in depth for fire protection still merits attention (site rep weekly 8/10/01). Also, it may be worthwhile to postpone finalizing the TSRs until after they have been incorporated into a set of draft procedures and those procedures have been validated by operations personnel.

Fire Protection: LANL has been investigating delayed signal transmissions from facility fire alarm panels to the central alarm station. For nuclear facilities, such problems might lead to delayed fire department response, possibly violating assumptions made in safety analyses. Personnel training is currently being used as a compensatory measure (i.e., dial 911). DOE and LANL are initiating a site-wide fire alarm system replacement project, which may address the longer term issue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 12, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 12, 2001

Recommendations 94-1/2000-1: DNFSB staff members Contardi, Kasdorf, Leary (OE), and Plaue were on site this week reviewing nuclear material stabilization activities and planning. The staff was encouraged by both the increased DOE support and the increased DOE/LANL emphasis on applying sound project management principles to these activities. While both funding and the level of activity have increased recently, project planning is still highly preliminary. DOE and LANL were not ready to discuss with the staff the program specifics, such as target stabilization dates, by material category, that are being used for planning purposes (i.e., dates other than FY 2010 for completing stabilization). LANL expects to be ready for these discussions within a few months and to have a draft program execution plan with resource-loaded schedules in February 2002.

Since 1995, LANL has stabilized nearly 6,000 items and achieved a significant risk reduction. However, progress has been slow during the last 2 years, and the inventory to be stabilized has increased. About 90% of the stabilization progress occurred prior to FY 00. The extended TA-55 shutdown to address the March 2000 Type A event also slowed progress (site rep weekly 9/28/01).

Currently, LANL has about 5,600 items, programmatic and excess, that need to be stabilized and properly packaged or disposed as waste. A large fraction are in older, non-standard containers (i.e., not the drop-tested, screw-lid, vent-filtered design). The schedule problem is compounded by the fact that the LANL 94-1 budget fell nearly four-fold between FY 96 and FY 01 (\$15.1M and \$3.9M, respectively), causing processing lines to be idled and experienced personnel to be transferred to other programs. While DOE recently provided supplemental funding (\$6.8M), it is likely that renewing processing and increasing qualified staffing without impacting other projects will be critical path.

The staff observed that LANL continues to study a multitude of options. Besides end date (per LANL, FY 2010), the risk reduction profile with time may be a useful measure for weighing these options. It appears worthwhile now to aggressively pursue options with the least programmatic uncertainty and work toward maximal and efficient campaigning of materials. The staff also continues to believe that the process vs discard decision for materials can be streamlined, possibly by taking advantage of lessons learned at other sites (e.g. RFETS). The container surveillance program could also be improved to increase confidence in container integrity and provide a basis for assumptions being made about the impact of aging on older packages and materials. The priority of processing legacy vs new residues continues to merit examination. The staff will continue to work closely with DOE and LANL to address these and other questions on accelerating LANL stabilization activities.

Emergency Operations Center (EOC) Replacement Project: On October 2nd, DOE approved the performance baseline (CD-2), the project execution plan, and the start of construction (CD-3) for the EOC Replacement Project. LANL is pursuing a design-build acquisition strategy. The seismic requirements are those for Performance Category 2 (PC-2, i.e., an essential facility) with ductile detailing and with base shear loads set by using a reduced ductility factor (doubles the seismic load). PC-2 loads are also being used for systems important to EOC operation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 19, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 19, 2001

DNFSB staff members Blackman, Jordan, Rosen, and Shackelford were on site this week reviewing design, procurement, configuration management, and maintenance of safety-related systems.

TA-55 Fire Protection Yard Main Replacement (FPYMR) Project: The FPYMR Project had its ground-breaking this week, marking the start of construction. The project is intended to replace the leaking fire water loop and improve system reliability (site rep weekly 8/31/01). Looking forward, construction will increase risk during periods when the building is penetrated and when firewater is not available to sprinklers. Last month, LANL proposed and DOE approved with comment additional controls to mitigate these risks. Some of these controls are as follows:

- ? Construct a temporary confinement structure in the basement around the new north-side building penetrations until confinement is reestablished, not to exceed 12 days
- ? Place operations in standby while the south and west side laterals are installed through building penetrations, not to exceed 8 days
- ? Establish a fire watch during subsystem tie-in and upon loss of the in-service firewater tank
- ? Place operations in standby if the fire suppression system cannot be returned to operability, and within 2 hours if the single, in-service firewater tank goes out of service

Because of the complexity of the modifications, DOE also prohibited simultaneous work involving confinement breach, flow path interruption, and tank or fire pump modification. LANL is developing an integrated construction schedule to meet the time and sequencing restrictions.

Quality Assurance (QA): The staff was briefed on recent activities to improve laboratory QA. During the last 2 years, numerous internal and external reviews have identified institutional QA issues at LANL. Currently, individual facilities and projects have QA programs that were developed more or less in isolation. They are inconsistent, of varied pedigree, frequently expert-based instead of standards-based, and generally not well implemented. QA oversight and accountability also need improvement. DOE appears committed to developing their local QA expertise and increasing oversight. Earlier this year, DOE contracted a nuclear QA expert to assess the program, in response to a Board letter (1/22/01). The subsequent review focused on QA elements involving design control and procurement for the CMR upgrades and the TA-55 FPYMR project. A report is expected shortly. This effort has provided the foundation for future improvements on the DOE side.

LANL management also understands the issues and considers making improvements a high priority. LANL is close to completing an updated, internal assessment and developing a corrective action plan to move forward. LANL is also planning to strengthen QA management by appointing a Senior Quality Officer, and establishing a Quality Assurance Council made up of senior line management. Key organization changes are expected within the next 3 months. Similar to the initiative to improve conduct of operations (site rep weekly 8/31/01), improving institutional QA is expected to be a long process, requiring continuous management emphasis and attention. One key to success may be for the institutional program to evolve from the best features of several well-developed facility and project programs that are now in place. Success will clearly require frequent and close interaction between the facility/project level and the institutional level throughout the improvement process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 26, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 26, 2001

Staff members Kasdorf and Leary (OE) were here this week attending the annual 94-1 R&D review. Martin and Nichols were also on site reviewing development of safety system design requirements.

Recommendation 2000-2: The site rep understands that DOE headquarters has suspended plans to conduct comprehensive fire safety reviews at DOE sites, including LANL (site rep weekly 9/14/01). Although these may resume, LANL is now exploring other options. LANL intends to send to DOE in November a plan for executing Phase II assessments and plans to begin these assessments in January. These developments may lead DOE to propose implementation plan changes.

Recommendations 94-1/2000-1: Recent 94-1 research and development (R&D) has focused on resolving moisture-related issues. Process control may be a viable option. Several studies presented this week indicated that, with the exception of chlorides, materials calcined at 950°C should meet the STD-3013 moisture requirements if ambient glovebox humidity is controlled to a reasonably low level. Also, DOE sites are moving away from using super-critical fluid extraction (SFE) for moisture measurements. LANL has investigated the recent SFE problems, considers the causes to be understood, and is continuing SFE development. Future R&D is expected to focus on gas generation – particularly, on reducing the conservatism in the current STD-3013 design pressure requirements.

LANL Authorization Bases (AB): LANL has made 3 major AB submittals to DOE this year (i.e., safety analyses and controls). These are for the critical experiments facility (TA-18), the plutonium processing facility (TA-55), and the weapons engineering and tritium facility (WETF). To date, DOE has reviewed two of these packages (TA-55, WETF) and acted on one (WETF). Throughout this process, DOE has been concerned about the quality of these submittals (site rep weekly 9/28/01).

LANL senior management has recently reviewed these submittals and has also concluded that improvements should be made. This year's submittals were driven by contractually imposed deadlines. They were not made using the LANL internal AB review process that has been in development. This week, LANL proposed performing an independent and rigorous quality check of these documents, considering DOE observations to date, and then resubmitting to DOE after final sign-off by the cognizant Associate Director. DOE and LANL would also revise the master schedule for AB document development. This will likely slow down the AB improvement effort but increase its probability of success. Appropriate prioritization and resource-loaded scheduling with contingency appear key. LANL intends to use the lessons learned to improve the process.

Critical Experiments Facility (TA-18): Like nearly all other LANL facilities, TA-18 needs to improve its performance on Technical Safety Requirement (TSR) compliance (site rep weekly 9/7/01). A recent DOE-EH letter to LANL discusses 3 TSR violations in TA-18 this year and states that TA-18 self-identified instances where corrective actions in 2000 were incorrectly reported as closed. The trend indicates that TSR training conducted in the facility was not adequate, particularly for surveillance requirements. LANL is pursuing further corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 2, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 2, 2001

Los Alamos Neutron Science Center (LANSCE): On Monday, DOE approved a Basis for Interim Operation (BIO) for LANSCE experiments involving neutron scattering by actinide targets. These will be Hazard Category 3 activities (HC-3). The targets will consist of double-encapsulated solid samples containing up to 60 grams of Pu-239 equivalent (PuE). The experiments support the Stockpile Stewardship and Management Program and are expected to continue through 2003. LANL anticipates some future experiments will need to be conducted at elevated temperatures, which is not currently approved. This will require DOE and LANL to revisit the actinide BIO.

Plutonium Handling and Processing Facility (TA-55): TA-55 has discovered that the most hydraulically remote sprinkler heads in PF-4 will not deliver the minimum flow density specified in the original facility design and the FSAR (i.e., 0.19 gpm/ft² over a minimum of 1500 ft²). LANL asserts that the original design requirement was not based on actual risk factors, such as combustible content, and that the as-built system will deliver 0.15 gpm/ft², sufficient to meet current NFPA codes for chemical laboratories (e.g., NFPA 45, NFPA 13 Ordinary Hazard Group 1). LANL has submitted to DOE a positive Unreviewed Safety Question (USQ) based on this discovery. DOE review and action on the USQ are forthcoming.

Decontamination and Volume Reduction System (DVRS): LANL has about 2,400 m³ of TRU waste that is oversized (e.g., gloveboxes) and stored in about 300 fiberglass-reinforced wooden crates. The crates range from 10 to 40 feet in length and from 4 to 12 feet in width and height. This is a form unsuitable for shipment to WIPP. The radiological contents of about one-tenth of the crates have been well characterized. Current knowledge of the remainder is based primarily on waste generator records. LANL believes that about half the crates could be processed, one at a time, in a radiological facility (i.e., less than 8.4 gm PuE), and nearly all (95%) could be processed in a HC-3 facility (i.e., less than 450 gm PuE, 900 gm PuE for critical safe forms). A small number of crates (~14) may require a HC-2 facility, depending on results of further characterization (e.g., Pu-238 content).

To prepare this waste for shipment, LANL is proposing to start up the DVRS within the next 2 months as a radiological facility and to transition this facility in future years to HC-3 and maybe eventually to HC-2. DVRS operations will be manually intensive and involve unpacking crates, fixing or removing contamination, segregating low level waste, and packaging for shipment. Oversized components will be hoisted and lowered into a shearing and compaction machine (a car crusher) that would reduce metal objects to pucks that can be loaded into standard waste drums. The facility has several safety features including PC-2 structure, dry-sprinkler fire suppression, 2-hour rated fire walls for both bays and building, HEPA filters on bay exhaust and on building supply and exhaust, and an emergency diesel generator to ensure ventilation remains negative. As of this week, the startup team has not completed a startup plan for radiological operations (it's close) or a transition plan, safety analyses, and function classification required for later HC-3 or HC-2 operations. Without the latter, it is difficult to say now that, once contaminated, upgrading the facility to HC-3 or HC-2 operations in the future won't entail either prohibitively expensive modifications or burdensome administrative controls. Additional forethought, such as a well-developed transition plan, appears warranted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 9, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 9, 2001

Critical Experiments Facility (TA-18): The site rep understands that the pace of some operations is increasing in TA-18. Earlier this week, an operator removed highly irradiated target foils from COMET, a general-purpose assembly machine, and received about 200 mrem in less than two minutes. For perspective, the total annual exposure for all facility personnel has been less than 1 man-rem. Also, next Tuesday, LANL intends to reconfigure COMET for the next series of experiments – the fourth reconfiguration this year. Normally, reconfiguration is done after a one-to-two week shutdown; however, conducting this evolution next week is expected to result in operators working in a high radiation area. Reconfiguration typically takes 1 to 3 hours. The facility is increasing emphasis on as-low-as-reasonably-achievable (ALARA) practices for these tasks.

High Efficiency Particulate Air (HEPA) Filters: TA-54 has instituted a nuclear-grade HEPA filter inspection process for the Decontamination and Volume Reduction System (DVRS) and has recently rejected 21 of an order of 59 filters received (i.e., about 35 percent rejection). The inspection criteria are based on the applicable DOE HEPA filter standards. Specifically, 12 were rejected for defects such as media deviation, gasket problems, and face-guard damage, and 9 were rejected because they were received improperly stacked on the pallets. Of particular interest, these HEPA filters had already been through and passed inspections at the vendor, at the DOE HEPA filter test facility, and at LANL receipt inspection, which raises questions at LANL and elsewhere on the consistency and thoroughness of these types of inspections.

TA-18 Flood Retention Structure (FRS): The site rep believes that DOE and LANL need to clarify responsibilities and make progress toward resolution of open issues with the FRS, including those identified in the Board letter and staff report issued this week. Some of these issues have been known for some time. Particularly, in May, DOE approved a positive Unreviewed Safety Question related to the FRS, subject to several conditions equivalent to Technical Safety Requirements (TSRs). Among these were LANL submitting to DOE a structural review, an emergency action plan, and maintenance and inspection procedures. In July and September, LANL submitted a maintenance/inspection plan and an emergency action plan. DOE action is imminent, but the site rep understands that there are issues. In August, LANL identified several key uncertainties. Among others, these included the roller-compacted concrete strength, foundation strength assumptions, and erosion controls. It appears appropriate to move quickly to address these uncertainties, finalize an emergency action plan, and implement appropriate FRS maintenance and inspection procedures.

LANL Authorization Bases (ABs): DOE and LANL have an aggressive schedule for AB upgrades during the next 6 months (site rep weekly 10/26/01). For the plutonium processing facility (TA-55), DOE has provided feedback to LANL and next week, a small, joint DOE-LANL team plans to review the current TA-55 hazard analyses. LANL intends to submit a 90% package for TA-55 in late December, receive DOE comments in February 2002, and submit the final package in April 2002. In the same time-frame, LANL will be preparing and DOE will be reviewing similar submittals for TA-18 and the Weapons Engineering Tritium Facility (WETF). Frequent positive engagement between DOE and LANL, as well as establishing a mutually acceptable resource-loaded schedule and interim milestones (such as the TA-55 review next week), could contribute to timely success.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 16, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 16, 2001

Radiography Facility: TA-8 Building 23 (TA-8-23) has been used since the late 1940s for non-destructive testing of high explosive (HE) and nuclear components. Overnight storage is prohibited. The facility has adequate separation from other facilities, a fire alarm system, lightning protection, x-ray machine interlocks, but no confinement features and no installed fire suppression. It also has a natural gas line to an equipment room, which needs to be considered in accident analyses.

In late 2000, DOE designated TA-8-23 as a Hazard Category 2 Nuclear Facility. At that time, a DOE-approved authorization basis did not exist. In April 2001, LANL submitted to DOE a Justification for Continued Operation (JCO). In parallel, LANL is preparing technical safety requirements (TSRs) and a safety analysis report, now at 70 percent complete. On October 29th, DOE approved the JCO subject to some conditions considered equivalent to TSRs. Among others, these include mass limits on cased HE and plutonium, as well as prohibitions on uncased HE, heat sources (Pu-238), radiography sources (Co-60), and combined HE/radioactive material operations (e.g., HE with depleted uranium). The last impacts planned operations, and DOE has suggested that LANL consider submitting an unreviewed safety question with justification. Resolution is pending.

Plutonium Handling and Processing Facility (TA-55): As of October 31st, LANL reported that about 80 percent of the TA-55 Type A corrective actions have been completed (site rep weekly 9/28/01). Some of the improvements remaining include: improving formality of operations; completing component labeling; capturing normal system lineups on system drawings; verifying actions on maintenance and testing of compression fittings and teflon seals; addressing minor-to-moderate glovebox vulnerabilities found during recent inspections; and implementing a self-assessment process to improve reliance on the skill of the worker.

While DOE and LANL have been tracking milestone completions, an independent DOE assessment and verification of closure remains to be done. Such assessments are required by DOE Order 414.1A, *Quality Assurance*, and the corresponding DOE-AL supplemental directive on corrective action tracking systems. The site rep believes that verification is overdue. DOE-AL has prepared a Criteria Review and Approach Document (CRAD) and is close to completing a verification plan based on the supplemental directive requirements. The plan still needs to be coordinated with LANL, and discussions between DOE and LANL this week indicated that there is some confusion. Tentatively, DOE believes that verification of the completed actions will be done in January.

Chemical and Metallurgical Research Building (CMR): Thursday morning, a tractor-trailer rig hauling low level waste containers had its trailer de-couple as the rig was exiting the CMR parking lot onto Diamond Drive. The trailer slid back about 10 feet and landed on its front leg supports. Radiological controls and security personnel responded appropriately. The trailer was found to be mechanically sound. There was no release of radioactivity from the containers, and they have been moved to TA-54. LANL is

investigating to determine the cause of the event.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 14, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 14, 2001

LANL Authorization Bases (ABs): The AB upgrade schedule is aggressive. The LANL resubmittal for the Weapons Engineering Tritium Facility (WETF) appears to be the highest priority and is expected in late January 2002 (site rep weeklies 11/23/01, 9/28/01).

Plutonium Handling and Processing Facility (TA-55): The following are noteworthy:

- c The ventilation ductwork between the exhaust filter plenums and the building structure is considered to be a Safety Class design feature to prevent an accidental release. The site rep understands that duct inspections done several years ago identified minor internal surface corrosion but that nominal wall thickness was basically the same as during construction. During the next two months, the facility intends to develop a routine preventive maintenance program to monitor the condition of the Safety Class ductwork. The program is currently envisioned to be a visual and an ultrasound inspection every one and five years, respectively.
- c Recently, there have been several contamination events in the aqueous processing operations, including one skin contamination. Several of the events are attributed to service-life failures. The facility has concluded that an increased emphasis on engineered barriers, plant maintenance, and radiological controls practices is warranted. Management has reviewed the events, lessons-learned, and expectations with personnel. Also, work area supervisors are assessing process equipment age, reliability, and risks to identify improvements.

These initiatives are commendable. The site rep believes that the increased, complex-wide emphasis on facility infrastructure and vital safety systems (e.g., Recommendation 2000-2) has raised awareness. In this context, the facility itself – particularly, the facility management and the DOE facility reps – self-identified the specific issues leading to these initiatives. Resources required and available are to be determined.

Decontamination and Volume Reduction Facility (DVRS): System testing and questions on startup requirements have delayed the LANL and DOE readiness assessments (RAs) for DVRS at least a month (site rep weekly 11/2/01). The LANL RA was scheduled to occur this month. The advantage of expeditious startup is timely reduction of TA-54 combustible loading. The disadvantage is that the currently proposed startup strategy could potentially allow incompletely characterized packages to be opened in the facility, leading to unanalyzed conditions.

The basic question is the chemical and radiological hazard categorization at initial startup. LANL has proposed that the facility be started up as a low-hazard, radiological facility and in a year or two transition up to Hazard Category 3 (HC-3), and possibly HC-2. However, recent LANL analyses has reduced by half the number of packages that may be processed before the facility transitions to HC-3. At this time, the project lacks completed safety analyses and functional classification that would support a HC-3 startup. They have drafts. The site rep is still looking for a systematic transition plan to HC-3 and a conservative set of controls on source term, safety equipment, and procedures in the interim. Some but not all of these elements are in place. DOE is reevaluating the startup strategy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 21, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 21, 2001

Staff member C. Coones was on site this week reviewing the TA-55 fire suppression system.

Plutonium Handling and Processing Facility (TA-55): The TA-55 fire suppression system is safety significant because it protects workers and provides defense-in-depth for safety class systems. The staff has observed that a number of questions linger on the system (e.g., site rep weekly 12/7/01). Recently, DOE and LANL have been working to address these. DOE and LANL agree that more information is needed on the sprinkler system, fire pumps, and storage tanks, and that timely resolution is required to support the TA-55 Authorization Basis resubmittal in April 2002.

At this time, DOE and LANL believe that there are no imminent safety concerns that warrant operational restrictions. Current information indicates that 2 of about 20 sprinkler heads in the most hydraulically remote north-side room would have major flow degradation (~18%) and 3 others would have slight degradation (3%). The symmetrically located south-side room may also have a similar number of heads with degraded flow, but that remains to be evaluated. Transient combustibles in these spaces are low, based on monthly surveillance. Three of the four fire pumps deliver required flow at pressure. The fourth will be tested within the next few weeks. Questions on pump suction head, minimum storage tank level, and HEPA filter cooldown spray requirements all need to be addressed.

LANL believes that there are no design impacts on the fire loop replacement project as a result of updating internal fire suppression requirements. LANL has asked the project to update the flow analyses, using the revised assumptions, and determine the pump characteristics that could be the basis for the new Technical Safety Requirements. The staff believes that flow analyses of interim configurations, such as during system tie-in and pump house upgrades, are also warranted to ensure adequate interim fire suppression is available.

Decontamination and Volume Reduction System (DVRS): This week, DOE withheld concurrence with LANL categorizing DVRS as a low hazard, radiological facility (site rep weekly 12/14/01). Both the chemical and radiological hazards require further assessment. DOE observations included the following: (a) the proposed categorization was incorrectly based on mitigated consequences (e.g., it credited fire suppression); (b) the analysis did not consider accident consequences from explosive hazards that LANL indicated may be present; (c) cited radiological inventories were inconsistent; (d) significant, non-conservative uncertainties may exist in the currently projected container inventories, possibly by up to an order of magnitude based on comparisons of historical records to modern assay results; and (e) worker hazards, such as falling into the shear bailer, were not addressed. Based on these observations, it appears that there may be a further reduction from earlier estimates of the number of containers that can be processed before the facility transitions up to Hazard Category 3.

DOE requested LANL to resolve these issues and hold a formal comment disposition meeting in January to expedite hazard categorization.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 28, 2001

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 28, 2001

The laboratory is closed from Tuesday, December 25, to Wednesday, January 2.

Plutonium Handling and Processing Facility (TA-55): LANL is close to completing the installation of the Pu-238 Scrap Recovery Line, a new aqueous processing line for recovering and purifying Pu-238 oxide. The objective is to be able to produce ½ kg Pu-oxide per month, 10 months per year. This is a batch process with a separate glovebox being used for each major unit operation: comminution (ball milling), nitric acid dissolution, anion exchange, oxalate precipitation, hydroxide precipitation, filtration, and calcination/oxygen-16 exchange (calcination is at 750 °C for 2 hours). The gloveboxes are normally sealed from each other. Transfers are made via tubing for solutions and via covered metal containers and pass-through doors for solids.

When operational, the Scrap Recovery Line will be a Hazard Category 2 activity based on the Pu-238 inventory. Per DOE direction, the safety class controls include an inventory administrative limit and specifications for the anion exchange resin on type, shelf-life, dry-out restrictions, and recovery/render-safe processes. These controls are in addition to the normal safety class features for Pu-238 operations (i.e., building structure, filter plenums, connecting ductwork, and seismically qualified gloveboxes). Safety significant features include the covered metal containers for moving solids and the stainless steel mesh that surrounds each anion exchange column. DOE also is requiring LANL to develop a TSR-level control on transient combustibles within the glovebox line, as well as safe handling procedures for certain chemicals used in the process.

Currently, LANL anticipates a management self-assessment in February, the LANL readiness assessment in March/April, the DOE readiness assessment in June, and startup by August.

TA-18 Flood Retention Structure (FRS): DOE has obtained from the Army Corps of Engineers a proposal to undertake activities necessary for resolving open issues with the FRS, including those identified in a Board letter and staff report in November (site rep weekly 11/9/01). The proposed activities include performing a baseline FRS inspection, core drilling and testing the roller compacted concrete and underlying foundation material, and preparing a concrete materials and foundation completion report. DOE action on the proposal is imminent. These activities also support the turnover of FRS responsibilities from the Corps to DOE and LANL. Timely resolution of these issues continues to be warranted, as well as finalizing the FRS emergency action plan and FRS maintenance and inspection procedures.

Transuranic Waste Inspectable Storage Project (TWISP): Last week, TWISP retrieved its last waste drum, reaching this milestone two years ahead of schedule and \$13M (26 %) under-budget. Since 1995, TWISP has retrieved about 17,000 drums and 200 fiberglass reinforced plywood crates in TA-54. The containers had been stored for nearly two decades in dense-packed arrays on asphalt pads under plywood, plastic, and earthen cover. Retrieval operations were conducted using a Hazard Category 2 safety basis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 4, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 4, 2002

The laboratory reopened on Wednesday, January 2, from the holiday recess.

DOE Independent Oversight Review: The DOE Office of Independent Oversight and Performance Assurance (DOE-OA) is planning an on-site evaluation in early Spring, covering Integrated Safety Management (ISM) core functions, the safety management system, the emergency management program, and the functionality of a selected essential safety system (e.g., Recommendation 2000-2).

In preparation, a DOE-OA team will be on site next week for a scoping visit, which will be focused on the following areas: ISM accomplishments, changes in emergency and environmental management as a result of the Cerro Grande Fire, LANL institutional actions as a result of the TA-55 Type A event, lessons learned from Recommendation 2000-2 reviews, and contract changes related to safety improvements (e.g., implementation of the DOE Conduct of Operations order, 5480.19). DOE-OA team members are also scheduled to walk down the ventilation system for the Chemistry and Metallurgical Research Building (CMR). The CMR ventilation system is currently not on the list for 2000-2 Phase 2 reviews (site rep weekly 12/7/01).

Emergency Operations Center (EOC) Replacement Project: The design for the EOC replacement project is currently at 60 percent with anticipated completion in July 2002. This project is an FY 01 line item intended to address emergency management issues identified during the May 2000 Cerro Grande Fire. In October 2001, DOE approved LANL pursuing a design-build strategy (site rep weekly 10/12/01). Currently, the new EOC is envisioned to be a two-story building, nearly 38,000 ft², that will consolidate LANL's emergency management and response activities, as well as Los Alamos County Fire, Police, and 911 dispatching. The dispatching center will be continuously manned. Besides EOC and dispatching, the building would include space for telecommunications, a standby diesel generator, uninterruptible power supply, boilers, chillers, other electrical/computer equipment, and a large garage for emergency vehicles. Building construction would consist of a cast concrete foundation, grout-filled masonry walls, and metal/concrete decks for the 2nd floor and roof. Ground-breaking and construction start is expected within 3 to 4 weeks.

LANL Authorization Bases (ABs): In mid-December, LANL submitted to DOE a new master schedule for delivering upgraded AB documentation for both nuclear and non-nuclear facilities (site rep weekly 11/23/01). The new schedule reflects the increased workload to improve analyses, as well as the additional time for LANL quality assurance and management review. The initial submittal will be for the Weapons Engineering Tritium Facility (WETF) later this month, followed by the Critical Experiments Facility (TA-18) in mid-March and the Plutonium Handling Facility (TA-55) in early April. After that, major submittals for the remaining nuclear facilities without current ABs are expected at a pace of about one per month through January 2003. DOE and LANL appear focused on timely delivery, review, and approval of high-quality safety analyses. Close attention to this is required to ensure each of these facilities is able to safely operate within a well-understood safety envelope and efficiently accomplish its national security mission.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 11, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 11, 2002

Facility Operations and Maintenance: This week, LANL announced its intention to compete the laboratory's maintenance and services contract, which has been held by Johnson Controls Northern New Mexico (JCNM) since 1997. Current contract value is about \$145M. In the announcement, LANL indicated that the contract needs to be competed in keeping with the recent operations realignment and the different approach being pursued for facility operations and maintenance.

Chlorine Dioxide Event: On Tuesday, an uncontrolled energetic reaction occurred in a non-radioactive chemical laboratory in TA-54 West. The laboratory is in the same building as a component decontamination shop (e.g., for respirators). The site rep understands that two researchers were working to develop a chloride dioxide hydrate that could be safely packaged, transported, and stored when one observed an unexpected temperature increase and both began to evacuate the room.

The subsequent reaction ruptured and plastically deformed a 3,000 psi-rated pressure vessel, destroyed a fume hood, and generated energetic missiles that perforated walls and caused significant damage. Due mostly to their alertness and quick action, the two researchers escaped without serious injury. The site rep believes that appropriate immediate and supplemental actions were then taken, including timely communications to workers and the public of the nature of this event. LANL has initiated an investigation. At this stage, DOE and LANL are asking the right questions about work authorization, hazards communication, hazard analysis, and implementation of controls.

Critical Experiments Facility (TA-18): On Wednesday, the TA-18 Facility Manager suspended operations of PLANET due to a reliability issue with the antiquated reactivity control system. PLANET is a general purpose vertical assembly machine used frequently for criticality training. Criticality is achieved by stacking enriched uranium plates on a fixed upper platform and a movable lower platform. The latter is positioned by a hydraulic lift and a fine-control stepper motor.

This week, during maintenance on the stepper motor control system, the lower platform began to rise toward the upper platform without operator action. Since the assembly had been unstacked to half that required for criticality, personnel safety was assured before the maintenance began. However, this is the fifth failure of this control system in the last 7 weeks. In the other cases, the control system failed to move the lower platform on command; however, in this case, the platform appears to have moved on its own. No critical operations were done in the time between the first and the final failure. To address the reliability issue, LANL plans to install a new control system, potentially resulting in a 2 to 4 month impact on related programs.

Quality Assurance: LANL has several initiatives underway to improve safety, quality, project management, and formality of operations. Many of these resulted from internal LANL reviews and external reviews by DOE, the Board, and other organizations (site rep weekly 8/17/01). In the past, LANL has astutely identified problems and creatively developed solutions but has had difficulty in instituting lasting change. The site rep has observed that progress appears to be occurring now in formality of operations, but early steps to achieve institutional quality assurance improvements have not materialized as expected. This may warrant increased management attention.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 18, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 18, 2002

The site rep was at DNFSB-Headquarters in Washington D.C. this week. This report filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 25, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 25, 2002

Chemistry and Metallurgical Research Building (CMR): This week, CMR management curtailed operations, since CMR has had 7 contamination events so far this month, 6 of which occurred in the last two weeks (4 bootie, 2 personal article, and 1 skin contamination). This is prudent. Each of these events individually involved low risk; however, collectively, they could be viewed as precursors to a potentially more significant future event. Contamination control is a recurring problem in CMR due to legacy contamination, increased workload, and occasional poor work practices in unforgiving radiological conditions (e.g., researchers working with contaminated hoods). Last September, CMR provided DOE an action plan to reduce the number of contamination events in the long term. Key elements included changing worker behavior and awareness (e.g., peer review, recognition of good practices and habits); reviewing the history and condition of individual rooms (e.g., legacy contamination); and clarifying personnel protective equipment requirements (e.g., use of gloves). This is a good start. The issue warrants continuing close management attention in detail to execution.

Decontamination and Volume Reduction System (DVRS): DOE and LANL have agreed upon a path forward to start up the DVRS as a radiological facility, process a small number of the fiberglass-reinforced crates with low TRU waste inventory, and then transition the facility to Hazard Category 3 (HC-3) operations. The possibility remains that a small number of packages may have inventory exceeding the HC-3 threshold and will require processing, in future years, in either a HC-2 facility or in DVRS with appropriate short-term compensatory measures (site rep weeklies 11/2/01, 12/21/01).

The Inventory Control Plan considers startup in 3 phases: (1) cumulative inventory of containers processed not to exceed 85% of the HC-3 threshold; (2) additive inventory not to exceed the HC-3 threshold, based on subtracting out assayed waste streams; and (3) full HC-3 operations with appropriate controls. Readiness assessments (RAs) would be performed before Phases 1 and 3. The site rep understands that shear-bailer operations (e.g., for glovebox size reduction) will not be permitted until HC-3 operations are authorized. One clear advantage of this approach is the early experience that will be gained by starting on the low activity packages. Thorough RAs are advisable to assess preparations for these manually intensive radiological operations. The pre-RA management self assessment is scheduled to begin next week.

Chlorine Dioxide Event: LANL is investigating the vessel rupture event of January 8th using methodology from the DOE accident investigation guide (G 225.1A). DOE has a representative working with the LANL team. The site rep understands that the team is approaching this investigation with a level of rigor equivalent to a Type B accident and has targeted having a draft report for factual accuracy review within the next two weeks (site rep weekly 1/11/02).

LANL Authorization Bases (ABs): This week, LANL submitted to DOE the proposed authorization basis for the Weapons Engineering Tritium Facility (WETF). This is the first major AB submittal under the new master schedule and should be a good test case on whether DOE and LANL have improved their processes for delivery and approval of major safety analyses (site rep weekly 1/4/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 1, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 1, 2002

Bamdad, Jordan, and Martin were on site this week reviewing TA-18 activities.

Critical Experiments Facility (TA-18): TA-18 has unique capabilities and personnel with unique expertise to support criticality safety training, emergency response, nuclear non-proliferation, arms control, and stockpile stewardship. DOE is pursuing relocating TA-18 capabilities, because its facilities are 30 to 50 years old and are increasingly expensive to maintain and operate (e.g., annual security and operating costs have escalated at a rate of 16 % per year during the last five years).

In a letter to the NNSA Administrator this week, the LANL Director expressed strong support to relocate the TA-18 mission to a new facility designed to meet today's requirements. The letter emphasized that many of these activities have grown significantly since September 11th. The letter states that both CMR replacement and TA-18 mission relocation are urgently needed in the near-term, and construction should start as soon as possible since neither facility can be safely and securely operated beyond 2010. A final environmental impact statement for TA-18 mission relocation is expected imminently, leading to a record of decision in March. LANL is developing a transition plan and has a conceptual design effort underway to facilitate comparison of alternatives. To date, LANL has been thorough in close-coupling preliminary safety analyses with the design activities. If the preferred alternative is chosen (TA-55), preliminary design would start in late Spring.

While the emphasis now is encouraging, TA-18 mission relocation is years away, and recent events indicate that current TA-18 operational and safety infrastructure needs to be improved. For example, three of five critical assemblies are now shutdown, hindering operations. PLANET was shut down last month and will require a 2 to 4 month unanticipated outage to replace antiquated control equipment (site rep weekly 1/11/02). SHEBA has been shut down since September 2000 because of an unacceptable potential for flammable gas buildup in the vessel head space (DOE does not currently plan to relocate SHEBA). Facility management has observed that a carefully planned path forward exists to restart two assemblies (FLATTOP and SHEBA) and has expressed confidence in the two currently operating machines (GODIVA and COMET).

TA-18 also has had several Technical Safety Requirement (TSR) violations in the last year, due in part to operator inattention and to a diffuse authorization basis that is scheduled to be upgraded within months (site rep weekly 11/30/01). Last week, the facility reported a Technical Safety Requirement (TSR) violation involving plutonium oxide material brought on site for a limited term project in June 2001. The material was still on site past November 2001, exceeding the period authorized by DOE.

Collectively, these and other issues may indicate a potential need for an operational assessment, leading to a prioritized list of improvements that need to be made to support TA-18 safely and efficiently performing its National Security mission until the replacement project is completed. LANL has implemented a similar limited-upgrade program at CMR that has increased short-term confidence in the safe operations of that facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 8, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 8, 2002

Weapons Engineering Tritium Facility (WETF): WETF has had two events in the last two weeks that indicate that improvements are needed in emergency response planning and training, facility preventive maintenance, and system checkout before gas transfers. This week, operators transferred gas to an unintended location because of an incorrect system alignment. There was no release. Recurrence could be prevented by an independent verification of system alignment before transfers.

Last Wednesday, WETF released about 175 Curies of 1% oxidized tritium to the environment while responding to a system leak into a glovebox and from there into a process room. While the consequences were minor (1 mrem or less), the lessons are important. During the event, the installed glovebox tritium monitor saturated. The facility then connected a high range portable monitor, which in turn not only saturated but also leaked – significantly increased the release to the room. In hindsight, attaching the portable monitor could not have provided useful information. Before it was connected, the glovebox was performing its confinement function. The facility later determined that, during this period, tritium levels in the room were about 7 orders of magnitude lower than those in the glovebox. Also, the two leaking fittings are similar and susceptible to improper connection or being loosened by line vibration. The event might have been prevented by either a periodic tightness check of installed fittings or an integrity check on the gas transfer path before the transfer. Currently, WETF does rate-of-rise integrity checks on lines when modified. Implementing both practices may be worth pursuing. After this week's event, WETF curtailed operations. The facility has done a good job investigating these events and needs to be thorough in following up on lessons learned.

Preliminary Functional Classification: Engineering design and safety analyses need to be tightly coordinated, whether designing a new facility or modifying an existing one. Preliminary function classification (PFC) is a primary interface mechanism for achieving this integration. PFC involves an early and recurring identification of potential engineered safety features and systems. It forms the rational basis for proceeding with design. PFC may initially be based on analyses from older facilities or on engineering judgement arising from, in some cases, up to five decades of relevant experience.

In four recent projects reviewed, there appears to have been little to no effort or intent to establish functional classification, including PFC, in advance of the final accident analyses, which can be years away. In fact, there is resistance to this approach because, if engineering judgement or early analyses prove wrong, then PFC may have missed important safety systems, or project funds may have been expended on systems that are later concluded not vital to safety.

The site rep believes that there needs to be a greater effort in LANL projects to formally establish early and iterate on a reasonably conservative set of potential safety systems, in advance of final accident analyses. The risks of using the PFC process can be addressed by timely iteration and active programmatic risk management. If managed, these risks can be less than those posed by not using the PFC process, which could lead to a major iteration late in detailed design, a major unanticipated upgrade, or a major reconstitution of system pedigree. What often occurs in these cases is that the design or facility is not corrected. Instead, the project defaults to using administrative controls over engineered safety features. This can be avoided by a proper, balanced use of the PFC process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 15, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 15, 2002

Critical Experiments Facility (TA-18): Flattop, a spherical benchmark critical assembly, has been shutdown since February 2000, except for one special DOE-approved test. Last month, LANL submitted to DOE a positive Unreviewed Safety Question Determination (USQD) involving a Flattop interlock that is described in the safety basis but does not exist. The interlock was intended to prevent resetting the SCRAM unless the three control rods are fully retracted (their minimum reactivity position). As is, an inexperienced operator could quickly reset the control system after a SCRAM, move the safety blocks in while control rods are partially inserted, and cause an unanticipated criticality, albeit with lower reactivity than existed before the scram. Rather than install the interlock, LANL proposes adding a TSR administrative control that cautions operators not to reset the SCRAM before the control rods are fully retracted. DOE action is forthcoming.

The site rep understands that this discrepancy was first recognized in February 2000; that the missing interlock was one of eight Flattop discrepancies described 19 months ago (July 2000) in a LANL evaluation of the authorization basis design configuration; and that Flattop has operated once during this period (August 2000), which was for a special test to resolve a safety basis question on the reactivity insertion rate of the safety blocks. DOE and LANL are pursuing questions raised by these events, including timeliness and coordination among safety basis activities. Site rep weeklies, dated 1/11/02 and 2/1/02, discusses related issues.

Facility Management: LANL is pursuing standardization of practices and consolidation of facility management units. Overall, these developments are positive; however, the resulting realignments and other changes will have safety implications. As part of this effort, clarifying and strengthening the facility manager's role may be appropriate. A facility manager is in a unique and challenging position that, in many organizations, carries responsibility for all activities within the facility. His or her chances of success improve if the facility's boundaries are well-defined and manageable in scope. The facility manager then needs necessary and sufficient authority to meet these responsibilities, as well as full organizational support from above and below. Reenforcing the facility manager's role can improve efficiency and effectiveness, which will also improve safety.

Work Controls: LANL is piloting an expanded skill of the craft (SOC) approach for work control that will reduce the requirement for task hazard analyses (site rep weekly 9/14/01). LANL defines SOC work as discrete tasks to be done by either a qualified craftsman with the expertise to identify and control the hazards or by workers using a written procedure that specifies the hazards and controls. No separate, formal task hazard analysis is done when work is authorized as SOC.

The expanded approach moves away from authorizing SOC tasks by specific task type to controlling it by worker qualification (i.e., a controlled qualification criteria checklist). Preliminary feedback from the pilot includes: "facility coordinators find the [SOC approach] much more efficient to be able to provide input to the process by simply declaring work to be SOC; the craft and/or zone management then concur or amend as necessary." While some craft work can probably be safely and efficiently performed using this approach, there also appears to be cases where a simple craft evolution might have unforeseen consequences on operations and safety unless it is properly reviewed and controlled.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 22, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 22, 2002

Weapons Engineering Tritium Facility (WETF): WETF resumed gas transfer operations last week (site rep weekly 2/8/02). Corrective actions included implementing an independent verification of valve positions for tritium container loading and unloading operations, as well as a thorough rate-of-rise integrity check for gas transfers of more than 1 gram. After 30 days, the facility will reevaluate these actions. WETF is also pursuing a locking device to prevent the mechanical fittings from loosening and is evaluating potential preventive maintenance improvements for fittings and valves. The site rep believes that these are appropriate followup actions to the events reported earlier this month.

Radiography Facility: TA-8 Building 23 (TA-8-23) is a 1940s era building that is used for nondestructive testing of high explosive (HE) and nuclear components. In late 2000, DOE designated TA-8-23 as a Hazard Category 2 nuclear facility, although this facility did not have a DOE-approved authorization basis (AB). In October 2001, DOE approved a Justification for Continued Operations (JCO) for TA-8-23 subject to conditions considered equivalent to Technical Safety Requirements (TSRs). Among those was a prohibition on combined HE/radioactive material operations (site rep weekly 11/16/01). In December 2001, DOE approved a limited-term JCO that permitted radiography of two assemblies of combined HE/radioactive material (site rep weekly 12/7/02). In January 2002, DOE approved a JCO addendum that removed this restriction.

On February 14th, LANL completed a TA-8-23 readiness assessment (RA), which reported several post-start findings. Among these is the facility's backlog of unreviewed safety questions (USQ). The RA report states that AB staffing may not be adequate to keep up with the work load for a new Hazard Category 2 Facility. The LANL master schedule for AB upgrades indicates that LANL will submit a 10CFR830 compliant safety basis for TA-8-23 by May 30th. This may become challenging if the USQ backlog and facility AB staffing issues are not addressed.

Emergency Exercise: On Wednesday, DOE (SO-40) conducted a mid-day, no-notice emergency exercise at LANL, based on a postulated glovebox fire in the Chemistry and Metallurgical Research Building (CMR), Wing 5. Facility actions and external notifications were simulated. The Emergency Operations Center (EOC) was fully activated in about 20 minutes of initiating recall. Based on the information available, the postulated event was categorized as a Site Area Emergency, as expected, a few minutes after full activation.

The site rep observed the exercise from the EOC. Overall, the EOC response was proficient. The May 2000 Cerro Grande Fire experience is still fresh. Information management in the existing EOC is challenging. While facility condition reports were timely, the site rep believes that the EOC should have had quicker access to information on personnel accountability, affected room location, room radiological and chemical inventory, and any injuries or contaminated personnel. Information management should improve when the new EOC is completed (preparation of the construction site is underway). The DOE (SO-40) exercise assessment is expected in about one month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 1, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 1, 2002

Staff Reviews: The site rep attended a Standing Management Team meeting at Pantex this week to determine the status of laboratory support for Pantex operations. Boyd, Feldman, Jordan, and Von Holle were at LANL this week reviewing chemical safety. The staff team was briefed on the status of the nearly completed LANL investigation of the chlorine dioxide explosion (site rep weekly 1/11/02). Boyd and Jordan also observed nuclear chemistry research operations in TA-48, and CMR.

Plutonium Handling Facility (TA-55): The Fire Protection Yard Main Replacement Project is intended to replace the leaking fire water loop and improve its reliability (site rep weekly 11/23/01). Progress has been slow but deliberate. The construction force began fusing the main body of the first replacement piping section in early February. Last weekend, the first section was successfully hydro-tested. A DOE readiness assessment began this week, focused on tie-in preparations and implementation of controls (e.g., controls to minimize periods of increased risk, such as during a confinement breach). Tie-in of the first section could occur as soon as next Friday (March 8th), following the readiness assessment and a series of flushes.

Weapons Engineering Tritium Facility (WETF): DOE review of the LANL proposed WETF safety basis continues (site rep weekly 1/25/02). The staff is reviewing it in parallel. LANL identified the safety class features as the facility structure, tritium containment vessels, and Pu-238 sealed sources (used for calibrating calorimetry). The proposed safety significant features include: tritium monitoring, gas containment, gas handling, and waste treatment; fire protection; environmental chamber over-temperature protection; glovebox inert and oxygen monitoring; and the uninterruptible power supply for monitoring systems.

Decontamination and Volume Reduction System (DVRS): This week, the staff (Boyd, Jordan, Keilers) toured DVRS and discussed preparations to first start it up as a radiological facility and later transition to a Hazard Category 3 (site rep weekly 1/25/02). The staff learned that shear-bailer operation could occur prior to that transition. Also, the facility is pursuing the possibility of using glovebox decontamination processes developed and used at Rocky Flats.

DVRS will require manually intensive radiological operations and warrants a rigorous startup process. A facility management self-assessment (MSA) began on January 25th. The facility manager prudently suspended it a week later due to equipment and procedure problems. The MSA is now expected to restart in mid-March and will be followed by LANL and DOE readiness assessments. Because of the unique startup strategy being pursued, the DOE Site Office Manager (acting) is the startup approval authority.

Critical Experiments Facility (TA-18): LANL is poised to begin a readiness assessment next week for relocated storage of Special Nuclear Material, subject to resolution of seismic robustness questions and DOE approval of the hazard analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 8, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 8, 2002

Boyd, Contardi, Hunt, Kasdorf, Leary, Malen, Plaue, and Wong were on site this week reviewing operations, 94-1 progress, inactive nuclear material storage, and the new scrap recovery line.

Plutonium Handling Facility (TA-55): The staff reviewed startup preparations for the Pu-238 scrap recovery line (site rep weekly 12/28/01). Startup is scheduled for August. The staff found the project team technically very competent, and the project proceeding in a deliberate manner. The staff raised questions on the formality of the safety basis controls, project management, and operator training, as well as on the technical basis of certain design features credited in the safety basis.

Recommendations 94-1 /2000-1: LANL discussed with the staff a new draft stabilization and packaging baseline sent to DOE last week. By the draft, LANL would qualify workers during the next 2 years, process most materials between 2004 and 2008, and complete processing in 2009. After rampup (2004), the processing schedule appears aggressive. Key assumptions are not yet documented.

LANL also indicated that safe, secure vault storage on site is near capacity and needs to be carefully managed and improved on to support current operations. Shipments off site are limited by restrictions on shipping containers and receiver sites. On-site storage demands will likely increase to support future missions and other needs. For example, DOE tasked LANL in December 2001 to identify and establish storage in FY 02 for about 350 sealed Pu-239 neutron sources that may prove difficult to disposition. Progress on 94-1 (e.g., Pu stabilization and packaging, residue disposition) would permit more efficient storage and free up vault space. Therefore, DOE and LANL would likely benefit from both a safety and a mission perspective if 94-1 objectives were vigorously pursued.

Critical Experiments Facility (TA-18): During the review of inactive TA-18 materials, LANL discussed with the staff about 30 poorly characterized drums of predominantly uranium and about 2 dozen potentially embrittled plastic containers of excess uranium solutions. Accelerated characterization and disposition of these materials appears warranted.

Also this week, the readiness assessment for the special nuclear material (SNM) relocation project was completed. A large inventory of SNM was relocated Thursday. DOE approved the project's safety basis, subject to review and approval of the seismic analysis and installation of any seismic anchorage or supports required on or before March 29th. During a tour, the staff observed anchorage embeds already being installed. The staff will review the seismic analysis when it is available.

Conduct of Operations: Properly preparing and validating procedures and then performing procedures as written are key elements of conduct of operations, which LANL has committed to implement in FY 02 (site rep weekly 8/31/01). The LANL Director has set an expectation that the quality of LANL operations match the quality of its science and technology. Last week, the staff observed programmatic personnel in a facility not performing a procedure as written. The responsible group is now pursuing validation of its procedures prior to their next performance. It may be worthwhile for other groups to consider verifying that their procedures can be and are being performed as written, as part of implementing conduct of operations into programmatic work.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 15, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 15, 2002

LANL Authorization Bases (ABs): This week, LANL proposed to DOE a new TA-18 authorization basis, which applies to the Critical Experiments Facility. The improved AB ought to address some operational issues seen in the last year. This is the second major AB submittal under the new master schedule. DOE action is forthcoming on the WETF submittal (site rep weeklies 1/25/02, 2/15/02).

Tritium Operations: Last Monday (3/4/02), tritium contamination up to 200,000 dpm/100 cm² was detected in uncontrolled spaces in the Tritium Systems Test Assembly Facility (TSTA), including the shoes of four personnel. TSTA is a Hazard Category 2 (HC-2) facility in TA-21. There were no continuous air monitor (CAM) alarms during the event. The contamination was traced to an area where process piping had earlier been removed from a glovebox inside a radiological buffer area. Local tritium contamination levels were up to 12 million dpm/100 cm².

It is not clear yet why this loss of contamination control occurred. LANL is in the process of removing contaminated equipment from TSTA in an effort to reduce source-term, downgrade TSTA to a radiological facility in 2003, and eventually inactivate the facility. The site rep understands that equipment has been removed from several gloveboxes recently without a problem, and that facility operations personnel are investigating why this event happened.

Plutonium Handling Facility (TA-55): On Wednesday, an alpha contamination event occurred in TA-55 that led to CAM alarms, two personnel with positive nasal smears, and one with skin contamination. Bioassay results are forthcoming. The event occurred when an employee removed copper vacuum tubing from a plastic waste bag and began cutting out lead-solder fittings so that the tubing would not need to be disposed of as mixed waste. The tubing was contaminated and had been previously removed from a glovebox being decommissioned.

LANL is still investigating this event and is already taking appropriate action to prevent recurrence. At this point, division management believes that personnel may not have been performing work per the applicable hazard control plan and radiological work permit and that there may have been shortcomings in training and supervision. As a result, management has stood down the team involved with the job, pending approval of a corrective action plan; directed a group all-hands meeting to discuss the event and lessons learned; and taken action to improve direct supervision and daily communication and feedback from workers on job hazards and work authorization. The site rep understands that, longer term, the facility will look at the effectiveness of worker training. LANL plans dramatic increases in staffing in this area during the next year.

Dynamic Experimentation: This week, the site rep toured a TA-16 assembly building that used to be a HC-2 facility (2000), was derated, and is expected to be declared a "temporary nuclear facility" intermittently, beginning several years from now. The facility is structurally robust. Equipment appears well-grounded. Housekeeping and combustible control look good, but fire protection (e.g., sprinkler head type) and seismic support of overhead appurtenances may warrant examination. It would be worthwhile to resolve these issues and put in place appropriate configuration management and maintenance well in advance of any future readiness assessment for nuclear operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 22, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 22, 2002

Tritium Operations: LANL is considering improvements in contamination control and monitoring in tritium facilities as a result of the uncontrolled contamination in the Tritium Systems Test Assembly Facility reported last week. LANL has indicated that thorough contamination controls are warranted for tritium system maintenance and modifications because tritium surface contamination is difficult to quickly detect. Per the facility, smear surveys were done following the job in question, and these did not detect the elevated levels. Instead, they were discovered later during a daily smear survey. The contamination had spread sufficiently that it took about a week to clean up. Possible improvements mentioned include increasing use of booties; placing a removable surface around any glovebox that has been opened; and investigating use of more-sensitive, real-time surface contamination monitors.

Plutonium Handling Facility (TA-55): Contamination control in TA-55 may warrant increased attention, particularly in the process chemistry area. Last Friday, an elevated weekly fixed head airborne sample was reported for one room in this area. The site rep understands that this has been traced to a single particle on the sample, possibly dispersed by nearby maintenance in a normally inaccessible raceway. On Saturday, workers in another room were conducting a radiological survey and discovered a brown spot where a line attaches to the top of a glovebox. Workers measured 0.5 million dpm alpha on a wet cheesecloth that had been swiped over the brown spot, and they left the room. There were bootie contaminations from this event but no continuous airborne alarms. Nasal smears were negative. Workers subsequently covered the dark spot, decontaminated and surveyed the room, and released it for operations. There may be similarities between these events and those reported in site rep weekly 12/14/01. Corrective actions discussed at that time may need reemphasis.

Critical Experiments Facility (TA-18): Last week, LANL issued a Planet Control System Design Document, describing changes being made to address reliability issues (site rep weekly 1/11/02). The key changes appear to be replacing the early 1980s vintage computer, motor controller, and amplifier with modern components similar to those used in SHEBA and Comet; shifting the platen motor power source from building power to the more-restricted, Plan 3 AC power; and making the watchdog feature that detects a computer hang-up a stand-alone function, thereby eliminating a failure mode.

DOE Independent Oversight Review: On Monday, the DOE Office of Independent Oversight and Performance Assurance (DOE-OA) began an on-site safety and emergency management inspection, which will last two weeks (site rep weekly 1/4/02). The inspection team has about two dozen members. The inspection plan emphasizes assessing DOE and LANL management performance, local self-assessment processes, and feedback and improvement mechanisms. The team is observing facility operations, primarily in the Chemistry and Metallurgical Research Building (CMR) and the Radiological Liquid Waste Facility (TA-50). It is also reviewing the functionality of selected essential safety systems (CMR fire protection and ventilation), as well as environmental protection, monitoring, and waste management. Emergency management is also being assessed by a program review and tabletop exercises involving key LANL emergency response personnel. DOE-OA plans to deliver a draft report to the site in mid-April and should have a near-final draft by the end of April.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 29, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 29, 2002

Von Holle and Martin were on site this week attending the Enhanced Surveillance Campaign 2002 Review. They also met with LANL personnel to discuss the W78 disassembly process at Pantex.

DOE Independent Oversight Review: The DOE Office of Independent Oversight and Performance Assurance (DOE-OA) completed their on-site review this week. The inspection team mentioned numerous findings, both positive and negative, during daily management briefs. From these discussions, the site rep believes that some of the more significant improvements needed are in the areas of DOE and LANL issue management and formality of self-assessments, DOE local subject matter expert staffing, LANL work control via work packages and operating procedures, DOE and LANL emergency management training, and timeliness for emergency management decisions.

In the area of vital safety systems, the team complemented the Chemistry and Metallurgical Research (CMR) Facility on improved configuration management but considered that more work is needed on the maintenance backlog, fire suppression analysis (e.g., water-hammer in external supply), and use of system engineers. The inspection team will return to validate findings the week of April 8th.

Recommendation 2000-2: The first DOE-LANL Phase II assessment begins next week (site rep weekly 12/7/01). It will cover the LANL institutional maintenance program and last about one month. The site-wide fire protection review starts the following week, and that will be followed by Phase II assessments for the Plutonium Facility (TA-55) fire alarm system, and the Radiochemistry Laboratory (TA-48) fire suppression system and confinement ventilation.

At this point, the maintenance review is the only one that appears to have a specific assessment plan developed. It will focus, at least initially, on TA-18 and CMR. The latter was just reviewed by DOE-OA during the last two weeks. The site rep believes that this team will bring a different perspective and perhaps more detailed knowledge of LANL maintenance practices and facilities. That said, it appears that DOE and LANL could improve coordination of these types of reviews.

Critical Experiments Facility (TA-18): On Thursday, LANL began the Planet control system modifications described last week to improve system reliability. This was screened as a negative Unreviewed Safety Question (site rep weekly 1/11/02).

Authorization Basis (AB): The DOE formal action on AB changes has sometimes led to confusion in the applicable LANL facilities. DOE needs to conduct technically thorough reviews; however, the occasional practice of identifying extensive technical issues and then approving AB changes and assigning new controls as equivalent to Technical Safety Requirements may be contributing to diffusion of the ABs, particularly if LANL does not then update the AB documentation. Several improvements may be warranted. One with immediate benefit would be for the responsible DOE organization to obtain DOE facility representative input before taking formal action.

Public Interaction: On Wednesday, the site rep briefed the Citizens Advisory Board on the role of the DNFSB and discussed the progress made to date and that still required in nuclear material stabilization under Board Recommendations 94-1 and 2000-1 (site rep weekly 10/12/01).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 5, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 5, 2002

The site rep attended a Standing Management Team meeting at Pantex this week to determine the status of laboratory support for Pantex Operations.

Chlorine Dioxide Event: As of Thursday (4/4/02), LANL has not yet issued the investigation report on the January chlorine dioxide explosion in TA-54 West (site rep weeklies 1/11/02, 3/1/02). The site rep believes that the conclusions may have implications on Safe Work Practices for both nuclear and non-nuclear facilities. Timely corrective actions would then be appropriate since Safe Work Practices are one of LANL's main mechanisms for implementing Integrated Safety Management.

Self-Assessment Process: During the Type A investigation of the March 2000 Pu-238 uptake event, DOE identified a need for a comprehensive review of the LANL self-assessment program. Recently, DOE completed such a review with LANL assistance. DOE concluded that LANL is making progress, but improvements are still needed, particularly in the following areas: senior management awareness of assessment results; management accountability for developing and completing corrective actions; integration of existing assessment systems, including external reviews; and sharing of assessment results. DOE observed that the program now partially meets applicable DOE policy and order requirements. LANL is currently reorganizing the Operations organization and increasing focus on performance assessment. This could provide a path forward for implementing these improvements.

Critical Experiments Facility (TA-18): LANL is installing a missing interlock on Flattop that is described in the current authorization basis but apparently was never installed (site rep weekly 2/15/02). In January, LANL proposed to DOE adding an administrative control instead of installing the interlock, because of questions on the as-built configuration and because of other administrative controls in place that should protect personnel (i.e., CASA evacuation before and during Flattop operation). In mid-March, DOE withheld approval of the proposed administrative control. DOE and LANL have since determined that the interlock could be installed using existing hardware and relays.

Authorization Basis (AB): This week, LANL submitted to DOE, on schedule, the proposed updated AB for the Plutonium Facility (TA-55). DOE action is forthcoming on the proposed ABs for TA-18 and the Weapons Engineering Tritium Facility, submitted in March and January, respectively.

High Pressure Tritium Facility (HPTF): DOE concurred last week with LANL downgrading HPTF in TA-33 from a Hazard Category 2 nuclear facility and removing it from the nuclear facility list, since it has a tritium inventory well below the 1.6 gm upper limit for a radiological facility.

HPTF began operation in 1955 and was used for filling high pressure experimental vessels and for transferring low pressure gas. In 1990, operations were halted because the facility did not meet current DOE requirements, including safety requirements. Recently, LANL has engaged in an extensive effort to deinventory and to offgas remaining systems and components via a hood and a monitored stack. The current tritium inventory is estimated to be about one-third gm, and monitored release rates are about 1 Curie (10^{-4} gm) per day.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 12, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 12, 2002

Coones and Jordan were on site this week observing activities related to Recommendation 2000-2.

Recommendation 2000-2: The 2nd and 3rd DOE-LANL Phase II assessments began this week, focused on the Radiochemistry Laboratory (TA-48) fire suppression and the Plutonium Facility (TA-55) fire alarm systems (this is a correction to the 3/29/02 report). These are really being conducted as one review, will last two weeks, and will include some site-wide program elements (e.g., wildfire). The site-wide maintenance assessment started on April 1st. The site-wide fire alarm system review is scheduled to begin in mid-June. The TA-48 confinement ventilation review was suppose to be conducted this month, but appears to be on hold.

The staff believes that the reviews this week got off to a slow start. These two assessments rely heavily on the generic criteria and review approaches (CRAD) document generated last year for Phase II assessments and appear to lack assessment-specific plans, contributing to the slow start. All three assessments that are underway may also have been affected by last-minute changes in team leadership. Currently, the two remaining Phase II assessments have no assigned team leads, a problem DOE is working to correct. Early results from the fire protection reviews indicate a need for configuration management improvements in TA-48 and for a consistent tracking system for fire-protection related deficiencies in both facilities. The staff also believes that LANL requirements need to be more specific for flame-resistant protective clothing for welders.

DOE Independent Oversight Review: The DOE Office of Independent Oversight and Performance Assurance (DOE-OA) returned to LANL this week to validate their report (site rep weekly 3/29/02). DOE-OA described LANL as vastly improved in Integrated Safety Management (ISM), compared to what was seen several years ago in the last similar review; however, opportunities for improvement exist. The DOE Site Office and LANL are preparing a corrective action plan to address findings.

Authorization Basis (AB): This week, DOE issued the Safety Evaluation Report (SER) for the Weapons Engineering Tritium Facility (WETF) upgraded AB, submitted in January. The staff intends to review the SER next week. The next step for LANL is to develop a Technical Safety Requirement (TSR) implementation plan and submit it to DOE for approval. Based on the DOE SER comments, it appears that LANL perhaps could have more thoroughly validated the proposed TSRs from an operations standpoint (e.g., operations walk-down of draft procedures in the facility with the proposed TSRs). If so, further refinement in the TSRs may be needed.

Also this week, DOE approved a Basis for Interim Operation (BIO) to permit moving and storing an irradiated target assembly in the Los Alamos Neutron Science Center (LANSCE). It will be stored at an inactive target station, considered to be Hazard Category 3 (HC-3). Total inventory is about one-fifth the HC-3 limit, and is mostly due to other sources already present (i.e., irradiated depleted uranium shielding). The target assembly is robust and consists of the inconel-jacketed tungsten target surrounded by beryllium and lead reflectors. It weighs nearly 8 tons and will be shielded by a lead and steel cask. It will be stored as a backup for the new target assembly to be installed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 19, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 19, 2002

McConnell and Nichols were on site this week reviewing tritium facility operations.

Weapons Engineering Tritium Facility (WETF): DOE approved the new WETF authorization basis last week, subject to 16 conditions of approval. This is based on DOE review of the 151 hazard scenarios, 14 evaluation basis accidents, 11 proposed safety-related systems, 8 proposed limiting conditions of operation, and 9 programmatic controls. The dominant accidents are fires involving the entire inventory. The inventory is assumed to be mostly in tritium storage containers and, to a lesser extent, in systems within gloveboxes. The nearest site boundary is 425 meters away.

The WETF safety strategy is highly dependent on the tritium storage containers, considered to be Safety Class; however, not all the containers currently in use are as robust as assumed in the safety analysis. Therefore, DOE has imposed more restrictive inventory limits than LANL proposed, as well as a schedule by when most of the inventory will be in robust containers. Besides containerization, DOE is requiring LANL to perform an aircraft crash analysis and to investigate and address deficiencies in National Electrical Code compliance, fire protection, and on-site transportation.

Authorization Basis (AB): In response to site rep weekly 3/29/02, the DOE Site Office has identified several needs and is pursuing improvements in the AB review, approval, and verification processes.

Regarding WETF, the AB as proposed by LANL and approved by DOE appears to meet the intent of the DOE Nuclear Safety Management Rule (10 CFR 830), but not excessively. Also, when approving the WETF AB, DOE observed that there are still apparent quality issues in the LANL AB preparation and internal review processes. These need to be addressed quickly and thoroughly, given the expected pace this year of major AB submittals for nuclear facilities (about one per month).

Recommendation 2000-2: The DOE team has completed the field work for the two Phase II fire protection assessments discussed last week and expects to issue their findings within a few weeks. In a related area, an interagency wildfire management team held a public meeting this week in Los Alamos. Fuel moisture levels have been trending close to the 10 year low and are lower now than they were in April 2000, one month before the Cerro Grande fire. As a result, LANL has imposed appropriate outdoor restrictions. Longer term, LANL plans to thin about 10,000 acres before the end of FY 03.

Chemistry and Metallurgy Research Facility (CMR): DOE and LANL have nearly completed the multiple-year CMR Upgrades Project and are closing out the project. Extensive improvements have been made to the Operations Center facility monitoring system; emergency lighting and notification; HEPA filtration; duct and hood washdown systems; stack monitors; differential pressure monitors; hot cell controls; and fire alarm and suppression. Transient combustibles were also reduced. Perchlorate-contaminated HEPA filters were replaced. Work remains on the emergency personnel accountability system and internal power distribution. Estimated cost at completion is about 13 % below the \$106M project baseline (total estimated cost in late 1999). For their efforts, the project received the 2001 Deputy Secretary's Excellence Award.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 26, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 26, 2002

Plutonium Facility (TA-55): The Fire Protection Yard Main Replacement Project has been progressing relatively smoothly; however, the entire fire suppression system (old and new) was inadvertently pressurized this week while personnel were preparing to hydrotest a newly installed section. The facility is investigating the event.

Chemistry and Metallurgical Research Building (CMR): CMR is investigating a double failure that likely led to a small amount of contamination outside controlled spaces. On Wednesday, one Wing 7 room had a continuous airborne monitor (CAM) alarm, indicating contamination in a controlled space. The room was secured. Early Thursday morning, a programmable logic controller (PLC) failed, resulting in Wing 7 supply and exhaust ventilation shutting down (a safety-related system). Ventilation was restored, but subsequent surveys discovered contamination outside the door to the room that had the CAM alarm. The facility is preparing a recovery plan.

CMR also reported this week that four plutonium oxide sample vials fell to the floor as they were being removed from a hood. The oxide was double-contained, within inner and outer glass vials. The vials were in a plastic container. The plastic container's lid came loose as it was being lifted. The outer glass vials broke for two of the samples, leaving the inner glass vials as the single barrier protecting personnel in the room. CMR is treating this as a near-miss for personnel uptake and is taking appropriate actions.

Weapons Engineering Tritium Facility (WETF): This week, DOE advised LANL that higher temperature-rated seals need to be used on tritium storage containers (i.e., rated at 482 °F). As reported last week, robust containers are one of the more important engineered features in WETF. DOE indicated willingness to consider alternatives if proposed by LANL.

Authorization Basis (AB): Overall, DOE and LANL have a thorough AB preparation, review, and approval process, but there are some weaknesses that could affect safe and efficient operations. Readiness assessments (RAs) are done before starting up new operations or implementing AB changes. Several people involved here with the AB preparation and review process believe that missteps made during the AB preparation phase should be recognized and could be corrected during the RA phase. The site rep believes that RAs are unlikely to provide that assurance. While an RA team may judge whether an approved safety control is adequately implemented, it is unlikely to question the approved basis for that control. Also, when AB deficiencies are recognized at the RA phase, most facilities find the necessary corrective actions highly disruptive. Those actions may require time-consuming engineered backfits, procedure changes, and operator retraining. Such backfit activities rarely result in solutions as acceptable as those that are developed in advance.

In another area, the site rep has observed that the periodic AB update process is not being rigorously managed because of the high priority assigned on achieving full AB upgrades by April 2003. While the priorities are appropriate, lack of rigor in maintaining updates appears to have caused operational problems in the past. Such problems may occur this next year until the full upgrades are in place.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 3, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 3, 2002

Laboratory Support for Pantex Operations: The site rep attended a Standing Management Team meeting at Pantex this week. The W-88 Step 2 project is expected to establish its baseline early next month (i.e., cost, schedule, scope); however, at this critical juncture, it appears to be coping with loss of key project personnel (Pantex, DOE), as well as reduced LANL support in recent weeks.

Recommendations 94-1/2000-1: The site rep understands that DOE and LANL are considering a flat out-year budget that does not support the draft stabilization schedule discussed with the staff in March (i.e., ramping up, processing most of the material between 2004 and 2008, and completing processing in 2009). Such a budget would likely extend the schedule for stabilizing legacy materials into the next decade. Without stabilization and packaging or disposition, the risks associated with these materials can only be expected to increase with time.

Applying full resources to LANL 94-1 activities would reduce longer-term costs and permit more efficient material storage, freeing up vault space (site rep weekly 3/8/02). The latter improves not only safety but also LANL's ability to support high-priority national security missions. The resources required at LANL to achieve timely stabilization appear to be an order of magnitude less than required for 94-1 activities at some other DOE sites (e.g., Savannah River Site, Hanford). DOE and LANL would likely benefit in multiple ways if 94-1 objectives were vigorously pursued.

Recommendation 2000-2: DOE and LANL have three Phase 2 assessments that are either underway or with completed field work: two fire protection assessments and an institutional maintenance assessment. Collectively, these Phase 2 review teams have or will assess the Plutonium Facility (TA-55), Radiochemistry Laboratory (TA-48), Chemistry and Metallurgical Research (CMR) Building, and Critical Experiments Facility (TA-18). Except for TA-18, facility walk-downs are complete.

No reports are issued yet; however, these assessments have identified issues with inspection, testing, and maintenance of fire protection systems at both the facility and institutional level, particularly with the frequencies and data records for these activities. Complicating matters is that, between 1998 and 2000, LANL proposed and DOE approved equivalencies to the applicable codes (NFPA-25, NFPA-72) that reduced many inspection, test, and maintenance frequencies. Some of the issues now being raised may impact previous assumptions that formed the bases for reducing the frequencies.

Based on preliminary oral feedback from these assessments, LANL began last week facility-specific evaluation of the issues. This is proactive. Also, the DOE Site Office this week directed LANL to take corrective actions such as developing an NFPA-25 assessment program for nuclear facilities, reporting periodically the mean-time-to-repair for fire protection system impairments, and expediting development of a plan to implement a comprehensive maintenance history program.

NMED Cleanup Order: On Wednesday, the New Mexico Environmental Department (NMED) issued a draft order to DOE and LANL, containing environmental investigation, cleanup, and reporting requirements, and a compliance schedule (CY02 - CY11). NMED expects to issue the final order following a 60-day public comment period.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 10, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 10, 2002

Jordan, Martin, Quirk, and Roarty were on site this week reviewing the critical experiments facility (TA-18) proposed authorization basis, machine modifications, SNM inventory, and operations.

Chlorine Dioxide Event: LANL progress on addressing the January chlorine dioxide explosion in TA-54 West and implementing corrective actions appears to be lagging. The investigation report is not yet issued. When issued, it may have implications on laboratory work control, Safe Work Practices, and Integrated Safety Management (site rep weeklies 1/11/02, 3/1/02, 4/5/02).

Authorization Basis (AB): Due to escalating resource estimates, DOE and LANL are considering broader use of Bases of Interim Operation (BIOs) to bring nuclear facility ABs into compliance with the Nuclear Safety Management rule (10 CFR 830) by April 2003. DOE already planned to use BIOs for the Chemistry and Metallurgical Research building (CMR) and the critical experiments facility (TA-18). New candidates for BIOs include the radiochemistry laboratory (TA-48), the waste characterization and reduction facility, and possibly others.

Critical Experiments Facility (TA-18): The staff is reviewing TA-18 operations, inventory, and proposed AB changes. Overall, TA-18 is making progress on addressing issues reported earlier this year. Godiva and Comet are working well. Planet has been shutdown since November 2001. Control system upgrades are in place and will be tested next week. Flattop has been inoperable since February 2000. Its upgraded control rod drive system and missing interlock are installed. LANL anticipates restart in June. SHEBA has been inoperable since August 2000 due to the flammable gas generation question. LANL has submitted an Unreviewed Safety Question Determination to DOE and anticipates restart in July. The gas generation issue may require modifications to resolve (e.g., instrumentation to confirm head-space flow and inerting).

The upgraded AB proposed by LANL in March is still under review by DOE. Overall, it appears to be an improvement but will require further clarification and supporting equipment upgrades. Regarding the special nuclear material (SNM) inventory, TA-18 appears to have made a good start at identifying materials no longer required and has proposed to DOE an active material management program as an AB administrative control. Some excess uranium material has already been shipped. Progress is being made toward near-term disposition of excess SHEBA uranium solutions, now stored in potentially embrittled plastic containers. In about two months, LANL expects disposition plans for roughly 30 drums of poorly characterized uranium-based material. CMR receipt capability and throughput appears to be the rate-controlling step for disposition of some excess uranium in TA-18.

Decontamination and Volume Reduction System (DVRS): DVRS will require manually intensive radiological operations and will process packages of increasing hazard with time (site rep weekly 3/1/02). DOE and LANL plan to start up DVRS in phases: first as a low-hazard, radiological facility, upgrading later to a Hazard Category 3 and possibly even Hazard Category 2 nuclear facility. The site rep understands that LANL has resubmitted the hazard analysis to DOE and plans to begin its readiness assessment (RA) next week. A DOE RA is scheduled for the end of June.

FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 24, 2002

The site rep office was closed this week. This report is provided for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 31, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 31, 2002

Gwal, Jordan, Martin, White, and Collier (OE) were on site last week reviewing lightning protection.

Lightning Protection: The Board staff team last week observed that LANL is making progress overall in complying with NFPA 780 requirements on facility lightning protection. However, several issues remain open. For example, the frequency of facility inspections does not always comply with either NFPA 780 requirements or the LANL Operations and Maintenance Manual. Deficiencies found in inspections do not always appear to be repaired on a timely basis. Impacts to the lightning protection systems are not always considered when changes are made to the roof structures or appurtenances. In the new authorization basis for the Weapons Engineering Tritium Facility (WETF), DOE and LANL rated the lightning protection system as safety class but that system has not been adequately inspected or maintained. Also, the new WETF Technical Safety Requirements (TSRs) list the NFPA 780 lightning protection system as a design feature requiring annual in-service inspection. Given this system is safety class, a surveillance requirement, possibly to more stringent standards than used in other facilities, may be warranted. The staff is pursuing these issues with DOE and LANL.

Dual Axis Radiographic Hydrodynamic Test Facility (DARHT): DOE and LANL have categorized DARHT as a moderate hazard non-nuclear facility that may occasionally be required to perform a nuclear activity (reference: DAHRT Final EIS, 8/95). The staff has been reviewing the additional hazards posed during such activities and the development of controls. During last week's review, the staff observed that little progress has been made toward engineered lightning protection controls that would address a future hazard at the DARHT firing point even though this hazard had been identified long ago. Other plans for this activity appear well considered. DARHT is now evaluating replacing gravel at the firing point with a concrete pad as part of beryllium remediation. It may be cost-effective and efficient to include lightning protection controls in the design of the new concrete pad. This appears to be a worthwhile opportunity to enhance safety. This condition could have been recognized sooner if DOE and LANL made more effective use of preliminary function classification to iterate early-on between safety analyses and design, as discussed in site rep weekly 2/8/02.

Decontamination and Volume Reduction System (DVRS): The management self-assessment and LANL readiness assessment (RA) are complete. The DOE RA is scheduled to begin June 24th. The site rep understands that the LANL RA had 5 pre-starts, 8 post-starts, and 37 observations. While there are several positive observations, it appears from the findings that the LANL RA may have been more of a "management-assist" than typical and that several of the post-starts and observations may involve worker safety issues and formality of preparation, process, and operations that warrant action before startup. DOE and LANL are pursuing resolution of these issues.

Recommendation 2000-2: More attention appears to be needed on jump-starting the delayed Phase II assessment of the Radiochemistry Laboratory (TA-48, RC-1) ventilation system. This assessment was put on hold in early April due to lack of assigned team leadership (site rep weekly 4/12/02). The reports for the two fire protection reviews are near completion. The institutional maintenance review is continuing, and in the site rep's opinion, is progressing slowly but satisfactorily.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 7, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 7, 2002

The site rep was in training this week, Monday through Wednesday, and attended the Standing Management Team meeting at Pantex, Thursday and Friday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 14, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 14, 2002

Chlorine Dioxide Event: The site rep understands that LANL issued the investigation report this week, five months after the event (site rep weeklies 1/11/02, 5/10/02).

Recommendation 2000-2: DOE/LANL Phase II assessments have identified weaknesses in the LANL program for inspection, testing, and maintenance for fire protection systems (site rep weekly 5/3/02). While present conditions do not constitute an imminent hazard, DOE and LANL have begun to move quickly to understand and correct these weaknesses in advance of issuance of the final assessment reports. In particular, LANL has begun a review of inspection, testing, and maintenance procedures for fire detection, alarm, and suppression systems, and on May 30th, issued a path forward to further investigate and correct deficiencies during the next few months. Overall, the site rep has been impressed with the speed and frankness in addressing these emergent issues.

Annual Emergency Exercise: The annual emergency response exercise occurred last Wednesday, focused on the Weapons Engineering Tritium Facility (WETF). The scenario simulated a fire, tritium release, and several highly exposed, injured personnel. The site rep understands that overall the exercise went well and that opportunities for improvements were identified, including: communications, simulation, incident command post timeliness, and resource allocation and commitment to the exercise (e.g., police, fire department, radiation protection personnel).

Critical Experiments Facility (TA-18): On May 28th, LANL management authorized restart of the Planet critical assembly. Planet has been shutdown longer than 5 months for control system upgrades (site rep weeklies 1/11/02, 5/10/02). LANL conducted a management self-assessment and a readiness assessment (RA) before startup authorization. Pre-start conditions addressed include updating and verifying as-built control system drawings and completing TSR surveillance requirements for calibration of SCRAM settings and nuclear instrumentation. Post-start conditions to be addressed include updating the Planet system design description and crew qualification training material. Based on the Planet upgrade experience, LANL identified needs to improve documentation of changes during the design and development stages for new projects, as well as the qualification records for personnel performing design, quality, and verification functions.

Waste Management: As part of Cerro Grande fire rehabilitation, DOE and LANL are pursuing several risk reduction activities in the waste management areas. For example, TA-54 has a large, distributed transuranic (TRU) waste inventory, intended for WIPP. DOE and LANL have estimated that about 2,000 drums of high wattage waste constitute about 60% of the accessible (i.e., above-ground) and potentially dispersible source-term. DOE is pursuing an approach to accelerate shipment of the high wattage drums; considering a plan to accelerate shipment of the remaining TRU waste inventories; and evaluating a proposal to build a fire-rated industrial building for TRU waste storage – the High Activity Waste Storage Facility. In the radioactive liquid waste area (TA-50 - hazard category 3), the Cerro Grande rehabilitation efforts include a membrane process unit, pump house, influent storage (an additional 300,000 gallons), and ventilation upgrades. DOE and LANL have made recent improvements in program liaison, coordination, and strategic planning of these activities, which should increase the chances of success.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 21, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 21, 2002

Nichols was on site last week reviewing the Unreviewed Safety Question (USQ) process.

Lightning Protection: The lightning protection issues previously discussed continue to warrant attention (site rep weekly 5/31/02). On the positive side, DOE has pursued with LANL having a utility pole grounding cable survey conducted at LANL nuclear facilities. The site rep understands that 25% had unsatisfactory high resistance (4 of 16 poles). This may warrant corrective action.

Authorization Basis (AB): Overall, DOE and LANL have a thorough AB preparation and review process, but there is room for improvement. Last week, the staff reviewed a small sampling of USQ documentation, and observed the LANL USQ training course, and found these to be excellent. In other areas, the Board staff has observed that improvements may be needed, particularly in functional classification, mapping from functional classification to controls (i.e., either engineered features or technical safety requirements), and then implementing appropriate controls. The site rep continues to pursue these areas in need of improvement.

Plutonium Facility (TA-55): The Fire Protection Yard Main Replacement Project is intended to replace the leaking fire water loop and improve system reliability. The project is running several weeks behind due to emergent problems, as well as AB constraints that prohibit performing too many complex activities in parallel (site rep weekly 10/19/01). Also, a polyethylene pipe section unexpectedly fractured while it was being sawed this week. LANL and the piping manufacturer are investigating. Meanwhile, the existing loop continues to occasionally leak. Last week, an approximately 1000 gal/day leak to an admin building occurred and was repaired. Overall, LANL appears to be well-managing the risks associated with the current system by maintaining fire water availability. Completing this project on a timely basis continues to warrant management attention.

Critical Experiments Facility (TA-18): This week, LANL authorized startup of Flattop following a successful readiness assessment. SHEBA (the fissile solution machine) is now the only one of the five critical assemblies that is not operational. Flattop has been inoperational since February 2000 due to problems with the control rod drive system. A sticking control rod issue has been resolved by mounting the drive system to the underside of the table. Previously, it sat on the floor. Also, a missing interlock has been installed and tested successfully. It prevents SCRAM reset until all control rods are fully retracted. LANL had proposed using an administrative control instead of installing the interlock (site rep weekly 2/15/02), but pursued the engineered control based on DOE feedback. The site rep understands that it took four attempts before the interlock was successfully installed: twice due to inadequacies in configuration management (i.e., as-built records) and the third time due to improper restoration of removed connections. With DOE encouragement, TA-18 has learned from this experience and improved configuration management, as well as hired system engineers, and improved document control. TA-18 continues to pursue configuration control improvements.

Decontamination and Volume Reduction System (DVRS): The DOE readiness assessment was to start next week but has slipped to the week of July 15th (site rep weekly 5/31/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 28, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 28, 2002

The site rep was at Pantex this week to assess the status of laboratory support for Pantex operations.

Chlorine Dioxide Event: On June 14th, LANL issued their investigation report on the January liquid chlorine dioxide explosion in a non-nuclear facility (site rep weekly 1/11/02). The report indicates that, based on informal hazard analysis and peer review, personnel modified the experiment to produce a higher concentration product, including increasing the chlorine feed concentration to 100%. The revised experiment exceeded conditions assumed in the Hazard Control Plan (e.g., 4% chlorine feed limit). While personnel were sensitive to some increased hazards (particularly, exothermic gas generation), they missed the fact that the changes made could lead to condensation in a vessel downstream of the gas generators. The liquid phase is energetic and unstable.

The LANL investigation determined that the root cause was performance of the experiment without adequately following the LANL Safe Work Practices, which is the LANL mechanism for implementing Integrated Safety Management (ISM) into programmatic work. The report concludes with seven judgements of need. Some are specific to the affected LANL division while others involve institutional changes (e.g., changes to the Laboratory Implementing Requirements - LIRs). The latter includes improving peer review requirements, clarifying pressure safety and packaging & transportation requirements, and consolidating hazard analyses into one process so that consistent identification and communication of hazards occurs among all personnel involved in the work. LANL stated that corrective actions, both planned and completed, will be submitted to DOE by the appropriate organizations. The Board's staff is reviewing the LANL report, since it will likely have implications on both nuclear and non-nuclear programmatic work at LANL.

Recommendation 2000-2: In the process of conducting the Phase II maintenance review, TA-18 (Critical Experiments Facility) has determined that the fire alarm and detection functional tests may not have been performed since September 1999, based on lack of records. The tests are required annually by the Safety Analysis Report. TA-18 has terminated experimental operations, stationed fire-watches, and is scheduling to test all the TA-18 detectors this week. Operations will resume once testing in each building is complete. LANL believes that the annual tests were inadvertently omitted in 1999 when preventive maintenance scheduling was transferred from one database to another (i.e., from the Facility Maintenance System to Passport).

TA-18 Flood Retention Structure (FRS): Progress has been made in addressing questions raised in a Board letter (11/5/01) on the FRS, but several actions remain incomplete. The site rep understands that DOE has contracted with the Army Corp of Engineers to inspect the structure, currently scheduled for the week of July 22nd. Core drilling of the roller compacted concrete is done. Results are forthcoming. Additional drilling is underway upstream and downstream to determine if a sand and gravel layer exists beneath the foundation. Slopes have been seeded for erosion control. The outlet side is being excavated to install rock gabions. This work was impacted by heavy rain the evening of June 21st. Similar erosion control improvements are planned on the inlet side.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 5, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 5, 2002

The site rep was in training Monday and Tuesday of this week.

Plutonium Facility (TA-55): The following are noteworthy:

- C On Monday (7/1/02), DOE signed out its response to the Board's letter on the new Pu-238 Scrap Recovery Line (4/23/02). To the site rep's knowledge, DOE and LANL have pursued few, if any, safety improvements in response to the Board's letter – such as, full consideration for engineered controls over administrative controls, even for those administrative controls that DOE approved as Safety Class. Also, the DOE and LANL plan is to incorporate those administrative controls into the Technical Safety Requirements during the next normal revision, not prior to startup of the new line (i.e., September 2002).
- C The LANL readiness assessment (RA) for the new Pu-238 Scrap Recovery Line starts next week. The DOE RA is expected in early to mid August. DOE and LANL appear to be placing a high reliance on the RA teams identifying any safety issues, not only in operations, but also in the design and the authorization basis areas.
- C Last Thursday, personnel inadvertently dropped a double-contained can of plutonium oxide during a bag-out operation. While the can remained intact, the dispersed contamination from the can's surface was sufficient to set off continuous airborne monitors (CAMs) in several rooms, leading 15 people to evacuate these rooms to the corridor. Two individuals had low-level positive nasal smears (i.e., anticipate minimal health consequences). The site rep understands that personnel involved did not confirm the integrity of the bag-out bag prior to the operation, as required by procedure.
- C Last Friday, PF-4 (plutonium operations) had a partial loss of ventilation when five fan motors tripped during maintenance on the control system. Zone 1 ventilation (i.e., for gloveboxes) continued operating. LANL is investigating to determine the cause.
- C Site rep weekly 6/21/02 reported polyethylene piping for the Fire Protection Yard Main Replacement Project that unexpectedly fractured while it was being cut. The site rep now understands that the piping has normally been cut with a chain saw but was cut in this case with a regular saw (i.e., sharper notch). The piping vendor has reviewed the fractured piping, observed that the polyethylene piping can fail in a non-ductile manner in certain instances of high localized stress, and believes that the fracture surface appearance does not indicate an anomaly. As an independent check, LANL has also had a Savannah River Site (SRS) piping expert review the vendor's report. That expert observed that the reported strength properties are within specification and that the fracture shear area was comparable to the cleavage area, indicating ductile behavior. DOE and LANL are pursuing closure of this question.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 12, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 12, 2002

The site rep was at Pantex part of this week, discussing laboratory support for Pantex operations.

Authorization Basis (AB): Both DOE and LANL need to improve integration between operations and AB activities, as well as tracking AB issues to closure. This is a recurring issue. Recent examples are as follows:

- C LANL conducted a special operation in the hazard category 2 Radiography Facility (TA-8-23) after DOE approved related AB changes but before DOE validated that the AB controls were in place. DOE validation is a standing requirement, typically reiterated in DOE AB approval memos to LANL.
- C LANL was two days late submitting a Weapons Engineering Tritium Facility (WETF) transportation plan required by the DOE Safety Evaluation Report (SER). The plan involves installing vehicle barriers and speed limit signs, and referencing the applicable Laboratory Implementing Requirement (LIR). It appears that DOE considers this a violation of SER conditions of approval equivalent to Technical Safety Requirements (TSRs).
- C DOE approval of the TA-18 material relocation project AB was contingent on DOE also approving related seismic analyses. LANL has completed the analyses, but to the site rep's knowledge, DOE has not yet taken action on these analyses (site rep weekly 3/8/02).

Plutonium Facility (TA-55): The LANL Readiness Assessment (RA) for the Pu-238 Scrap Recovery Line started Wednesday and continues into next week. DOE and LANL expect their RA teams to identify safety issues beyond those associated with operations. The site rep now understands that further procedure changes are anticipated as a result of the step-by-step walk-downs by the LANL RA team. This raises questions on the extent of pre-RA procedure validation.

This week, the site rep reviewed some of the current procedures. It is challenging to determine if all the AB controls are incorporated and to assure that they will be retained in future revisions. The controls are not yet captured in Technical Safety Requirements (TSRs). Some procedure steps implementing AB requirements are indicated as such, but not all. There is no apparent mapping (e.g., a linking database) between each AB requirement and the implementing procedure step(s).

Several AB controls are embedded in the Master Equipment List (MEL) maintenance schedule. This includes the Safety Class controls that resin is covered with solution, checked weekly, and that the resin is within its 5-year operational life, checked semiannually. The site rep has found no dose limits imposed on the resin. Under some conditions, it appears that a Pu238-loaded resin column without flow might dry out in less than a week. DOE and LANL are relying on the auto-elution system to prevent dry-out but consider it to be defense in depth. The MEL also requires the facility to report a non-conformance if the schedules cannot be met. The site rep believes that a non-conformance report may not generate the visibility and response that potentially violating a Safety Class control should warrant.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 19, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 19, 2002

The Board and a staff team were on site this week, reviewing the application of safety management standards to high priority defense nuclear projects.

Plutonium Facility (TA-55): The laboratory readiness assessment (RA) was completed this week for the new Pu-238 Scrap Recovery Line. The site rep understands that the RA team identified improvements that are needed in procedures and in quality assurance. The DOE RA is expected to occur in mid-August. Startup is scheduled for September.

LANL has evaluated the recent loss of PF-4 room and corridor ventilation (site rep weekly 7/5/02). The loss occurred when five fan motors tripped during the replacement of a ventilation control system backup power supply. LANL has determined the replacement power supply was defective.

DOE and LANL are exploring the possibility of conducting radiography operations in PF-41. This building was previously designated but never used as the Nuclear Materials Storage Facility (NMSF). It appears that PF-41 may be pursued as a replacement for the current Radiography Facility (TA-8-23) – a Hazard Category 2 facility, located in a 1940s era building, and used for nondestructive testing of high explosive (HE) and nuclear components. Logistically, there are advantages to using PF-41 to radiograph components made in PF-4. At this time, it is unclear whether the scope also includes HE components. The latter would introduce a new, unevaluated hazard inside the fence of TA-55. DOE is discussing the possibilities with the site rep.

Decontamination and Volume Reduction System (DVRS): The DOE RA was completed this week, and the RA report is expected next Friday (site rep weekly 6/21/02). The RA scope covers startup as a radiological facility. After a period of operation, DOE and LANL expect to complete further readiness assessment activities (possibly ORRs) and transition DVRS to Hazard Category 3 and potentially Hazard Category 2. One DOE finding involves clearly demonstrating that the hazard control plans implement the safe work practice requirements (i.e., Integrated Safety Management). Other tentative DOE RA pre-start findings include improving:

- C configuration management (e.g., putting set points in the Facility Design Description)
- C operations formality (e.g., daily pre-op checks on alarms)
- C emergency management (e.g., update pre-fire plans, as well as site maps to show DVRS)
- C fire protection (e.g., install seismic bracing shown on drawings, NFPA 25/72 inspections)
- C worker safety (e.g., consider heat stress factors, Be hazard characterization)

The site rep believes that DVRS startup is important since it addresses risks associated with radioactive waste forms stored in several hundred fiber-glass reinforced plywood boxes. It is equally important to identify the safety systems likely to be needed to support future operations, and then implement appropriate configuration management. To the site rep's knowledge, this has not been done, and DOE and LANL will likely default to administrative controls. DVRS might benefit from preliminary functional classification, similar to other activities discussed (site rep weekly 5/31/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 26, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 26, 2002

Plutonium Facility (TA-55): The DOE readiness assessment (RA) for the new Pu-238 scrap recovery line is tentatively scheduled to begin August 19th.

Decommissioning Activities: A LANL subcontractor is preparing to open and non-destructively characterize a pair of buried, 50,000 gal tanks in TA-21 containing radioactive sludge. Estimated transuranic inventory is 200-400 gm (12-25 Ci). This exceeds the threshold for Hazard Category 3 (HC-3) and is a quarter to half the HC-2 threshold.

The tanks were used between 1945 and the mid-1970s as liquid radioactive waste receiver tanks, and they have been inactive for two decades. Standing liquid wastes were pumped out when TA-21 plutonium operations ceased. The plan has been to excavate to each tank's opening, lift the cover with a backhoe, allow the tank to naturally ventilate, monitor the tank head-space for combustibles and airborne radioactivity, and then complete characterization activities.

Questions arose this week on the hazards, the adequacy of controls, and the assessment of readiness to conduct this operation. In particular, it appears that the possibility that the tanks are sealed, allowing flammable gases to accumulate, can not be ruled out at this time. It also appears that better contamination control during excavation and filtered ventilation to prevent an airborne release would be appropriate. The site rep understands these questions are being pursued.

Chemistry and Metallurgical Research Building (CMR): CMR is celebrating its 50th anniversary this week. It continues to play a key role in actinide research, analytical chemistry, and material characterization. CMR is also likely key to disposition of the excess uranium solutions now at TA-18 (SHEBA fuel) and the 9 large spherical vessels containing SNM at TA-55. The latter is discussed in the new 94-1 Implementation Plan submitted by DOE this week.

Last week, the Secretary of Energy approved the mission need (CD-0) for the CMR Replacement Project. Conceptual design, preliminary hazard analysis, and NEPA activities are scheduled to begin shortly. Holmes and Narver is leading the architect-engineer services team during this phase. Estimated completion of conceptual and preliminary design phases are in 8/03 and 9/04, respectively. The scope potentially includes current CMR operations (except hot cells), as well as similar actinide chemistry activities now done in TA-55, new storage vault(s), large vessel activities, and contingency space for future missions. The schedule range for completion is 9-14 years. DOE will establish the project baseline (cost, schedule, and scope) at the end of preliminary design.

Radiography Facility (TA-8-23): TA-8-23 is currently operating under a Justification for Continued Operation (site rep weekly 2/22/02). LANL expects to submit a safety basis in September. TA-8-23 is more than 50 years old, and lacks seismic, confinement, and engineered fire suppression features. As discussed last week, DOE and LANL are considering shifting radiography operations to TA-55 (PF-41-NMSF). Based on discussion with DOE, it appears likely that radiography of either high explosive or high heat (Pu-238) components will only be permitted in TA-8-23.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 2, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 2, 2002

Decommissioning Activities: DOE has provided comments and LANL management has increased attention on ensuring that the tank characterization activity discussed last week will be safely conducted and that pre-start readiness will be adequately assessed.

Plutonium Facility (TA-55): Last Wednesday night, PF-4 shutdown all ventilation in a controlled manner in order to repair a minor instrument air leak. While ventilation was shutdown, the facility was depending on confinement integrity without differential pressure to prevent a release. This is permitted by the Authorization Basis (AB). Following the repair (about 1 hour), TA-55 restored ventilation, confirmed no release of radioactivity, and returned to normal operation. LANL is planning system upgrades to eliminate this single-point failure mode in the future.

There were options physically available to perform this minor repair without shutting down ventilation. Specifically, either process air or nitrogen could have been valved in through an existing cross-connect and thereby maintained instrument air capacity while the repair was made. These options were not pursued because of a DOE AB requirement to keep process air isolated from instrument air. Nuclear facilities are expected to strictly adhere to these requirements; however, in this case, this may have put the facility into a potentially more vulnerable position. It may have been better if DOE and LANL had evaluated the relative risks of the options available on a timely basis that supported facility operations and then pursued the least risk alternative, revising the AB if necessary and appropriate, possibly even on a temporary basis.

Lightning Monitoring: Last Friday, the Radiography Facility (TA-8-23) discovered that it had operated that day and been unaware of a one-hour lightning warning. The facility's AB requires action during a lightning warning if certain types of operations are being conducted. By chance, none of those operations were underway, and Friday's operation actually was completed in the morning, while the lightning warning occurred in the afternoon. To meet the AB requirement during special operations (and as good practice at other times), TA-8-23 has an informal agreement with another LANL division (DX) to be notified when lightning conditions arise. However, no notification was made last Friday. The facility is now pursuing a formal agreement on notification. There are other possible improvements (e.g., an auto-dial alert system).

Longer-term, LANL intends to delete the notification requirement from the facility's AB. LANL believes that notification provides little additional safety over the "Faraday-cage like" building and the periodic verification of compliance to the applicable standard (NFPA-780). The site rep believes that there may be transient operations (e.g., vehicle loading or unloading) when lightning notification and safely securing operations may be appropriate AB requirements.

Critical Experiments Facility (TA-18): This week, DOE issued the Safety Evaluation Report (SER) for the new TA-18 AB, submitted by LANL in March (site rep weekly 5/10/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 9, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 9, 2002

Authorization Basis (AB): DOE and LANL are updating numerous ABs this year; however, plans for verifying their implementation appear highly preliminary and not resource-loaded. Particularly on the DOE side, the site rep believes that increased coordination and rigor are warranted.

Facility Operations and Maintenance: On Thursday, LANL announced that a team led by Kellogg Brown and Root Inc. will replace Johnson Controls Northern New Mexico (JCNNM) as the site services contractor. Others on the team are Shaw Infrastructure Inc. and Los Alamos Technical Associates Inc. Transition begins October 1st. The contract is for 5 years and valued at \$145M/yr.

Plutonium Facility (TA-55): TA-55 violated a Technical Safety Requirement (TSR) on Thursday when the facility took one building exhaust fan out of service for maintenance and did not verify operability of its complementary fan and plenum within one hour. Operability was confirmed within about 4 hours. DOE and LANL are pursuing why this occurred.

DOE and LANL have slipped the final readiness assessment for the new Pu-238 scrap recovery line to allow time to address issues raised in a Board letter (4/23/02). LANL has told the site rep that they are considering engineered solutions in place of administrative controls and that they will declare readiness only after senior management is satisfied with how these issues are addressed.

Radiochemistry Laboratory (TA-48): The current TA-48 authorization basis for perchlorate operations consists of a DOE approval letter (2/01), a Justification for Continued Operation (JCO), and a hazard control plan (HCP). The DOE approval letter included specific requirements, as TSR-level, for 10 minute washdowns of the glove box fume hood and the ventilation ducts after fuming operations. The HCP requires weekly ventilation duct washdowns of "about 10 minutes," regardless of whether fuming operations were done that week or not.

DOE and LANL have been investigating this week to determine whether all of these requirements have been met, particularly whether washdowns of 10 minute duration are being done after fuming operations. LANL documentation to show compliance is poor. At this time, it appears possible that a repeated violation of a TSR-level requirement in the DOE approval letter may have occurred.

Critical Experiments Facility (TA-18): TA-18 is making progress on reducing the excess material inventory (site rep weeklies 3/8/02, 5/10/02). The facility recently shipped several special nuclear material (SNM) items to TA-55 and most of the Omega West reactor fuel inventory to Oakridge. Eight fuel rods remain and are expected to be repackaged and shipped by the end of August.

Next week, LANL will also likely start shipping excess uranium solutions (SHEBA fuel) to the Chemistry and Metallurgical Research Building (CMR), one bottle at a time. At CMR, the solutions will be converted to uranyl salt and then shipped back to TA-18 for storage and potential future use. The solutions are now stored in about two dozen plastic bottles offering limited protection. They will be transferred to new bottles and shipped in 6M containers for safety reasons. TA-18 is also working with CMR to develop a path-forward to address about 30 poorly characterized drums of uranium.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 16, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 16, 2002

The site rep was off site Monday through Thursday.

Plutonium Facility (TA-55): TA-55 began tying in the new fire water main on two sides of PF-4 last weekend and expects to complete these tie-ins today. While substantial progress has been made to date, the fire water main replacement project is experiencing increased cost and delay. Without changes, it is now expected to be completed after the site services contract shifts to a new contractor on October 1st. The site rep understands that a transition plan is being developed. It appears that the remaining work may be accomplished on an extended schedule, possibly with a transition management team, or it may be reduced in scope, resulting in an improved but less capable replacement system than originally intended.

Radiochemistry Laboratory (TA-48): Last week, DOE approved a new TA-48 authorization basis (AB) for a 2 year interim period. It consists of a Basis for Interim Operation (BIO), Technical Safety Requirements (TSRs), and the DOE approval letter. It identifies several safety-significant systems (e.g., gloveboxes, containers, hot cell shielding, fire barriers, flammable gas inerting), several safety-related administrative programs, and one limiting condition for operation, which is to keep the actinide inventory less than about one-fifth the Hazard Category 3 (HC-3) upper limit.

TA-48 is 46 years old. It does not meet current requirements, particularly for fire protection and seismic; therefore, DOE requested cost-benefit analyses for upgrades. TA-48 also uses hazardous materials, such as perchloric acid, natural gas, and propane, that are administratively controlled. During the next 2 years, LANL is pursuing reducing the radiological inventory and downgrading TA-48 from HC-3 to a radiological facility. Options being considered include relocating actinide research operations to a HC-2 facility: either the Chemistry and Metallurgical Research Facility (CMR) or the Radioactive Materials, Research, Operations and Demonstration Facility (TA-50-37).

Readiness Assessments: DOE and LANL are making needed improvements to their process for readiness assessments (RAs) and operational readiness reviews (ORRs). The process now is more expert-based than standards-based. Requirements are captured in the DOE startup/restart order (DOE O425.1B), a DOE-Albuquerque supplementary directive issued in March 2001, and LANL operational notices referencing DOE requirements, issued in August 2000 and January 2002.

Weaknesses in the DOE/LANL process (as well as absence of key individuals) may have contributed to LANL recently performing an evolution in a HC-2 facility before DOE validated that the controls were in place (site rep weekly 7/12/02). Also, some uncertainty exists on when and how DOE and LANL will validate the phased implementation of new TSRs approved as part of the AB upgrade effort. This appears to have delayed ORRs for startup of a new addition to the Weapons Engineering Tritium Facility (WETF). Other nuclear facilities here are expected to have upgraded ABs approved during the next 8 months, and they can all be expected to face similar issues. Better coordination in developing TSR implementation plans might help. LANL has prepared draft institutional procedures on the RA process. DOE and LANL expect to finalize these procedures by September 30th.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 23, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 23, 2002

Authorization Basis (AB): DOE and LANL are increasingly concerned with the pace of Technical Safety Requirement (TSR) violations or near-violations (e.g., site rep weekly 8/9/02 discusses two). This is not a new issue. The site rep previously reported on a thorough LANL TSR performance review that resulted in sound recommendations on how to improve (site rep weekly 9/7/01). If facilities were pursuing these improvements, it is reasonable to expect that the number of violations reported would increase in the near term but the significance of the events should decrease. This does not seem to be the case here; however, reporting TSR violations should not be discouraged. Reporting leads to lessons-learned that can improve the process.

It may be appropriate for DOE and LANL to systematically review the recent events, update the previous LANL study, and pursue with vigor implementing improvements in TSR performance and formality of operations. Some of this is underway. That said, ambiguous communications, diffuse AB requirements, over-reliance on key individuals, inattention, incomplete documentation, and management level of awareness all appear to have played a role in recent events. Some problems are traceable to both DOE and LANL. The current AB upgrade effort provides an opportunity to improve the TSRs by ensuring they not only form a complete set from a safety standpoint, but also are operationally clear, correct, concise, and assembled in one place (i.e., operator-friendly). More and broader attention may be warranted on developing, implementing, and verifying these new controls.

Radiography Facility (TA-8-23): DOE has performed few readiness assessments (RAs) at LANL in the last year. Most recent RAs have been done by LANL and observed by a DOE facility representative. This week, DOE performed a readiness assessment (RA) on the Radiography Facility under its current AB – a Justification for Continued Operation. The RA team reviewed procedures and walked through radiographing a special nuclear material (SNM) item. Tentative findings and observations include the needs for documented certification of high explosive handlers; improved formality of radiological operations and TSR completion; and better preparation and drills, as well as clarified responsibilities, for responding to an SNM drop. Longer term, the facility expects to submit to DOE a new AB in September, which will require separate validation. The site rep expects the pace for this type of DOE and LANL readiness assessment, one focused on AB changes, will increase.

Infrastructure: LANL has a large number of pressure, vacuum, and cryogenic systems that pose a hazard in varying degrees. Many of these systems have little, if any, documentation indicating systematic inspection by a certified inspector. In 1999, LANL issued a Laboratory Implementation Requirement (LIR) capturing current pressure safety criteria. LANL is nearing completion of an effort to catalog these systems per the LIR, and is about to begin a multi-year screening effort. Detailed inspections are expected to be performed concurrent with screening on a risk-prioritized basis.

Decontamination and Volume Reduction System (DVRS): DOE and LANL expect to authorize DVRS startup as a radiological facility soon. Operations could begin next week (site rep weekly 7/19/02). Seismic bracing of fire protection piping has been downgraded from a pre-start finding and remains to be completed. The initial plywood boxes to be processed contain low source-term items.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 30, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 30, 2002

Wildfires: Two major wildfires broke out Monday west of Los Alamos in the Jemez mountains. The fires were slowed by rain on Wednesday and should be fully contained this weekend.

Plutonium Facility (TA-55): The Fire Protection Yard Main Replacement Project is progressing and is receiving increased management attention because of the previously reported cost/schedule issues. DOE and LANL anticipate rebaselining the project next month with no reduction in final system capabilities (site rep weekly 8/16/02).

Critical Experiments Facility (TA-18): Last week, DOE approved the seismic analysis to support the material relocation project that was authorized in March (site rep weeklies 3/8/02, 7/12/02). LANL sized the anchorage based on an equivalent static analysis and peak acceleration assuming 5% damping. DOE has concluded that the storage system is capable of withstanding a Performance Category 3 (PC-3) seismic event, given that the anchorage is installed as designed to prevent tipping. LANL has installed and confirmed the anchorage is as designed. As-built drawings are being prepared. One remaining question is the need for a dynamic analysis to confirm assumptions made in the static analysis. Longer-term, LANL is considering other storage enhancements that, if implemented, might reduce or eliminate the need for this storage system.

Waste Management: Operators manned the Radioactive Liquid Waste (RLW) Treatment Facility (TA-50) during the 2000 Cerro Grande fire to manage storage and prevent an untreated release. As part of the rehabilitation project, DOE and LANL are now considering upgrades to provide remote monitoring and control capabilities, new influent storage tanks, and a new pump station, to be housed in a separate 10,000 ft² addition.

The preliminary safety analysis indicates that this would be a Hazard Category 3 (HC-3) nuclear operation. A number of controls are described, but no safety-significant systems are identified. The actual inventory relies on generator facilities meeting a restrictive waste acceptance criterion. The existing RLW Treatment Facility is now a HC-3 operation, although the potential exists that DOE and LANL will categorize it as HC-2 after the new Authorization Basis is submitted next month. This might impact design requirements for the new addition.

The new addition would consist of a metal building above grade and a concrete vault structure below grade (26 feet), permitting gravity flow. Six horizontal storage tanks (300,000 gal total) and a multi-level pump room would be housed in the below-grade vault. New double-wall piping would tie the addition into the existing facility. Design criteria are based on PC-2 seismic/wind hazards. The design is nearly complete and underwent an external independent review this week. DOE and LANL intend to pursue awarding a design-build contract in November, and to complete the project and authorize operations in FY-03. Overall, this appears to be a well-run project that should improve the facility's safety, as well as the robustness of LANL's RLW complex to upset conditions.

Quality Assurance: Slow progress is being made in improving institutional quality assurance at LANL. The Board's staff is planning a review of this area, as it affects safety, in October.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 6, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 6, 2002

The site rep was at Pantex this week to assess the status of laboratory support for Pantex operations.

Recommendation 2000-2: Last year, DOE and LANL identified five Phase II assessments to be conducted (site rep weekly 12/7/01). Three are complete, and two are remaining. Specifically, DOE has reported results for the Plutonium Facility (TA-55) fire alarm system; the Radiochemistry Laboratory (TA-48) fire sprinkler system; and the site-wide maintenance program. The TA-48 ventilation assessment was postponed and is now scheduled to start the end of this month. The site-wide fire alarm system is planned to be reviewed when sufficient progress is made on the partial system replacement project. That assessment is now anticipated in December.

Fire Protection: The completed DOE/LANL Phase II assessments identified weaknesses in the LANL program for inspection, testing, and maintenance for fire protection systems (site rep weekly 6/14/02). While these weaknesses do not constitute an imminent hazard, LANL has prepared and is executing a corrective action plan. It appears progress is being made. LANL has completed an initial review of applicable inspection and maintenance procedures, identified improvements, and implemented compensatory measures. LANL has also developed a new surveillance procedure to improve and standardize fire protection inspections at the facility and institutional levels. Specific deficiencies found are being entered into an issue tracking system. LANL is also beginning to track mean-time-to-repair for fire protection impairments in nuclear facilities. The site rep believes that these issues are receiving and continue to warrant close management attention.

Integrated Safety Management (ISM): On June 14th, LANL issued their investigation report on the January liquid chlorine dioxide explosion in a non-nuclear facility (site rep weeklies 1/11/02, 6/28/02). The LANL investigation determined that the root cause was performance of the experiment without adequately following the LANL safe work practices, which is the LANL mechanism for implementing ISM into programmatic work.

The site rep believes that LANL conducted a technically thorough investigation. While corrective actions have been underway since the incident occurred, to the site rep's knowledge, a consolidated corrective action plan has yet to be issued. It remains unclear that a complete set of corrective actions has been identified and the extent to which they are being pursued. This likely has implications on both nuclear and non-nuclear programmatic work.

Facility Operations: LANL has a facility revitalization project with objectives that include improving productivity, integrating facility management, and optimizing safe, secure, cost-effective operations and maintenance. As part of this effort, LANL is close to implementing a more centralized management structure. A key element is that facility managers will report to an institutional lead manager. Prior to 1995, LANL had such a central organization. LANL is now trying to gain the benefits of centralized management while retaining the responsiveness of a distributed organization. Under the new system, roles and responsibilities will be defined in facility service agreements. Divisions will remain responsible for some elements, such as the authorization basis. Implementation is expected to begin next month and continue through the next year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 13, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 13, 2002

Critical Experiments Facility (TA-18): The LANL independent Reactor Safety Committee reviewed TA-18 this week. In its closeout, the Committee observed that TA-18 is working on national priority missions; morale is high; and facility operations, management, and coordination have improved during the last 2 years. The pending relocation decision is a concern of many – particularly the consistency of vision, the continuity of mission, and the sustainability of national asset capabilities. Operationally, 4 of the 5 critical assemblies are up; 2 returned to operation in June. SHEBA remains down, but the facility has a plan to restart it in a few months. Configuration management is improving. Earlier this year, TA-18 hired 3 systems engineers with mechanical, electrical, and instrumentation/control expertise. The Committee's report is forthcoming.

Last week, DOE approved the LANL plan to implement the new TA-18 safety basis, approved by DOE in July (site rep weekly 8/9/02). The safety basis hazard analysis identified about 400 scenarios, of which about 100 challenged the evaluation guidelines. Because of similarities, these were grouped into 21 evaluation basis accidents. To address these accidents, the facility now has 11 safety class and 19 safety significant systems. DOE elevated SNM containers to safety class, since the buildings do not meet Performance Category 3 (PC-3) seismic/wind requirements. Other safety class features include safety shutdown mechanisms, seismically qualified storage configurations, shielding, building structure, the Flood Retention Structure, and one assembly's controls and seismic restraints. Some safety class features are yet to be installed – such as, a new in-core temperature measurement system – and are being addressed in the interim by compensatory measures.

TA-18 has determined the changes in hardware and procedures required, has prioritized the changes, and is managing implementation like a project (e.g., using a work breakdown structure). The facility has also prepared a cross-walk that links the new safety basis controls to the systems performing the safety functions, and to the relevant operations, maintenance, and surveillance procedures. High priority is assigned to safety basis training and certain modifications: in-core instrumentation, sample well closures, hydraulic fluid spray shields, and robust containers. A number of studies also are high priority, including those on automatic seismic isolation valves for natural gas lines, Flood Retention Structure maintenance, SCRAM response time testing improvements, and cost/benefit analysis for potential upgrades (e.g., building seismic). LANL expects to complete most high priority items during the next 3-6 months, and the longer term items during the next 18 months.

Authorization Basis (AB): DOE has 3 major upgrade packages for action, applicable to the following Hazard Category 2 (HC-2) facilities and activities: the TA-55 Plutonium Facility, submitted in April; site-wide transportation, submitted in August; and the TA-8-23 Radiography Facility, submitted last week. DOE is also evaluating a LANL request to downgrade one of the two TA-21 tritium facilities to HC-3 in preparation for deactivation. The other TA-21 tritium facility will likely be handled similarly, pending transfer of operations to the TA-16 Weapons Engineering Tritium Facility (WETF). Looking ahead, LANL anticipates submitting upgrade packages for the TA-50 Radioactive Liquid Waste Treatment Facility within the next two weeks; the TA-54 Waste Storage & Disposal Facility (Area G) in October; and the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRR) in November.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 20, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 20, 2002

White (DNFSB staff) was on site this week observing a DOE lightning protection review.

Lightning Protection: The DOE lightning protection review followed up previous DOE reviews of the last 2 years, as well as staff observations discussed in a Board letter (8/6/02). These reviews have driven improvements, albeit slow, in the LANL lightning protection program. Progress has been hampered somewhat by informal issue transmittal, tracking, and closure by DOE and LANL.

DOE and LANL recently designated the Weapons Engineering Tritium Facility (WETF) lightning protection system as safety class, which is unique at LANL (site rep weekly 5/31/02). The DOE team questioned the appropriateness of designating NFPA 780 systems as authorization basis (AB) controls. For WETF, LANL has addressed many of the deficiencies found during the staff's May review and reinspected the system. However, during a tour this week, one air-terminal was discovered to be disconnected, illustrating the needs for clear criteria, frequent inspection, and roof top configuration control. WETF also needs to consider instrument line surge suppression. The WETF system's operability and surveillance requirements, and inspection acceptance criteria need better definition, given the safety class designation. Also, the Chemistry and Metallurgical Research Facility (CMR) system still has deficiencies that were observed during the staff's May review, particularly lack of roof perimeter air terminals. These need resolution.

Decommissioning Activities: This week, LANL conducted a management self assessment (MSA) of a subcontractor's plan to open and non-destructively characterize a pair of buried radioactive sludge tanks in TA-21 (site rep weekly 7/26/02). Estimated transuranic inventory is 200-400 gm (12-25 Ci). Safety controls are substantially improved. Regarding the potential for flammable gases and a puff release, the subcontractor believes that the tanks are not sealed and pressurized, and, if they were sealed, the lower flammable limit would not be exceeded. As precautions, the subcontractor is planning on periodically monitoring, hand excavating with non-sparking tools, and remotely opening each tank. The possibility of gas sampling before opening is being considered if an existing vent can be found. The MSA team's report is expected on Monday. DOE is reviewing the process concurrently. If approved, excavation could start next Friday (9/27/02), and characterization could be completed during the following 2 weeks

Plutonium Facility (TA-55): Last Friday morning, PF-4 shut down all ventilation in a controlled manner in order to perform annual calibration on instrument air system switches. While ventilation was shutdown, the facility was depending on confinement integrity without differential pressure to prevent a release, as permitted by the AB. Following the evolution (about 3.5 hours), TA-55 restored ventilation, confirmed no radioactivity released, and returned to normal operations. This is the second time in two months that TA-55 has had to rely on this passive filtration mode for confinement due to a minor evolution. It is driven by existing AB requirements to keep process air and nitrogen isolated from instrument air. As discussed before (site rep weekly 8/2/02), there are options. The site rep understands that LANL is examining options to decrease reliance on the passive mode and improve reliability of the instrument air system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 27, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 27, 2002

Burnfield, Contardi, and Jordan were on site this week reviewing the internal dosimetry program, Recommendation 2000-2 status (vital safety systems), and the chlorine dioxide event followup.

Authorization Basis (AB): Last Friday, DOE provided LANL comments on the proposed on-site Transportation Safety Document, which will require its resubmittal (site rep weekly 9/13/02). DOE stated that this package was one of the first in the complex developed to meet the Nuclear Safety Management rule (10 CFR 830, subpart B); that there is little precedence for the document and its associated Technical Safety Requirements (TSRs); and that DOE headquarters also has seen questions from many sites on how to achieve a compliant Transportation Safety Document. That said, the issues raised by DOE appear to be fundamental, involving identification of hazards, derivation of a complete set of controls, quantitative justification of controls, and linkage between accident analysis and TSRs. LANL is revising the document with increased focus on quality and plans to resubmit it shortly.

Plutonium Facility (TA-55): DOE has been reviewing the TA-55 AB upgrade package since April. The site rep understands that the review cycle has been extended for the following reasons: (a) allow a DOE-LANL iteration on the proposed TSRs; (b) allow LANL to complete/evaluate fire suppression hydraulic calculations that may affect TSR setpoints; (c) allow LANL to address DNFSB issues on the new Pu-238 scrap recovery line (Board letter 4/23/02); and (d) allow LANL to improve the Transportation Safety Document. These activities are in process. The need for the fire suppression calculations is driven by issues raised by the staff in December 2001 (site rep weekly 12/21/01). In January, DOE and LANL linked these issues to the AB upgrade submittal, but the issues have since lingered. The Pu-238 scrap recovery line issues are the topic of a separate LANL process hazard analysis, expected now sometime within the next couple of months.

Integrated Safety Management: Last Friday, DOE provided LANL comments on a draft corrective action plan in response to the January liquid chlorine dioxide explosion in a non-nuclear facility (site rep weeklies 1/11/02, 6/28/02, 9/6/02). DOE observed that, while some actions have been taken, a significant length of time has lapsed between the event and the development of the corrective actions. DOE emphasized that the plan needs to capture the full scope of actions required; it needs deliverables that constitute objective evidence; and it must be formally managed and tracked to closure. Several DOE comments indicate that the site-wide implications ought to be considered, which affects nuclear facilities. In discussions with DOE and the staff this week, LANL described the actions being taken by the affected division and at the institutional level. Particularly, LANL has identified several groups that have demonstrated superior performance in Safe Work Practices. LANL is forming a team of working-level managers from those groups to identify opportunities to improve hazard identification, risk categorization, work control, training, and other areas related to the safety of programmatic work. DOE and LANL expect the corrective action plan to be finalized in mid-October.

Critical Experiments Facility (TA-18): Erosion control improvements have been pursued for the Flood Retention Structure, such as downstream gabion baskets; turf matting; and contouring and hydroseeding disturbed areas. Upstream stabilization improvements are scheduled to begin this Fall (e.g., partial spoil pile removal). Concrete core drilling is done, and a report is forthcoming.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 11, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 11, 2002

Recommendations 94-1/2000-1: LANL has placed the unsheltered containers on cradles intended to prevent their motion during an earthquake.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Tuesday, DOE provided LANL comments on the proposed new RLWTF authorization basis (AB). Since 1963, the TA-50 RLWTF has collected, treated, and disposed of LANL radioactive and other liquid wastes. LANL anticipates a line item for a replacement facility in FY 06 and decommissioning the current facility tentatively in 2010. The facility currently operates as a Hazard Category 3 (HC-3). DOE and LANL are taking less credit for segmentation in the new AB and are pursuing HC-2.

LANL proposed no safety class systems, based on low predicted consequences to the public from the bounding accident – a seismic induced fire (i.e., about 10% of the evaluation guidelines). As safety significant, LANL recommended the fire suppression system, the transuranic waste tanks/piping, and the transuranic caustic storage tank vents. The facility's safety posture depends on generator facilities not exceeding limits, and LANL discussed a source term limit (120 Ci alpha) as a Technical Safety Requirement (TSR). DOE considers the AB needs improvements before it can be approved, particularly in controlling the inventory, analyzing the aircraft crash accident and fire suppression effectiveness, and evaluating seismic and other natural phenomena hazards against Performance Category 2 requirements. LANL is working on the resubmittal.

Authorization Basis (AB): The DOE site office AB team has assigned highest priority to achieving safety bases that are compliant with the DOE Nuclear Safety Management Rule (10 CFR 830) by April 2003, but resources are limited. Consequently, several other activities with AB implications are being affected: such as the LANL facility management realignment, the TA-21 radioactive tank characterization, and the TA-50 RLW tank upgrades (see site rep weeklies 9/6/02, 9/20/02, and 8/30/02, respectively).

The facility management realignment is motivated by real needs, but key questions exist on execution: particularly on the chain of command and the roles and responsibilities for the AB and for AB-designated safety systems. The TA-21 tank characterization begins to address a legacy waste issue that has persisted for decades. The TA-50 tank upgrades address lessons learned during the Cerro Grande fire, when the RLWTF had to be continuously manned. Similar impacts for other emergent operational or programmatic issues may occur between now and April 2003.

Chemistry and Metallurgical Research Building Replacement Project (CMRR): Geotechnical /seismic investigation fieldwork could begin October 21st, pending receipt of permits. The investigation focuses on a primary and two alternate locations. The scope includes 2 deep and 4 shallow seismic characterization borings (~600' and 150' deep, respectively), and 45 geotechnical characterization borings (50'-100' deep). Most of the latter are arranged in a 100' by 100' grid pattern over the primary location. Existing boring data is also used, which includes one deep boring. LANL intends that this effort address all the potential design data needs. The staff is reviewing the plan.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 18, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 18, 2002

Martin, Schapira, and Stevenson (OE) were here this week reviewing quality assurance.

Quality Assurance (QA): LANL is making incremental progress in improving institutional QA (site rep weeklies 8/30/02, 1/11/02, 10/19/01). For example, the Institutional Quality Management Implementation Plan has been in development for more than 5 months and, although improved, continues to be draft. The draft plan calls for a 2 year implementation schedule. Several divisions and projects need quality programs in place sooner and are putting programs in place now – independent of the institutional effort. The primary mechanism intended to coordinate the institutional effort with the divisions and projects is a policy-making Steering Group and a lower-tier Working Group. The Steering Group has met several times since the Board's last visit (7/18/02). The Working Group, charged with refining and coordinating implementation details, first met last week and still appears to lack definitive direction and assigned membership.

On the positive side, higher-tier documents to standardize procurement quality have been developed, and a computerized system is to be implemented in December. Also, some LANL divisions with nuclear facilities have established formal QA programs (NMT) or plan to do so within the next 6 months (DX, ESA). However, these efforts have not been coordinated with the institutional effort. The likelihood of disparate programs persisting in the future could be reduced if such coordination took place and if these division had representatives on the Working Group. While improving QA has senior DOE/LANL management attention, the rate of progress on the institutional program during the last year appears inconsistent with this being assigned a high priority.

Integrated Safety Management (ISM): Increased attention may be warranted to personnel complying with safety requirements (i.e., formality of operations), based on the following isolated events: (1) About 2 months ago, two technicians in one facility experienced mild electrical shocks in two separate events – one attributed to equipment failure and the other to a lock-out-tag-out failure. DOE and LANL have followed up. (2) On September 26th, two craft personnel accessed a radiography facility roof while intermittent radiography operations were being conducted and contrary to access controls. Event reconstruction and preliminary dose assessments indicate no dose was received. (3) More recently, a subcontractor damaged a gas line while modifying a non-nuclear new-construction facility. The damage was discovered later when the gas line was pressurized. (4) Also recently, one nuclear facility had a room become contaminated due to poor waste handling practices, effectively shutting down that room's operations. Occupants discovered the room was contaminated one evening, but it wasn't reported until next morning. In the interim, the room was an unposted contamination area. The site rep has discussed these events with DOE/LANL management.

Chemistry and Metallurgical Research Building (CMR): CMR has completed ventilation repairs to Wing 3 and is restoring it to normal operations. All CMR wings will then be operational. Wing 3 hoods are still out of service, but will be systematically function-checked. Individual processes will be started up after the process hazards are reviewed and readiness confirmed according to division procedures. Wing 3 will be primarily used for uranium operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 25, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 25, 2002

Authorization Basis (AB): DOE and LANL are updating numerous ABs this year. Implementation and verification appear to warrant more management attention, as well as more rigorous planning, coordination, and resource-loading (site rep weeklies 7/12/02, 8/9/02).

The Weapons Engineering Tritium Facility (WETF) is the first LANL facility with an updated AB. This week, WETF temporarily secured operations because of overdue commitments for implementing new Technical Safety Requirements (TSRs). In July, DOE and LANL agreed upon the implementation schedule. About half the commitments were due this week. Last week, WETF proposed slipping about half of the commitments, based on recent operational and programmatic demands, as well as on a slip in the contractor operational readiness review (ORR) – intended, in part, to verify AB implementation. This ORR is now scheduled to start Nov 12th. DOE has informed LANL the proposed schedule changes are unacceptable. LANL has requested clarification.

The Critical Experiments Facility (TA-18) is the second LANL facility with a major updated AB. While implementation is well planned (site rep weekly 9/13/02), it remains to be seen whether it will be successful. Longer term, LANL has plans to establish an Operations Support Group to assist nuclear facilities in formality of operations and AB implementation. That initiative appears to be lagging due to funding issues.

Integrated Safety Management (ISM): The site rep understands that LANL has an independent team reviewing the event, reported last week, involving crafts personnel accessing a radiography facility roof while intermittent operations were being conducted. This is positive.

On October 10th, DOE concurred with the LANL corrective action plans for the January liquid chlorine dioxide explosion in a non-nuclear facility (site rep weekly 9/27/02). The affected LANL division has completed about half of their corrective actions. Also, LANL is forming a team to review hazard analyses processes, to identify best industry practices (based on a study of outside organizations), and to recommend improvements. If fully pursued, this should lead to institutional improvements to both LANL hazard analysis tools and safe work practices. The latter is LANL's mechanism to implement ISM into programmatic work for both nuclear and non-nuclear operations.

Critical Experiments Facility (TA-18): Last week, LANL announced that a criticality experiment had been completed in the Planet assembly involving a 6 kg nickel-clad neptunium-237 (Np-237) sphere and about 60 kg of highly enriched uranium. Preliminary data reportedly shows that the critical mass for Np-237 is less than expected based on computer models. Future experiments will determine the Np-237 critical mass with various reflectors. This series of experiments was 12 years in preparation and was done in support of DOE programs for criticality safety, non-proliferation, and emergency response. TA-18 has the only operational general-purpose machines in the United States capable of these types of experiments.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 1, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 1, 2002

The site rep was off site Monday through Thursday.

Plutonium Facility (TA-55): The Fire Protection Yard Main Replacement Project continues to make progress and is receiving increased management attention because of previously reported cost/schedule issues (site rep weekly 8/30/02). PF-4 work is completed. East pumphouse and water tank improvements should be completed within a few weeks. Two major sections of loop piping and two sets of lead-in piping remain. DOE expects the entire replacement system (i.e., connection to all the buildings) to be operational in December.

Waste Management: DOE-EM and LANL have committed to accelerating LANL characterization and offsite shipment of Transuranic (TRU) and Mixed Low Level (MLLW) legacy waste by 20 years (i.e., from 2030 to 2010). In particular, they are working to accelerate shipment of about 2,000 drums of higher-wattage TRU waste from TA-54 to WIPP by the end of FY04. This effort – referred to as the "Quick-to-WIPP" initiative – will result in a significant risk reduction for TA-54 once it is completed. While these 2,000 drums comprise about 8% by number of the TA-54 TRU drums, they are about 60% of the TA-54 accessible (above-ground) and potentially-dispersible TRU inventory.

WIPP shipments must be accelerated to achieve the planned TRU waste shipping schedule and the Quick-to-WIPP risk reduction. Two WIPP shipments were completed in FY02. LANL and the DOE Carlsbad Field Office are working to complete more than 90 shipments in FY03. In October, LANL made 3 shipments and plans another shipment next week. Future challenges include upgrading the Authorization Basis (AB) for existing waste characterization, packaging, and loading operations, as well as for new operations involving a modular unit for visual examination/repackaging and two full characterization lines.

Readiness Assessments: DOE and LANL are making needed improvements to their process for readiness assessments (RAs) and operational readiness reviews (ORRs). The site rep previously reported that the process is more expert-based than standards-based; that weaknesses in the process may have contributed to a nuclear facility performing an evolution in July before DOE validated that approved controls were in place; and that uncertainty exists in how the process will be used to validate the phased implementation of new Technical Safety Requirements (site rep weekly 8/16/02).

DOE has reviewed and LANL has issued formal institutional requirements for startup and restart of facilities and activities (LIR 300-00-08.0). A LANL supporting guidance document is nearly completed. The DOE Site Office is also formalizing its internal roles and responsibilities for assessing readiness. The site rep understands that facility coordinators will receive training on the new requirements next week. While there remains much to be done in this area (particularly for assessing the new AB implementations), this constitutes progress.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 8, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 8, 2002

Weapons Engineering Tritium Facility (WETF): WETF is in the process of transition from an old authorization basis (AB) to a new, improved one. On October 25th, the site rep reported that WETF temporarily secured operations because of overdue commitments for implementing new Technical Safety Requirements (TSRs). This action was driven by an AB compliance issue and did not constitute an emergent safety issue, since the facility continues to operate safely under the previous AB. However, it demonstrates the difficulties that can arise during the process of TSR development, implementation, and verification. A facility may need to operate for an extended period under an old AB, while developing procedures, training personnel, and finally demonstrating capability to comply with a new one. During this period, there is potential for confusion.

WETF is currently conducting a management self-assessment (MSA) for both starting up Building 450 and implementing the new TSRs. WETF management believes that the facility is close to meeting the overdue commitments and that it will demonstrate implementation during a contractor operational readiness review, scheduled to begin shortly. Next week, a DNFSB staff team will be on site reviewing the status of TSR implementation at LANL facilities, including WETF.

Plutonium Facility (TA-55): On August 9th, the site rep reported that LANL is considering engineered solutions in place of administrative controls for the new Pu-238 scrap recovery line and that DOE/LANL had slipped the project to allow time to address issues raised in a Board letter (4/23/02).

While progress was made in August and September, the project may now be backsliding. For example, the site rep learned this week that the ion exchanger reservoir concept is no longer being pursued based on results from a challenging and potentially questionable resin dryout calculation. Resin dryout could lead to conditions conducive to an energetic reaction. The significance of such a reaction is being reevaluated but was previously deemed to require Safety Class controls. The reservoir concept was a relatively straightforward engineered feature intended to extend the period before resin dryout, although it perhaps needed refinement to expand the range of upset scenarios it addressed. For the same reasons, the project is also not considering automatic detection or alarms that might provide early indication of leaks or losses leading to resin dryout. On another issue, the project has not examined alternatives nor substantiated cursory estimates for modifications to address the solution transfer strategy questions (i.e., their proposed use of temporary flexible tubing).

On the positive side, the project expects, within a week or two, to submit to DOE a revised process hazard analysis (PrHA). The site rep has been told that the PrHA will address all the questions and issues, include a more thorough examination of the hazards, and propose better safety controls and engineered features. The project has been proceeding at risk in parallel with the revised PrHA development. Before it can proceed to readiness assessments, the PrHA will be reviewed by the responsible LANL division, by an independent LANL team (the Office of Authorization Basis), and by the DOE Site Office. Given the potential weaknesses discussed above, this should represent a good, thorough test of the DOE/LANL authorization basis review and approval process. The site rep is communicating concerns with the direction of this project with DOE/LANL management.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 15, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 15, 2002

Bamdad, Jordan, and Martin were here this week reviewing Technical Safety Requirement (TSR) implementation. Also, a DOE Price-Anderson Office of Enforcement team was here reviewing recent TSR non-compliances and radiological events in defense nuclear facilities.

Authorization Basis (AB): LANL is quickly standing up the new Operations Support Group to assist nuclear facilities in consistently implementing new TSRs and improving formality of operations (site rep weekly 10/25/02). The Weapons Engineering Tritium Facility (WETF) is the first at LANL to be implementing new TSRs, followed closely by TA-18 (the Critical Experiments Facility). Coordination and planning for WETF have been problematic, but several key issues appear to have been resolved on Thursday. The current plan is that LANL will verify implementation of most of the TSRs during the upcoming LANL operational readiness review (ORR) and consider phasing in the new TSRs in a controlled manner soon thereafter. DOE will observe the LANL ORR verification. The previous plan was to implement the new TSRs all at once after the DOE ORR, now scheduled for January. While there are differences in verification strategy, the phased-in approach is similar to that taken by TA-18 and is advantageous if properly sequenced. It places more rigorous operational controls in place sooner and could reduce the potential for confusion caused by operating to one set of rules while practicing to another for an extended period.

Weapons Engineering Tritium Facility (WETF): Besides improved operational controls, the new WETF AB mandates using improved tritium storage containers and considering upgrades to fire walls that are currently 1 hour rated (site rep weeklies 8/10/01, 4/19/02, 4/26/02). In fact, 65% of the inventory is suppose to be in improved containers by April 2003. Last April, DOE advised LANL that higher temperature-rated seals need to be used on tritium storage containers and that alternatives could be considered. It appears that, based on progress made, increased management attention may be warranted on reaching agreement and aggressively pursuing engineered features that more fully address WETF fire scenarios and thereby achieving the intent of the new AB.

Integrated Safety Management: LANL has investigated several recent events and identified personnel not following existing requirements as a cause or a contributor to these events (e.g., site rep weeklies 10/18/02, 10/25/02). While corrective actions have been taken in each case in the affected facility, there is an increasing recognition here among management that the needs exist to (1) clearly identify management expectations and (2) possibly extend actions to other facilities or institutionally. Also being considered is the need to improve trending and evaluation of lower-tier events that could be precursors to more significant events or serious accidents, thereby increasing visibility to management of emergent safety trends. If pursued, these would be positive actions.

Plutonium Facility: The site rep understands that LANL expects the revised process hazard analysis for the Pu-238 scrap recovery line to be submitted to DOE on December 2nd.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 22, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 22, 2002

Pajarito Laboratory (TA-18): TA-18 has secured higher-energy radiography and radioactive source operations pending determination of why two people had unanticipated, elevated gamma dosimetry results in October. The results were less than one-fifth of the federal annual limit (5 Rem) but appear high for this type of operation if it is properly controlled. LANL is also reviewing relevant hazard control plans to ensure hazards are properly identified and appropriate controls are in place.

Also, progress has stalled in reducing the TA-18 inventory of excess SHEBA uranium solutions (site rep weekly 8/9/02). In August, TA-18 started to ship these solutions, one bottle at a time, to the Chemistry and Metallurgical Research Building (CMR) to be converted into salt, packaged, and returned to TA-18. CMR has had operational problems with the conversion, including continuous air monitor alarms. CMR is addressing the problems and planning a management self-assessment before resuming this activity. LANL anticipates relocating this operation within CMR in January to make room for new cleanout equipment for the large metal vessels under Recommendations 94-1 /00-1. While progress on cleaning out the large vessels has been long in coming, this is likely to further delay conversion of the TA-18 excess solutions. Close coordination appears warranted.

Weapons Engineering Tritium Facility (WETF): The LANL operational readiness review (ORR) for Building 450 startup and TSR implementation began this week. The site rep understands that the ORR team is doing a thorough job, but that the ORR is being extended. This has raised good questions on the facility's state of readiness and whether the ORR is shifting to a management-assist. The DOE Site Office is pursuing these questions. Also this week, the DOE Site Office approved with comment a WETF fire hazard analysis crosswalk, a fire suppression system failure modes and effects analysis, and an electrical code inspection/replacement program. These evaluations were required as conditions of approval in the DOE Safety Evaluation Report in April. These should increase focus on fire protection upgrades that could enhance facility safety.

Decommissioning Activities: LANL is updating neutron activation calculations and hazard analyses and controls for Omega West Reactor (OWR) decontamination and decommissioning (D&D), following last Friday's determination that radionuclide inventory may exceed the Hazard Category 3 (HC-3) level. The activation products (e.g., tritium, cobalt-60) are likely bound to some degree within the material matrix of the vessel and its components, including a beryllium reflector. DOE/LANL downgraded OWR to a radiological facility in 1995, possibly based on low expected dispersability. Currently, the reactor area is contained within a tent with HEPA filtration and will receive a weekly combustible material survey. The reactor itself is capped with a metal plate. LANL has secured D&D operations in the reactor area but resumed such operations in the adjacent office and laboratory, which are separated from the reactor area by a berm. The DOE Site Office has pointed out that this demonstrates the need for vigilance before downgrading nuclear facilities. LANL has several facilities (e.g., TA-21 tritium facilities) which are being considered for downgrading and D&D.

Chemistry and Metallurgical Research Building Replacement Project (CMRR): Geotechnical/seismic investigation fieldwork began last Friday (site rep weekly 10/11/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 29, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 29, 2002

The laboratory was closed Thursday and Friday.

Radiochemistry Laboratory (TA-48): TA-48 is operating as a Hazard Category 3 (HC-3) nuclear facility under a justification for continued operation (JCO). In August, DOE approved a new TA-48 authorization basis (AB) for a 2 year interim period, consisting of a Basis for Interim Operation (BIO) and Technical Safety Requirements (TSRs), as discussed in site rep weekly 8/16/02.

Last Friday, DOE approved the TA-48 TSR implementation plan. The site rep understands that implementation is to be essentially completed by mid-January 2003 and ready for verification. This schedule appears compressed, and the effort has not started well. On October 2nd, the facility reported to DOE that counting facility propane sensors had been reset from 30% to 25% LFL, consistent with the DOE approval memo, but mid-November inspections determined that the reported change had not been made. Thorough verification of TSR implementation appears warranted.

Authorization Basis (AB): On November 8th, the DOE Site Office approved the LANL on-site transportation safety document (TSD) and associated TSRs (site rep weekly 9/27/02). The DOE preference is for LANL shipments to fully comply with Department of Transportation (DOT) requirements. However, in some cases, DOT certified or equivalent packages are not available due to physical configuration or other reasons. The TSD provides a framework for those cases and for the development of on-site, activity-specific controls that ensure the level of overall safety is maintained. These controls are to be captured in DOE-approved transportation plans. DOE directed that existing transportation plans be reviewed in the context of the new AB (e.g., vehicle speed and weather limitations), and resubmitted for approval. Implementation is also to be verified.

Facility Operations: DOE is close to acting on a LANL proposed site-wide JCO that would allow a major facility management realignment (site rep weeklies 9/6/02, 10/11/02). The proposed realignment involves consolidating numerous facility management organizations under a single, institutional lead manager. The goal is that this unified organization would then move forward to identify, plan, and implement needed organizational improvements while minimally impacting nuclear facility operations. LANL has stated that roles and responsibilities during the transition would remain consistent with current, specific AB requirements.

Specifically, each owning division leader would continue to be responsible for the AB and AB compliance, for the division's facilities and buildings, and for programmatic equipment and operations. The division leader would delegate authority for the building envelope to the institutional lead manager, which would then pass to the deployed facility manager. Facility Service Agreements are being developed to define roles, responsibilities, authority, and accountability. LANL will also conduct readiness reviews prior to realignment. Before the JCO expires (4/10/03), LANL will review the organizational changes against facility AB documents to determine what changes, if any, are necessary to the ABs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 6, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 6, 2002

Hadjian, Jordan, Jones, Ralston, and Rizzo (OE) were on site this week reviewing the CMRR geotechnical investigation, the LANL ground motion design criteria, the TA-18 flood retention structure, and the status of new projects, including the new Emergency Operations Center.

Facility Operations: The DOE site office has approved the LANL facility management realignment proposal discussed last week. DOE requested more details be provided within 30 days.

Critical Experiments Facility (TA-18): DOE and LANL have designated the flood retention structure (FRS) as safety class, but resolution of the Board's structural questions of a year ago has been slow (site rep weeklies 9/13/02, 6/28/02, 12/28/01, 11/9/01). Results from Army Corps of Engineers testing of the roller-compacted concrete are now expected in March 2003. Preliminarily, it appears that the concrete long-term durability (e.g., 2 decades) may be affected by alkali-silicate reactions leading to micro-cracking. The period of increased flood risk may also extend beyond the original 3 year estimate, due to recent drought and inhibited post-fire recovery. Low rainfall also means little measured runoff data to substantiate flood models, increasing uncertainty in projections. Timely completion of testing and analyses appears warranted to confirm FRS adequacy for an extended period.

Plutonium Facility (TA-55): Last week, DOE requested LANL resubmit a process hazard analysis for a TA-55 laser ablation experiment. The experiment involves eroding a plutonium (Pu) metal sample using a low-energy pulse laser, reacting the released Pu with a gas, depositing it on a cryogenic surface, and studying the frozen matrix with an infrared spectrometer. The Pu sample is loaded into a custom-made assembly, called a cryohead, while inside a glovebox or hood. The cryohead is removed from the glovebox and mounted on the spectrometer, thereby becoming the primary containment. LANL declared the experiment a positive Unreviewed Safety Question Determination (USQD) based on use of a containment not described in the authorization basis. DOE requested that LANL determine the maximum amount of Pu that could be vaporized by the laser (rather than assume the entire sample is vaporized in an unmitigated accident) and provide rationale for designating the cryohead as a safety-significant design feature, requiring TSR controls.

Waste Management: The TA-54 Radioassay and Nondestructive Testing facility (RANT) is key to the Quick-to-WIPP risk reduction program, since it is used to load shipping containers for WIPP (site rep weekly 11/1/02). RANT is currently a Hazard Category 3 (HC-3) nuclear facility and doesn't meet Performance Category 2 seismic requirements. To support Quick-to-WIPP, LANL has proposed raising RANT's inventory limit seven-fold (i.e., to 6 kg Pu equivalent) and operating RANT as HC-2 under a limited-life Basis for Interim Operation (BIO). This BIO would expire on June 1, 2003 or when a full RANT BIO is implemented, whichever occurs first. The proposed interim controls are primarily administrative. DOE action may occur quickly since LANL would like to initiate higher-inventory shipments within a few weeks. The full BIO is expected in March 2003 and may propose upgrades, including seismic.

Weapons Engineering Tritium Facility (WETF): The LANL Operational Readiness Review (ORR) resumed this week and will likely be completed by December 17th. WETF used the break last week as an opportunity to improve operations with respect to earlier ORR team observations.

December 13, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 13, 2002

The site rep was off-site this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 20, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 20, 2002

Jordan was on site this week reviewing the status of the TA-18 mission relocation conceptual design.

DOE-NNSA Management: Effective today, the NNSA Los Alamos Site Office reports directly to headquarters. NNSA expects this office's staff to increase from 75 to 95 personnel by October 2004 to support the increased local mission. Staffing plans are due in January. NNSA has also set an objective that its work force will be certified to ISO 9001 (a quality management standard) in 2004.

Weapons Engineering Tritium Facility (WETF): The LANL Operational Readiness Review (ORR) was completed last week. The ORR team briefed their findings this week and will issue their report early next month. The scope included Building 450 startup and new authorization basis implementation (i.e., new Technical Safety Requirements - TSRs). During the 3-week review, the team identified about 46 pre-start findings, 11 post-start findings, and 45 observations. WETF has been closing pre-starts as the ORR progressed. About 2 dozen remain open, mainly involving TSR implementation and related operator training and qualification. Four safety system surveillance procedures also need to be rewritten and were not reviewed by the ORR team. In January, WETF plans to bring in the new LANL Operations Support Group to mentor the facility (site rep weekly 11/15/02). Timing of the LANL declaration of readiness and the DOE ORR are both open.

The site rep believes that WETF has been working hard to get the new TSRs implemented, but much remains to be done. Longer-term, LANL needs to improve the readiness assessment process – particularly, broad-based understanding of the process – to be consistent with DOE requirements.

Radiochemistry Laboratory (TA-48): The Recommendation 2000-2 Phase II confinement ventilation review is complete. The review team found issues with the as-built configuration, the configuration and maintenance management programs, and conduct of operations. The report concluded that the facility was unable to fully demonstrate operability and reliability of confinement ventilation commensurate with the facility's Hazard Category 3 (HC-3) rating.

TA-48 is 46 years old and was designated a HC-3 nuclear facility in recent years, apparently with few substantive changes. Since August 2000, it has operating under a Justification for Continued Operation. In August 2002, DOE approved a two-year interim authorization basis that LANL has committed to implement by February 2003. LANL has also committed to reducing inventory and downgrading TA-48 to a radiological facility within 2 years. LANL may expedite this due to recent events. Given the nature of the Phase II findings, as well as fire protection, electrical, and seismic deficiencies, it appears that improvements may be needed, even if the facility is down-graded, if it is to operate as a radiological facility for an extended period (site rep weeklies 8/16/02, 11/29/02).

Plutonium Facility (TA-55): LANL has delayed submittal of the revised process hazard analysis (PrHA)

for the Pu-238 scrap recovery line. LANL independent review of the PrHA is underway.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 27, 2002

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 27, 2002

The laboratory was closed Wednesday through Friday.

Plutonium Facility (TA-55): On December 17th, NNSA sent LANL a preliminary notice of violation for unauthorized TRU waste staging and storage in PF-185 (site rep weeklies 8/24/01, 9/7/01).

Authorization Basis (AB): On December 11th, the NNSA site office established a standard site boundary for safety analyses. NNSA has observed several variations on the assumed site boundary in dose calculations for postulated nuclear facility accidents. The standard site boundary appears more conservative than that assumed in some prior analyses - particularly, the use of the full length of East Jemez Road in addition to the Royal Crest Trailer Park boundary.

The site boundary question is complicated since LANL has commercial ventures on site and public access roads passing through the site. Per DOE STD-3009, NNSA considers such roads to be within the site boundary if NNSA or LANL has the capability to control the road during an emergency. By agreement, commercial ventures on LANL property are subject to LANL emergency evacuation procedures and are not considered public receptors. NNSA expects the standard site boundary to be incorporated in the next annual update of nuclear facility safety analyses, if not made sooner.

Pajarito Laboratory (TA-18): The site rep understands that the unanticipated gamma dosimetry results for two individuals in October have been traced to an evolution that was conducted off site (site rep weekly 11/22/02). It appears that the dosimetry results may not represent actual doses to the individuals, but this is still being investigated. Weaknesses in controls may have contributed to this event (e.g., dosimetry requirements during off-site activities and during betatron operations).

Decommissioning Activities: LANL is pursuing removal of reactor components from the Omega West Reactor (site rep weekly 11/22/02). The radioactive inventory is principally tritium and cobalt-60 in the beryllium reflector and its supporting steel and aluminum framework. Estimated contact radiation levels are 1,100 R/hr, necessitating short-duration and remote operations.

NNSA has specified a number of administrative controls at the safety-significant level, including: minimize local combustible loading; secure unrelated local operations; secure operations if there is a loss of ventilation; inspect and certify lifting and rigging equipment; reevaluate rigging if remote video inspection identifies reflector damage occurring during the lift; remove as single unit to minimize releases; and ship in a shielded cask and dispose in TA-54 within one day of packaging.

Waste Management: NNSA and LANL have identified weaknesses in interpretation of surveillance requirements for the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRR), a HC-2 nuclear facility. The weaknesses mainly involve the frequency and extent of inspections verifying waste drum inventory. LANL is invoking stricter data recording on daily drum movements and will revise operations and facility procedures by end of February. Longer-term, LANL is preparing a proposed updated authorization basis for WCRR operations that may address the weaknesses.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 3, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 3, 2003

The laboratory was closed Monday through Wednesday.

LANL Management: University of California (UC) has announced the resignation of the LANL Director and Principal Deputy Director, effective January 6th. An interim Director has been appointed.

Waste Management: NNSA has approved the limited-life Basis of Interim Operation (BIO) for the TA-54 Radioassay and Nondestructive Testing facility – RANT (site rep weekly 12/6/02). This allows RANT to package Hazard Category 2 inventories of waste for expedited shipment to WIPP during the next 6 months. NNSA estimates this will reduce TA-54 (Area G) risks nearly 30 percent.

Authorization Basis (AB): NNSA and LANL face challenges in upgrading ABs before April 2003 per the Nuclear Safety Management rule (10 CFR 830) – particularly for solid and liquid radioactive waste operations (TA-50, TA-54) and for the Plutonium Facility (TA-55). Progress has slowed since September (site rep weekly 9/13/02). The site rep understands that LANL anticipates making submittals for the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRR), the TA-50 Radioactive Liquid Waste Treatment Facility, and the TA-54 Waste Storage & Disposal Facility (Area G) within the next few weeks.

The TA-55 AB upgrade appears problematic, and its current status is unclear. LANL made a massive submittal in April 2002 (i.e., about 6,500 pages). NNSA provided informal comments last summer, and LANL began an iteration on the Technical Safety Requirements. In September, NNSA and LANL indicated a delay was occurring to allow finishing fire suppression hydraulic analyses and to satisfy competing demands – including revisions to analyses for the Pu-238 scrap recovery line and for LANL site-wide transportation (site rep weekly 9/27/02). During the extended review process, key reviewers appear to have become unavailable. The TA-55 AB was last revised in 1996. This submittal is suppose to address a number of issues, including Board issues, that have risen in the interim.

Critical Experiments Facility (TA-18): NNSA has decided to relocate the TA-18 security category I/II activities to the Device Assembly Facility (DAF) at the Nevada Test Site (NTS). This includes four of the five critical assemblies, 2.4 MT of special nuclear material (SNM), and about 10 MT of thorium and natural and depleted uranium. The record of decision (ROD) was signed on December 5th and distributed more recently. NNSA also announced that the security category III/IV activities, including the Solution High Energy Burst Assembly (SHEBA), would be addressed in a separate ROD in 2003. The drivers for relocation are the increasingly high security costs and aging infrastructure at TA-18. Considering the alternatives, the ROD indicates that the DAF option offered the least construction risk (considering facility age, design complexity, and extent of modifications) but has potential for higher material transportation and life-cycle costs. The latter is due to the campaign mode contemplated. The site rep understands that the tentative project milestones are conceptual design (10/03); preliminary design (10/04); construction start (10/05); construction completion (4/08); move completion (2009). A few of the challenges are maintaining key criticality training and research capabilities, including key personnel, thorough this transition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 10, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 10, 2003

Von Holle was on site this week reviewing preliminary safety analyses for an experiment and potential improvements in safe work practices. Also, the site rep attended a Standing Management Team meeting in Albuquerque to determine the status of laboratory support for Pantex operations.

Radiochemistry Laboratory (TA-48): LANL has temporarily suspended operations in the TA-48 Alpha Wing and is reducing radioactive inventory as a result of the 2000-2 Phase II confinement ventilation review and recurring issues with formality of operations (site rep weekly 12/20/02). With this week's shipments, LANL believes the current inventory is about 75 % of the Hazard Category 3 (HC-3) lower limit, which may permit TA-48 to be downgraded to a radiological facility. NNSA and LANL are currently pursuing two tracks in parallel: (a) evaluate mission impact, inventory, and the inventory management system to support a likely LANL proposal to downgrade TA-48 and (b) pursue implementation of the HC-3 authorization basis by February 5th, as previously planned.

The site rep believes the TA-48 issues extend beyond the confinement ventilation system, considering cumulatively last year's two Phase II assessments (i.e., fire suppression, confinement ventilation), the NNSA safety evaluation report findings (e.g., seismic, fire protection), and occurrence reports (e.g., perchlorate controls, circuit breaker arcing). It may be worthwhile for TA-48 to improve formality of operations and then demonstrate they can appropriately control hazards and the inventory, maintain safety systems in an operational status, and apply adequate controls (e.g., meet 10 CFR 835), even if the facility is downgraded to the radiological facility level. Longer term, the safety issues raised in the NNSA safety evaluation report still appear to warrant being addressed.

NNSA Technical Staffing: NNSA technical staffing issues raised by the Board more than a year ago persist at this site, particularly a shortage of local qualified subject matter experts (ref: Board letter 10/10/01). For example, given the scale of LANL activities, the NNSA site office would appear to rate a full-time emergency management specialist. Instead, emergency management is a collateral duty of the single site office industrial hygienist. The DOE Office of Assessment identified this as a weakness last year. Also, LANL facility maintenance practices are a well-recognized area needing improvement, as previously reported. The NNSA site office currently lacks even a part-time maintenance specialist. Additionally, the site office authorization basis team is tasked with technically reviewing extensive ABs for plutonium and radioactive waste facility operations. Several of these ABs are already submitted or to be submitted during the next few months. This team is currently understaffed by one-third and is being supervised, on an acting basis as a collateral duty, by another site office manager. NNSA is now reviewing complex-wide federal staffing needs, including the needs of this site office (site rep weekly 12/20/02).

Integrated Safety Management (ISM): LANL has formed a team to review hazard analyses processes, to identify best industry practices (based on a study of outside organizations), and to recommend improvements. This was a corrective action from the January 2002 liquid chlorine dioxide explosion in a non-nuclear facility (site rep weekly 10/25/02). The site rep understands that the team is considering improvements to institutional requirements for initial risk determination, independent and management review, hazard assessment training, and other areas. This is positive.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 17, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 17, 2003

Safety-Related Infrastructure: On January 9th, DOE directed LANL to deobligate remaining Cerro Grande appropriation funds, currently estimated at \$75M. The impact is still being evaluated; however, it appears far-reaching and will likely result in cancellation of projects that address significant vulnerabilities identified during and after the Cerro Grande fire (May 2000) – such as partial site-wide fire alarm system replacement and radioactive liquid waste facility upgrades.

The site-wide fire alarm project was intended to address significant vulnerabilities with the current system, which is about 2 decades old and an order of magnitude more complex than originally intended. It did not evolve in a controlled manner. It is a shared system with other demands that often automatically have higher signal transmission priority. LANL has reported numerous problems with the system, including a 2001 event when it took about 15 minutes for a fire alarm signal to reach the central alarm station. While LANL has compensatory measures in place (e.g., operator training to both pull the alarm and call 911), the current system suffers from reliability issues that appear to adversely impact not only life-safety but also timely emergency response for nuclear facilities.

The radioactive liquid waste facility upgrades are part of waste management risk mitigation. This facility is nearly 4 decades old and had to be manned during the Cerro Grande fire to prevent environmental release of low-level radioactive and chemical liquid waste. The upgrade project would have added a new pumping station, new influent monitoring and control capability, and new influent storage capability – reducing the probability of a radioactive/chemical environmental release.

Plutonium Facility (TA-55): Last Wednesday, a worker was opening an inner container of Pu-238 in a glovebox using vise grips and “felt” the outer container grab the glovebox glove. The worker observed a spot on the glove, closed his fist, and alerted others. Radiological controls personnel responded. Non-involved personnel evacuated the room. Personnel remaining in the room donned respirators. The worker then withdrew his hand from the glovebox while Radcon personnel simultaneously rolled up his surgeon’s glove. During the event, there were no airborne monitor alarms and no measurable release of contamination. Nasal smears were negative. The site rep believes that the immediate actions and followup review by the facility were thorough and appropriate. This reflects well on the facility’s training and preparation. However, the consequences of this event could have been more significant if the worker had been less observant (i.e., Pu-238 contamination release into a room with personnel not in respirators). While operators appear to have followed procedures (e.g., can edges were taped), it may be appropriate to confirm that sufficient actions are being taken to prevent glove-tears, particularly for Pu-238 operations.

Authorization Basis (AB): LANL has submitted for NNSA approval the TA-54 (Area G) updated AB, the TA-55 updated technical safety requirements (TSRs), and the TA-55 revised process hazard analysis for the new Pu-238 scrap recovery line (site rep weeklies 12/20/02, 1/3/03). Also, NNSA has approved downgrading the Radioactive Materials, Research, Operations and Demonstration Facility (RAMROD) from Hazard Category 2 (HC-2) to a radiological facility, based on an estimated Pu holdup less than one-quarter the radiological facility limit. RAMROD has been in cold standby for 3 years and will be used for personnel training and process development for plutonium operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 24, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 24, 2003

Safety-Related Infrastructure: Senator Pete Domenici's office issued a press release this afternoon indicating DOE will restore the \$75M Cerro Grande recovery funding suspended on January 9th.

Radiochemistry Laboratory (TA-48): This week, LANL began a readiness assessment (RA) to verify implementation of the new TA-48 authorization basis for Hazard Category 3 nuclear operations (site rep weekly 1/10/03). One key area being assessed is the facility's ability to manage and control its radioactive inventory and thereby assure that assumptions made in accident analyses are not violated. Inventory management and control is also a key factor if TA-48 is to be downgraded to a radiological facility in the near future. The site rep understands that the LANL RA team is identifying problems in this and other areas. A staff review of TA-48 is scheduled for next Thursday.

Plutonium Facility (TA-55): The Fire Protection Yard Main Replacement Project is nearly completed. Last Sunday, workers removed the cross-over valve between the old and new fire water loops and placed TA-55 buildings entirely on the new loop. This eliminates the possibility of some accident scenarios involving a rupture of the old loop impairing the new loop. Seismic upgrades on the two pump houses and associated tanks are also complete. Remaining work primarily involves removing old components, grouting the old loop in place, and backfilling trenches.

Decommissioning Activities: The Omega West beryllium reflector was successfully removed from the reactor in one piece earlier this month and is scheduled to be shipped to TA-54 in mid-March (site rep weekly 12/27/02). While radiation levels were 3 to 5 times higher than expected (i.e., 5,000 R/hr), the highest individual exposure was 40 mrem – an indicator of a well-executed activity. Workers this past weekend were removing other reactor internals, and again found radiation levels about 5 times higher than expected (about 3 R/hr). They proceeded with the job, and collectively received a dose higher than originally expected. Two workers may have received doses of about a Rem each. Generally, Omega West decommissioning activities have gone well, but the level of radiological protection supervision and the work suspension limits (i.e., when to stop and reassess) may warrant review.

Authorization Basis (AB): The NNSA Site Office has rejected the TA-54 (Area G) AB upgrade package, submitted by LANL on January 10th. The primary issues appear to be level of completeness and adequacy of addressing previous NNSA comments. NNSA and LANL have concluded that the current TA-55 AB complies with the nuclear safety management rule (10 CFR 830) and have postponed action on that update. In the last week, LANL submitted the packages for the TA-50 Radioactive Liquid Waste Treatment Facility and for the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRR). Currently, a high-quality upgrade for TA-54 appears to be the limiting step for LANL reaching the milestone of having submitted compliant ABs by April 2003.

Radiation Protection: Last week, the NNSA Site Office formally raised questions on an apparent low level of objective evidence supporting a LANL triennial assessment of occupational radiation protection. NNSA informally requested supporting documentation in November and December and is pursuing this in order to validate the LANL assessment process and results.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 7, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 7, 2003

Facility Operations and Maintenance: LANL completed transition this week to the new support services contractor, KSL (site rep weekly 8/9/02). The site rep has met the KSL senior management. They bring fresh perspective on facility maintenance practices and appear dedicated to worker safety.

Radiochemistry Laboratory (TA-48): NNSA has directed LANL to operate TA-48 using the safety basis approved last August, subject to two conditions: only operations necessary to reduce the radioactive inventory to below Hazard Category 3 (HC-3) levels are permitted in the Alpha Wing and the Basement Vault; and normal operations are permitted in other areas provided the inventory is below HC-3 levels. TA-48 is receiving help in strengthening the inventory control program from the new LANL Operations Support Group, OSG (site rep weekly 11/15/02). The OSG is thinly manned but making a difference here and in other facilities at LANL.

Critical Experiments Facility (TA-18): This week, LANL restarted the Solution High Energy Burst Assembly (SHEBA), which has been down since August 2000 due to a flammable gas generation question (site rep weeklies 5/10/02, 9/13/02). SHEBA is operating under Technical Safety Requirements (TSRs) approved last summer and verified to be in place by a LANL readiness assessment last November. The TSRs include two limiting conditions of operation that control flammable gas. One is an integrated power limit (i.e., total fissions in one day). The other requires the nitrogen cover gas system to have a specified flow, based on daily measurements. The accident analysis indicates that the power limit is sufficient to prevent conditions conducive to a detonation or deflagration. The TSRs also require periodically verifying that cover gas flow is sufficient to limit oxygen and hydrogen gas concentrations to less than 1 % by volume.

Design Criteria: Last week, NNSA directed LANL to prepare a corrective action plan for addressing issues identified in a crosswalk of LANL engineering processes to DOE criteria on explosive and nonreactor nuclear facility safety (DOE G 420.1-1). The focus is mainly on improving institution requirements for construction project management, including requirements for systems engineering, fire hazard analyses, defense-in-depth, and software quality assurance.

Decommissioning Activities: LANL and the Omega West Reactor D&D subcontractor have agreed to stricter hold-point and communication controls as a result of the event 2 weeks ago when work proceeded after radiation levels were found that were greater than expected (site rep weekly 1/24/03). This job involved removing interlaced graphite bricks in a confined area that had radiation levels up to 20 R/hr. Based on review of the event with LANL and the subcontractor, it does not appear that a less man-rem intensive approach would have worked that didn't generate other challenging hazards (e.g., profuse airborne graphite dust with activation products). LANL is receiving advanced notice of planned radiological work, hold points, and projected doses. Hold points and reevaluation occur now when an activity's radiological conditions exceed those expected by 20% or more. Within a few days, the subcontractor expects to complete removal of reactor internals and begin biological shield removal and radioactive waste shipments. The latter will continue until mid-March when the Be reflector will be shipped to TA-54. Decommissioning is expected to be done this summer. Overall, the project appears to be well-managed and to be using appropriate radiological controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 14, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 14, 2003

Facility Operations: LANL is proceeding with facility management realignment and consolidation under a site-wide Justification for Continued Operation, JCO (site rep weekly 11/29/02). The goal is that this unified organization would identify, plan, and implement needed improvements while minimally impacting nuclear facility operations. This effort appears well-motivated and is intended to address real institutional needs. The JCO expires in April and may require attention to ensure it is adequately closed out by that time.

LANL has stated that roles and responsibilities during this transition would remain consistent with current, specific AB requirements. The site rep has observed that several key personnel in facility operations (e.g., from TA-55, CMR) are being transferred to other LANL areas that need assistance. While this addresses institutional needs, less-experienced personnel may now be called upon to recognize and respond to emergent conditions in these facilities. This aspect is worth considering in the timing and selection of these transfers. Longer term, LANL management appears to recognize the needs for improvements in succession planning, training, and mentoring of operations personnel.

Authorization Basis (AB): The site rep believes that the NNSA site office and LANL can achieve the April 10th deadline for AB upgrades here, but it is going to be tight. It depends on quality of LANL analysis and documentation and ability of NNSA to spot issues and provide feedback early.

Last week, LANL resubmitted the TA-54 (Area G) AB upgrade package, which was revised to address NNSA comments (site rep weekly 1/24/03). This week, NNSA sent back the Radiography Facility (TA-8-23) AB package, which LANL submitted last September. The Radiography Facility is in an older building (1940s era). It was added to the nuclear facility list in 2000 and has been operating to a JCO. The building lacks seismic, confinement, and engineered fire suppression features and is heated by a natural gas fired boiler. This facility radiographs high explosive and nuclear components, including sealed heat sources containing Pu-238 oxide. NNSA raised several issues involving the conservatism in natural gas deflagration calculations and the completeness of analyses and of the proposed controls, particularly for the heat sources.

Longer term, NNSA and LANL are beginning to plan for how to maintain and continuously improve the ABs. The site rep believes that the annual update process here previously has been ineffective and thereby contributed to past AB violations, AB near-misses, and AB-operations interface issues. LANL appears to be moving toward an improved, resource-loaded annual update process.

Waste Management: The TA-54 Radioassay and Nondestructive Testing facility (RANT) is key to the Quick-to-WIPP risk reduction program, since it is used to load WIPP shipping containers (site rep weekly 12/6/02). RANT is approved to operate as a Hazard Category 2 (HC-2) under a limited Basis for Interim Operation (BIO) that expires on June 1, 2003. DOE is conducting a readiness assessment (RA) next week to verify implementation of this limited BIO. The site rep understands that the full BIO has slipped to late April, leaving about 1 month for its review, approval, implementation, and verification (i.e., RAs). Timing appears problematic and worthy of management attention to ensure an adequate, implemented RANT safety basis while best supporting the Quick-to-WIPP program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 21, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 21, 2003

Martin, Stevenson (OE), and Von Holle were on site this week observing a LANL design review for a dynamic experiment confinement system.

Plutonium Facility (TA-55): Last Saturday, TA-55 shut down ventilation in a controlled manner for 6 hours due to an emergent need to secure instrument air. This was a planned shutdown. After restoring ventilation and completing confirmatory surveys, the facility resumed normal operations. On Wednesday, TA-55 determined that a large number of weekly fixed head airborne samples were reading high, based on preliminary counts. At this time, there are not any other indications of a significant contamination release (e.g., no continuous airborne alarms after ventilation restored, no elevated airborne monitor readings, no elevated contamination readings from daily radcon surveys, no trend of contamination found on personnel exiting rooms). LANL is investigating this event.

Instrument air reliability and its impact on confinement ventilation is a recurring issue. LANL is replacing the instrument air compressors to improve reliability. As previously discussed, alternatives are available that could improve confinement ventilation reliability, such as using process air or nitrogen as a backup to instrument air (site rep weekly 1/31/03).

Recommendation 2000-2: One Phase II assessment remains to be done at LANL. The site rep understands that the design for the partial site-wide fire alarm system replacement has nearly reached the stage where DOE and LANL anticipate conducting this remaining assessment. Timing is open.

Recommendations 94-1/2000-1: LANL has begun to systematically sort and package unneeded lower-risk residues for disposal at WIPP. This will reduce inventory and handling risks, improving safety, as well as lower costs, permit more efficient storage, and free up vault space, improving LANL's ability to support high-priority national security missions (site rep weekly 5/3/02).

Quality Assurance (QA): While much remains to be done, progress is being made in institutional quality assurance (site rep weekly 10/18/02). In January, NNSA agreed that LANL had resolved earlier comments on the institutional quality management implementation plan. NNSA still has concerns on the current QA reporting structure and is closely monitoring progress. This plan has been in development for awhile and appears to be a starting point. LANL has also completed a current program description, has nearly completed a gap analysis, and is refining planning and cost estimates. There continues to be a pressing need to achieve these improvements. For example, an NNSA facility rep recently reported an ejected connection during a non-radioactive vessel test, due in part to weaknesses in quality assurance.

Backfit Analysis: University of California has suggested that the LLNL backfit analysis methodology be considered here to decide if hardware modifications, procedure changes, or compensatory measures are warranted when a new standard is invoked. LLNL has a formal process that involves establishing an assessment team knowledgeable of a nuclear facility's safety systems, performing a gap analysis and a more detailed alternatives analysis, and submitting recommendations to the responsible Associate Director for approval and to the NNSA Site Office for concurrence. This could lead to improvements in LANL engineering processes and in achieving compliance with DOE criteria on explosive and nonreactor nuclear facility safety (DOE G 420.1-1).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 7, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 7, 2003

Facility Operations: LANL has established a Nuclear Safety Executive Board to elevate the details and closure of emergent nuclear safety issues to senior management attention.

Nuclear Materials Management: NNSA and LANL have made progress in nuclear material management. However, a significant inventory of excess material is here or is planned to be shipped here soon that lacks a clear disposition path (Board ltr 5/20/02, site rep weekly 3/8/02).

There are successes. TA-18 has shipped about 0.5 MT of uranium-based materials to Oak Ridge and continues shipments. This includes old CMR material and Omega West Reactor fuel (site rep weekly 8/9/02). CMR has also resumed processing TA-18 excess uranium solutions (SHEBA fuel) and has processed about one-quarter of those solutions. This activity will likely be interrupted to relocate equipment within CMR (site rep weekly 11/22/02). LANL also plans to characterize 34 questionable drums of excess uranium this year and disposition them during the next two years.

There are also problems. LANL excess nuclear materials without a current disposition path include: about 0.5 MT of fuel-grade plutonium (Pu) and Pu contaminated highly enriched uranium (HEU); some non-MOX specification plutonium; about 5,000 transuranic sealed neutron sources; and a small inventory of U-233. The U-233 has been waiting awhile for Oak Ridge containers. The sealed sources are among those being actively recovered from around the US by the Off-Site Source Recovery Project (OSRP). Most of the 5,000 sources already here have been consolidated into about 300 waste drums; however, they currently have no pathway out of LANL, primarily because of programmatic issues involving eligibility for WIPP. The other materials also have no clear pathway, primarily because of programmatic issues affecting multiple DOE sites. These issues involve resource allocation, consistent material definitions and requirements, and coordination between sites (both NNSA and DOE-EM) that have similar excess materials.

Plutonium Facility (TA-55): TA-55 continues to thoroughly investigate the numerous high fixed head airborne samples reported in site rep weekly 2/21/03.

On Saturday 2/22/03, two pipe fitters received a possible inhalation dose, based on positive nasal smears (37 dpm alpha max), and had skin contamination (500 dpm alpha max). This resulted when they opened a leaking steam condensate line for repair with insufficient radiological controls. The workers were in one-pair of anti-c's but without respirators. The work authorization did not require respirators, a Radiological Work Permit (RWP), or assign radcon coverage. During work planning, the assumption was made that no contamination was present – based on no detectable activity in leaked water and no contamination found when the system was last opened, which was more than a year ago. This system is in the PF-4 basement near the ceiling and connected to a lab room. NNSA and LANL recognize it should have been treated as potentially contaminated.

The facility's immediate and supplemental actions appear appropriate. Involved personnel were decontaminated and placed in a diagnostic bioassay program. Facility management has reviewed this event with appropriate personnel and has directed that no intrusive work without an RWP may be performed unless it is specifically approved by facility management. TA-55 is still considering what permanent improvements need to be implemented in this area.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 14, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 14, 2003

The staff held a video conference with NNSA and LANL on Friday on LANL fire protection.

Plutonium Facility (TA-55): TA-55 has nearly completed the investigation of the numerous high fixed head samples reported in site rep weekly 2/21/03. The LANL technical review appears thorough. PF-4 ventilation was secured in a controlled manner for 6 hours on Saturday 2/15/03 due to an emergent need to secure instrument air. While ventilation was secured, the blowers for the fixed head air sampling system continued to operate, providing a motive force. This system discharges into a ventilation recirculation system at a point upstream of the HEPA filters. Idling the recirculation system while running the fixed head air sampling system led to backflow into lab rooms from contaminated ductwork, thus providing the source term. Rooms involved with aqueous operations tended to have the higher samples, which is expected. These operations produce easily distributed, fine particle oxides that are now present in the ducts from legacy events. Improvements to prevent recurrence are still being considered. One worthwhile improvement would be to increase instrument air reliability – including a possible backup – and thereby minimize the need for securing confinement ventilation.

Nuclear Materials: LANL has recently identified several unrelated cases of unknown or poorly characterized nuclear materials including: 8 drums containing either tritium (5), plutonium (1), or hazardous chemicals (2) in TA-41; 2 casks with unknown contents in TA-48; 26 unknown samples and one Cm-244 sample in a cooler in a trailer in TA-59. Additionally, the site rep understands there are several drums of problematic legacy tritium material from TA-33 stored in WETF, some poorly characterized containers in CMR, and the 34 drums in TA-18 discussed last week.

Some of these materials have caused problems. For example, the TA-33 material was the source of an unanticipated room and stack release of tritium from WETF in January 2001. The TA-59 samples provided the source term for an event two weeks ago when a LANL employee's badge became contaminated (120,000 dpm alpha) and contamination was taken off-site. Subsequently, elevated contamination levels were found in the van in which the employee was working. Results so far indicate no health consequences, but this appears fortuitous. Material control and radcon practices for this operation appear weak. In all these cases once identified, LANL appears to have put in place appropriate interim controls for the current configuration. Disposition planning may need more attention in an integrated sense at the institutional level. Longer term, a more disciplined, comprehensive effort may be needed to find, characterize, track, and then timely disposition such materials.

Recommendation 2000-2: NNSA and LANL have finalized a corrective action plan to address fire protection system issues identified last year as part of the Recommendation 2000-2 Phase II assessments (site rep weekly 9/6/02). Some of these corrective actions rely on institutional improvements anticipated during the next 2 years, such as implementation of LANL maintenance and engineering program manuals and procedures to standardize facility operations. This is part of the Facility Revitalization Project. The remaining LANL Phase II assessment will be focused on the site-wide fire alarm system and is scheduled to begin next month. It assumes completion of the partial system upgrade. Preliminary design of the partial system upgrade is essentially complete, but project baselining and start of detailed design are slipping until July due to a change to a design-bid-build acquisition strategy.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 21, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 21, 2003

Leary (OE), Rosen, and Tontodonato were here this week reviewing nuclear material stabilization.

Recommendations 94-1/00-1: Since 1995, LANL has stabilized about 59 % of its 94-1 excess and programmatic inventory and achieved significant risk reduction. About 4,850 items remain to be stabilized and packaged or disposed as waste (site rep weekly 5/3/02). During the last 2 years, LANL has developed and nearly finalized a comprehensive, resource-loaded plan to stabilize the remaining items by late 2010, based on level out-year funding with escalation (about \$11M per yr). The staff has not seen details of this plan, which is expected to be complete in a couple of months; however, it appears that LANL is already executing to it and making better progress on both repackaging programmatic material and stabilizing and/or discarding excess material. Progress is also apparent in development of a STD-3013 outer can welder and in design of equipment for large vessel clean-out. The latter is to be installed in the Chemistry and Metallurgical Research Building (CMR), Wing 9.

There may also be opportunities for acceleration. Some higher-risk materials, based on isotopic content, will not be stabilized until the 2007-2010 period, due to delays in equipment design, installation, and startup for the high exposure line. This line's glovebox shells are already in place. The delay appears mainly due to priorities assigned last year to meet the level out-year budget. LANL intends to work some of these materials in the existing lines as the opportunity arises, such as before the TA-55 annual inventory and line clean-out each December. LANL has also begun to systematically sort and package the lower-risk residues for disposal at WIPP. LANL should be in a better position to improve processes and accelerate the schedule after gaining more experience in both direct discard of lower-risk items and use of existing lines to address the higher-risk materials.

Integrated Safety Management: Close attention continues to be warranted on personnel following safety requirements (i.e., formality of operations), on adequate work planning to meet requirements, and on improving on-floor supervision with emphasis on safety requirements when appropriate (site rep weeklies 10/18/02, 11/15/02, 1/10/03). Institutionally, LANL has taken positive steps at the group level to improve supervision. The site rep also understands that the LANL team reviewing safe work practices institutionally has identified needed improvements in requirements, but that most of the benefit is likely to come from better implementation. This may apply not only to programmatic work, but also facility, maintenance, and construction activities. Facility work is controlled through a different process than that being reviewed by the LANL team but may benefit from the same recommendations. Much could be gained by a few well-planned initiatives to ensure personnel understand and comply with safety requirements, including maybe simplifying some requirements to achieve this end. The staff is planning a review week after next of LANL work planning, performance, and feedback that will examine this area.

Nuclear Materials Management: More attention may be warranted to characterizing the 34 questionable drums of excess uranium in TA-18, as well as processing TA-18's excess uranium solutions (SHEBA fuel). Plans exist but appear to need better coordination. The operation to convert the excess uranium solutions to salt is being displaced from CMR Wing 9 to make room for the large vessel clean out operation discussed above. Currently, it appears it will be restarted in a couple of months in Wing 5 at limited throughput and then moved to Wing 3 toward the end of the fiscal year. In the last week, LANL has identified resources that should help keep this on track.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 28, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 28, 2003

Authorization Basis (AB): As of this week, NNSA considers that 13 out of the 18 LANL nuclear facilities have AB's compliant with the Nuclear Safety Management rule (10 CFR 830). NNSA has provided formal comments to LANL on proposed ABs for the remaining five. Of these, the site rep believes that the AB for TA-54 (Area G) appears to face the most challenges. NNSA considers the current TA-55 AB to be compliant and will finish review of a major revision to it after April 10th.

Plutonium Facility (TA-55): PF-4 had an unanticipated one-minute loss of ventilation yesterday, interrupting operations for about an hour. It appears that a construction worker may have inadvertently secured cooling water to one of the new instrument air compressors. The compressor self-monitors cooling water pressure and shut down. It is unclear why the backup compressor did not start up. There were no radiological consequences from this event.

Decommissioning Activities: The beryllium reflector from Omega West Reactor was shipped to TA-54 this week and placed in an underground shaft. Transportation and disposal went smoothly and were completed within the 24 hour period specified in the AB. This shipment removes the principal remaining source term from Omega West – specifically, the activation products bound within the reflector and associated framework. The reflector had contact radiation levels up to 5,000 R/hr when it was removed from the reactor in January (site rep weekly 1/24/03).

Nuclear Materials: Site rep weekly 2/14/03 discussed 8 poorly characterized drums in TA-41 containing either tritium (5), plutonium (1), or hazardous chemicals (2). TA-41 is located in Los Alamos Canyon. This week, LANL shipped the drum thought to contain the highest inventory to a facility where it can be safely dispositioned (LANL estimate: 14,000 curies tritium). LANL has adequate controls in place for the remaining drums. Plans for their disposition continue.

Radiochemistry Laboratory (TA-48): While progress is being made, TA-48 faces challenges operating within its Hazard Category 3 authorization basis (site rep weekly 2/7/03). Earlier this month, TA-48 received an irradiated target shipment before notifying NNSA and before allowing NNSA to complete a required inventory verification. Also, last Wednesday, a natural gas valve was left open near the hot cells, leading to a facility evacuation. Because of the hazard, the natural gas system is considered safety-significant in the AB, but formal operating procedures and controls are lacking. The facility first recognize the AB implications of this event late this week.

Weapons Engineering Tritium Facility (WETF): The WETF safety strategy is highly dependent on the tritium storage containers, considered Safety Class. Last April, NNSA required WETF to place 65% of its inventory in improved containers by April 2003. NNSA and LANL still have not reached closure on use of improved tritium storage containers with higher temperature rated seals.

Timing also remains open for the DOE Operations Readiness Review (ORR) covering Building 450 startup and new AB implementation (site rep weekly 12/20/02). The site rep understands that the LANL ORR report is also still not finalized, nearly 4 months after that ORR. The issues are well known, and LANL appears to have a reasonable plan to implement the AB and prepare for the ORR.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 4, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. Keilers
SUBJECT: Los Alamos Report for Week Ending April 4, 2003

Keilers was off site this week. Anderson, Burnfield, Jordan, Volgenau (OE), and Von Holle were on site reviewing safety aspects of work planning and work performance.

Plutonium Facility (TA-55): The TA-55 authorization basis (AB) considers the fire suppression system to be safety significant because it protects workers and provides defense in depth for safety class systems. However, there are long-standing questions on the adequacy of flow to hydraulically remote sprinkler heads in PF-4 (site rep weeklies 11/2/01, 12/7/01, 12/23/01). LANL has asserted previously that the original design requirements were not based on actual risk factors, such as combustible content. These design requirements are included in the current AB. In December 2001, NNSA agreed with LANL that this condition did not constitute an imminent safety concern. Further action was postponed to allow key personnel to focus on site-wide AB upgrades during the last year in order to comply with the Nuclear Safety Management rule (10 CFR 830). The AB upgrades are now nearly complete.

Recently, LANL informed the staff that 40 of the approximately 970 PF-4 sprinkler heads would not deliver the minimum flow density specified in both the original design and the AB (i.e., NFPA-13, Ordinary Hazard Group II), and 10 of these would not meet a less stringent standard typically specified for chemical laboratories (Ordinary Hazard Group I). The site rep understands that the affected sprinkler heads are spread among several laboratory rooms and tend to be a small fraction (e.g., 10 %) in any particular room. LANL appears now to be considering facility modifications to address this condition. Since these issues have been long-standing and involve the AB, it appears that timely progress toward closure would be appropriate.

Lighting Protection: NNSA approved last month a LANL corrective action plan that is intended to address lightning protection issues raised in a Board letter dated August 6, 2002. Since last September, NNSA and LANL have improved the formality of issue transmittal, tracking, and closure on these and other lightning protection issues identified during the last 2 years (site rep weekly 9/20/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 11, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 11, 2003

On Friday, the site rep attended a meeting in Albuquerque on lab support for Pantex operations.

Integrated Safety Management (ISM): Last Friday (4/4/03), an employee was burned in a non-nuclear facility when a thermoplastic and aluminum compound he was removing from a petri-dish flash-ignited within an open hood. LANL is investigating. There may be parallels between this event and the chlorine dioxide explosion last year (site rep weeklies 1/11/02, 10/25/02). If so, this could indicate continued weaknesses in work controls for programmatic activities – particularly, in the LANL system of safe work practices. Institutionally, safe work practices are one of the main mechanisms for LANL implementing ISM in both nuclear and non-nuclear facilities. LANL's investigation of last year's event was thorough but institutional followup is still incomplete.

Chemistry and Metallurgical Research Building (CMR): Last Thursday (4/3/03), CMR Wing 5 had a partial ventilation shutdown, possibly due to crafts personnel inadvertently bumping a switch. This was a skill-of-craft job. There may be parallels to the TA-55 loss-of-ventilation two weeks ago when a worker inadvertently secured cooling water to a compressor (site rep weekly 3/28/03). In both cases, safety systems were impacted. On the positive side, the CMR operations center saw the ventilation fluctuation and decided to evacuate the wing since the fluctuation was unexpected. LANL systematically investigated the problem on Friday and returned the wing to normal operations.

Radiochemistry Laboratory (TA-48): On March 26th, two people picked up contamination on their clothing while performing elution in the hot cells. It appears the contamination resulted when pump lines were removed. Since this is similar to an event earlier this year, TA-48 has stopped this activity until it can be investigated and proper controls can be implemented. This is positive.

On March 19th, TA-48 had a natural gas leak near the hot cells due to a valve left open, detected by smell; however, the facility did not enter its emergency procedures and did not evacuate (correction to site rep weekly 3/28/03). The facility believes that an unsafe condition was a potential but did not actually exist – because the leak was isolated within 30-35 minutes after detection and, if gas were uniformly distributed, it would have been more than 18 hours before the space reached the lower explosive limit. This logic appears incorrect because of gradients and potential ignition sources. The event raises questions in addition to those involving the adequacy of procedures and controls for the natural gas system, considered safety-significant under the TA-48 authorization basis. The contrast to CMR's conservative response to the less hazardous condition discussed above is noteworthy.

Nuclear Material Management: LANL has recently identified several unrelated cases of unknown or poorly characterized nuclear materials (site rep weekly 3/14/02). While acknowledging the positive that these items are being found, NNSA has questioned the process used to identify and track such legacy items. NNSA has asked LANL to report on how these issues are being addressed, whether they constitute an institutional issue, and whether enhanced standards or requirements are needed.

In the TA-48 case, one of the two questionable casks was in a posted radioactive material storage area that is located right next to a shed containing propane bottles, a forklift, and other combustibles. NNSA is pursuing this possible hazard with facility management. The questionable cask has been relocated.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 18, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending Apr 18, 2003

Quirk was here this week reviewing TA-18 instrumentation & control and software quality assurance.

Authorization Basis (AB): LANL met the April 10th deadline to submit AB upgrades, per the Nuclear Safety Management rule (10 CFR 830). NNSA is currently reviewing the proposed upgrades for waste operations (TA-50, TA-54), radiography (TA-8-23), and facility management realignment (site-wide). Nuclear facilities continue to operate under previous ABs during the NNSA review.

Preliminary Notice of Violation (PNOV): Last Thursday, NNSA sent LANL a PNOV for several nuclear safety issues that arose last year. Specific events involve the following facilities (refer to site rep weekly of date in parenthesis for details): the Critical Experiments Facility (1/11/02, 2/15/02), Plutonium Facility (3/15/02), Radiochemistry Laboratory (8/9/02), and non-nuclear radiography facility (10/18/02). NNSA also identified examples where LANL processes for identifying causes and correcting quality problems were not effective - a longstanding institutional issue. Based on the longstanding nature, NNSA considered escalating the severity level of the quality improvement findings; however, NNSA decided against this because of significant commitments LANL has made to strengthen senior management and implement site-wide improvements to quality processes. While it's in the early stages, the site rep has seen progress in this area.

Critical Experiments Facility (TA-18): Last July, DOE approved a new TA-18 AB that includes 11 newly designated Safety Class systems – intended to address about 100 hazard scenarios that challenge the evaluation guidelines (site rep weekly 9/13/02). Among these systems are the existing scram chains and the new in-core temperature monitoring systems. The latter are in design now. They are intended to provide a signal to the existing scram chains and thereby prevent fuel and irradiated samples from melting and partially vaporizing during a rapid, uncontrolled reactivity insertion while in delayed critical mode. Such an event hypothetically leads to TA-18's highest consequence accident, unless prevented by a scram. LANL has compensatory measures in place until the monitoring systems are installed (e.g., sample size limits, reduced neutron flux trip set points).

There appear to be significant engineering challenges to developing a temperature-based scram system that is capable of measuring peak temperature during a fast transient; has adequate response time; has justified trip set points; meets standard Safety Class requirements (e.g., separation); and can be shown, via combined analysis and test, to satisfy the AB functional requirements. While the design is being competently executed, neither the new in-core system, as currently envisioned, nor the existing scram system appear to fully meet standard Safety Class requirements. The shortfalls warrant justification. An independent design review, perhaps by the LANL Reactor Safety Committee, may be helpful at identifying improvements (TA-18 agreed). To address some challenges, TA-18 is having to develop engineering procedures that are currently not specified fully at the institutional level, such as: Safety Class guidance, back-fit guidance, commercial item dedication, and independent design reviews.

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF had a tritium release into a glovebox and from there into a process room. The room was evacuated, operations were secured, and the tritium (about 0.7 Ci) was exhausted to the environment via an approved stack. Health consequences were minimal (2 mrem to the effected worker). LANL has appropriately investigated this event and identified potential weaknesses that need to be reviewed and corrected.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 25, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 25, 2003

Radiochemistry Laboratory (TA-48): NNSA has agreed with LANL that TA-48 can operate under the approved Hazard Category 3 safety basis with specific constraints until May 15th or until NNSA has verified the inventory (site rep weekly 2/7/03). Two pertinent questions now involve the facility's residual inventory (i.e., holdup) and the adequacy of the facility's inventory control practices. Pending resolution, LANL would like to downgrade TA-48 to a radiological facility; however, both the path forward to address the above questions and the details of whatever is to replace the current safety basis appear open at this time. While, it may be possible to downgrade TA-48, the remaining worker hazards are significant enough to warrant LANL and NNSA attention.

Dual Axis Radiographic Hydrodynamic Test Facility (DAHRT): LANL is celebrating its 60th anniversary, and ceremonies this week included dedication of DAHRT. DAHRT consists of two flash x-ray machines at right angles to a high explosive firing site. It can be used to capture time-resolved stereo images of weapon component mockups at the moment of implosion. The first axis began operation in Fall 2000 and has been used for 6 major experiments. In March, NNSA approved closeout of the construction phase, which includes the second axis. LANL expects to complete second axis commissioning in late 2004. DOE and LANL have categorized DARHT as a moderate hazard non-nuclear facility that may occasionally be required to perform a nuclear activity.

Plutonium Facility (TA-55): This week, LANL submitted documentation to NNSA to demonstrate that TA-55 has manufactured a nuclear weapons pit, QUAL-1, using fully qualified processes. NNSA is reviewing the package. If accepted, this culminates a 6 year LANL-wide effort to restore the nation's ability to manufacture certifiable pits that meet all quality requirements. The last such pit was made at Rocky Flats 14 years ago. Since February 1998, LANL has made 18 pits in the development leading up to QUAL-1. LANL now plans to make about 6 pits per year to support certification efforts and plans to develop capability to make about 10 stockpile pits a year by 2007.

Radiography Facility (TA-8-23): NNSA has agreed with LANL that TA-8-23 can operate under its current Justification for Continued Operation (JCO) until September 2nd or until NNSA approves the new safety basis proposed by LANL to comply with 10 CFR 830. TA-8-23 is a Hazard Category 2 nuclear facility. It is more than 50 years old, is heated by natural gas, and lacks seismic, confinement, and engineered fire suppression features. TA-8-23 also has radiographic inspection capabilities that are unique at LANL and support national security missions. To address some hazard scenarios, LANL has committed to remove the natural gas from the facility by May 15th and to shutoff the natural gas at the supply valve in the interim. This is positive.

Critical Experiments Facility (TA-18): Similar to TA-8-23, TA-18 also has Hazard Category 2 nuclear operations in buildings heated by natural gas. To address this, the TA-18 safety basis includes automatic gas shutoff valves as controls to prevent a follow-on explosion after a seismic event. The site rep understands that TA-18 is now also considering removing natural gas.

Recommendation 2000-2: The one remaining LANL Phase II assessment will be focused on the site-wide fire alarm system and is scheduled to begin May 12th. It assumes completion of the partial site-wide system upgrade, which is in preliminary design (site rep weekly 3/14/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 2, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 2, 2003

LANL Management: DOE has decided to compete the LANL contract, now held by University of California, when it expires in Sep 2005. In testimony, NNSA has stated that the failures at LANL are real but are also the failures of a few, and that the vast majority of LANL personnel continue to perform in an exceptional manner. NNSA also stated that it is difficult to see how any organization could have done more to deal with that problem than the University of California has since Dec 2002.

During this same period, the site rep has seen positive LANL initiatives to improve nuclear safety. This includes establishment of a Nuclear Safety Executive Board to increase senior management visibility to emergent nuclear safety issues, as well as startup of an operational mentoring program to provide guidance and training to LANL management at multiple levels in critical nuclear safety elements, formality of operations, and work control.

Weapons Engineering Tritium Facility (WETF): The WETF safety strategy depends on tritium storage containers, considered to be Safety Class. The safety basis assumes the containers are capable of withstanding 120 C. A year ago, NNSA advised LANL to pursue higher temperature seals on these containers (i.e., 250 C) to increase thermal margin. This was based on DNFSB staff input and lack of any apparent reason not to pursue high temperature seals. Last week, WETF provided NNSA a review on why higher temperature seals should not be mandated for all the containers. WETF stated that these are secondary containers; they have other components (e.g., a pressure gage) that would likely fail at temperatures less than 250 C; and the higher temperature seals are harder to use and have higher leakage incidence than polymer seals. The component temperature limits mentioned are inconsistent with those in a LANL March 2000 container study. NNSA is evaluating this information, as well as LANL progress in increasing the WETF inventory that is in improved containers (e.g., rated at 120 C).

Pantex Support: The site rep attended the Standing Management Team (SMT) meeting at Pantex Thursday to determine the status of laboratory support for Pantex operations. The SMT includes experienced federal, laboratory, and Pantex contractor personnel and has been responsible for defining and managing requirements for integrated safety improvements for Pantex nuclear weapon processes (i.e., SS-21, IWAP). While not always effective in the past, the SMT has emerged as a vehicle for NNSA to manage, leverage, and prioritize multiple-contractor resources and thereby achieve timely resolution of issues and timely implementation of safety improvements.

Under the NNSA re-engineering, it appears that NNSA is now on a path to reduce the federal role in the SMT and to reduce the SMT's integration function. This may be problematic for several reasons: (1) Contractors would be expected to determine and assign priorities among themselves within the bounds of their own contracts. This could result in each contractor firmly advocating a course that most efficiently meets his own contract; however, that course may not be most efficient for the overall NNSA complex or in the best interest of timely implementation of safety improvements. (2) It's unlikely federal management could evaluate and referee such situations on a timely basis without continuous active technical engagement by federal staff. Lack of such engagement could slow down timely implementation of safety improvements. (3) The SMT has added visibility to emergent issues on individual projects and appropriately asked if they apply to other projects. Reduced emphasis on integration would likely reduce pressure for individual projects to benefit from such lessons learned.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 9, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 9, 2003

Integrated Safety Management: LANL management is reviewing recent recommendations by a LANL team for potential improvements in institutional safe work practices (site rep weeklies 10/25/02, 3/21/03). Safe work practices are the formal mechanism that LANL uses to implement ISM into programmatic (i.e., non-facility) work.

Decommissioning Activities: In January, LANL reported that environmental sites here contain radionuclide inventories that have not been categorized per the Nuclear Safety Management Rule (10 CFR 830). LANL proposed categorizing and controlling inactive waste sites as less than Hazard Category 3 (HC-3) using methodology approved last September by DOE-EM for EM sites. Last week, the NNSA Site Office non-concurred with the LANL proposal.

This week, LANL informed NNSA that the two TA-21 General's Tanks may contain a kg of plutonium requiring categorization as HC-2 but that they are not a hazard now in their present buried configuration. These tanks were used between 1945 and the mid-1970s as liquid radioactive waste receiver tanks. They have been inactive for two decades and need to be characterized (site rep weeklies 9/20/02, 10/11/02). LANL is preparing a safety analysis for characterization activities.

Waste Operations: TA-54 is a HC-2 nuclear facility used for solid waste operations, including storing and shipping transuranic (TRU) waste to WIPP. It is currently storing about 20,000 TRU waste drum-equivalents in fabric dome storage, containing more than 0.1 MCi Pu-239 equivalent. Nearly two-thirds of this inventory is in 2,000 higher wattage drums that, last year, DOE and LANL committed to having off-site by the end of FY 04. This is the Quick-to-WIPP initiative. Progress so far has been slow – only 15 of these drums have shipped since December.

The TA-54 Radioassay and Nondestructive Testing facility (RANT) is key to the Quick-to-WIPP initiative, since it is used to load shipping containers for WIPP. NNSA has extended from June 1 to September 4 the authorization for RANT to operate as a HC-2 under a Limited Life Basis for Interim Operation (site rep weekly 2/14/03).

Last month, LANL submitted the TA-54 updated safety basis, to comply with 10 CFR 830. The analyses of the postulated accident scenarios predict high consequences for extremely low probability events, primarily because they postulate that the highest source term drums are collocated and participate in the accident. Based on the analysis, LANL proposes that TRU waste containers, container banding, domes, and dome door restraints as safety class and the lightning protection system as safety significant. LANL also proposes technical safety requirements including inventory limits (in total and by dome) intended to control and distribute the inventory. This may be an area requiring more rigor. Meanwhile, more attention on accelerating the Quick-to-WIPP initiative appears appropriate.

Chemistry and Metallurgy Research Building Replacement (CMRR) Project: The draft environmental impact statement (EIS) was distributed this week. The Notice of Availability will be published in the Federal Register next week. The comment period runs to June 30. The Final EIS and a Record of Decision are scheduled for Nov 2003 and Jan 2004, respectively.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 16, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
J. J. McConnell, Deputy Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 16, 2003

The site representatives were at DNFSB-Headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 23, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 23, 2003

Work Controls: Last Monday, LANL reported that 9 people received small tritium uptakes (up to 8.3 mrem) when cutting and removing copper piping in the Ion Beam Facility (TA-3-16) and that this was an activity outside the scope of the skill-of-craft work package used to authorize the job.

The Ion Beam Facility is an excess, shutdown facility awaiting disposition. The authorized work included general upkeep and removing loose items for salvage. The workers were removing piping to get to a shield wall. Their intent was to remove part of the wall and thereby gain forklift access to salvage a large pedestal magnet. The room had been downgraded to radiologically uncontrolled status, although tritium contamination had been found in other similar systems in the building and other equipment in the room. During post-job surveys, radcon personnel found tritium contamination inside the pipes – identifying the hazard after the work. LANL management has stopped this job, directed a stand-down of such surveillance and maintenance activities at LANL excess facilities, and is reviewing surveillance and maintenance work requests for similar problems. LANL is also performing a causal analysis of this and similar events to ensure common factors are identified and institutional improvements are pursued.

Plutonium Facility (TA-55): TA-55 reported a Technical Safety Requirement (TSR) violation this week because un-calibrated differential pressure gauges are being used to confirm that HEPA filters are unplugged. TA-55 has a TSR to periodically confirm that differential pressure across filter plenums are within specification. The TSR surveillance procedure requires verifying gauge calibration. The NNSA facility reps recently observed daily rounds and determined that the gauges are not calibrated. LANL previously recognized this condition for about 68 gauges and has been planning to correct it. On Tuesday, NNSA approved continued operation with the un-calibrated gauges. LANL plans to replace the gauges with calibrated ones by June 30th.

On Tuesday, TA-55 had a low-level personnel contamination event when replacement heater elements were moved from one room to another via an introduction hood, glovebox lines, and the trolley system. The source remains to be determined. Seven glove box gloves in two different rooms had contamination but were apparently intact. LANL lines of inquiry include: self-survey requirements during glovebox work within a single line, between lines, and between rooms; worker compliance with these requirements; and the practicality of avoiding skin contact to anti-Cs at the conclusion of work.

The NNSA Site Office has assigned priority to complete by June 1st its review of the process hazard analysis (PrHA) for the new Pu-238 scrap recovery line (site rep weekly 1/17/03). LANL has stated that a need exists for about 9 kg of clean Pu-238 by Sep 04 and that LANL has 1 kg from running the bench-scale unit (a high man-rem activity) and maybe another kg from other sources. LANL has indicated that meeting this schedule requires near-term PrHA approval, Jul-Aug readiness assessments, Sep-Oct startup, and then “sprint mode” operation (i.e., 8 kg/yr rate) for at least part of the remaining period.

Radiochemistry Laboratory (TA-48): The NNSA Site Office has extended LANL authorization to operate TA-48 under the approved Hazard Category 3 safety basis until today (site rep weekly 4/25/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 30, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 30, 2003

Nichols, Martin, and Von Holle were on site this week reviewing LANL processes for developing weapons response data, which are vital inputs to Pantex safety analyses.

Plutonium Facility (TA-55): On Tuesday, LANL submitted to NNSA a revised process hazard analysis (PrHA) for the Pu-238 scrap recovery line. Changes were made to incorporate recent NNSA informal comments. On Thursday, NNSA approved with comments the revised PrHA. NNSA and LANL will have a schedule for readiness assessments and startup in about a week.

Substantive changes from the LANL January submittal are: (1) one of the five analyzed accidents had higher consequences (ball mill jar ejection), and the predicted dissolver deflagration energy increased; (2) the dissolver pot is safety significant; and (3) explicit proposed Technical Safety Requirements (TSRs) were withdrawn, although there are descriptions of what is considered to be TSR-level controls.

NNSA and LANL assert that public safety is assured by the existing building structure and confinement, and glovebox seismic integrity (i.e., safety class). They also assert that worker safety is assured by new features: unique ion exchange (IX) resin type, IX rupture disk, ball mill containers, ball mill steel lid and latch (i.e., safety significant). There are also new administrative controls: glovebox Pu-238 and combustible inventory limits, monthly IX liquid level inspection, resin replacement requirements (dose, dryness, age), and dissolver argon flow and pre-op test requirements. The ball mill lid interlock, IX exterior steel mesh, and IX auto-elution system are defense-in-depth.

Recommendation 2000-2: NNSA has completed the Phase II assessment of the site wide fire alarm system, including the partial system upgrade currently in design. This is the last Phase II assessment at LANL. The report is imminent. The assessment team observed that the system has about 22,000 alarm points and 250 fire control panels of numerous brands. About 80% of the panels need to be replaced or modified to resolve major signal delay issues (site rep weekly 1/17/03). The team made several suggestions including standardizing on one or two panel designs, as well as considering an additional project to upgrade 75-100 buildings not in the current project. Fewer panel designs should simplify maintenance and reduce life-cycle costs, since it reduces requirements for training, vendor services, and spare parts. LANL needs on-site expertise in these systems since fire alarm vendor support in many cases is 100 miles away.

The team also observed that many facilities are not scheduling fire system maintenance on time, resulting in only part of the required maintenance being accomplished. NNSA and LANL recognize that this is unsatisfactory. Improving maintenance priorities and efficiency is one of the main drivers for the LANL facility management realignment now underway (site rep weekly 2/14/03).

Radiochemistry Laboratory (TA-48): NNSA has downgraded TA-48 from Hazard Category 3 to a moderate hazard radiological facility, based on a LANL analysis, an NNSA facility walk-down, and a LANL demonstration of inventory controls. TA-48 is also in the process of restarting two facility areas that had higher inventories earlier in the year (site rep weeklies 1/31/03, 4/25/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 6, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 6, 2003

Broderick, Gwal, Jordan, and White were here reviewing electrical and lightning protection systems.

Weapons Engineering Tritium Facility (WETF): During the next 2-3 months, WETF intends to transition to its new authorization basis (AB), which was approved in April 2002. The new AB mandates several systems as safety class – intended to protect the public. These include tritium storage containers and the NFPA 780 lightning protection system. Questions have lingered for more than a year on the adequacy of these systems to perform safety class functions: such as, the high temperature sealing requirements for the tritium storage containers and the level of operability required for the lightning protection system (site rep weeklies 4/26/02, 5/31/02, 11/15/02, Board letter 8/6/02). In March, a lightning protection consultant to LANL reported on the system and concluded that it is unlikely to prevent arcing in areas used for tritium handling and storage (i.e., fulfill its safety class function), but that the containers themselves are robust to lightning effects. Given that WETF is operating now and in transition to the new AB, it appears worthwhile for NNSA and LANL to assign high priority to quickly addressing these issues.

Lightning Protection Systems: NNSA and LANL are increasingly relying on NFPA 780 lightning protection systems as safety-related engineered controls for nuclear facilities. This may be inappropriate, particularly for safety class systems. Besides WETF, the new Critical Experiments Facility (TA-18) AB specifies an NFPA 780 system as safety class, and the proposed TA-54 waste operations AB would specify an NFPA 780 system as safety significant. A Board letter last August and a DOE headquarters on-site review last September questioned the appropriateness of depending on NFPA-780 systems for nuclear facility controls (site rep weekly 9/20/02). These appear to be examples where more in-depth design/backfit review is warranted to ensure each engineered control will perform its designated safety function and that practical operability requirements are defined.

Plutonium Facility (TA-55): On Tuesday, TA-55 reported a high fixed head air sample reading (53 DAC-hrs weekly sample) in a room that was subsequently found to have a small nearby area of removable contamination. LANL is investigating what work was recently performed in this room.

Also on Tuesday, a worker opened a container of Pu-238 via a glovebox glove and then discovered contamination on one of his surgeon's gloves. RadCon personnel responded. After personnel surveys, the room was evacuated and controlled. Subsequent investigation identified a relatively new glove with a tear (installed in April). Two local fixed head air samples were elevated (max: 472 DAC-hrs daily sample), but there were no skin contaminations, and nasal swipes were negative. The 5 affected personnel are being placed on diagnostic bioassay. The site rep observes that there was a similar Pu-238 glove tear in January (site rep weekly 1/17/03). It may be appropriate to confirm that sufficient controls are in place to prevent glove-tears, particularly for Pu-238 operations.

Chemistry and Metallurgical Research Building (CMR): The CMR AB specifies that ventilation is safety significant because it protects the public and worker from releases from spills and moderate fires (along with safety class fire suppression). However, the electrical power needed to run ventilation is general service and doesn't have a diesel generator backup. Functional classification of electric power, as well as emergency lighting to facilitate evacuation, may warrant reconsideration.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 13, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 13, 2003

Plutonium Facility (TA-55): On Tuesday, TA-55 reported another failed glovebox glove in the Pu-238 operations (see last week's report). The worker discovered the failed glove while monitoring his surgeon gloved hand after closing an interconnecting spool-piece door between two gloveboxes. Radcon responded and detected in excess of 1M dpm on the worker's left gloved hand. Like last week, the room was evacuated and controlled. Subsequent investigation identified this was an older glove (installed in October 2000). All fixed head samples in the room were elevated. The one at the workstation with the failed glove read 1065 DAC-hrs (daily sample). There were no continuous airborne monitoring alarms, and no skin contaminations. One worker had an elevated nasal smear. The 5 affected workers are being placed in diagnostic bioassay. On Wednesday, the site rep toured the space with LANL and a DOE facility rep. It appears that this glove failed by being mechanically pinched. A piece of glove was visible, wedged in the threads of the spool-piece door closure.

Because of repeated glove failures, TA-55 has started an investigation to determine if there are any common causes between the Pu-238 related failures. This appears necessary but insufficient. LANL recognizes that the gloves are the weakest link in the safety-significant glovebox confinement system. LANL thoroughly investigates each failure, and periodically has pursued means to reduce failures. The site rep believes LANL could be well-served by implementing a continuous improvement effort for glovebox gloves and glovebox operations to minimize these failures. Areas to consider may include engineering, quality assurance, and operator training. Several DOE sites rely on glovebox operations, likely have similar issues, and could all benefit from active sharing of lessons learned.

Radiochemistry Laboratory (TA-48): Two weeks ago, NNSA downgraded TA-48 to a radiological facility (site rep weekly 5/30/03). On Thursday, TA-48 reported that their inventory exceeded the radiological facility limit. This resulted from a data entry error in the material control database for a Pu-238 sample. TA-48 has frozen material receipts and has suspended its Pu-238 operations. The site rep believes that LANL has better facilities for Pu-238 chemistry than TA-48. Given the tiny amount of Pu-238 a radiological facility can handle before exceeding material-at-risk limits (i.e., max: 36 mg – provided there is no other source term), it isn't clear why these operations should be conducted in TA-48 in its present status as a radiological facility. These activities could be a hold-over from TA-48 operations up to two weeks ago as a Hazard Category 3 nuclear facility.

Chemistry and Metallurgical Research Building Replacement Project (CMRR): On Monday and Tuesday, the site rep attended an NNSA/LANL workshop on the CMRR Project. This project is intended to replace the aging CMR Building and maintain LANL capabilities in actinide analytical chemistry and material characterization, as well as increase LANL secure vault space. It is about midway through the conceptual design phase (roughly, 3% design stage). LANL estimates the cost range is \$420M - \$955M and schedule range is 9 - 14 years. Near-term schedule includes layout selection in September, record of decision next January, and start of preliminary design next March.

Quality Assurance: DOE Office of Assessments (DOE-OA) is conducting a complex-wide review of suspect counterfeit item controls and practices. A DOE-OA team was here this week and completed its field investigative work on NNSA Site Office and LANL practices.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 20, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 20, 2003

Plutonium Facility (TA-55): Last Thursday, two TA-55 workers had skin contamination as a result of a glovebox glove failure in Pu-239 aqueous operations. The workers discovered the contamination when they frisked their hands and feet at the lab room exit. Radcon personnel responded and controlled the room. One worker had a positive nasal smear. One fixed head air sample was elevated (16 DAC-hrs). The two workers were decontaminated and placed on diagnostic bioassay. This is similar to other recent events (site rep weeklies 5/23/03, 6/6/03, 6/13/03).

Because of recent glove failures, TA-55 management curtailed non-essential glovebox work. TA-55 has approximately 7,000 pairs of glovebox gloves and recognizes that they constitute the weakest link in its glovebox confinement system – an engineered control. There is a high reliance on administrative controls, particularly proper frisking at the glovebox after removing hands from the gloves. During the curtailment, the facility is training workers on recent experiences, best glovebox practices, glove inspection; inspecting frequently used gloves (those not requiring step-ladder access); inspecting each glovebox for sources of acute insult to gloves (i.e., pinch points, sharp objects, heat/abrasion sources); and performing a sampling inspection on newer gloves.

Recommendations 94-1/00-1: LANL is making progress in design and procurement of large vessel clean-out equipment for the Chemistry and Metallurgical Research Building (CMR) Wing 9 – a Recommendation 94-1 milestone (site rep weekly 3/21/03). Equipment is now being procured. However, the safety analysis, including preliminary functional classification, is lagging. It is being worked, but programmatic risk (i.e., cost, schedule, scope) is increased until it is satisfactorily shown that the safety analysis and the design are sound and in phase with each other.

Weapons Engineering Tritium Facility (WETF): The WETF safety strategy depends on tritium storage containers, considered to be Safety Class (site rep weeklies 6/6/03, 5/2/03). The safety basis assumes the containers are capable of withstanding 120 C. NNSA has directed LANL to pursue higher temperature container seals (i.e., 250 C) to increase thermal margin; however, new questions are emerging that cast doubt on container high-temperature performance (i.e., above 120 C), such as pressure gage integrity and decreasing container material strength with temperature. It appears prudent to address these questions quickly, given the importance of the containers. A worthwhile objective at this point may be to increase overall thermal margin, if practical, but retain a lower temperature rating for safety analysis that is consistent with current uncertainties in the failure modes.

Authorization Basis (AB): Last Fall, the NNSA Site Office approved the LANL on-site transportation safety document (TSD) and associated Technical Safety Requirements – TSRs (site rep weekly 11/29/02). NNSA prefers that LANL shipments fully comply with Department of Transportation (DOT) requirements. However, in some cases, such packages are not available. The TSD provides a framework for developing controls that ensure overall safety. LANL intends to capture and propose the activity-specific controls in transportation plans for NNSA approval.

Progress on these transportation plans has been slow. They play a key role in specifying the controls that NNSA and LANL are depending on for specific shipments – to the point where they may need to be considered, all or in part, as the TSRs for specific shipments. There is some confusion on this aspect, which may warrant clarification.

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 27, 2003

Anderson, Batherson, Daniels, Hunt, Jordan, and Winters were on site this week reviewing radioactive waste management and decontamination and decommissioning activities. The site rep was off site this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 3, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 3, 2003

Critical Experiments Facility (TA-18): NNSA has suspended work on the TA-18 mission relocation to the Nevada Test Site because of recent increases in the projected costs to complete the project (site rep weekly 1/3/03). The project has reached the 90 % conceptual design stage (i.e., about 4 % overall design). NNSA has begun several assessments to find the cause of the increases, and plans to complete these assessments and determine a path forward by the end of this month.

Plutonium Facility (TA-55): The LANL and NNSA readiness assessments (RAs) for the Pu-238 scrap recovery line are tentatively scheduled for next week (7/7-11/03) and early August (8/4-8/03), respectively, but this appears optimistic. It's not yet clear to the site rep that the scope for either RA has been fully defined; procedures updated, verified, and validated; personnel trained on the updates; and readiness reviewed by TA-55 management via demonstration. These may be complete or could occur quickly, leading to a declaration of readiness for the LANL RA. The site rep intends to observe portions of the LANL RA when it occurs.

Engineered Controls: As required by 10 CFR 830, LANL has updated LANL nuclear facility authorization bases, including engineered controls. NNSA action on some updates is pending. NNSA and LANL need to apply more attention to ensuring that all the engineered controls selected have clearly defined safety functions, that they will fulfill those functions, and that they constitute a complete set. Some other sites have systematic approaches to engineered controls institutionalized in "Conduct of Engineering" manuals. LANL has a solid effort started to develop a similar approach, but it will take time to implement. Meanwhile, the site rep believes uncertainty exists here on whether some designated engineered controls will fully meet the intent. The staff has identified several examples including: WETF lightning protection and containers, CMR electrical power/ventilation, TA-18 flood retention structure and new temperature scram system, TA-55 fire suppression and Pu-238 safety systems (e.g., site rep weeklies 11/8/02, 12/6/02, 4/4/03, 4/18/03, 6/6/03). To the site rep's knowledge, issues from only one system from this list are resolved or nearly resolved.

Contamination Events: Regarding recent glovebox glove failures, TA-55 completed near-term actions and resumed non-essential glovebox work the week of June 20th (site rep weekly 6/20/03). Longer-term actions continue. Last week, a Pu-238 worker had contamination found and removed from a fingernail. Contamination was then found in two glovebox gloves in use less than a year. In an unrelated event, an airborne release occurred in one room, traced to a glovebox door actuator leak.

Also last week, the Chemistry and Metallurgical Research building (CMR) reported high fixed head air samples for two consecutive weeks in one room in early June (e.g., 67 DAC-hrs, weekly sample). CMR was unable to link these to particular events but did find elevated surface contamination on hood tops and supports (i.e., 20-70 dpm alpha on half the swipes). It appears close management continues to be warranted at CMR to contamination control and tracking fixed head sample results.

Tritium Facilities: NNSA has downgraded the Tritium Systems Test Assembly Facility (TA-21-155) from Hazard Category 2 to a radiological facility, based on less than 0.5 g tritium inventory. This building originally supported the Rover program and, between 1984 and 2000, was used for fusion research. It has been de-inventoried and prepared for surveillance and maintenance mode and later decommissioning. High inventory components have been removed. Remaining components have residual inventory and are vented to the building. Stack effluent averages less than 1 Ci/day released.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 11, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 11, 2003

Stevenson and Von Holle were on site this week reviewing dynamic experimentation.

Pantex Support: The site rep attended the Standing Management Team (SMT) meeting at Pantex on Friday to determine the status of laboratory support for Pantex operations, including LANL support. The SMT is responsible for defining and managing requirements for seamless safety improvements (i.e., SS-21) for Pantex nuclear weapons processes. In June 2002, the SMT approved slipping completion of SS-21 for the W-88 from April 2004 to July 2004, due to scope growth from (a) accelerating bay tooling by 1 year (i.e., to 5/03 – still incomplete) and (b) incorporating a developmental primary assembly process specified by LANL that month. (Pantex site rep weekly 6/28/02).

This week, the W-88 SS-21 project informed the SMT that, because of delays in developing the new primary assembly process (a quality improvement), this safety-enhancement project is not expected to be completed until January 2006. This is a 17 month delay from the SMT approved baseline (7/04) and a 20 month delay from the original schedule (4/04). It is also beyond authorization basis and nuclear explosive safety study exemptions granted by NNSA (7/04 and 9/04, respectively), which will require NNSA to either suspend operations or extend the exemptions. It impacts availability of W-88 surveillance data. Per the project, even if the safety and quality improvements are decoupled now, the safety improvements would still be late – March 2005, an 11 month delay from the original schedule.

Price-Anderson Enforcement Letter: DOE Office of Enforcement (DOE-OE) informed LANL this week of its concern that LANL nuclear safety continues on a negative trend. DOE-OE observed that work control breakdowns that led to the recent Ion Beam Facility contamination resemble those that occurred in a TA-55 event in March 2002, raising questions on effectiveness of corrective actions. Also, the recurring TA-55 airborne releases, due mainly to glovebox glove failures, could indicate quality and work control issues. TA-48 exceeding its inventory limit as a radiological facility was also a flagged concern. DOE-OE took no action now because of LANL senior management commitment and because improvements being made will take time to be effective. They did state that escalated enforcement would be considered if non-compliances to the nuclear safety rule (10 CFR 830) occur at LANL (site rep weeklies 3/15/02, 4/18/03, 5/23/03, 6/13/03, 6/20/03 discuss the events above).

Plutonium Facility (TA-55): The LANL readiness assessment (RA) for the Pu-238 scrap recovery line began Monday. LANL expects it to conclude next week. Nearly all the procedures were updated between last Tuesday and Thursday (7/1-3/03), and management declared readiness. The RA team is the same as last July, and is using the same plan of action and implementation plan. This week, the team reviewed documents (e.g., closure of previous findings), walked down the line, and observed comminution and dissolution. These were demonstrated by the subject matter experts (PhDs) who are training the crew and who will supervise the operation after startup. Currently, the RA team does not consider the other operations significantly different than those observed last year, and does not plan to have those demonstrated again. In effect, this RA is a continuation of the RA of a year ago, focusing on the corrective actions from the last RA and on the subsequent changes due to the updated process hazard analysis, as identified informally by the individual team members within their areas of responsibility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 18, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 18, 2003

Shuffler was on site this week providing site rep assistance and observed plutonium and tritium processing, analytical chemistry, critical assemblies inspection, and solid/liquid waste operations.

Plutonium Facility (TA-55): The NNSA readiness assessment (RA) for the new Pu-238 scrap recovery line is scheduled to begin the week of August 4th. The LANL RA is in the report writing phase. The team expects to conduct a management out-brief and issue their report on or about July 29th. LANL considers that there has been only one RA – the one starting last week, and that last July's RA was never completed. While preliminary findings have not been disseminated, LANL seems confident that they will be ready for the NNSA RA the week of August 4th.

Waste Operations: DOE and LANL progress on the Quick-to-WIPP initiative is slow but improving – 51 of the 2,000 drums in this inventory have been shipped this FY, along with about 830 other drums. DOE and LANL expect to accelerate the pace. LANL was making about one WIPP shipment per week in March, went to two per week in May, and expects to go to three per week next month. For comparison, LANL only made two WIPP shipments in FY 02. Quick-to-WIPP shipments take longer to prepare, because of a shipping container evacuate and backfill requirement. Off-gassing can extend the process. They are also not full shipments, because of shipping certificate limits. However, the target 2,000 drums (8 % of the accessible inventory by number) warrant priority because they contain about two-thirds of the accessible source term. This is a significant risk reduction.

Weapons Engineering Tritium Facility (WETF): NNSA and LANL are assigning higher priority to addressing thermal-margin questions on WETF tritium storage containers, considered to be Safety Class. It remains to be seen whether overall thermal margin can be increased above that assumed in safety analyses by simply replacing the gaskets. The site rep believes lightning protection questions also need to be addressed to support new TSR implementation (site rep weeklies 6/6/03, 6/20/03).

WETF has been verifying and validating new surveillance procedures, required to implement the new TSRs approved in April 2002. Last month, WETF proposed TSR changes to address issues raised during the November 2002 LANL Operational Readiness Review (ORR) and in more recent LANL reviews. The changes were intended to address the potential for different interpretations. WETF proceeded at risk and incorporated these changes into surveillance procedures. Based on NNSA/LANL feedback, WETF resubmitted the TSR changes this week, focused just on TSR implementation, and is currently revising procedures again. The site rep believes that this appears to be a case where expectations between operations and safety basis management (both NNSA and LANL) have not been clearly set, agreed upon, and communicated. The net result is likely delay in full implementation of enhanced safety controls in the new TSRs – effectively delaying nuclear safety improvements.

Chemistry and Metallurgical Research Building (CMR): CMR reported this week a Technical Safety Requirement (TSR) violation from personnel not tracking all special nuclear material items within the material-at-risk (MAR) inventory system, a safety basis control. Personnel recognized an accumulation of small items that were each sub-accountable under the material control and accountability system, a safeguards control, and were not being tracked as MAR. CMR is rectifying the situation, including inventorying sub-accountable items. MAR limits were not exceeded.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 25, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 25, 2003

Integrated Safety Management (ISM): The site rep has observed increased management attention, leading to improvements in the investigation, trending, and reporting of safety issues by LANL, including nuclear safety issues. Examples include increased use of causal analysis; increased reporting of events in nuclear facilities under Price Anderson; and thorough investigations into two accidents that occurred in April in non-nuclear facilities (i.e., chemical flash-burn to a researcher, multiple compound fracture to a D&D subcontractor). The lessons learned identified by LANL, even those originating in non-nuclear facilities, are significant and have implications to nuclear operations.

To elaborate on one example, the LANL audits and assessments office recently reviewed conduct of operations in 7 LANL divisions. The team focused on procedures for higher risk work; interviewed management and workers; reviewed records, procedures, hazard control plans; and observed work being performed. The team reported that expectations for procedure development and use had not been clearly established; step-by-step procedures were not always followed; some procedural work was not being done with proper tools and/or personnel protective equipment; procedures were not always accurate, complete, current, and user-friendly; and equipment was not always properly maintained.

This was a solid review. LANL intends to address these findings as part of implementation of the DOE conduct of operations order, added to the contract in 2001. LANL is currently revising its conduct of operations implementation plan to take advantage of operations advisors recently assigned to key LANL managers. The Advisor Program was a commitment by the LANL Director during a Price Anderson enforcement conference (site rep weekly 4/18/03). This LANL initiative recognizes the need here to improve ISM processes in a manner that changes the culture and that will endure. This effort has the potential to increase emphasis on personnel following safety requirements, on adequate work planning to meet requirements, and on improving supervision with emphasis on safety requirements when appropriate – all areas warranting attention (site rep weekly 3/21/03).

Plutonium Facility (TA-55): LANL has proposed to slip the NNSA readiness assessment (RA) for the new Pu-238 scrap recovery line two weeks (i.e., to 8/18) to provide margin in addressing the LANL RA team's pre-start findings. The NNSA RA team will be here next Tuesday, tour the line, and attend the LANL RA team briefing to management. The LANL RA report should be ready then.

Weapons Engineering Tritium Facility (WETF): WETF will miss a July 25th milestone for Technical Safety Requirement (TSR) implementation. The site rep understands that WETF is curtailing programmatic work in order to focus on TSR implementation.

Authorization Basis (AB): NNSA has several proposed AB upgrades in for action including for the Plutonium Facility (TA-55, since April 2002), liquid & solid waste operations (TA-50, TA-54), TRU waste shipping container packaging (TA-54 RANT facility), and nuclear radiography (TA-8-23). Implementation of several approved ABs is also not going smoothly, particularly WETF and on-site transportation. LANL recently issued an institutional procedure for annual updates to ABs, but the schedules are undefined. A resource-loaded and effective annual update process could help minimize AB violations, AB near-misses, and AB-operations interface issues seen in the past.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 1, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 1, 2003

Radiochemistry Laboratory (TA-48): TA-48 is a radiological facility, recently downgraded from Hazard Category 3. On Wednesday, a researcher had a small amount of acid solution jet onto his face and drip into his eyes (amount released estimated to be on the order of a milliliter). He was wearing prescription safety glasses at the time. The researcher had just pressured a small ion exchange column by using a syringe attached to a rubber stopper at the top of the column. Apparently, the rubber stopper was not fully seated, allowing the solution to spray. Facility management considers the work being performed to be routine and the equipment used to be fairly standard for a radiochemistry lab.

Immediate and supplemental actions were prompt and appropriate, and included extensive eye flushing and medical attention. No permanent eye damage is expected. The responsible LANL division has committed to a review of the event for lessons learned, as well as a review of their work activities and whether appropriate eye protection is specified. LANL senior management also intends to conduct an investigation. The NNSA Site Office has observed that this event has similarities to some other recent events (e.g., site rep weekly 4/11/03). This work was planned, controlled, and authorized under the LANL safe work practices, which is the LANL mechanism for implementing integrated safety management (ISM) into programmatic work for both nuclear and non-nuclear facilities.

Plutonium Facility (TA-55): NNSA is evaluating the impact of the Board's letter of today on the Pu-238 scrap recovery line and on the upcoming NNSA readiness assessment (RA). The site rep understands that NNSA is now planning on starting the RA after briefing the Board on August 21st. LANL has not yet declared readiness, although was planning on the NNSA RA starting that week.

The LANL RA report is nearly complete. It is based on team observations made last month and a year ago (7/02). It remains to be seen that the cumulative scope of the LANL RA completely covered the new authorization basis approved in May 2003. Preliminarily, the LANL review has about 30 pre-start and 20 post-start findings, of which about half were reported as complete on Tuesday. LANL recognizes that there are lessons learned from this RA that can improve the LANL RA process.

Weapons Engineering Tritium Facility (WETF): WETF has proactively ceased programmatic work and placed the facility in warm standby so that personnel can focus on implementing the technical safety requirements (TSRs) initially approved in April 2002. NNSA modified the TSRs on July 17th. The objectives now are, by November 2003, achieve TSR implementation and be ready for an NNSA operational readiness review (ORR) for Building 450 startup.

Recommendations 94-1/00-1: On Tuesday, the NNSA Site Office Manager concurred in a LANL project execution plan that describes the scope, cost, and schedule for substantially completing 94-1 nuclear material stabilization activities at LANL by end of CY 2010 (site rep weekly 3/21/03). The plan now goes to NNSA headquarters for final review and approval. It is a living document and includes provisions for periodic progress reporting and for formal change control. It is the culmination of two years of work and is an improvement in resource-loaded planning here necessary to complete 94-1 nuclear material stabilization activities. It could be a roadmap to eventual success if it is approved and then consistently funded and managed and fully executed through the out-years.

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 8, 2003

Jordan, March, and Shields were on site this week to review LANL fire protection. Also, the site rep was at Pantex on Thursday to determine the status of laboratory support for Pantex operations.

Plutonium Facility (TA-55): On Tuesday, a continuous air monitor alarmed in a Pu-238 waste storage and management room while two workers were inventorying containers. The two workers evacuated and were found to have high facial, hair, and skin contamination and high nasal swipes (2,500 dpm max - nasal swipes). They were decontaminated, taken to LANL medical, and released. Initial dose assessments are expected in 2 weeks.

The affected room is sealed. LANL has suspended Pu-238 operations and is working on a recovery plan. The NNSA Site Office has begun a Type B investigation. The team arrives next week. The DOE Order 225.1A *Accident Investigations* criteria for a Type B include a single personnel exposure resulting in total effective dose equivalent between 10 and 25 Rem. LANL is fully cooperating.

During the critique on Wednesday, LANL personnel indicated the following. The containers have Pu-238 residues and waste (e.g., cheesecloth) that are to undergo pyrolysis. These containers are a can-bag-can configuration. The cans are of the slip-lid type and taped. The inner can and the plastic bag have filtered vents. Some containers have been there for years. After a while, some containers exhibit degradation – rust. Efforts were made in December 2002 and in March 2003 to pull out visibly rusted containers. The containers handled on Tuesday had no unusual visible characteristics.

The site rep has the following observations. While the cause of this event is unknown, the containers are suspect. LANL has made slow progress on Recommendation 94-1 nuclear material stabilization for several years. Progress improved in 2003. The 94-1 activities are intended to improve safe storage and expedite residue disposition. One key improvement TA-55 has made is development and widespread use of the TA-55 standard can design, basically screw-top cans with lid filters. The TA-55 standard cans have been available since about 1998 and provide a more robust packaging system than that described above. It is unclear why Pu-238 operations would continue to store their residues and wastes for years in a storage system that visibly degrades and is not the most robust system available – particularly since these materials are possibly the most hazardous radioactive materials in TA-55, at least by isotopics. After room stabilization, investigation, and recovery, expedited safe disposition of these materials may warrant high priority, regardless of whether they are the direct cause of this event.

Weapons Engineering Tritium Facility (WETF): On Thursday, WETF declared a positive unreviewed safety question determination on the temperature rating for standard tritium secondary storage containers, designated Safety Class. The safety basis assumes the containers are capable of withstanding 120 C. NNSA has directed LANL to pursue higher temperature container seals (i.e., 250 C) to increase thermal margin; however, questions have persisted for months on performance above 120 C (e.g., site rep weeklies 5/2/03, 6/20/03). LANL now believes the container aluminum body would fail at 165 C. The site rep observes that similar longstanding questions exist on function of the WETF lightning protection system, designated Safety Class (site rep weekly 6/6/03). Resolution of the container and lightning protection questions may affect previous conclusions on safety basis engineered controls, as well as what constitutes appropriate technical safety requirements (TSRs).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 15, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 15, 2003

On Thursday, the staff held a video-teleconference with LANL, the NNSA Site Office, and DOE headquarters on the Board's issues with the Pu-238 scrap recovery line hazard analysis and controls.

Integrated Safety Management: More attention is needed on workers following safety requirements (i.e., formality of operations), on adequate work planning to meet requirements, and on improving on-floor supervision with emphasis on safety requirements when appropriate, as further illustrated by this week's events. In the Plutonium Facility (TA-55), 3 workers were exposed to a mist that caused a slight burning sensation and difficult breathing. They were attempting to clear an obstruction in a non-radioactive line by using compressed air. Upon investigation, TA-55 management identified issues in defining work, identifying hazards, mitigating hazards, and following the work package as written. They are following up. In the Radiochemistry Lab (TA-48), the evolution that resulted in the "acid-to-the-eyes" event 2 weeks ago was restarted this week then suspended when a worker received a skin contamination. TA-48 management has suspended work done under the affected hazard control plan. Besides work control, this event raises questions on formal restart of a suspended activity and compensatory measures applied until a formal investigation of the previous event is complete. The site rep understands that this week's event will be incorporated into the LANL investigation underway.

Plutonium Facility (TA-55): On Wednesday, the NNSA Type B investigation began on last week's Pu-238 contamination event. The team appears well-qualified and is from multiple DOE sites, including the Savannah River Site (non-NNSA). The team leader anticipates completing the investigation on or around October 3rd. A new question that emerged this week is why the continuous air monitor alarmed in an adjacent room that doesn't appear to be directly connected to the affected room. Last week, this alarm was attributed to radon. The affected room is also adjacent to another room that contains the new Pu-238 scrap recovery line. NNSA intends to wait until after the in-facility investigation work is completed and analyzed before authorizing the start of the NNSA readiness assessment (RA) for the new line. As of Wednesday, the LANL RA report had not yet been finalized.

Authorization Basis (AB): Better institutional criteria are needed here and need to be consistently applied for functional classification, evaluating worker hazards, and designating AB controls. Engineered features are designated as "safety significant" (SS) when a hazard analysis determines they are of particular importance to defense in depth or worker safety. An administrative control may warrant SS designation if an engineered control is impractical. This designation of controls is part of the functional classification process described in DOE-STD-3009. In April 2002, DOE revised this standard so that functional classification as SS would be considered not only for prompt worker fatality and serious injury but also significant worker radiological or chemical exposure.

This week, when discussing a significant worker hazard scenario, LANL indicated that the criteria for SS used in one major facility is a calculated accident dose of 5 Rem to the maximal exposed off-site individual and thereby concluded an SS-level control to protect workers was unwarranted. While this covers the defense in depth aspect, the worker safety aspect specified in the DOE standard was apparently missing, particularly for significant radiological or chemical exposure to workers. This and previous observations raise questions of whether LANL has adequate criteria that are being consistently applied (e.g., site rep weekly 7/3/03). This has implications on recent evaluations, such as the Pu-238 scrap recovery line analysis and the new ABs prepared as 10 CFR 830 updates.

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 22, 2003

The site rep was in Albuquerque NM and in Washington D.C. this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 29, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 29, 2003

Plutonium Facility (TA-55): The NNSA Type B investigation on the 8/5/03 Pu-238 contamination event continues. The suspect containers have been relocated to a glovebox line and planning for non-destructive examination is underway. The moveable cage holding the containers in the affected room has been restored to comply with authorization basis seismic requirements (i.e., cage is closed and chained to the wall). The cause of this event and the initial dose estimates for the workers are still to be determined. The containers remain the primary suspects.

Last Monday (8/18/03), one crafts worker had positive nasal smears after contamination was found in the torso area of his anti-Cs, and the worker has been put on prompt bioassay. The worker had been engaged in dismantling equipment in a Pu-239 glovebox and was using leather gloves over the glovebox gloves while cutting, a best practice. Upon investigation, contamination (400k dpm alpha, 1k - 4k dpm removable) was found on the small window between the gloves. The glovebox gloves are intact. Air monitor indications were elevated but not to a level that would set off an alarm. The site rep understands that the pathway for the release from the glovebox remains undetermined. Speculation centers on the window gasket, which has been taped over with metal tape.

On Wednesday, the NNSA Site Office issued a clarification and amendment to the Pu-238 scrap recovery line technical safety requirements (TSRs). Some key aspects are:

- NNSA named the dissolver argon flush system, the dissolution vessel vent interlock, and the oxalate filtrate storage vessels as safety-significant. NNSA believes that both the dissolution vessel and these storage vessels would be capable of withstanding a hydrogen deflagration. Fill-vent line valves for these storage vessels have also been removed for defense-in-depth.

The site rep observes that, per the LANL PrHA, the oxalate filtrate storage vessels are larger, made of different material, and in a different glovebox than the dissolution filtrate storage vessels. The NNSA letter includes a LANL structural analysis of the latter as an attachment.

- NNSA imposed specific ion exchange resin replacement requirements, including a lower dose limit (now 500 Mrads) to be based on total Pu residence time calculated before and after each run. The dose limit may be reevaluated later as process operational experience matures. NNSA considers these to be do-not-exceed TSR limits.
- NNSA stated that there shall be a proceduralized surveillance on ion exchange column liquid level, including a daily check to detect leakage before initiating glovebox operations.
- NNSA required LANL to define hazard scenarios and critical process steps that require 2-person verification, such as those required to prevent a nitric acid - HAN reaction. When submitted and if acceptable, NNSA intends to approve this list as part of the safety basis.

NNSA also asked LANL to complete an unreviewed safety question determination on thermal vs material-at-risk limits for this operation and to provide an analysis of the safety impacts of alternatives (e.g., 2-shift operation) and a comparison of the relative merits of the scrap recovery line vice more production emphasis on the bench scale process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 5, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 5, 2003

On Thursday, the staff held a video-teleconference with LANL and NNSA on LANL fire protection.

Integrated Safety Management (ISM): Work control is a significant issue at LANL for both facility and programmatic work. On Tuesday, as part of a non-nuclear decommissioning, subcontractor personnel not in appropriate protective equipment cut two locks and accessed an energized 13.2 kV electrical cabinet that they had been incorrectly told was deenergized. While there were no injuries, the potential for arcing and severe injury existed. The site rep also understands that the LANL Electrical Safety Committee has raised concerns with other recent electrical safety near-misses.

Recent LANL investigations indicate that the work control issues are not just limited to facility work, as described above. The needs to complete previously identified corrective actions and, in the short-term, focus on implementation of current safety requirements are clear – i.e., workers understanding and following safety requirements (i.e., formality of operations), adequate work planning to meet requirements, and improving supervision with emphasis on safety requirements. LANL is working on short-term improvements to current requirements, hazard analysis tools, and work control processes.

Longer term, LANL has begun an initiative to integrate work management practices for both facility and programmatic maintenance. The objective is one process for work control, including analyzing hazards and planning and doing work safely and securely. Several internal and external studies during the last 2 years, including LANL accident investigation reports, have identified the need for such integration, and not just for maintenance. Even so, this could be a big step forward when implemented.

Weapons Engineering Tritium Facility (WETF): Last month, WETF curtailed programmatic work to focus on technical safety requirement (TSR) implementation, to be verified by a LANL readiness assessment (RA) at the end of September. NNSA is closely monitoring progress. On Thursday, NNSA approved a reduced inventory limit and a schedule for shifting about 25 % and 50 % of the inventory to more robust containers (at least 165 C fire rated) during the next 4 months and next year, respectively.

On the safety class lightning protection system questions, LANL committed in early 2002 to perform an engineering study on the potential effects of lightning on WETF. In March 2003, a lightning protection expert hired by LANL reported that the WETF system cannot be expected to prevent arcing in tritium storage and handling areas – in other words, it would not fulfill the safety class function. On August 19th, the Board sent NNSA a letter on this. The site rep understands that NNSA and LANL now plan to bring in a different lightning protection expert and have him assess the system. While providing different and beneficial perspective, this appears unlikely to resolve the issues.

Plutonium Facility (TA-55): The NNSA Type B investigation on the 8/5/03 event systematically continues. Initial dose assessments span a wide range but are consistent with those warranting a Type B investigation. Radiography of one suspect container indicates material is outside the inner can.

Decommissioning Activities: The Omega West Reactor site now resembles a dirt parking lot. Only some confirmatory surveys and site restoration (e.g., storm water drainage) remained, as of early August. LANL has reported that the 2-year decommissioning project is 2 ½ months ahead of schedule and under budget. This was a radiologically complex project that was well executed (site rep weeklies 2/7/03, 3/28/03). Omega West Reactor was used for nuclear research between 1956 and 1992.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 12, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 12, 2003

Integrated Safety Management (ISM): As a result of recent events, the LANL Director on Tuesday bluntly explained to LANL personnel and contractors his expectations and standards on safety, security, and compliance. These include continuously improving safety, demonstrated senior management involvement in all aspects of safety, a culture that does not accept poor safety practices, and workers that will not gloss over safety problems. He listed common causes of recent accidents - poor hazard identification; lack of focus on procedures; failure to manage work changes; failure to stop work when necessary; overall lack of accountability; failure to extrapolate lessons learned across all LANL organizations; poor management of subcontractor work; lack of formality "when it counts"; and not looking after one another's safety.

LANL is planning training and a series of mentored management walk-arounds during the next 3 months to pursue this initiative. LANL is also initiating Division-level self-assessments to determine whether hazard control plans are current and approved and required training has been completed. The site rep views these as a positive start and responsive to events such as those reported last week.

Plutonium Facility (TA-55): The NNSA Type B investigation continues. LANL resumed Pu-238 operations on or around August 13th but, on Thursday, curtailed Pu-238 operations that generate residues and waste. LANL took this action based on issues that the NNSA accident investigation (AI) team identified that day with the residue/waste storage containers being used (i.e., the slip-lid cans).

On Monday, AI team and LANL personnel entered the affected room. The AI team noted that 2 of the 4 movable cages are not restrained in a manner that would meet Authorization Basis (AB) seismic requirements. One had a single restraint. The other was unrestrained. LANL restrained the cages, but questions remain on whether the restraints would withstand the evaluation basis earthquake. The Technical Safety Requirements (TSRs) list the cages as a design feature but are silent on the seismic requirement and do not require inspections. The Dec 1996 NNSA AB approval letter imposes the seismic requirement. Furthermore, it states that, until the cages are upgraded, LANL is required to put degraded containers in racks that are seismically qualified. The reference to degradation is puzzling.

Based on this, the NNSA facility reps and TA-55 management have identified that several design features in the current AB (1996) and subsequent NNSA approval letters do not have adequate flowdown into the TSRs. TA-55 is pursuing this issue. NNSA approved the AB in 1996, approved TSR rev 1 in 1999, and has modified the AB in various approval letters. LANL submitted an AB revision in Apr 2002 and several months later resubmitted the TSRs. The needs are clear and longstanding for a TSR revision that is complete, effective, and user-friendly and for a complete and verified implementation (e.g., site rep weekly 8/23/02, 10/25/02, 1/3/03). Several other Board questions (e.g., passive ventilation) also are suppose to be addressed by this next TA-55 AB revision.

Weapons Engineering Tritium Facility (WETF): The site rep understands that personnel recently observed lightning above WETF and, near simultaneously, a blue glow or flash in a WETF processing room. No injuries or damage occurred. Roof air terminals, part of the NFPA 780 lightning protection system, were also not damaged. This may indicate that, if there was a strike, it bypassed the Safety Class lightning protection system and found entry into the building. This alternate path to ground would be consistent with that described by a lightning protection expert in Apr 2003. NNSA owes the Board a response to its questions on the effectiveness of this system as a Safety Class control.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 19, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 19, 2003

Weapons Engineering Tritium Facility (WETF): WETF is proceeding systematically and appears to be on track for full Technical Safety Requirement (TSR) implementation in November.

Radioactive Liquid Waste Operations: On Wednesday, the TA-50 Radioactive Liquid Waste Treatment Facility (RLWTF) discovered a leak at a weld in the receipt and storage tank for TA-55 transuranic (TRU) caustic waste – the highest activity waste stream entering this facility. About 300 gal of waste leaked into secondary confinement, which is equipped with an automatic sump pump. There was no environmental release. Tank level appears to coincide with the leak site and is at about two-thirds tank capacity (2500 gal). TA-55 has secured discharges going to this tank.

The site rep understands that waste neutralization, transfer, and receipt procedures are under review. The tank is about two decades old. A thorough tank integrity inspection and an operations and maintenance review appear to be warranted. An extended period without caustic waste receipt capacity could lead to a liquid waste backlog in TA-55 and mission impacts. The RLWTF is an aging facility being considered for replacement (site rep weekly 10/11/02).

Radioactive Solid Waste Operations: DOE and LANL have committed to shipping about 2,000 drums of higher-wattage TRU waste from TA-54 to WIPP by the end of FY04. This effort – referred to as the "Quick-to-WIPP" initiative – will result in a significant risk reduction for TA-54 once it is completed (site rep weeklies 11/1/02, 7/18/02). Progress was slow early this year but is improving. As of Thursday, LANL had shipped 1312 drums to WIPP this fiscal year, including 140 of the higher wattage drums. LANL is currently making about 3 WIPP shipments per week and expects to be making 4 per week by January. Cost per drum has dropped about 4-fold due to efficiency improvements. About 300 of the higher-wattage drums are problematic because they need to be repackaged, requiring close coordination on authorization basis, work planning, and operations. Overall, this risk reduction effort appears poised for success if fully-resourced.

LANL has about 2,400 m³ of TRU waste that is oversized (e.g., gloveboxes) and has been stored in about 300 fiberglass-reinforced wooden crates for years. While the total source-term is lower than the drums discussed above, issues with the integrity of these boxes (one collapsed a few months ago) and with combustible loading make these a concern. Last summer (2002), LANL started up the Decontamination and Volume Reduction System (DVRS) as a radiological facility to begin processing the crates and putting the waste into a form suitable for WIPP. The site rep understands that DVRS operations have been curtailed and that DVRS is unfunded for FY-04. This is unfortunate for two reasons. First, DVRS provides a pathway for addressing the crate integrity and combustible material concerns. Second, DVRS requires manually intensive operations that would benefit from allowing an appropriate learning curve for the workforce – a benefit that could be lost from curtailing operations.

Critical Experiments Facility (TA-18): TA-18 has nearly completed installing the safety class temperature scram systems in SHEBA and Planet and is about to begin testing. In a July 9th letter, the Board raised questions about the ability of these systems to perform their intended function, how their designs are reviewed, and how they will be verified when installed. Per the Board's letter before removing interim controls, NNSA needs to provide a report to the Board that demonstrate that the temperature scram systems will operate reliably and effectively to prevent overheating assemblies. A well-conceived testing program could assist in addressing these issues.

The site representative was at DNFSB-Headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 3, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 3, 2003

Andrews, Bamdad, Deplitch, Fortenberry, and Jordan were on site this week reviewing integrated hazard analyses. Nichols and Von Holle were on site attending the energetic materials conference.

Integrated Safety Management (ISM): On Saturday (9/27), five TA-55 workers reported to the Los Alamos Medical Center after being exposed to vapors while soldering a piping joint for a rerouted coolant line. The coolant (originally freon, later a freon-like substitute) was used for a glovebox machining operation curtailed about a year ago. The workers had just cut the line in two places with a pipe cutter, had observed liquid spraying from the line, and had bagged one end. It appears that the line had not been properly drained and vented prior to the work, that the workers were not informed of the line's status, that the workers were not formally trained on freon, and that the workers did not recognize the liquid as an abnormal condition. Soldering supplied heat that likely caused the coolant to chemically breakdown, producing irritating vapors and an acrid smell. While the workers were adequately protected from radiological hazards (including use of HEPA-filtered respirators), questions exist on whether this chemical hazard was identified, analyzed, and controlled. As a result, all TA-55 facility work was curtailed. Each work package is undergoing review by LANL and KSL prior to re-releasing the work. LANL is initiating an investigation.

Readiness Assessments (RAs): The site rep believes that the LANL RA process needs improvement. The site rep recently received the Management Self Assessment (MSA) report and the LANL RA report for starting up the new TA-55 Pu-238 scrap recovery line, dated 7/6/03 and 7/29/03 respectively (site rep weeklies 7/11/03, 8/1/03). The MSA should have been the most rigorous review in the startup process. The MSA report consists of a checklist, 3 documented management walk-arounds during simulated operations, and no apparent findings. The LANL RA report had 88 findings – 31 require pre-start correction, 20 are post-starts, and 37 are observations. Twelve pre-starts remained open at the time of the RA report. The type and number of RA findings indicate that the MSA was not sufficiently rigorous and that the RA was more a management-assist than appropriate. The LANL RA itself was a continuation of activities of a year ago and was conducted before NNSA approved the startup notification report (9/9/03). While the recent RA activities apparently reviewed all procedures, they did not include demonstration of some operations that had significant changes in safety basis requirements. The site rep believes these types of RA issues are not unique to TA-55. LANL has acknowledged that there are lessons that need to be learned from this to improve the RA process.

WIPP Shipments: LANL has suspended shipments of transuranic (TRU) waste to WIPP as a result of a finding during last week's Carlsbad Field Office annual audit. Specifically, it appears that LANL may have shipped several drums to WIPP without certifiably demonstrating they were greater than 100 nCi/g TRU. While LANL performs non-destructive analysis on the drums, the analysis has not always adequately confirmed that drums were above WIPP's disposal threshold. This suspension delays shipment of higher wattage drums under the Quick-to-WIPP initiative.

Weapons Engineering Tritium Facility (WETF): NNSA has verified that WETF has properly prepared, trained, and demonstrated 4 of 8 new surveillance procedures required to implement the new technical safety requirements (TSRs). WETF is planning a contractor RA in mid-November on the full implementation and on closure of open items for Building 450 startup (site rep weekly 8/1/03). The NNSA Operational Readiness Review for Building 450 startup is scheduled for January 2004.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 24, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending October 24, 2003

Blackman and Stevenson were on site this week participating in a dynamic experiments design review.

Authorization Basis: The TA-55 safety basis needs updating. Safety basis updates are expected to be proposed and approved once per year, but this has not occurred for LANL nuclear facilities. The current TA-55 safety analysis report and technical safety requirements (TSRs) were approved in 1996 and 1999, respectively. NNSA has yet to act on an update proposed by LANL in April 2002. NNSA has made resolution of several issues raised by the Board and its staff over several years contingent on this update (e.g., continued acceptability of the passive ventilation mode, adequacy of fire suppression in hydraulically remote locations). Recently, NNSA informed the staff that action would be taken before year's end. However, the update proposed in April 2002 itself now likely needs updating.

This delay may impact safety. Example - the controls proposed in the April 2002 update may not reflect the latest DOE requirements on worker safety (DOE STD-3009, CN 2, also dated April 2002). Example - the current TSRs do not specify periodic in-service inspection of design features to ensure they perform their safety function (site rep weekly 9/12/03). Example - a set of experiments to characterize long term performance of 3013 containers in support of Board Recommendation 94-1 has been waiting safety basis approval for about 10 months. Example - a 3 year delay has occurred in resuming robotic calorimetry after upgrades (1998-2000). The delay appears due in part to lack of closure on safety basis issues. TA-55 has a large inventory that needs to be periodically assayed via calorimetry to meet safeguard requirements. During this hiatus, these assays have been performed manually, increasing worker dose and ergonomic and handling risks. Last Friday, NNSA approved page changes to the 1999 TSRs that (a) reflect the as-built robotic calorimetry room fire rating is not as high as previously approved (1 vs 2 hr) and (b) compensate by reducing the transient combustible load limit, an administrative control. While an engineered control is preferred, this is a positive step. There are likely other examples. Overall, expedited reevaluation of the TA-55 safety basis is warranted.

Solid Waste Operations: On October 2nd, NNSA disapproved the proposed safety basis update for the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRRF) because of comments on natural phenomena hazards (seismic, wind), natural gas hazard, fire protection, ventilation, and TSR operability. NNSA requested that LANL submit a corrective action plan within 30 days that addresses the issues. WCRRF is primarily used for visual examination and repackaging activities to support transuranic shipments to WIPP, a high priority for TA-54 risk reduction. LANL has stated that WCRRF has limited remaining service life (i.e., 5 years). It may be worthwhile to promptly consider interim controls that ensure safe operation while the benefits of upgrades are studied. Long-term site-wide risk reduction may warrant accepting a short-term increased risk from WCRRF operation with well-justified interim controls. Expediting alternatives to WCRRF (i.e., modular units) may also be worthwhile.

Liquid Waste Operations: LANL has proposed and NNSA appears poised to approve a path forward on the leaking caustic waste receipt tank in the TA-50 Radioactive Liquid Waste Treatment Facility (site rep weekly 9/19/03). The leak site is at the 42 % level. The short-term plan is to resume operations by transferring receipts from TA-55 through the TA-50 leaking receipt tank directly to the processing system (i.e., the neutralization tank). Transfers are expected to occur weekly and have a maximum volume of about 76 gal, including flush water (equivalent to about 7 % of tank volume if it were held up in the tank). The tank is within a concrete vault that would contain any release. LANL plans to replace the tank and associated piping during the next 6 to 12 months.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 31, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 31, 2003

Hadjian, B. Jones, Jordan, and Rizzo (OE) were on site reviewing bases for seismic and flood hazard analyses and their application to the CMR replacement facility and TA-18 flood retention structure.

Integrated Safety Management (ISM): Next Monday (11/3), LANL begins implementing a single work management approach that addresses common safety issues identified in recent assessments and accident investigations (site rep weekly 10/17/03). This is an interim action until longer-term improvements can be implemented, expected next May. LANL provided a detailed orientation on the approach to about 1,000 people this week. The need for interim action was driven by a recognition that work at LANL is generally performed safely and consistent with industry standards, but a significant injury or near-miss has occurred on average every 6 weeks during the last 6 to 8 months (e.g., site rep weeklies 10/18/02, 4/11/03, 8/15/03, 9/5/03, 10/3/03). Thorough LANL investigations of these events identified common safety issues. NNSA oversight and involvement was pivotal in the scope and timing of the action. While success is not assured, the site rep believes that these are the most positive actions that have taken place here to improve worker safety during the last two years.

Weapons Engineering Tritium Facility (WETF): This week, WETF completed ahead of schedule the implementation of 8 new technical safety requirement (TSR) surveillance procedures, required by the safety basis approved in April 2002. To support implementation, NNSA this week approved TSR page changes to clarify the control room halon fire suppression requirements. LANL curtailed WETF programmatic activities on July 25th so that the facility could focus on TSR implementation. WETF plans to resume programmatic activities in a phased manner under a senior supervisory watch. Overall, implementation has been long in coming. Facility management and personnel, assigned operational advisors, and the NNSA facility rep all played key roles in this accomplishment.

WETF also reported this week that the lightning protection system has undergone repairs to fix all deficiencies and been inspected by LANL for compliance with NFPA-780. An independent inspection is scheduled next week. A Sandia lightning protection expert is also conducting a review of the system for possible improvements. LANL will provide conclusions to NNSA by November 14th.

Chemistry and Metallurgical Research Building (CMR): The CMR TSRs includes a program intended to ensure that material not in active use is placed inside robust safes to protect it during catastrophic events, such as a major fire or earthquake. On October 17th, CMR reported a TSR violation, based on a determination that this program was not properly implemented. Specifically, items within safes were found to not be packaged consistent with that used for surrogate items during qualification tests of the safes in 2000. This issue may not have been recognized for an extended period because (a) the tested package configurations are not clearly documented in the TSRs, CMR procedures, or the qualification report, and (b) there appears to be no standard packaging procedure that is used by the different programmatic groups working in CMR. Since October 17th, CMR has clarified the procedure for using the safes, and inspected and repackaged items as deemed necessary. It appears worthwhile for LANL to consider standardizing packaging as part of both the planned CMR safety basis upgrade (expected in January) and the planned LANL review of confinement pedigree for all TA-55 and CMR plutonium items outside a glovebox environment (site rep weekly 10/17/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 7, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 7, 2003

The staff held two tele-conferences with NNSA and LANL this week on the Board's August 19th letter on WETF lightning protection and CMR electrical systems (e.g., power to ventilation).

Lightning Protection: NNSA and LANL are increasingly relying on NFPA 780 lightning protection systems as safety-related engineered controls for nuclear facilities (site rep weekly 6/6/03). The NNSA Site Office asserted this week that the NFPA-780 lightning protection system for the Weapons Engineering Tritium Facility (WETF) needs to be Safety Class and needs improvements to reduce risk. LANL expects an outside expert to report on possible improvements next week. Besides WETF, the Critical Experiments Facility (TA-18) also has an NFPA-780 lightning protection system designated as Safety Class. Per LANL, CASA 1 and 3 NFPA-780 deficiencies have been corrected, and are undergoing inspection. CASA 2 deficiencies require a system overhaul that has been designed. LANL has also proposed designating NFPA-780 systems as Safety Significant in several other nuclear facilities. NNSA and LANL may need to better define institutionally the criteria for operability, maintenance, and configuration management for these systems, based on explicit rationale traceable to the accident analyses, and then demonstrate these systems will fulfill their assigned safety function. This has not yet happened for lightning protection systems.

Chemistry and Metallurgical Research Building (CMR): The CMR replacement facility (CMRR) is in conceptual design. Several key decisions, such as the extent of CMR upgrades and the appropriateness of the current CMR safety basis (a BIO and interim TSRs), have hinged on CMRR being ready in the 2010 time-frame. The site rep understands that CMRR is now not expected to be ready until sometime well after 2010. It may be worthwhile for NNSA and LANL to periodically review previous assumptions and conclusions (e.g., from cost-benefit analyses) in light of CMRR progress and assess the merit of potential improvements versus the continued risk of operating without them. This week, LANL informed the staff it is initiating such a review for the safety basis.

Transportation: This week, LANL suspended on-site shipments of fissile material until emergent questions are resolved on procurement testing of shipping containers. Specifically, the containers (DOT 7A) are required to be capable of withstanding several tests, including a pre-conditioning series of 1-foot drops on each quarter followed by a 1 to 4 foot free drop in a configuration causing the maximum damage (required drop height set by mass). It appears that one source for these containers may not have been conducting the pre-conditioning drops and that, when conducted, tested containers were failing at a lower mass than expected. LANL plans to invoke weight restrictions based on full testing of these containers and then resume on-site fissile shipments in a deliberate manner.

Plutonium Facility (TA-55): One of several questions remaining before startup of the new Pu-238 scrap recovery line is the manner and pedigree of verification of acid concentration during the precipitation process in order to avoid an energetic acid-HAN reaction. LANL asserts that this would be a non-energetic "effervescent" reaction that would not challenge the safety-significant glovebox. LANL bases this conclusion on an experiment (7M acid and 2M HAN) documented in a viewgraph presentation. This appears to the site rep as substandard justification upon which to justify control selection. While NNSA has accepted this, NNSA has also requested and LANL will propose a TSR administrative control – most likely as part of a two-person verification program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 14, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 14, 2003

On Friday, the site rep attended a meeting in Albuquerque on lab support for Pantex operations.

Integrated Safety Management (ISM): LANL is assigning high priority to implementing an interim work control process intended to improve worker safety (site rep weekly 10/31/03). This is part of a longer term effort to systematically improve and integrate the current programmatic, facility, and sub-contractor work management systems into one system. By Friday, LANL senior management is expected to have identified Responsible Division Leaders for all facilities, assigned delegations, and developed a risk-based schedule for implementing the interim process during the next few months.

Plutonium Facility (TA-55): LANL has prepared and NNSA has agreed to a plan for assessing and recovering the Pu-238 contaminated room that is the subject of the recent NNSA Type B investigation (site rep weekly 8/8/03). The plan has 4 phases: (1) assess radiological conditions and residue inventory; (2) reconfigure residue items and interim storage; (3) decontaminate the room; (4) repack and store residue items until disposition.

The assessment phase (phase 1) is expected to begin next week and involves contamination and radiation surveys, work area decontamination, and assessment of the room's inventory and packaging. Information from this phase will be used in planning and establishing safety controls for the later phases. Room entries are to be made using full-face respirators with appropriate continuous air monitor alarm set-points. During the reconfiguration phase (phase 2), items will be over-packed in plastic filtered bags and placed in either TA-55 standard cans or 55-gal WIPP type filtered drums (min: 6 packages per drum). During the final repackaging (phase 4), most of the inventory will go through pyrolysis to ash and be packaged in a "stainless steel can - plastic bag - TA-55 standard outer can" configuration. LANL is pursuing whether these materials can ultimately be disposed of at WIPP.

Critical Experiments Facility (TA-18): TA-18 has nearly completed installing the Safety Class temperature scram systems in SHEBA and Planet. In a July 9th letter, the Board raised questions about the ability of these systems to perform their intended function, how their designs were reviewed, and how they will be verified when installed. NNSA owes the Board a response prior to LANL removing interim safety controls. NNSA is planning to conduct an independent design review of these systems, patterned after a similar NNSA review done in 2002 on a Sandia reactor control system upgrade. This effort could help resolve some issues and focus those remaining.

Weapons Engineering Tritium Facility (WETF): NNSA owes the Board a rapid response on the functionality of the WETF NFPA 780 lightning protection system, which NNSA has designated Safety Class. This designation resulted from a postulated accident scenario involving lightning-induced failure of multiple tritium storage containers with a fire. This week, the second lightning protection expert issued his report (site rep weekly 9/5/03). While some conclusions differ (e.g., higher flash probability), both experts have concluded that (a) lightning-induced rupture of multiple containers is incredible and (b) the much lower consequence scenario involving burn-through of thin-wall system tubing is the dominant lightning-related risk. For perspective, the system inventory limit is the same as that in a single container, and systems are only loaded to this level about 10 % of the time or less. This scenario's consequences would not normally merit Safety Class controls. NNSA addresses the fire risk via other controls, such as fire suppression, robust containers, and combustible limits. The second expert's report included 11 options to consider if further lightning risk reduction is desired.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 21, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 21, 2003

Integrated Safety Management: LANL continues to make progress on implementing interim work control improvements, to be completed by January 1st. This is a difficult, large-scale task that has required many activities to stop work until their work definition, hazard analyses, controls, and authorizations have been updated. To facilitate this effort, the NNSA Site Office and LANL have jointly established six “technical assist” teams that will engage during the next few weeks at the facility or construction project level with four objectives: (1) identify course corrections now; (2) ensure consistent implementation across LANL; (3) provide assistance in the field; and (4) provide feedback for the longer term improvements.

While the site rep agrees this warrants high priority, the site rep is concerned that NNSA has staffed these teams by pulling nearly two-thirds of the NNSA facility reps (FRs) out of their facilities (e.g., CMR, WETF, Waste Operations, DAHRT, Radiography Facility). This is clearly a relative-risk decision. The NNSA Site Office is not staffed for this function. While successfully implementing interim controls will reduce risk, the FRs play a key role in other risk reduction activities. In the past, the FR Program here has been one of the mostly timely and effective mechanisms in bringing safety issues to the attention of NNSA and LANL senior management.

Plutonium Facility (TA-55): This week, TA-55 completed the assessment phase (phase 1) for recovering the Pu-238 contaminated room. TA-55 plans to next begin room decontamination (phase 3) after necessary controls are in place, followed by interim repackaging and storage (phase 2).

Emergency Preparedness: On Wednesday, a local phone company equipment failure degraded off-site and some on-site communications for several hours, including off-site communications to the Emergency Operations Center (EOC). The site rep understands that local 911 service was available but also degraded. Some nuclear facilities rely on 911 service as a compensatory measure for weaknesses in the site-wide fire alarm system (site rep weekly 1/17/03). This week’s event appears worthy of exploring for lessons learned.

Feedback and Improvement: In the last year, LANL has significantly improved both self-reporting and verifiable closure of safety issues in nuclear facilities via the Price Anderson Program. The number of Price Anderson reviews is up for 2003 compared to previous years (14 % more than 2002, 56 % more than 2001). This appears due to better reporting and not to an increase in problems, based on a comparison to other measures (e.g., ORPS). The problems existed before. Now their visibility to NNSA and LANL management has increased. Similarly, the NNSA and LANL closure process for these issues is more rigorous than in the past and under better control by senior management.

Quality Assurance (QA): This week, an NNSA team assessed how well the NNSA Los Alamos Site Office (LASO) has established and implemented key QA program elements and conducts oversight on LANL QA. Based on their preliminary conclusions and on other observations, the site rep believes that LASO is making progress but still lacks a formal, well-defined QA Program. LASO has elements of a program. Areas for improvement might include documents and record management (e.g., both operations and authorization basis approval records); issues management; self-assessments; lessons-learned. LASO is increasing QA staffing and is committed to issuing shortly a quality assurance plan (now draft) and a Functions, Responsibilities, and Authority Manual.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 28, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 28, 2003

Waste Operations: LANL is moving forward on a plan to resume WIPP shipments, which LANL suspended in October (site rep weekly 10/3/03). Resuming safe, properly certified shipments is key to DOE and LANL meeting the commitment to ship about 2,000 drums of higher-wattage TRU waste from TA-54 to WIPP by the end of FY04 (currently: 7 % done). The plan involves compliance analyses, retraining, conduct of operations assessments, and management self-assessments for 30 activities – followed by readiness assessments (RAs) for 6 activities. The NNSA Site Office Manager is the startup authority for the final activity, expected to be completed in December.

On November 5th, LANL submitted a corrective action plan for the disapproved safety basis for the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRRF - site rep weekly 10/24/03). WCRRF is primarily used for visual examination and repackaging activities to support WIPP shipments. Key elements of the plan are a fire hazard analysis update, seismic upgrade feasibility study, criticality safety update, natural gas removal study, comment resolution meetings with NNSA – all leading up to a resubmitted safety basis in April 2004. In the meantime, LANL is complying with restrictive inventory limits in the current safety basis (i.e., HC-3 inside the building, HC-2 storage outside the building). Success requires close NNSA and LANL management attention.

Engineered Controls: The site rep continues to believe that uncertainty exists on whether some designated engineering controls in LANL nuclear facilities will perform their intended safety function (site rep weekly 7/3/03). There appears to be little site-wide guidance on how to evaluate newly designated safety systems, such as requirements to conduct independent design adequacy reviews, ensure appropriate standards are selected, perform gap analyses, follow up with cost-benefit analyses for upgrades, and define meaningful operational inspection criteria. LANL has a solid effort underway to develop institutional requirements and recently established the position of Facilities Chief Engineer. This person is expected to provide technical leadership and be the authority having jurisdiction on LANL engineering standards, except those assigned elsewhere (i.e., fire protection, electrical safety). These initiatives are still in early stages, will take time to implement, and are limited to facility work – even though LANL programmatic divisions have responsibilities for many safety systems.

Weapons Engineering Tritium Facility (WETF): WETF is undergoing a readiness assessment (RA) focused on preparation for Building 450 startup and verification of Technical Safety Requirement (TSR) implementation. This includes examining closure of 67 pre-start findings from the LANL Operational Readiness Review (ORR) from a year ago (site rep weeklies 11/22/02, 12/20/02). The RA should conclude in early December. The DOE ORR is tentatively scheduled for late January but may slip due to the site-wide priority on implementing the interim work control improvements.

This week, WETF declared a positive unreviewed safety question based on new information indicating a 10 % increase in the frequency of the bounding, lightning-initiated tritium release. The new information came from a custom site analysis during the 2nd expert's lightning protection review: particularly, predicted flash probability is 46 times higher than the previous. Among the 2nd expert's conclusions are (1) a scenario that results in breach of one or more tritium storage containers is incredible; (2) the facility and lightning protection system designs cannot prevent arcing, but either the system or facility will provide the lightning attachment point, reducing total current; and (3) the dominant lightning-related contributor to overall risk is breach of thin-walled tritium system tubing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 5, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending December 5, 2003

Martin and Stevenson were on site this week participating in a dynamic experiments design review.

Integrated Safety Management (ISM): Last Wednesday (11/26), LANL issued the results of its investigation into the five TA-55 workers exposed to toxic vapors (i.e., refrigerant degradation products) while soldering a piping joint for a rerouted coolant line (site rep weekly 10/3/03). The identified direct cause was worker failure to recognize abnormal conditions. The root causes were failures in the ISM process: specifically in defining the work, identifying the hazards, ensuring performance. Many organizations were involved. Roles and responsibilities were not clearly identified. Communications were disjointed. Organizations made assumptions about other organizations' responsibilities for hazard analysis and development and verification of controls. The radiological hazard was the focus to the exclusion of other hazards. There was no effort to incorporate and resolve different requirements contained in various work documents. The LANL investigation team concluded that the interim work control improvements now underway could conceivably have prevented the accident had they been in place at that time – particularly, the requirements for a single person-in-charge, clear roles and responsibilities, and verification walk-downs. The LANL team also identified areas where the interim work control improvement effort needs to be strengthened.

Waste Operations: Last Friday (11/28), the NNSA Site Office approved with comment the upgraded safety basis for the TA-54 (Area G) solid waste operations (site rep weekly 5/9/03). The analyses of the postulated accident scenarios predict high consequences for several low probability events. LANL is limited in available engineered controls. NNSA approved TRU waste containers, pallet banding, waste storage domes and door restraints as safety class; approved the lightning protection system as safety significant; and approved shaft covers, pit overburden, and SeaLand containers (for fiberglass reinforced plywood crates) as other design features. The key administrative controls are inventory limits. This includes an NNSA-imposed requirement to meet the Quick-to-WIPP commitment – ship off-site about 2,000 drums of dispersible, higher-source term material by September 2004. NNSA directed LANL to submit within 60 days a plan for stepping down the material-at-risk limit over time.

The site rep agrees with the high priority NNSA has assigned to the Quick-to-WIPP initiative. This is the best near-term action available to achieve significant risk reduction in Area G. On engineered controls, the specification of functional requirements and the assurance that the selected design features will meet requirements are substandard; however, it appears that nearly all the engineered controls available without major capital investment have been pursued. The site rep also believes that NNSA and LANL should pursue operation of the Decontamination and Volume Reduction System (DVRS), which is unfunded for FY-04. DVRS could address plywood crate integrity concerns, reduce collocated combustible and radioactive inventory, and thereby reduce risk (site rep weekly 9/19/03). While SeaLand containers may be appropriate for crates that won't be processed for some time, that pathway increases crate handling and associated risks and may become an excuse to delay processing the crate contents into a form acceptable for WIPP. DVRS is their only foreseeable disposition path.

Quality Assurance (QA): NNSA in its approval letter for the Area G safety basis identifies several quality issues with the LANL safety analysis. Separately, on Tuesday, the NNSA Service Center reported similar quality issues with the LANL SAFEKEG Safety Analysis Report for Packaging (SARP). Besides common quality concerns, transportation container certification issues such as these may affect DOE capability to perform its missions and achieve risk-reduction throughout the complex.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 12, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending December 12, 2003

Contardi, Kasdorf, Leary (OE), Rosen, and Tontodonato were here this week reviewing LANL nuclear material management and stabilization, including 94-1 progress and the TA-55 Type B investigation.

Recommendations 94-1/00-1: It's been nearly 10 years since the Board's initial recommendations on nuclear material stabilization. LANL is the last remaining DOE site without an implementation plan accepted by the Board. Since 1995, LANL has stabilized about two-thirds of the excess and programmatic inventory identified by LANL as 94-1. LANL has also made progress this year in processing and in designating more material for WIPP; however, a sense of urgency has been lacking – from both NNSA and LANL. Due to the Type B and increased recognition of worker safety issues, LANL is now engaged in a comprehensive evaluation of the inventory, packaging, storage, and management of nuclear materials. Three example areas that could accelerate progress are: (1) reevaluation of the economic discard limit (EDL) - currently residues with little value are being processed to meet an outdated EDL; (2) expediting design, installation, and startup of a dedicated line for processing non-weapons grade plutonium (i.e., the exposure reduction line) – while the gloveboxes are there, the line is not scheduled to startup until the 2007 time-frame; (3) development and application of institutional standards. Considering both safety and mission implications (i.e., vault space, Type Bs), higher priority on closely managing, stabilizing, and disposing of residues is overdue.

Federal Oversight: LANL has made progress during the last year in self-assessment and performance assurance, but both the issues that have occurred and the extent of progress that has taken place indicate a continuing need here for strong federal oversight. The NNSA Los Alamos Site Office (LASO) has played a pivotal role in LANL making progress; particularly in operations, subject matter expert (SME) reviews, and increasingly program liaison (e.g., lab support of Pantex). Recent examples include the strong federal roles in the initiation and development of the interim work control improvements and in the TA-55 type B investigation. For example, the NNSA Type B team identified safety issues that led LANL to suspend Pu-238 operations that generate waste or residues. Recent LASO efforts to help define scope and resource requirements for lab support of Pantex are noteworthy.

While these are encouraging, LASO appears to have technical staffing issues that constrain it from meeting its current responsibilities – much less meeting expanded responsibilities under the NNSA re-engineering. For example, NNSA has performed few readiness assessments (RAs) or comparable verifications at LANL during the last 2 years, relying mostly on the NNSA facility reps (FRs) to monitor LANL verifications. That said, the number of FRs has dropped nearly in half during that period (from 18 in late 2001 to 11 now), and collateral duties impact their in-facility time. Currently, only 4 FRs are deployed in their assigned facilities. The rest are on temporary assignment providing technical assistance to LANL in implementing the interim work control improvements. For a few weeks now, major facilities (i.e., CMR, solid/liquid waste operations, DARHT, radiography facility) have lacked day-to-day FR oversight (site rep weekly 11/21/03). This “tech-assist” is expected to end soon, but illustrates a common practice, increasingly used, that dilutes FR oversight.

LASO has increased the number of local SMEs from 2 to 4 in the last year. Recent hires are for maintenance and fire protection, but there still are weaknesses in SME support – such as sufficient qualified support for vital safety systems. The NNSA Albuquerque Service Center (100 miles away) has supported some verifications, but NNSA appears only marginally effective in using this resource.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 19, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 19, 2003

Plutonium Facility (TA-55): NNSA released this week the Type B investigation report on the 8/5/03 Pu-238 contamination event. The report identifies the direct cause as an airborne release from a degraded package containing cellulose material (i.e., cheesecloth) and Pu-238 residues. The root causes were (1) the LANL division failed to balance management attention and resources between accomplishing the programmatic mission and providing an appropriate level of protection for the workers handling Pu-238; (2) DOE, NNSA, and LANL failed to adequately evaluate and understand the magnitude of the worker safety risks that they have accepted for the activities conducted by the Pu-238 Group; (3) DOE, NNSA, and LANL managed DNFSB Recommendations 94-1/00-1 as projects for addressing legacy materials storage rather than as an effort to mitigate potential hazards to workers.

The failed package had been stored in the room since 1996, and was a can-bag-can configuration as previously described (site rep weekly 8/8/03). Chemical, radiolytic, and thermal decomposition of the contents and packaging caused the inner can and plastic bag to fail. Corrosion of the outer can appears to have caused the breathable seams to seal, allowing gas to build up. Simple handling of the package was sufficient to dislodge the corrosion and allow contamination to vent to the room. The failure mechanisms for all 3 "barriers" can occur simultaneously and independent of each other. The failure was similar to previous container failures that have been the subject of well-known reports since 1994.

The NNSA report states that the consequences could have been much greater and that it was nothing more than fortunate geometry and timing of the release that limited the consequences to exposed employees. Furthermore, there was no packaging configuration design; no analysis of contents and package material compatibility; no control on what could be placed in the package; no formal periodic package surveillance; no residue processing schedule; no limit on the quantity of Pu-238 that could be stored in the room; and no hazard control plan in place for the room or the activities conducted in the room. The identified issues are not limited to LANL but also include NNSA Site Office oversight of Pu-238 operations; DOE-NE and NNSA division of responsibilities for funding and oversight; and DOE, NNSA, and LANL management of 94-1 and 00-1 nuclear material stabilization. LANL has begun corrective actions for activities within its scope, such as the comprehensive inventory evaluation discussed last week. A corrective action plan is forthcoming.

Weapons Engineering Tritium Facility (WETF): LANL has completed a thorough readiness assessment (RA) for WETF on the full TSR implementation and on closure of open items for Building 450 startup (site rep weekly 8/1/03). The NNSA Operational Readiness Review is now expected in April 2004. The RA team complemented the facility on the TSR implementation effort but observed the need for improvements in configuration management, maintenance, and conduct of operations.

Training: Recently, LANL conducted an assessment of institutional training and identified issues that could impact nuclear facilities, such as not all lab organizations are effectively staffed and managed to facilitate a systematic training process that supports LANL missions; to the extent that training evaluations are done, they are not endorsed at the appropriate management level nor are results used to develop corrective action plans; and there is no policy governing worker disqualification following a training course failure. LANL is developing a corrective action plan. The NNSA Site Office has also begun an assessment of both institutional and facility-specific training.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 26, 2003

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 26, 2003

Weapons Engineering Tritium Facility (WETF): NNSA continues to owe the Board a rapid response on the functionality of the WETF NFPA 780 lightning protection system, which NNSA has designated safety-class (site rep weekly 11/18/03). LASO has provided input to NNSA headquarters. During the last year, two experts have concluded that lightning-induced rupture of multiple containers is incredible and that the much lower consequence scenario involving burn-through of thin-wall system tubing is the dominant lightning-related risk. The remaining lightning-related scenario that could drive a need for safety-class controls appears to be one involving a lightning initiated fire that spreads to multiple rooms. WETF defenses against this scenario included fire barriers and storage containers (both safety-class), fire suppression (safety-significant), and the combustible control program.

The site rep observes that the lightning protection system does nothing to prevent fires initiated by other sources - in fact, WETF had a small, uncontrolled flame from a failed electrical component under a glove-box in May, comparable to a small candle flame. More attention also is warranted on periodic inspection and upgrades of the safety-class fire barriers - particularly, upgrading the 1-hr fire rated wall between the vault-like room and the adjoining process room. NNSA and LANL may need to re-examine WETF fire accident scenarios and the selected controls in a more holistic sense.

Engineered Controls: NNSA and LANL need to apply more attention to ensuring that the engineered controls selected have clearly defined safety functions, that they will fulfill those functions, and that they constitute a complete set. The WETF issue above is an example. Other examples are described in site rep weeklies 7/3/03 and 11/28/03. LANL has a solid effort underway under the Integrated Facility Management Program to develop institutional procedures, but that effort is not fully funded this year. Several of the procedures are now being piloted in LANL Waste Operations - e.g., screening design changes, developing a design change package, designating vital safety systems and systems engineers.

There are also several other unfunded critical needs - e.g., inventorying vital safety systems, fully updating master equipment lists (MELs, a recurring issue seen in several assessments), and developing an implementation plan for the revised DOE Facility Safety order (DOE O 420.1A). MELs are being updated for nuclear facility fire protection equipment. The systems engineer program is funded. Some aspects of DOE O 420.1A are moving forward, such as training and qualification of systems engineers.

LANL also has some projects that have developed mature approaches to conduct of engineering, such as the Dynex Vessel Design Team (a recent recipient of an NNSA Award for Excellence). This team is working at the state-of-the-art and, in fact, has made advances that will likely improve national consensus codes. An independent Blue Ribbon Panel has mentored the Dynex project, contributing to this success. The panel has conducted 37 in-depth reviews during the last 4 years (cumulative time: 150 days), providing critical technical feedback. The project constructively accepted the feedback and made improvements in vessel design, quality assurance, and configuration management. Recently, the DARHT 2nd axis commissioning team (also working at the state-of-the-art) adopted some of these improvements, such as continuous peer review, bi-monthly independent reviews, and configuration management. NNSA and LANL would be well-served to review these two projects and possibly others (e.g., the Pu-238 scrap recovery line, the TA-18 temperature scram installation) for common lessons learned that could lead to site-wide improvements in engineered controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 2, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 2, 2004

LANL declared the new EOC operational last week before closing for the holidays (12/25/03-1/2/04). LANL management is also pursuing engaging with an industrial partner to help improve operations in nuclear and high hazard facilities.

Waste Operations: Last week, NNSA approved the updated safety basis for RANT - the Radioassay and Nondestructive Testing Facility (TA-54-38), subject to 16 conditions of approval. RANT has been up-rated to a Hazard Category 2 (HC-2) nuclear facility. RANT does nondestructive testing of TRU waste packages and loads them into TRUPACT containers for shipment to WIPP. Approved safety-class engineered controls include vented waste packages, building structure, fire suppression, TRUPACTs, pipe over-packs (for sealed sources). The interior fire wall and bridge crane were designated as safety-significant. The main administrative controls (LCOs) are on material inventory and the fire suppression system operability. WIPP shipments have been on hold since October (site rep weekly 10/3/03). Resuming safe shipments is key to LANL reducing TA-54 risks via the Quick to WIPP program.

NNSA directed that the RANT safety basis (BIO, TSRs) expire in 5 years (12/08) and that cost-benefit analyses be done on seismic vulnerabilities. While LANL believes the facility met code when it was constructed (1989), it's questionable it meets either PC-1 or PC-2 requirements now. NNSA also questioned the adequacy of the fire suppression to activate during small to medium fires.

Welding Issues: LANL has identified, via self-assessment, that some welding processes used on site may not have complied with national consensus codes and that this may have resulted in (a) welding not being done by welders who were qualified and holding current certification; (b) welding procedures not appropriately reviewed and approved prior to use; and (c) welding equipment and materials not procured and controlled to defined procedures. The site rep understands these issues extend to some nuclear facilities (e.g., CMR) and that LANL is preparing a corrective action plan.

Chemistry and Metallurgical Research Building (CMR): NNSA owes the Board a rapid response on safety system functional classification issues at CMR – particularly, whether that portion of the electrical distribution system that supplies power to supply and exhaust fans warrant functional classification as safety-significant (ref: Board letter 8/19/03). The current CMR Safety Basis (a BIO) credits ventilation as the safety-significant backup to the safety-class fire suppression system to protect the public. In discussion with the staff, NNSA has asserted that the passive ventilation mode provides adequate protection (i.e., no power requirement), but justification is lacking. CMR functional classification is expected to be examined when the BIO is updated. The BIO update has slipped from January 2004 to March 2004.

Critical Experiments Facility (TA-18): NNSA also owes the Board a response on the ability of new TA-18 safety-class temperature scram systems to perform their safety function (Board letter 7/9/03). The response is due prior to LANL removing interim safety controls or by September 2004, whichever occurs first. Last month, NNSA Albuquerque Service Center conducted an independent review of the new systems installed in SHEBA and Planet. The number of issues raised by this independent review indicate there would be value to including this project in a site-wide lessons-learned review of conduct of engineering, if one were to be conducted as discussed last week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 9, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 9, 2004

Plutonium Facility (TA-55): This week, TA-55 began decon of the room contaminated by Pu-238 last August (site rep weekly 8/8/03). The job was planned and the work released via the new interim work control process. Controls selected are appropriate. Workers were instructed to inspect containers before moving them. TA-55 still needs to complete a Unreviewed Safety Question (USQ) before removing containers for access to decontaminate the cages. Relatedly, DOE Office of Enforcement plans in early February to conduct an on-site investigation into the contamination event.

Radiological Protection: The NNSA Site Office has requested LANL to promptly submit interim compensatory measures that address compliance issues with the Occupational Radiation Protection Rule (10 CFR 835). LANL Audits and Assessments identified the issues in a partial assessment in early November and reported their findings in late December. They plan to assess all elements of the Rule in one-third increments during the next 3 years.

The LANL team concluded that the radiation protection program generally implements the elements of the Rule that were reviewed; however, weaknesses exist in communicating radiation hazards and controls to workers and in meeting qualified training standards and record-keeping requirements. They observed that, without communicating and controlling the hazards and without providing qualified training, the laboratory cannot ensure the safety of workers and compliance with regulations. The team did identify noteworthy practices, particularly the quality management efforts in the radiation protection services group. The site rep observes that the training and qualification issues here are similar to those identified during a LANL institutional training review last fall. Issues with communication of hazards and controls also drove NNSA and LANL to pursue the interim integrated work control improvements currently underway (site rep weeklies 10/17/03, 12/19/03).

Authorization Basis (AB): In November 2003, the NNSA Site Office approved LANL proposed categorization of 11 environmental sites as Hazard Category 2 or 3 nuclear facilities, and requested LANL to perform a USQ evaluation on another 12 sites that are within the boundaries of existing nuclear facilities. One other candidate site is still being evaluated. LANL proposed these facility classifications after reviewing about 900 potential environmental release sites. The new Hazard Category 2 (HC-2) sites include material disposal areas in TA-21, TA-49, TA-50 and an underground spent resin tank in TA-53. The new HC-3 sites include material disposal areas in TA-21 and TA-54, sodium storage tanks in TA-35, former liquid disposal areas or treatment sites in TA-10 and TA-35.

Los Alamos Neutron Science Center (LANSCE): NNSA and LANL consider LANSCE to be a non-nuclear facility with exceptions: the 1L spallation target and certain actinide experiments in the Lujan Center and an inactive target station in Area A are considered HC-3. LANSCE is governed by four separate AB documents – 3 BIOs and an interim safety assessment – approved between 2000 and 2002. LANSCE appears to be compliant with this AB. They plan to submit an integrated AB this summer.

The NNSA Site Office has identified that LANSCE has not yet addressed all the recommendations in a Fire Hazard Analysis (FHA) prepared in 2002 after the AB documents were approved. The main open issue appears to be combustible loading in the Lujan Center – due to 8 tons of bare polyethylene shielding surrounding the 1L target's thick steel shield. LANSCE is assigning higher priority now to the remaining FHA recommendations and is planning to clad the polyethylene when funds are approved.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 16, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 16, 2004

Integrated Safety Management (ISM): Last September, 5 workers in the Plutonium Facility (TA-55) were exposed to highly toxic vapors while soldering a rerouted coolant line in a poorly ventilated anti-contamination tent. The event and conclusions of a thorough LANL accident investigation have been previously reported (site rep weeklies 10/3/03, 12/5/03), but they warrant further consideration.

Even though there had been months of planning, the workers had no forewarning of possible toxic hazards. One of their first indications of a problem was when they observed spraying liquid from a line that they thought had been purged. They continued to work. Their first warning was when they experienced respiratory distress after heating piping joints for about 5 minutes. Per the LANL report, if they had not immediately evacuated the tent, there could have been serious injuries, including possible fatalities.

During the investigation, LANL identified multiple breakdowns. Some were driven by conflicting safety controls. Others resulted from mis-communication, misunderstandings on responsibilities, and reliance on conversation or other records over work-site walk-downs. For example:

- Due to radiological control and waste minimization concerns, the workers were wearing flammable coveralls and latex gloves while working with the acetylene torch, counter to their flame permit. This has some similarities to conditions that resulted in a fatality at Oak Ridge K-25 in 1997. In that case, the worker's vision was more obstructed, and he was working alone.
- During the actual work, the workers expressed conflicting concerns on when to operate the ventilation blower – considering the potential for contamination spread vs the need for air flow during hot work. Even then, the controls in place did not include local task exhaust recommended by the coolant Material Safety Data Sheet when applying heat.
- The tent was an informal addition to the work package, and the hazards it presented were not evaluated. It may have amplified the toxic vapor concentration by an order of magnitude.
- There were multiple opportunities by various organizations to identify the chemical hazards during the planning phase, but they did not engage appropriate subject matter experts. They did not realize how ill-informed they were on the hazards, and incorrectly identified the hazards on multiple work package forms. Since no chemical hazards were identified, the workers believed that all the hazards had been identified and removed.

The LANL report includes a gap analysis of the event against the new integrated interim work controls being implemented (site rep weekly 10/31/03). It concludes that these new work controls could conceivably have prevented the accident, but they must be strengthened. The site rep believes that these new controls are the most positive actions that have taken place here to improve worker safety during the last two years. This event and LANL's subsequent investigation strongly reinforce the needs for full implementation and continued improvement in LANL work control.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 23, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 23, 2004

Management: A team from the Institute of Nuclear Power Operations (INPO) was on site this week providing insight on potential improvements to the lab's corrective action program.

Quality Assurance (QA): While many LANL organizations implement QA (e.g., pit manufacturing), LANL does not have a DOE approved institutional QA Program and has self-reported that it is non-compliant with the QA provisions in the Nuclear Safety Management Rule (10 CFR 830, subpart A). Last April, NNSA concurred in a LANL plan to achieve institutional compliance in about 2 years - by March 2005. This requires a major effort and is proving tougher than originally projected. It's behind schedule. Areas where improvements have been made include: establishment of a senior management quality steering group; issuance of lab-wide requirement documents (LIRs) for software QA, issue management, and management assessment; internal assessments on training, weapons engineering; new expertise assigned full-time to institutional QA, both within LANL and the NNSA Site Office; and the INPO review of LANL corrective action programs. Last week's first meeting of the QA network was very encouraging. LANL has dozens of enthusiastic QA professionals with years of experience distributed throughout the lab. The QA network provides an opportunity for them collectively to help improve the institution. They need their management's support to make this a priority. By vigorous follow-through, LANL could achieve a state where business, safety, and mission improvements are driven more by assessments and less by events, such as accident investigations.

Training: One QA criterion is to train and qualify personnel so that they are capable of performing their assigned work (10 CFR 830.122, criterion 2). The NNSA Site Office is conducting a training assessment, to be done in May. A LANL institutional assessment last August identified that not all lab organizations are effectively managed to facilitate using a systematic-approach-to-training process that supports the mission; training evaluations, to the extent they are conducted, are not endorsed at the appropriate management level; evaluation results are not used to develop corrective action plans; training and qualification contractual requirements are not all reflected in lab implementing documents, nor have all required actions been implemented. Two earlier LANL reviews (1/03, 10/02) identified similar issues. LANL has a corrective action plan for the August assessment and is obtaining off-site expert assistance. Sufficient information appears available now to identify priority training improvements that could enhance safety and mission performance (site rep weekly 12/12/03).

Weapons Engineering Tritium Facility (WETF): This week, the NNSA Site Office modified the WETF Technical Safety Requirements (TSRs) and approved a positive Unreviewed Safety Question Determination involving an increase in lightning strike frequency (site rep weekly 11/28/03). NNSA asserts that tritium storage container burn-through is credible without a maintained lightning protection system (LPS); that the LPS prevents fires; that the 2 expert evaluations on LPS were mitigated analyses; and that for these and other reasons, the LPS needs to be Safety Class. NNSA states that this effort has reinforced the importance of the fire barriers and of the thermal adequacy of containers – both already Safety Class. NNSA continued to impose a stringent tritium inventory limit unless fire barriers are upgraded. LANL is performing a 3-month cost-benefit study of potential LPS improvements – ranging from mods to achieve Faraday cage equivalent protection to a local lightning early warning system.

TA-18 Mission Relocation: The conceptual design is near completion for relocation to the Nevada Test Site. NNSA is holding a review next week (1/27-28) in Washington DC of the CD-1 package.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 30, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 30, 2004

Quality Assurance (QA): In November 2002, the Secretary of Energy provided the Board a Quality Assurance Improvement Plan. The plan includes an action to validate and verify that QA programs are effectively implemented for vital safety systems (action 3.3). As an initial step, A NNSA-LANL team has completed a thorough independent assessment of the design, procurement, and operation of the new TA-18 in-core temperature monitoring system (ITMS). The team identified both lab-wide and TA-18 specific issues, as well as opportunities to improve these types of assessments. Their assessment continues next week on construction and fabrication and on software quality assurance.

Critical Experiments Facility (TA-18): In July 2002, NNSA approved a new TA-18 safety basis, which included developing and installing the new ITMS in each of the five critical assemblies. ITMS is intended to shutdown an assembly before partial core or sample vaporization. This postulated accident scenario is new for TA-18 and has low probability but high off-site consequences (i.e., 1000 Rem range). The ITMS is the Safety Class engineered control to prevent the accident. The systems have been installed in two assemblies, Planet and Sheba, but have not yet been through readiness assessments (RAs). As of last November, the RAs and a response to a Board letter (7/9/03) were the last remaining steps before ITMS are declared operational. Interim administrative controls are in place now.

As of this week, four independent sets of reviewers have raised issues on the ITMS – either (a) that a temperature based scram will be difficult to verify with confidence that it will work when needed, or (b) the temperature scram systems designed and installed in Planet and Sheba have not been adequately reviewed and do not meet the pedigree expected for Safety Class systems. The four reviews are:

Board letter (7/9/03) - A Board letter and staff report raised both these issues last year. Among many observations, the staff suggested that it might be better to pursue a nuclear instrument (NI) based scram as the Safety Class defense, given the challenges. NNSA has not responded to the Board's letter.

NNSA-LANL QA review - The review discussed above identifies significant design and procurement issues, particularly the need for LANL to charter an independent design review – not done to date. The team found, that while TA-18 has good QA processes, they failed sometimes to follow those processes.

LANL Reactor Safety Committee (RSC) - The last 3 RSC annual reports have stated that the RSC is skeptical as to the real benefit that will accrue from the ITMS. In FY 01, the RSC emphasized that the existing NI based scram systems must be maintained to existing requirements. Last November, the RSC reported that TA-18 had identified a possible need to redefine "burst mode" as greater than \$0.80 reactivity since the automatic temperature scram systems are not fast enough. It is unclear how such a redefinition would resolve slow temperature-scram response time and thereby improve nuclear safety.

NNSA Albuquerque Service Center - Last December, the NNSA Site Office chartered a Service Center review of the ITMS, which was completed this week. The review's scope was to determine whether the ITMS design, installation, and testing incorporated appropriate standards and requirements for its Safety Class function, and whether line management has a process to verify and document that the design was correctly developed, components properly purchased, and installation properly tested – for Safety Class. This was also a thorough review. The team concluded that the ITMS only met 1 of 17 criteria that were used to assess the system. LANL has not addressed all requirements expected for Safety Class systems.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 6, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 6, 2004

Plutonium Facility (TA-55): Last week, the NNSA Site Office endorsed a LANL recommendation to install a new diesel generator and upgrade TA-55 electrical switchgear so that power is automatically restored to key electrical loads, like confinement ventilation. LANL estimates that this will reduce risk by 18% and 6.5% to the public and workers, respectively. A funding source is to be determined.

LANL's electrical evaluation is based on the proposed new TA-55 safety basis, submitted nearly two years ago and still not acted upon by NNSA. At this point, the proposed safety basis itself needs updating (Site Rep weekly 10/24/03). Safety basis updates are expected to be proposed and approved once per year, but this has rarely occurred for LANL nuclear facilities. The current TA-55 safety analysis report and technical safety requirements (TSRs) were approved in 1996 and 1999. The need for this particular electrical power evaluation arose from a DOE commitment to the Board made in March 1996 and then revised in May 2001, when it was linked to the long-delayed new safety basis.

Recommendations 94-1/00-1: Progress has stalled on installing large vessel clean-out equipment in the Chemistry and Metallurgical Research Building (CMR) Wing 9 (site rep weekly 6/20/03). The delay is due in large part to unclear expectations between LANL and NNSA on whether this constitutes a major facility modification and on the maturity and pedigree required of the safety analysis before LANL takes receipt of major components. Ventilation components are already in place. Delivery of the confinement enclosure has been on hold since about January 5th. LANL submitted a process hazard analysis for approval on January 16th. NNSA action is pending.

This and other LANL projects have been adversely impacted by lack of clear, specific criteria on what constitutes a major facility modification requiring a preliminary documented safety basis (PDSA), as well as lack of explicit management commitment early in each project's lifetime on how safety basis development and NNSA safety basis approvals will be sequenced into the acquisition process. LANL construction management requirements do include checklists for assigning responsibilities during the conceptual phase for preparing a safety strategy and for identifying safety systems.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, NNSA approved the PDSA submitted in October for the new TA-50 pump house & influent storage facility, with 0.3M gal capacity. This is a new Hazard Category 2 nuclear facility addressing lessons from the Cerro Grande fire (site rep weeklies 8/30/02, 1/17/03). The project is nearly a year behind, in large part due to 3 iterations on the PDSA. The new tanks will normally receive low-level wastes (500 nCi/L, ~1 Ci max total). TA-55 transuranic liquids go elsewhere in RLWTF. The bounding accident assumes major combined upsets that dump the entire RLWTF inventory and a TA-55 discharge into the new tanks – 182 Ci Am-241 equivalent. This postulated accident has off-site consequences of about 5 Rem. Designated safety-significant systems include: tank vents; fire suppression; building design (PC-2); lightning protection; vehicle barriers; liquid system confinement; underground piping; and safety shower/eyewash units.

Authorization Basis (AB): Because of their importance, safety basis documents need to be quality documents – clear, complete, correct, concise. The recent NNSA approval record on WETF lightning protection lacks clarity, is incomplete, and may not be correct – it's unclear (site rep weekly 1/23/04). It is not a quality document. The NNSA letter also attempts to address broad issues and then imposes safety basis changes, bypassing the normal process of NNSA holding LANL responsible for formally recommending and justifying such changes. In essence, the "checker" became the "doer." NNSA has frequently commented on quality in LANL AB correspondence and could set a better example.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 13, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 13, 2004

Goff, Kupferer, Martin, and Quirk were here this week reviewing the new TA-18 temperature scrams.

Critical Experiments Facility (TA-18): NNSA owes the Board a report on how the new Safety Class in-core temperature monitoring systems (ITMS) will perform their intended safety function and thereby prevent core and sample damage (site rep weekly 1/30/04). While some progress has been made, the questions posed in the Board letter (7/9/03) and accompanying staff report remain open.

According to approved safety analyses, the ITMS is Safety Class to prevent postulated accidents with off-site consequences up to 1,000 Rem CEDE range. Only critical assemblies with transuranic cores or samples are capable of generating consequences in this range. Accidents for uranium fueled assemblies with small samples (e.g., less than ~25 g Pu metal) fall below the evaluation guidelines.

NNSA and LANL have no expectation of the temperature scrams working for higher reactivity insertions (e.g., above \$0.80, including Godiva & SHEBA burst operations). The current administrative controls are the primary defense against the accident and thereby appear to be Safety Class admin controls, in the sense of the Board's Recommendation 2002-3, *Requirements for the Design, Implementation, and Maintenance of Administrative Controls*.

In approving the temperature scrams, the NNSA vision is to remove the human element from the scram sequence for reactivity insertions ranging from \$0.20 to \$0.80. This range requires scram response times ranging from several minutes down to about 10 sec to prevent damage. In advance of ITMS being declared operational, LANL has admin controls and interim compensatory measures in place now to prevent the accident. These are also equivalent to Safety Class admin controls.

The admin controls cited above have not yet been evaluated per Recommendation 2002-3. The effectiveness of these controls relies highly on the training and qualification of the TA-18 operators. TA-18 currently is undergoing operations management turnover. TA-18 also has lacked a Facility Rep (FR) since mid-December and will likely not have a full-time qualified FR for several months.

The answer on whether ITMS will work depends on a benchmark study that TA-18 expects to issue in March. The answer on whether the design needs to meet Safety Class separation and independence requirements depends on a fault tree analysis still in review in TA-18. These are major open issues, considering that the new systems are installed in 2 assemblies and 90% designed for the other 3.

Another major issue with the ITMS is the lack of a thorough independent design review. TA-18 acknowledges this deficiency, but has not yet factored time into the schedule for such a review and for deliberate resolution of comments. TA-18 also has issues with the recent NNSA evaluations that raised questions on whether the designs have been correctly developed, components properly purchased, and installation properly tested for Safety Class (e.g., TA-18 used graded approach). NNSA and LANL now consider those evaluations as "draft" while TA-18 conducts factual accuracy reviews, to be done soon.

Besides ITMS, the staff reviewed TA-18 preparations to operate SHEBA (the Solution High Energy Burst Assembly) in burst mode. SHEBA has never been in burst mode. While progress is evident, there is a lack of independent review and of formality of closure for issues, some years old. Clear criteria are also needed on what would constitute an abnormality during approach to burst warranting further evaluation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 20, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 20, 2004

Critical Experiments Facility (TA-18): TA-18 has completed their factual accuracy reviews of the two external assessments of the new temperature scram systems (site rep weekly 1/30/04). The two assessment teams are updating their reports, based on the comments. At this time, the basic conclusion appears unchanged: LANL hasn't addressed all requirements expected for these Safety Class systems.

Waste Operations: In November, the NNSA Site Office approved with comment the upgraded safety basis for the TA-54 TRU solid waste operations. Safety analyses of the postulated accident scenarios predict high consequences for several low probability events. LANL has limited available engineered controls; however, NNSA believes that shipping ~2,000 drums with the highest, most dispersible inventory by end of FY 04 would reduce risks by, at least, 70%. This is the Quick-to-WIPP Program.

WIPP shipments have been on hold since October. LANL and the NNSA Site Office have engaged in an extensive effort to address issues and verify readiness. The Site Office recently requested DOE Carlsbad Field Office (CBFO) agreement with a proposed path-forward, including agreement to daily shipments to WIPP for four months, starting in June. The site rep observes that: (1) achieving this risk reduction in TA-54 appears to be essential; therefore, expedited resumption of safe and compliant WIPP shipments needs to be a management priority; (2) once shipments are restarted, operations need to be deliberate, since expedited operations (e.g., daily shipments) could lead to safety or compliance issues. It may be worthwhile for DOE to reevaluate the Quick-to-WIPP September 2004 deadline.

Authorization Basis (AB): The NNSA facility rep at TA-54 recently determined that the Pu equivalent definition in the TA-54 safety basis is unclear and is based on references to outdated documents. AB verification and implementation require clear definitions. NNSA has requested LANL to correct this.

Plutonium Facility (TA-55): Last week, LANL submitted to the NNSA Site Office the corrective action plan in response to the Pu-238 Type B investigation report (site rep weekly 12/19/03). The plan covers actions to minimize residues; conduct hazard analyses for packaging and storage; develop and implement improved work controls; verify those controls are in place; evaluate AB implications; establish a self-assessment program with specific criteria; establish a process to ensure flow-down of hazards and controls to work documents; and perform a comprehensive inventory assessment. DOE corrective actions in response to the Type B are still to-be-determined and require priority.

Cleanup of the Pu-238 contaminated room is progressing. LANL is preparing to submit an AB process hazard analysis for handling the residue containers and their interim storage in WIPP drums.

Chemistry and Metallurgical Research Building (CMR): Last Monday (2/9/04), management found deposits on the outer surface of one of the two Wing 3 exhaust fans. Initial samples indicated these were potentially shock-sensitive perchlorates at about 9 times the action level. CMR isolated the area, shutdown the fan, and prohibited Wing 3 work that could disturb ventilation. An emergency response team responded. Analysis last Tuesday of one sample indicates stable iron perchlorate. CMR is developing a work package to remediate visible perchlorates using appropriate personal protective equipment. CMR has a TSR admin control program focused on minimizing and controlling perchlorates, based on past experience. This event is motivating a review of that program.

FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 27, 2004

The site representative was at DNFSB-Headquarters all week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 5, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 5, 2004

Martin was on site this week reviewing the status of dynamic experimentation.

Integrated Safety Management (ISM): Last Thursday (2/26), two workers escaped serious injury when the mobile crane they were transporting struck a 13.2-kV overhead power distribution line, separating all 3 cables of the 3-phase distribution line. This was a near-miss to fatalities. Power was lost to a large area for 3.5 hours. The crane was being transported to DARHT to replace another crane that had been damaged by misuse. While this was a non-nuclear operation, the sequence of events and the potential consequences are disturbing. NNSA has expressed concerns about the formality of DARHT operations leading up to this event and requested LANL to develop a lessons-learned report. LANL is investigating to identify improvements in the integrated work management process and in lab-wide maintenance and operation of heavy equipment, including operator qualification.

Critical Experiments Facility (TA-18): NNSA owes the Board a response on the ability of new TA-18 safety-class temperature scram systems to perform their safety function (Board letter 7/9/03). The NNSA Site Office (LASO) has expressed serious concerns about safety, design, and procurement issues raised by recent assessments of these systems. LASO is directing LANL to address the issues and submit a comprehensive corrective action plan. LANL has suspended all work on the systems, and plans to complete an independent design review and to fully resolve the issues raised in the Board's letter. In the interim, the site rep believes that it would be prudent for NNSA and LANL to confirm that the admin controls and interim compensatory measures in place now to prevent the accident are effective. These are equivalent to safety-class controls (site rep weekly 2/13/04).

Weapons Engineering Tritium Facility (WETF): NNSA is overdue in its response to the Board on the functionality of the WETF NFPA 780 lightning protection system, which NNSA has designated as safety-class (Board letter 8/19/03; site rep weeklies 1/23/04, 12/26/03). LASO has provided input to headquarters. LASO recently made clear to LANL that WETF should reevaluate all accident scenarios, including lightning, in the next safety basis update. LASO is also pursuing an independent NNSA-led review by subject matter experts of WETF lightning protection effectiveness.

Last week, LASO also directed LANL to upgrade the tritium storeroom fire barrier, which is also safety-class, from 1-hour to 2-hour fire rating; to aggressively pursue transferring inventory to safety-class containers with ASME pedigree; and to create, for all LANL nuclear facilities, clear and enforceable Technical Safety Requirement (TSR) implementing procedures that specify operability requirements and time limits. Actions are to be completed by September 2004.

Chemistry and Metallurgy Research Building (CMR): NNSA is overdue in its response to the Board on safety system functional classification issues at CMR – particularly, whether that portion of the electrical distribution system that supplies power to supply and exhaust fans warrant functional classification as safety-significant (Board letter 8/19/03; site rep weekly 1/2/04). LASO has provided input to headquarters. LANL is currently reviewing all CMR safety systems as part of a safety basis upgrade to be submitted in April. The site rep observes that confusion persists on the significance of the questions here. The current CMR safety basis, a BIO, credits ventilation as the safety-significant backup to the safety-class fire suppression system to protect not only the workers but also the public.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 12, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 12, 2004

Integrated Safety Management (ISM): LANL is investigating two unrelated radiological events that have occurred within the last week: (1) Last Thursday (3/4), a CMR chemist received contamination on her lips, chin, and neck (up to 18k dpm) while working in a hood. Decontaminating the worker extended over a two day period. The worker was pouring a 3 M nitric acid and plutonium/uranium solution into a column in the hood. Room surveys found contamination on the floor and the hood's sash lip. (2) This Tuesday (3/9), two LANSCE workers discovered that they were working in an uncontrolled, unrecognized High Radiation Area (~170 mrem/hr neutron) and immediately exited. Preliminary dose estimates are low (7 and 25 mrem). The workers were replacing equipment in one flight path of the Lujan Center while beam was on in the two adjacent flight paths. Work planning appears to have been based on radiation surveys with beam secured in the two adjacent flight paths. As a result of this event, LANL has suspended Lujan flight path maintenance and construction activities.

Authorization Basis (AB): LANL senior management recently established an executive committee to track NNSA and LANL progress on AB issues and re-prioritize effort, as appropriate. During the last year, NNSA and LANL AB staff have focused on accident analysis and risk reduction for TA-54 Area G and paid much less attention to other activities. Four nuclear facilities have ABs that are 5 to 8 years old. The TA-55 AB is 7 years old, and its AB update has been waiting for approval for nearly 2 years. Since November, LASO has disapproved one AB update, and LANL has withdrawn three. While Area G risk reduction is important, more balanced AB priorities appear warranted.

Chemistry and Metallurgy Research Building (CMR): The CMR AB is 5 years old. LANL owes NNSA an AB update next month, including a review of functional classification of safety systems. CMR has systems that may be playing a safety class role but are not now designated as safety class. For example, CMR has a containerization program intended to ensure that material not in active use is placed inside robust safes to protect it during catastrophic events. Last Fall, items within these safes were found packaged inconsistent with that during qualification tests (site rep weekly 10/31/03). LANL plans to include this storage system as a safety class design feature in next month's AB update.

Engineered Controls: LANL has several initiatives underway that could improve conduct of engineering and maintenance if fully developed and implemented, including: (1) the engineering standards manual, which captures requirements; (2) institutional administrative procedures that standardizes practices to meet those requirements; (3) and an institutional systems engineering program, including deployed systems engineers who would be trained and qualified to these requirements and procedures.

The engineering standards manual is the most mature of these and includes, for example, disciplinary design requirements, but not design processes or review requirements. It was made applicable last Fall to both facility and non-weapon programmatic work. The institutional systems engineering program started training personnel last September. It is currently limited to just facility work; however, a recent LANL tentative list of vital safety systems indicates that nearly two-thirds of these systems are programmatic (i.e., 59 of 93). The administrative procedure development effort is part of the Integrated Facility Management Program and is vital if LANL is to standardize engineering and maintenance practices across the lab. While well-conceived, this effort is also only applicable so far to LANL facility work and has had limited effectiveness, perhaps because it needs more senior management support. This week, NNSA began explicitly assigning personnel to perform oversight of LANL vital safety systems, which is positive.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 19, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 19, 2004

The Board and a staff team were on site this week. On Wednesday, Andrews, Jordan, and Contardi were here for informal, separate discussions on TA-55 Pu-238 operations.

Formality of Operations: Two recent examples indicate a need for more formality here in closure of safety issues before new operations or restarts to ensure there are no omissions that could affect safety. First - when approving the TA-18 safety basis in 2002, NNSA stated that the Solution High Energy Burst Assembly (SHEBA) shall not operate in burst mode until several studies are submitted to and accepted by NNSA. This includes addressing potential common mode failure of the two identical dump valves, which are the two safety-class shutdown mechanisms. Last month, LANL informed the staff these actions were complete; however, NNSA has not received and accepted the studies, and it is unclear who at NNSA and by what formal mechanism NNSA intends to accept closure of these items.

Second - last September, TA-55 curtailed processes that generate Pu-238 waste and residues because of potential safety concerns involving deterioration of the slip-lid containers (site rep weekly 9/12/03). On February 23rd, TA-55 management approved a resumption plan for the curtailed operations; however, the approved plan is based on draft documents, including a hazard control plan and a work instruction still in development and a process hazard analysis not yet submitted to NNSA. It is unclear that all the reasons for curtailment have been identified and formally addressed; that prerequisites have been satisfied and formally verified; and that implications of the Type B corrective action plan have been considered. From discussion with LANL, the intent was to restrict resumed operations to those within the glovebox lines, including residue pyrolysis, but LANL needs to resolve the container issues. These concerns may be addressed by the integrated planning effort described below.

Plutonium Facility (TA-55): LANL is engaged in integrated planning to address several inter-related needs involving Pu-238 operations, including: (1) resuming operations that generate wastes and residues; (2) progressing on the Type B corrective action plan (CAP); (3) starting up the new scrap recovery line and delivering heat sources in time for the NASA New Horizons mission to Pluto. Scrap recovery line startup has several apparent prerequisites: an explicit Technical Safety Requirement (TSR) revision that captures all the applicable controls; formal closeout and verification of LANL readiness assessment (RA) findings from last summer (~90 total, including 31 pre-starts - site rep weekly 8/1/03); a new LANL RA; and the NNSA RA. The scope of the new LANL RA is to be determined, but could include resumption of residue-generating activities and implementation of new work control processes. An integrated schedule should be available early next week.

LANL is moving ahead on the Type B CAP (site rep weekly 2/20/04). Efforts to decon the room to date have been well-planned and well-executed, but progress is on hold pending LANL submitting and NNSA approving a process hazard analysis for temporary residue storage locations and configurations. LANL also needs both NNSA approval of the CAP, and DOE and NNSA action on judgements of need under federal responsibility. The latter includes NNSA developing comprehensive criteria for safe stabilization, storage, and disposal of Pu-238 bearing materials, considering the full life cycle. NNSA needs to take timely action on these to support LANL safely moving ahead with these activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 26, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 26, 2004

Von Holle was here this week participating in the annual review of the weapons enhanced surveillance program. DeLoach was also here reviewing the NNSA Facility Rep program.

Plutonium Facility (TA-55): Higher priority and increased management attention appear warranted on NNSA and LANL reaching agreement on the scope and schedule of the Type B corrective action plan (CAP). Particularly, NNSA needs to take appropriate and timely action on the judgements of need under federal responsibility and on the LANL proposed CAP. Also, during the last two weeks, LANL has developed a deliberate, resource-loaded schedule leading to start up of the new Pu-238 scrap recovery line in September. There are some details still to be worked out during the next few weeks, such as linkage to the Type B CAP. The schedule does appear to capture key elements, including closure of July 2003 LANL readiness assessment (RA) findings, a technical safety requirement (TSR) revision, a management self-assessment, another LANL RA, and the NNSA RA.

Welding Issues: LANL has self-identified that some welding processes used on site may not have complied with national consensus codes (site rep weekly 1/2/04). Issues include qualification and certification of welders for nuclear safety and other critical systems; weld filler procurement and traceability; qualified weld processes and procedures; code-compliant weld inspections. The scope of this problem is likely large. Last November, LANL visually inspected 90 welds in CMR safety systems and identified 22 welds that did not meet acceptance criteria (e.g., arc strikes, undercut, overlap, lack of fusion, blow-holes, poor workmanship). This was a sampling inspection of fire suppression, ventilation, and ventilation wash-down systems.

For new welds, LANL is close to issuing a site-wide notice to specify proper controls via the new integrated work management system. This will affect new work on systems involving nuclear safety, high pressure, or structural hoisting and rigging. Longer term, LANL intends to implement a compliant welding program via the LANL Engineering Standards Manual. For existing welds, LANL has committed to performing facility and program-specific assessments.

Integrated Safety Management (ISM): The DOE Office of Price-Anderson Enforcement issued their investigation report this week for the TA-55 Pu-238 uptake event (8/5/03), the TA-55 toxic vapor exposure event (9/27/03), and LANL radiological protection program issues. An enforcement conference is scheduled for April 13-14. DOE expects LANL to also be prepared to discuss five other recent events: the mobile crane striking the 13.2 kV overhead line; the CMR facial contamination; LANSCE uncontrolled high neutron radiation area; TA-18 temperature scram design issues; integrated work control confusion on walk-down requirements. LANL has several investigations underway. The events are summarized in site rep weeklies 12/19/03, 1/9/04, 1/16/04, 2/13/04, 3/5/04, 3/12/04.

Emergency Preparedness: This week, LANL conducted its first large-scale drill in the new Emergency Operations Center (EOC), which was declared operational last December. This was a tabletop exercise, simulating a wildfire under weather and dryness conditions similar to those during the Cerro Grande fire (May 2000). Federal and County agencies participated. LANL is preparing for a full exercise in June. The last such exercise here was in June 2002 (site rep weekly 6/14/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 2, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 2, 2004

Bamdad, Jordan, Kimball, Stevenson (OE), and Zavadoski were on site this week reviewing ventilation and ventilation-related accident analyses for TA-55 and CMR Replacement.

Critical Experiments Facility (TA-18): NNSA announced Wednesday that half the special nuclear material (SNM) at TA-18 will be shipped to Nevada Test Site (NTS) during the next two years, starting in September. Few details are available now on how this will be accomplished and how NNSA intends to maintain qualified staffing and minimize the impact on the criticality safety program that NNSA has committed to under Recommendation 97-2. The TA-18 Relocation Project completed a conceptual design in January and is waiting on Critical Decision 1 (CD-1). The plan was to complete preliminary design in 2005, start construction at NTS in 2006, move material in 2009, start operations in NTS and decommission TA-18 in 2011. It is unclear what the plan is now.

The site rep understands that the project is meeting next week in Nevada to develop a plan and that SNM for Recommendation 97-2 related activities will likely be first to move. There are options that could maintain some continuity in the 97-2 program. Considering local implications, it is unclear when or how NNSA and LANL will resolve issues on whether the new safety-class temperature scram systems will perform their credited safety function (Board letter 7/9/03). These issues are likely applicable regardless of where the assemblies are located. It is also unclear how NNSA and LANL intend to manage the risk of current TA-18 operations during the transition. In advance of the safety-class temperature scram systems being installed, LANL has admin controls and interim compensatory measures in place that are equivalent to safety-class. As discussed in site rep weekly 2/13/04, the effectiveness of these controls relies highly on the management, training, and qualification of the TA-18 operators – areas that may warrant closer scrutiny during this transition.

Plutonium Facility (TA-55): NNSA has accepted a LANL proposal to upgrade the TA-55 electrical switchgear so that power would be automatically restored to key electrical loads, like confinement ventilation; however, funding remains uncertain (site rep weekly 2/6/04). NNSA headquarters has deferred to the Site Office on funding. The situation resembles that in 1996, when the Secretary of Energy committed to the Board to upgrade emergency power for TA-55 glovebox ventilation, but the issue was never resolved. Separately, LANL is working with the staff to address questions on ventilation seismic capacity and on conservatism in leak path factors in the proposed safety basis (4/02).

Chemistry and Metallurgy Research Building Replacement (CMRR) Project: CMRR has completed conceptual design and expects a CD-1 within the next 2 months. There may be hidden assumptions that affect safety, such as assuming no ball-milling and no Pu-238 operations. These need to be explicitly reconciled against mission needs and addressed. The project would also benefit if it had NNSA-approved principle guiding criteria that capture the top-level design strategy (e.g., engineered controls over admin controls, the need for post-accident monitoring). As-is, the approach appears to copy the TA-55 ventilation strategy, which may not be the best for either mission or safety.

Weapons Engineering Tritium Facility (WETF): WETF appears well-prepared for an NNSA Operational Readiness Review (ORR), starting on April 19th. The scope covers the Technical Safety Requirement implementation and neutron tube target loading (NTTL) being transferred from TA-21.

April 9, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending April 9, 2004

The site rep was off site this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 16, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 16, 2004

Weapons Engineering Tritium Facility (WETF): The NNSA Operational Readiness Review (ORR) for Building 450 startup and WETF safety basis verification starts Monday.

Welding Issues: Last week, LANL declared a potential inadequate safety analysis (PISA) due to existing suspect welds on nuclear safety systems (site rep weekly 3/26/04). LANL has issued a site-wide notice to specify proper controls for new welds, and LANL systems engineers are visually assessing existing welds in nuclear safety systems, such as WETF tritium systems and TA-55 Pu-238 glovebox supports. Certified weld inspectors will inspect suspect welds found during these reviews. Initial assessment results should be available next week to support risk-based decisions on continued operation. This is a relatively quick look given the number of welds. LANL is developing a long-range plan for more detailed certified inspections of representative welds in all nuclear facilities.

Plutonium Facility (TA-55): NNSA has rejected a backward-looking Unreviewed Safety Question Determination involving cleanup of the room contaminated with Pu-238 last August. NNSA identified weaknesses in the 7-year-old final safety analysis report and could not verify that controls are adequate to address hazards in the room. It's unclear right now what the implications of this are on the cleanup effort and on addressing the large inventory of Pu-238 residues in the room.

TA-55 has clarified its strategy for resuming Pu-238 operations curtailed last fall because of concerns about residues stored in containers outside gloveboxes (site rep weekly 3/19/04). Residues are not to be removed and stored outside gloveboxes until after NNSA has approved a process hazard analysis and LANL has finalized associated hazard control plans and work instructions. Residues declared as waste may be removed from gloveboxes following existing waste handling procedures. Six operations are within scope: bench-scale aqueous scrap processing; fuel processing; pyrolysis & liquid residue processing; fueled clad decontamination; destructive testing and evaluation; and miscellaneous. Readiness for each will be verified by a management self-assessment (MSA). A validation walk-down with operator input, per the new integrated work control process, will be part of the MSA.

Radiography Facility (TA-8-23): Last week, NNSA formally suspended TA-8-23 operations with explosive and tritium items due to lightning protection deficiencies and confusion on the safety basis. TA-8-23 operates under a two-year-old Justification for Continued Operation (JCO). The safety basis confusion centers on whether the JCO and NNSA approval letter required the lightning protection system to be code compliant (NFPA 780). The lightning protection deficiencies were identified last July but have not been corrected. The facility had curtailed operations in March due to the lightning protection issues but had concluded that they were still within the safety basis. NNSA disagrees. LANL experts consider the system degraded but functional. The issues here (e.g., lack of clear operability criteria, delay in resolving known deficiencies) strongly parallel those identified in a Board letter of 8/19/03 for WETF. Institutionally, NNSA and LANL still need better criteria for operability, maintenance, and configuration management for these systems (site rep weeklies 3/5/04, 11/7/03).

Management: Ralph Erickson, the NNSA Los Alamos Site Office (LASO) Manager, was honored this week on the occasion of his retirement. Ed Wilmot has been assigned as the new LASO Manager.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 23, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 23, 2004

Weapons Engineering Tritium Facility (WETF): The NNSA Operational Readiness Review (ORR) started this week and will conclude next week.

Critical Experiments Facility (TA-18): LANL plans to conduct a management self-assessment (MSA) of TA-18 operations in early May in response to questions raised by the NNSA Site Office. Relatedly, NNSA and LANL are currently relying on a set of administrative controls and interim compensatory measures to prevent the most significant postulated accident in TA-18 – an uncontrolled reactivity excursion that causes melting and partial vaporization of a plutonium core or sample. These controls are the primary defense against this accident right now and appear to be equivalent to safety-class administrative controls, in the sense of the Board's Recommendation 2002-3, *Requirements for the Design, Implementation, and Maintenance of Administrative Controls*. However, most of these controls are missing from the current list of those to be verified in response to the Board's recommendation. The postulated TA-18 accident has the 2nd highest predicted consequence of any postulated accident in LANL nuclear facilities. It appears that these controls ought to be included and have priority for verification (site rep weeklies 4/2/04, 2/13/04, 1/30/04).

Plutonium Facility (TA-55): Higher priority and increased management attention appear warranted on NNSA and LANL reaching agreement on the scope and schedule of the Type B corrective action plan (CAP). Particularly, NNSA needs to take appropriate action on judgements of need under federal responsibility and on the LANL CAP proposed 2 months ago (site rep weeklies 3/26/04, 2/20/04).

Fire Protection: This week, The NNSA Site Office issued an assessment on fire protection system maintenance and requested LANL to provide a corrective action plan within 30 days. Among the institutional improvements needed are adequate funding to promptly restore impaired safety systems to service (based on lessons learned from a LANSCE fire-pump fire); adequate funding to reduce the deferred maintenance backlog; complete and accurate Master Equipment Lists (MELs). LANL is working to update the MELs for nuclear facility vital safety systems by September 2004.

Authorization Basis (AB): Annual updates of nuclear facility ABs have rarely occurred here. Also, neither LANL nor the NNSA Site Office maintains a complete list of AB documents. Some nuclear facilities maintain their own list. For example, it's been 7 years since the last TA-55 update was approved, and the current TA-55 list includes 88 documents (some of these are awaiting NNSA action). The diffusion of the AB over numerous documents for some facilities has been problematic for NNSA and LANL operations personnel who need to clearly understand what constitutes the AB. NNSA relies on LANL maintaining a complete list in the authorization agreements, as required by the applicable LANL Laboratory Implementation Requirement (LIR); however, neither LANL nor NNSA has enforced this requirement, and most authorization agreements are out of date (site rep weeklies 10/24/03, 2/14/03).

Radiography Facility (TA-8-23): LANL has placed TA-8-23 into cold standby due to self-identified non-compliances with the National Fire Alarm Code (NFPA 72), including with testing and inspection requirements. TA-8-23 is a Hazard Category 2 nuclear facility operating under a two-year old Justification for Continued Operation (JCO). Operations were already restricted because of lightning protection deficiencies and confusion on the authorization basis, as reported last week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 30, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 30, 2004

Integrated Safety Management (ISM): Several people in the Chemistry and Metallurgy Research building (CMR) were exposed this week to irritating vapors and received medical attention. The source was a battery charger in a space with potentially inadequate ventilation. LANL emergency personnel responded. There are questions on whether hazards were adequately identified and whether appropriate controls were place (e.g., formal equipment tag-out, personal protective equipment, monitoring equipment, flammable gas control). LANL is investigating.

Plutonium Facility (TA-55): TA-55 went into standby mode and suspended operations intermittently this week in order to troubleshoot the Uninterruptible Power Supply (UPS). The UPS failed last Friday during restoration from maintenance, raising reliability concerns, but the failure has not been repeatable. The system has since operated normally. UPS is safety-significant. When off-site power is lost, it provides power to select safety systems, including criticality alarms, the paging/general announcement system, and the facility control system. Compensatory measures are in place. While in standby, NNSA approved one special-case fissile material move to support a programmatic need.

Radiography Facility (TA-8-23): TA-8-23 resumed limited operations this week after implementing a standing order that requires posting an individual who can alert others in the event of a fire alarm.

Engineered Controls: NNSA and LANL need to apply more attention to ensuring that the engineered controls selected have clearly defined safety functions, that they will fulfill those functions, and that they constitute a complete set (site rep weekly 3/12/04, 12/26/03). Last Friday, LASO and LANL sent to NNSA headquarters a requested extension for a report to the Board on LANL plans to implement conduct of engineering and the DOE Facility Safety Order 420.1A (ref: Board letter 1/27/04, which includes a 90-day reporting requirement). While LANL has several solid initiatives underway for facility work, progress for programmatic work has lagged. LANL intends to move toward a single site-wide engineering program, covering both facility and non-facility work. Considering the magnitude of the task, LANL expects to have a plan by June 30th.

Administrative Controls: Board Recommendation 2002-3, *Requirements for the Design, Implementation, and Maintenance of Administrative Controls*, observed that there are administrative controls having a safety function that should be implemented with the same degree of rigor and quality assurance as that afforded engineered controls with similar safety importance. In March, LASO provided NNSA headquarters a list of LANL administrative controls to be verified in response to this recommendation. The list is a "shot-in-time" as some safety bases are being updated and some additional guidance and standards are being prepared.

The current list does not appear to meet the intent of DOE's implementation plan and the Board's recommendation and needs to be re-evaluated. It is not clear that all the nuclear facilities understood that the controls to be reviewed included not only administrative control programs but also limiting conditions for operations (LCOs) and surveillance requirements. It is also not clear that they understood that the controls to be identified are limited to those performing a function that ideally would be performed by a designated engineered safety system if such a system was installed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 7, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 7, 2004

Integrated Safety Management (ISM): LANL senior management is committed to improving the LANL integrated work management process. Last week, the LANL Director issued an instruction outlining his expectations, including that people focus on the intent of the process and not just the documentation. LANL also has revised the interim work management requirements to incorporate lessons learned since the new work control process was put in place last November (site rep weekly 10/31/03). This is still an overlay on the prior work control processes. Two challenges are (1) standardizing expectations and preparation of the responsible division leaders or their designees, who now have increased personal responsibility for implementing the process, and (2) streamlining implementation for repetitive tasks, such as low-risk maintenance and surveillance. LANL has committed to developing and implementing process improvements (e.g., hazard identification and support tools), delivering training, and issuing new institutional requirements by September 30th.

Critical Experiments Facility (TA-18): LANL conducted a management self-assessment (MSA) of TA-18 operations this week, and the report is forthcoming. Also, the site rep observes that the current TA-18 authorization basis (AB) implicitly permits both Godiva and SHEBA to operate in delayed critical mode with a 150 g plutonium equivalent sample and with excess reactivity approaching \$1.00. The other assemblies are limited to \$0.80 with Division Leader approval, \$0.50 otherwise. The safety basis does not include an analysis of Godiva and SHEBA in the delayed critical regime. Instead, it has analysis for operations above \$1.00 (i.e., burst mode) that led NNSA to impose additional controls, such as restricting the sample size to zero during burst mode operations. LANL has issued a standing order with more explicit controls for Godiva and SHEBA and will propose such controls in an upcoming Technical Safety Requirement (TSR) revision. LANL is also reviewing TA-18 experiments against the hazards and controls. Review of the sample size and reactivity limits appears warranted.

Plutonium Facility (TA-55): TA-55 has traced the uninterruptible power supply (UPS) failure reported last week to a likely transient in a bypass switch during restoration from maintenance. NNSA has approved a TSR change to limit the significance of any future similar failure. Also, TA-55 has completed an MSA on resuming the Pu-238 aqueous recovery bench-scale process without ion exchange. This MSA was an improvement over some observed last year. TA-55 appears to have benefitted from increased institutional support, particularly the Performance Surety Advisor Program. The MSA included stepping through the process and tracing implementation of controls down to procedures. Some of these controls evolved from a process hazard analysis (PrHA) that LANL submitted 2 years ago to NNSA as part of the AB update but that NNSA has not yet approved. While this PrHA is likely the best information currently available on the hazards, NNSA needs to complete its review to ensure appropriate controls are in place.

Weapons Engineering Tritium Facility (WETF): NNSA has completed its Operational Readiness Review (ORR) and is preparing its report. Tentatively, the team identified 3 pre-start and 24 post-start findings, most of which were linked to institutional issues (e.g., conduct of engineering, training, welding, maintenance, quality assurance). There were few AB issues. The site rep observes that the NNSA ORR was thoroughly and professionally conducted, and that WETF was well-prepared. This was the culmination of several years of hard work by LANL, the Site Office, and, more recently, the Performance Surety Advisor Program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 14, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 14, 2004

The site representative was at DNFSB-Headquarters all week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 21, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 21, 2004

Authorization Basis (AB): LANL nuclear facilities have declared several potential inadequacies in safety analysis (PISAs) recently. CMR declared a PISA on lack of controls for gasoline, fuel oil, and high explosive shipments near CMR. Such controls are assumed to be in place by the current AB. Radioactive Liquid Waste Treatment Facility (RLWTF) and Waste Characterization, Reduction, and Repackaging Facility (WCRRF), both in TA-50, have declared PISAs related to institutional welding issues (site rep weekly 4/16/04). TA-55 has declared PISAs on both discrepant Type A shipping drums and the bench-scale Pu-238 aqueous recovery operation (both discussed below). TA-18 and TA-55 have each declared PISAs related to container breach scenarios. It is positive that these issues are being reported; however, it may be worthwhile for NNSA and LANL to review them collectively to determine if there are systemic, institutional issues possibly related to the age of some of these ABs (i.e., time between reviews/updates), and the functionality and effectiveness of the selected controls.

Plutonium Facility (TA-55): NNSA has approved the corrective action plan (CAP) in response to the Pu-238 uptake event last August (site rep weekly 2/20/04). The CAP assigns actions to both NNSA and LANL; because of interdependencies, both must complete their actions on time for success. Last Tuesday (5/11), TA-55 declared a PISA on the bench-scale Pu-238 aqueous scrap recovery process. TA-55 recently resumed this process based on a hazard analysis submitted with the TA-55 AB update package two years ago but not yet approved (site rep weekly 5/7/04). Questions center on applicability of approved controls for the full-scale line (not yet started up) to the bench-scale process.

NNSA and LANL have established a joint team to re-review the two-year-old proposed TA-55 AB update (site rep weekly 3/12/04). NNSA intends to preserve independence by having separate personnel involved in the final approval review. Any additional updates would be incorporated into the NNSA safety evaluation report instead of revising the submitted safety analysis report. While expeditious, it would be less confusing if the AB was made complete and current prior to approval so that the safety analysis report and technical safety requirements were stand-alone documents.

Transportation: As a result of drop tests on DOT 7A packages, NNSA and LANL have imposed restrictions for on-site shipment of 55 gal drums containing fissile material (site rep weekly 11/7/03). Drums weighing 300 lbs or less are compliant to 49 CFR 173.465 requirements. Heavier drums can be shipped subject to a road closure and vehicle speed restrictions (35 mph). NNSA recently reported that about 65 % of the waste drums on site exceed 300 lbs; most of these are solidified waste; and about 6 % (~1,200 drums) both exceed 300 lbs and are in a dispersible form. LANL is evaluating the safety basis implications, such as for TA-54 Area G where the drums are considered safety-class. LANL is also preparing a plan to minimize generation of the heavier, non-solidified drums.

Radiation Protection: On May 5th, NNSA directed LANL to recalculate personnel internal dose estimates for the last year using the biokinetics model and reference man weighting factors from ICRP 30 and 26, respectively. The ICRP 30/26 approach was developed in the early 1980s, and a newer model and weighting factors are available (ICRP 60/66). However, the Radiation Protection rule (10CFR835) mandates use of ICRP 26. LANL had started to use the newer model with the older weighting factors (a possible data-to-model compatibility issue) and is planning to evolve to ICRP 60/66. The issues here may be applicable to other sites. An update to 10CFR835 may be warranted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 28, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 28, 2004

DOT 7A Drums: As discussed last week, LANL has imposed restrictions for on-site shipping of fissile materials using DOT 7A drums. To be DOT compliant, these containers are required to be capable of withstanding several tests, including a pre-conditioning series of 1-foot drops on each quarter followed by a 4 foot free drop in a configuration causing the maximum damage.

Besides transportation, several nuclear facilities rely on these drums to safely confine materials during normal and accident conditions and to ensure sub-criticality (e.g., TA-54, TA-55, CMR). These facilities are currently assessing their needs individually; however, since LANL moves drums between facilities, it may be more appropriate if LANL pursued one set of bounding lab-wide criteria, possibly including packaging and evaluation requirements for both new and existing drums. In particular, implementing unified, technically robust evaluation criteria could improve the confidence in these drums as the key safety-class design feature in TA-54 Area G (site rep weekly 12/5/03).

Nuclear Material Stabilization: On Wednesday (5/26), the NNSA Site Office and LANL provided NNSA headquarters with a proposed implementation plan for Board Recommendations 94-1 and 00-1, as requested by the Board letter of 2/12/04. The proposed plan focuses on excess items. Most programmatic items are now being considered out of scope for 94-1. Instead, LANL intends to ensure safe packaging and storage of programmatic items via a separate comprehensive plan being developed in response to the TA-55 Type B investigation. That plan is expected in August. Safe storage of both programmatic and excess items would be addressed in parallel and within the same time frame.

The proposed 94-1 implementation plan is based on a revised risk assessment considering not only source-term but also chemical reactivity and package age. Compared to previously proposed plans, it increases emphasis on early disposition of non-weapons grade plutonium items and would achieve comparable risk reduction about 2 years sooner for these materials. One exception is large vessel clean-out, which may slip a year or more. The plan also identifies opportunities for acceleration for weapons grade plutonium that NNSA and LANL appear likely to pursue.

Plutonium Facility (TA-55): There may be an emergent need to evaluate TA-55 processes that were judged acceptable based on the current 1996-era safety basis and then were started up within the last few years, particularly whether they meet current DOE safety requirements. NNSA is reassessing the Pu-238 bench-scale aqueous recovery process based on this logic. NNSA and LANL have targeted completing, within the next few months, a re-review of the entire TA-55 safety basis proposed 2 years ago. Thorough, expeditious action to update this safety basis could address the emergent need.

TA-55 fire suppression is a safety-significant backup to the safety-class building confinement system. Several fire suppression surveillance frequencies in both the current and proposed safety bases differ from those in DOE requirements and guidance and the applicable code (NFPA-25). Some examples include the frequencies for verifying level in diesel day tanks, demonstrating that fire pumps auto-start within a pressure set-point range, and conducting sprinkler flow tests. In 1999, the NNSA Site Office approved an equivalency for less-frequent fire pump testing but with caveats indicating the decision should be revisited. The current safety basis review would appear to be the best time to revisit this and ensure that adequate technical justification exists for any deviations from codes and standards.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 4, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 4, 2004

Investigations and Trending: During the last two years, LANL has improved its investigations and trending of events reported under both the occurrence reporting system and the Price-Anderson program (the new sub-occurrence reporting system here still needs work). In early 2003, LANL analyzed about 1,400 occurrence reports filed during the previous 8 years, and they have continued to update these trend analyses. Some LANL observations from both last year and this year include: most of the correction actions taken are at the facility-level instead of the institutional-level; most actions taken are procedural changes; few corrective actions specify a new or modified engineered control; and even fewer actions make a substitution or otherwise eliminate the hazard. While LANL has taken some actions in response to these valuable studies, it appears more could be done take advantage of lessons learned across the lab, as illustrated by the lightning protection example below.

Lightning Protection: In August 2002 and again in August 2003, the Board raised questions about the functionality of the NFPA 780 lightning protection system for the Weapons Engineering Tritium Facility (WETF). NNSA has designated this system as safety-class. Several of the questions involved maintenance and configuration management of the system. The NNSA/LANL response (3/18/04) discusses actions taken since last Fall to inspect the WETF lightning protection system, correct deficiencies, and ensure proper maintenance.

In March 2004, LANL curtailed operations in the Radiography Facility (TA-8-23), and subsequently, NNSA formally suspended TA-8-23 operations involving explosive and tritium items due to lightning protection deficiencies and confusion on the safety basis (site rep weekly 4/16/04). Radiography of other items continued. Both the specific deficiencies and the institutional lapses that led to delay in correction are nearly identical to that experienced earlier by WETF. Before resuming the curtailed operations, LANL plans to conduct a readiness assessment, which will likely examine the institutional lapses. Since several LANL nuclear facilities rely on the lightning protection system to perform a safety function, LANL would be well-served to address these issues at an institutional level.

Waste Operations: NNSA and LANL are pursuing expedited shipment to WIPP of about 2,000 drums with the highest, most dispersable inventory. To resolve a bottleneck for this effort, LANL is installing a glovebox in the TA-54 Decontamination and Volume Reduction System (DVRS) facility and is proposing that DVRS be used for a 5-month campaign for visual examination and repackaging of transuranic waste containers.

DVRS is currently operating as a radiological facility. This will require it be approved for Hazard Category 2 nuclear operations. In early April, LANL prepared a limited-life Basis for Interim Operation (BIO) that discusses the hazards and controls. Accidents postulated include spills, fires, drum deflagrations, and earthquakes. Safety systems proposed include as safety class: the waste drums; the external building and internal enclosure (designed to PC-2 load criteria); active, filtered ventilation; backup power for ventilation; and fire suppression. The glovebox and its supports, exhaust, atmospheric controls, and drum lift are all proposed as safety significant. Key administrative controls proposed include: inventory and drum limits; vehicle and forklift prohibitions; external door controls; and prohibition on drum stacking. NNSA is reviewing the proposed limited-life BIO.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 11, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 11, 2004

Martin, Nichols, Von Holle, and White were here this week reviewing LANL support for Pantex.

Critical Experiments Facility (TA-18): The Board has identified issues that need to be addressed in the near term to ensure continued safe operations in TA-18 (Board letter 5/21/04). Most of these issues focus on ensuring adequate controls for critical experiments with plutonium (Pu) metal.

This week, NNSA concurred in a LANL path-forward for these issues. Specifically, LANL identified three high-priority experiments involving kg-quantities of plutonium that need to be conducted before operations transfer to DAF. Two of these require Pu metal. LANL will request NNSA approval of a set of safety basis controls for the 3 experiments. Beyond these experiments, LANL intends to avoid challenging the evaluation guidelines by proposing a 10 gm Pu metal limit. These are positive steps.

Plutonium Facility (TA-55): NNSA and LANL need to assign higher priority to completing the cleanup and recovery of the room contaminated with Pu-238 last August, as well as addressing the inadequate storage configuration for Pu-238 residues now in this room. Significant systematic progress was made early in the year, but decontamination efforts have slowed – particularly in the vicinity of containers of residues that are on the floor or in cages – because there is no approved path-forward yet for these containers. LANL has started to bag the containers in place and is close to conducting a management self-assessment for resuming residue pyrolysis operations. To make progress, they need a technically sound and approved set of safety basis controls for packaging, handling, and storage of the residues and for temporary storage of outer drums that would provide a secondary barrier to release for some packages. NNSA and LANL need to expedite the hazard analysis preparation, review, and approval cycle started more than 3 months ago for these operations.

Waste Operations: NNSA has approved the safety basis for using the TA-54 Decontamination and Volume Reduction System (DVRS) for 5 months for visual examination and repackaging transuranic waste containers. This will require verification and approval to start up DVRS as a Hazard Category 2 nuclear facility. The approved engineered controls are as discussed last week, plus lightning protection and a roll-up door restraint as safety-significant. NNSA imposed 3 conditions of approval (i.e., 5-month duration, inventory limit, and readiness verification) and 8 Technical Safety Requirement (TSR) changes. NNSA also questioned whether the structure meets Performance Category 2 seismic requirements. A LANL May 28th report indicates that DVRS is built on fill over old waste pits and needs site-response characterization; the internal enclosure is susceptible to seismic anchor motion; and the building lateral load path relies on tension-bracing, which does not meet current LANL detailing requirements. LANL is evaluating future use of DVRS beyond this campaign.

Annual Emergency Exercise: On Wednesday, LANL conducted a full exercise centered around TA-54. The scenario involved a simulated car accident with injuries; an unrelated hostage and bomb threat; and a simulated explosive attached to chlorine cylinders on a truck bed, leading to activation of the Emergency Operations Center (EOC). NNSA and LANL evaluators identified several areas for improvement, such as: EOC internal communications; response to victims; use of checklists, aids, and logs; and on-scene command-and-control. LANL is still adapting to the new EOC.

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending June 18, 2004

Bamdad, Hadjian, Jones, Jordan, Kimball, and Rizzo (OE) were on site this week reviewing site-wide seismic design criteria; resolution of issues with the TA-18 safety-class flood retention structure; and the geotechnical characterization and the safety strategy for the CMR Replacement facility, which is under design. The Site Rep was off-site this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 25, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 25, 2004

Burns, Fortenberry, and Merritt were here this week for an overview of LANL operations.

Critical Experiments Facility (TA-18): NNSA and LANL will brief the Board on July 8th regarding the issues in the Board's May 21st letter. LANL has curtailed activity on the safety-class temperature-based scram systems because of the limited remaining life for TA-18 Security Category I/II activities (i.e., to 10/05). This increases reliance on administrative controls to prevent uncontrolled reactivity excursions. TA-18 has bounded the significance of this by restricting critical operations with more than 10 gm Pu to just 3 experiments (site rep weekly 6/11/04). LANL has committed to requesting NNSA approval in a new safety basis to continue two of the experiments and to conduct the third. However, LANL is continuing now with the two experiments in advance of requesting NNSA approval. While the experiments may be straight-forward, it seems that LANL should expeditiously identify to NNSA the administrative controls that are being depended on to fulfill the safety-class functions and the actions being taken to verify those controls are implemented and maintained.

Price Anderson Enforcement Letter: NNSA has sent LANL a preliminary notice of violation for the TA-55 Pu-238 uptake event (8/5/03), the TA-55 toxic vapor exposure event (9/27/03), and LANL radiological protection issues (site rep weekly 3/26/04). For the Pu-238 event, NNSA identified: two workers receiving exposures above the federal limit (5 Rem TEDE); inadequate work controls and failure to comply with those work controls that were in place; quality issues, particularly for the residue containers; safety basis violations, particularly for the seismic racks used to store containers; and radiological control deficiencies. The TA-55 toxic vapor exposure event resulted, in part, from some of the same work control issues. Due to the long-standing nature of some of the underlying problems, NNSA chose to escalate the severity level assigned to some of these violations (site rep weekly 7/11/03). NNSA expressed concerns with the history of known problems with the Pu-238 residue containers and with LANL assessment processes failing to identify these problems. NNSA observed that, while LANL has taken actions to improve work control and nuclear safety, there is still a long ways to go. NNSA expressed concerns on whether the compensatory measures put in place are sufficient to prevent significant safety events like the Pu-238 uptakes and encouraged LANL to take a fresh look at what needs to be done in the short-term to assure safe operations. From discussion with LANL management, they agree with the strong needs to continue to improve in these areas.

Radiography Facility (TA-8-23): On May 4th, TA-8-23 management found a screwdriver being used as a shim to maintain contact between a roll-up door and a micro-switch for a safety interlock. The need to shim the door may have been exacerbated by recent modifications to the underlying concrete pad. LANL critiqued the event and concluded that a breach in conduct of operations had occurred but not a safety basis violation. The event came to the attention of NNSA Site Office management last week as part of the review of a new safety basis to replace the current 2-year-old justification for continued operation (JCO). The JCO generically identifies X-ray machine safety interlocks as engineered safety features. NNSA concluded that the screwdriver constituted an unauthorized modification to a engineered safety system, resulting in a safety basis violation.

It's positive that TA-8-23 management responded to the jury-rigged interlock and initiated action; however, NNSA and LANL review of both the event and the subsequent response has raised questions at both the facility and institutional levels such as: the adequacy of training, the level of operators understanding of the safety basis, the formality of both nuclear safety systems management and the USQD process, and the adequacy of support by LANL institutional organizations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 2, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 2, 2004

Waste Operations: In November 2003, the NNSA Site Office approved with comment the upgraded safety basis for the TA-54 transuranic solid waste operations. Safety analyses of the postulated accident scenarios predict high consequences for several low probability events. LANL has limited available engineered controls; however, NNSA believes that shipping ~2,000 drums with the highest, most dispersible inventory would reduce risks by, at least, 70%. This is the Quick-to-WIPP Program. NNSA imposed a Safety Basis requirement that this program be completed by September 2004, although it has been acknowledged for several months now that this date is not supportable.

It now appears that the Quick-to-WIPP Program may not be completed until a year later – September 2005 – due to two factors: (1) LANL suspended WIPP shipments last October as a result of a finding during a Carlsbad Field Office annual audit, and while LANL has formally addressed the issues raised, the multi-agency process to approve resumption of shipments is not yet complete; (2) Last week, DOE corporately decided that Rocky Flats and Idaho shipments have priority over those from the other sites, including LANL. LANL had expected to resume WIPP shipments in the July-August time-frame, but it now looks like January 2005. LANL resumed full characterization this week and intends to have a backlog ready to go when shipments resume (site rep weeklies 10/3/03, 12/5/03, 2/2/04).

Plutonium Facility (TA-55): One of the more important safety basis admin controls for Pu-238 operations is ensuring that the material inventory within each unit operation stays below that assumed in the accident analyses (i.e., the material-at-risk assumption). The Pu-238 operations staff have begun verifying glovebox inventories every two weeks. During such a verification on June 15th, they determined that the inventory in one glovebox exceeded the material-at-risk limit by 10 % and corrected the discrepancy within an hour. Based on this event, TA-55 is considering further improvements in the material-at-risk controls proposed in the safety basis upgrade, now under review.

Critical Experiments Facility (TA-18): In May, LANL conducted a 3-day management self-assessment (MSA) of TA-18 operations (site rep weekly 5/7/04). The MSA report discusses the strong sense of pride, ownership, and accountability at TA-18, but mentions that personnel are concerned about: high levels of stress and anxiety, increasing programmatic pressure, and programmatic schedules and security requirements sometimes being prioritized over safety.

The MSA team made several recommendations including developing formal plans for program continuity that will maintain mission capability; developing a staffing plan that realistically establishes a path forward for TA-18 personnel; addressing the high level of distraction that is causing less management focus on day-to-day operational issues; addressing several training needs including formal job task analyses for key operations managers and in-depth training for all operators on safety basis accidents and controls; fully implementing new LANL-wide work control measures; and improving relationships with oversight organizations. The report includes a summary of the corrective actions planned; however, it appears that more ought to be done based on the team's findings (e.g., staffing analysis, training, management walk-around) and that ownership of the corrective actions ought to be assigned at the responsible division level or above. The site rep believes that, while many TA-18 management systems are working, the report validates concerns expressed in the Board's May 21st letter.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 9, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 9, 2004

Waste Operations: LANL solid waste operations (TA-54 Area G) suspended receipt of on-site waste last Wednesday when it was discovered that the total above-ground transuranic (TRU) waste inventory was about 56 % higher than expected and about 7 % higher than in the new approved safety basis, which is still to be implemented. The discovery was made when LANL started up a real-time inventory tracking system developed to ensure compliance with the new safety basis. To permit resumption, NNSA has approved a safety basis change to increase the inventory limit. NNSA continues to emphasize the importance of achieving the Area G risk reduction from the Quick-to-WIPP program. As reported last week, no LANL WIPP shipments are scheduled until Jan 2005, and the Quick-to-WIPP program is now not expected to be completed until Sep 2005. LANL does intend to take advantage of earlier shipment opportunities that may arise if there are delays at other sites.

Training: NNSA is assessing training at NNSA sites, including LANL, in response to a Board letter (7/9/03). The NNSA team has finished reviewing documentation implementing LANL nuclear facility training programs and has concluded that LANL could not demonstrate that a formal process is in place to ensure personnel meet minimum qualification requirements in the applicable DOE Order (5480.20A). NNSA has requested LANL provide a resource-loaded corrective action plan within 60 days. The assessment focused on facility-specific program descriptions and implementing documents. The review identified several systemic issues such as facility programs that are in place are expert-based rather than standards-based; LANL has not documented justification for concluding that some DOE training requirements are not applicable; Training Implementation Matrices are out-of-date; and programmatic weaknesses exist in instructor qualification, continuing training, and training and qualification for facility support personnel. The findings resonate with previous LANL assessments (site rep weekly 1/23/04). NNSA is starting performance-based assessments this month. Sufficient data appears available now to identify priority training improvements that could enhance safety.

Vital Safety Systems (VSS): LANL Audits and Assessments recently reported their findings from evaluating operation and maintenance of about one-third of the VSS at LANL, distributed among 8 LANL nuclear facilities. They found that an institutional plan to implement relevant requirements in the DOE Facility Safety order (O 420.1A) was not submitted to NNSA, as required; many VSS have inaccurate drawings; about half the corrective actions from previous assessments (e.g., 00-2 Phase IIs) are overdue, on average by hundreds of days; and lack of budget and low priority resulted in the VSS program not meeting expectations. LANL is walking down VSS and redlining drawings. LANL is also preparing an implementation plan for DOE O 420.1A as a result of a Board letter (1/27/04). If it is resource-loaded, this plan could provide a framework for addressing these important issues.

Weapons Engineering Tritium Facility (WETF): Many of the findings during the recent NNSA Operational Readiness Review (ORR) at WETF are institutional in nature (site rep weekly 5/7/04). About one-third of the post-start findings involve training and are related to issues discussed above. Several other findings involve configuration management, the master equipment list, system design descriptions, and the maintenance implementation plan, related to VSS issues discussed above. The most challenging pre-start finding involves the adequacy of information for verifying and validating operability of safety systems based on functional and acceptance testing requirements in applicable codes and standards. This finding is probably also applicable to other LANL nuclear facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 16, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 16, 2004

Matthews, Jordan, and Burns were here this week reviewing operations.

Management: On Friday, the LANL Director suspended all but essential operations as a result of recent significant safety and security events. By memo, he directed all LANL organizations to perform a point-to-point risk assessment of day-to-day activities. The duration of the suspension will depend on the formalities, complexities, and risks identified in each part of the lab's operations. LANL expects a staggered restart with some low-risk operations resuming quickly. The NNSA Site Office is working with LANL senior management to assess the risk group-by-group of resuming operations.

Integrated Safety Management (ISM): On Wednesday, a student received an eye injury while working under supervision with a laser in a non-nuclear facility. The event is under investigation and has implications for work control both in nuclear and non-nuclear facilities (site rep weekly 5/7/04). LANL has begun to take institutional actions in response to this event.

Training: LANL senior management is engaged in addressing the institutional training issues discussed last week and expects to have an integrated, resource-loaded corrective action plan by the end of August, as requested by the NNSA Site Office. LANL resources committed to training dropped by half between 1994 and 2002 and have since remained steady; training had become largely decentralized, expert-based, and poorly documented. Management attention is now increasing. While it will take time to fix, improving training may provide an opportunity to increase management and worker awareness and compliance with policies and procedures involving safety and security.

Critical Experiments Facility (TA-18): Last Friday, TA-18 curtailed all operations involving nuclear material on critical assemblies. They also curtailed nearly all operations involving accountable quantities of nuclear material, including movements. Operations involving Technical Safety Requirement (TSR) surveillance, the early material move, and sub-accountable quantities (e.g., check-sources) were allowed to continue under increased management attention (e.g., direct division-level management supervision of early move activities).

LANL management directed the curtailment after TA-18 discovered a TSR violation. Specifically, a material custodian failed to verify the material-at-risk (MAR) inventory in a shed before introducing a powder-form item. Furthermore, the safety basis prohibits powder-form MAR being stored in the shed; TA-18 did not comply with all the actions required in an LCO for when MAR is exceeded. LANL review of the event identified weaknesses in operator training and qualification related to compliance with admin controls and in operations management when key personnel are absent.

The admin controls violated here have no apparent direct role in preventing the reactivity excursion accident discussed in the Board's May 21st letter; however, the weaknesses found reinforce the concerns raised by the Board – the high reliance on admin controls, on operator training and qualification, and on operations management in preventing an accident with significant off-site consequences. The site rep understands that LANL will address the Board's issues in the resumption plan being prepared.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 23, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 23, 2004

LANL Shutdown: All but essential operations are shutdown, as discussed last week. The Secretary of Energy has stated that federal concurrence will be necessary if LANL is to resume operations with significant safety implications. LANL management has categorized all work activities into one of three risk levels: (1) little or acceptable risk (e.g., office work); (2) mid-range risk (e.g., light lab, routine industrial activities); and (3) higher risk (e.g., higher hazard non-nuclear and nuclear activities, certain security activities). LANL has a resumption plan in place for the level 1 activities, which emphasizes personnel behavior and compliance, human error prevention, and management interaction and accountability. Criteria for level 2 and 3 resumptions are still in development. Resumptions will be staggered and occur at the group or activity level.

During the last few years, LANL has improved several processes that will likely have a key role in verification and resumption of higher risk activities, including: (1) In late 2002, LANL issued updated procedures for formal readiness verifications before startups and restarts; subsequently, LANL facilities have trained and begun using these procedures, improving the rigor of verifications. (2) In late 2003, LANL issued a single integrated work control process. Since then, LANL has persisted in further improving work planning, hazard analysis, and work control; recent safety-related work control deficiencies appear due more to compliance issues than process issues. (3) LANL has started to make improvements in the management walk-around (MWA) process; an effectively implemented MWA process could enhance communicating expectations and improving behavior.

Four areas with nuclear safety implications that warrant close scrutiny during this stand-down are: (1) continuing safety system surveillance and maintenance (e.g., TSRs); (2) continuing essential waste operations, particularly managing the current TA-55 backlog and resuming activities that are part of the Quick-to-WIPP Program; (3) completing cleanup and recovery of the room in TA-55 contaminated with Pu-238 last August; and (4) moving forward on nuclear material stabilization activities (e.g., Board Recommendation 94-1 actions). At this time, NNSA and LANL appear to be applying appropriate emphasis to all these areas – except possibly the TA-55 contaminated room cleanup, which was lagging even before the stand-down (site rep weekly 6/11/04).

Plutonium Facility (TA-55): TA-55 reported on Monday that a TSR monthly surveillance of the fire suppression control valve lineup had been inadvertently performed two days late. TA-55 operations management is improving the sequencing of this maintenance to prevent recurrence.

Transportation: The currently approved safety basis for the Chemistry and Metallurgy Research Building (CMR) assumes no high explosive (HE) shipments and limited diesel fuel shipments occur near CMR. In May, CMR declared a potentially inadequate safety analysis (PISA) because there were no controls in place to protect these assumptions and, in fact, such shipments were occurring. On June 3rd, LANL proposed to NNSA both interim admin controls for restricting and rerouting such shipments and longer-term safety basis changes. NNSA action is pending. This week, LANL reported that 15 HE shipments had been made near CMR between mid-May and end of June, indicating that both CMR and the on-site transportation group had not implemented the interim controls. LANL is taking action to implement these controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 30, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 30, 2004

Burnfield was on site this week observing an NNSA assessment of LANL internal dosimetry. The assessment results are forthcoming (site rep weekly 5/21/04).

LANL Resumption Status: LANL resumed some low risk (i.e., level 1) activities this week. All but essential operations were suspended on July 16th. NNSA and LANL management are updating the risk characterization criteria and placing risk characterization under change control. They are converging but have not finalized verification and resumption criteria for moderate and higher risk activities (levels 2 and 3). LANL has established the COMPASS project to guide the resumption effort by using project management tools to monitor indicators and prioritize distribution of institutional resources. COMPASS stands for Culture and Operations Model Plan and Surety System. The work force is moving from a 9-day/80-hr to 5-day/40-hr schedule to support resumption. LANL management is the restart authority for activities not involving classified removable electronic media.

The NNSA Site Office continues to work on an oversight management plan, which will define federal activities required for concurrence in resumption of higher risk activities. The Site Office plans to request outside federal assistance, as appropriate, after the plan is developed. Currently, the Site Office and DOE Office of Assessment (DOE-OA) are coordinating an upcoming DOE-OA team visit that will focus on select LANL activities, including TA-55.

Plutonium Facility (TA-55): TA-55 has instituted daily inspection tours by cognizant personnel of facility spaces and programmatic equipment. Discrepancies are being repaired when found (e.g. some glove change-outs). TA-55 has also reviewed their work orders and is completing essential periodic maintenance using the integrated work control process. There is programmatic pressure to ship plutonium oxide for mixed oxide (MOX) fuel lead test assemblies. TA-55 expects shortly to resume preparing hazard analyses to support finishing cleanup of the Pu-238 contaminated room.

Chemistry and Metallurgy Research Building (CMR): CMR has issued a standing order to continue essential facility activities, which include surveillance rounds, fire alarm and suppression tests, transient combustible inspection, material-at-risk admin controls, ventilation inspection, etc. Cognizant programmatic personnel began inspections of lab spaces this week. CMR has some solid samples in process that appear stable and some liquid residues (tens of liters) that need disposition.

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF has continued to receive low-activity waste streams and resumed some low-level treatment processes and controlled discharges this week. The facility has questioned resumption of transuranic (TRU) waste treatment, which could impact TA-55. The TRU waste streams are stored, neutralized, clarified, precipitated, and cemented via a batch process. The clarifier (CL-1) is a rectangular carbon steel tank that has been in continuous service for longer than 2 decades. Facility management has identified external pitting and corrosion at the bottom of CL-1 along two sides converging at a corner. Internal condition is unknown. CL-1 may have experienced accelerated corrosion in the last year due to higher salt concentration and the collection of moisture during cooling of waste. The room has a berm to contain any leakage, but cleaning up after a leak would be radiologically challenging. Repair or replacement also looks difficult. More time to address the issue could be gained by expediting replacement of the leaking caustic waste receipt tank, but progress on replacement has been glacial (site rep weekly 10/24/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 6, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 6, 2004

Andrews and Nichols were here this week reviewing resumption and safety basis activities.

LANL Resumption Status: LANL has divided resumption of low-risk activities (i.e., risk level 1) into 348 projects and resumed about 80 % of these as of Friday morning; several nuclear facilities have not yet achieved level 1 resumption. Both the NNSA Los Alamos Site Office (LASO) oversight plan and the LANL resumption plan have been approved and issued. The LANL plan defines the process for verifying functional and organizational readiness to resume moderate and high hazard work (risk levels 2 and 3). The plan is based on LANL institutional startup/restart requirements, which were derived from DOE Order 425.1, *Startup and Restart of Nuclear Facilities*.

LANL plans to verify moderate risk activities through management self-assessments (MSAs); higher risk activities will receive both MSAs and lab readiness assessments (RAs). The assessments will focus on management competence, personnel behavior; work control (ISM); training and qualification; security; environmental protection; facilities/infrastructure; and authorization basis. LANL management will separately assess personnel culture by one-on-one interviews. To ensure quality and consistency, line management and assessment teams are receiving RA-focused training, and LASO and the LANL Performance Surety Division (which has institutional responsibility for the RA process) will have representatives on each assessment team. LANL infrastructure (e.g., health and safety, on-site transportation, waste operations) have priority for early assessments.

Before each assessment, its scope will be reviewed by the LANL Resumption Review Board (RRB) and approved by the LANL Director and LASO. After each assessment, the RRB will review and concur in the team's findings, as well as line management's resource-loaded corrective action plan and recommendation to proceed. A new Issue Review Board, which has authority to prioritize lab-wide resources, will increase focus on managing the findings and issues. The LASO Manager will separately concur in resumption based on input from his representatives on each assessment team and on the RRB. The LANL Director is the approval authority for resumption for non-CREM activities.

Plutonium Facility (TA-55): This week, LASO approved a safety analysis for packaging 39 seal-welded cans of Pu-oxide into 8 DOT Type B shipping containers and approved with DOE-EH concurrence an exemption from DOE readiness verification requirements (DOE O 425.1) for this activity. Four or five cans will be slipped into an inner shipping container that will then be rotated to vertical, mechanically capped, and slipped into an outer over-pack. The operation will be done using a reader-worker approach under senior supervisory watch. It requires 2 lifts of the loaded inner container, which will be controlled as critical lifts. NNSA pursued the exemption to support the MOX Program schedule and was not specific on which DOE O 425.1 requirements were waived. This type of operation would normally have had an MSA and an RA. LANL is performing a formal, rigorous verification. NNSA and LANL senior managers are walking down the process. LANL may load the first shipping container next Thursday.

Authorization Basis (AB): There is no discernible improvement in the AB preparation/review process since the staff's review last Oct or as a result of the Board's May 27th letter. LASO attributes previous issues to LANL lack of compliance with existing requirements and to insufficient federal resources. Better balanced priorities and a planned, resource-loaded, well-executed improvement effort are needed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 13, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 13, 2004

LANL Resumption Status: LANL has divided resumption of low-risk activities into 348 projects and resumed about 97 % of these as of Friday morning. LANL has also trained more than 800 people on the readiness verification process for resuming moderate and higher hazard activities (i.e., risk levels 2 and 3). The resumption process is as described last week. NNSA Site Office (LASO) oversight is being temporarily supplemented by a team from the DOE Office of Assessment (DOE-OA).

On Thursday, the LANL Resumption Review Board (RRB) began reviewing startup notification reports (SNRs), which define the activities to review for resumption, the review team constitution, the criteria, and the approach. At this time, LANL anticipates 33 management self assessments (MSAs) on level 2 and 3 activities, followed by 12 readiness assessments (RAs) of level 3 activities. As an example, TA-55 and CMR plan to present their first SNR to the RRB on Monday. It will cover nuclear infrastructure, including cleanup of the room contaminated with Pu-238 last August – a high priority. This will be followed by two other MSAs covering nuclear programs and Pu-238 operations.

A few of the challenges are (1) the large scope of some of these assessments, which will require smart sampling; (2) ensuring that all LANL moderate and higher hazard activities are captured within an appropriate assessment; and (3) achieving proper balance between timeliness to resuming national security programs and sufficient assurance that the safety/security/compliance objectives have been met. For example, each nuclear activity will be assessed against 53 individual criteria; a facility like TA-55 will have dozens of processes/activities that need to be assessed against each of these criterion, resulting in thousands of point-assessments. NNSA and LANL management are emphasizing assessments that are both thorough and timely. There is awareness that an overly-extended shutdown of nuclear operations can create new safety issues, such as those experienced at some DOE sites in the early 1990s, and that many issues found will need to be addressed on a timely basis after resumption.

Plutonium Facility: This week, LANL continued their accelerated preparations for loading shipping containers with seal-welded cans of plutonium oxide to support the MOX program. LANL has divided the operation into two parts: (1) loading/staging the shipping containers and (2) moving shipping containers to the transport. Readiness verification of the first part has been rigorous and will likely complete today after a final demonstration. There is a question on the safety-class pedigree of the seal-welded cans to withstand the full fire. These are STD-3013 inner cans of the ARIES design. Loading operations may begin early next week, pending resolution of the few remaining open items.

Authorization Basis (AB): Annual updates of nuclear facility ABs have rarely occurred here, and neither LANL nor LASO maintains a complete list of AB documents (site rep weekly 4/23/04). To rectify this, the LANL resumption plan includes a requirement that nuclear facilities have an approved authorization agreement (AA) in place prior to resuming level 3 activities. The AA will include a list of the documents that constitute the AB. Three months ago, LANL proposed to LASO a procedure that could streamline the process of preparing and updating AAs. The site rep understands that this procedure is still waiting action because of confusion on hazard categorization (HC) for some nuclear facilities (e.g., whether the Radioactive Liquid Waste Treatment Facility is now HC-2 or HC-3). Prompt LASO action on both the AA procedure and facility hazard categorization would be beneficial to support resumption activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 20, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 20, 2004

The Board and a staff team were on site this week reviewing resumption planning and status.

LANL Resumption Status: LANL has resumed all the low-risk activities (i.e., level 1). At this time, it's anticipated that there will be 43 management self-assessments (MSAs) for the moderate and higher risk activities (i.e., levels 2 and 3, respectively), followed by 16 to 18 LANL readiness assessments (RAs) for level 3's. As of Friday morning, the LANL Resumption Review Board (RRB) had approved 30 of 43 MSA startup notification reports, which establish the scope, team composition, and sampling for the MSAs. All LANL nuclear operations are now cleared to begin their MSAs, except LANSCE and TA-18. MSAs are expected to take 2 to 4 weeks. Several have started.

Plutonium Facility: This week, LANL began the accelerated campaign to load shipping containers with seal-welded cans of plutonium oxide to support the MOX program. LANL has reviewed analysis, testing, and manufacturing of the cans and confirmed that they meet safety-class pedigree.

Recommendations 94-1/00-1: LANL nuclear material stabilization activities are being impacted by the stand-down and warrant priority upon resumption to reduce risk. Also, NNSA rejected last week the LANL proposed process hazard analysis for the large vessel cleanout operation (site rep weekly 2/6/09). Impacts of both on the Secretary's proposed implementation plan are to be determined. Separately, the DOE Inspector General Office reported this week on its review of LANL stabilization activities and observed that multi-year delays have occurred because: the program was underfunded between 1997 and 2002; LANL has not made full use of project management tools; and NNSA has not incorporated incentives into the LANL contract. NNSA has generally agreed with the findings.

Authorization Basis (AB): In a letter and staff report (5/27/04), the Board observed that NNSA has not enforced the annual update requirements for LANL safety bases; that several nuclear facilities (e.g., TA-55) are operating now with safety bases that are 5 to 8 years old; that NNSA has established that the lack of current AB container requirements contributed to the TA-55 Pu-238 uptakes last August; and that more balanced priorities would be beneficial in improving facility safety bases.

NNSA and LANL acknowledge that there are significant quality and timeliness issues in the AB preparation and review process, resulting in a large backlog. To address quality, LANL intends to: establish a centralized safety basis management office; develop a new safety analyst qual standard; assign a safety analyst to the NNSA Site Office (LASO) for cross-training; pilot improved training for safety analysts; develop safety basis training for line managers; and set up an Unreviewed Safety Question (USQ) back-look program. The last is in response to a recent LASO observation that there has been a series of USQs declared as negative that should have been positive.

To address timeliness, LASO has initiated a high-priority risk management plan; arranged for support from 3 qualified headquarters analysts; hired 2 new but not yet qualified analysts and requested 4 more slots; issued a support contract to cover some document reviews; supported the LANL safety basis academy's development. LASO and LANL have also teamed to review and rework the TA-55 AB upgrade proposed in April 2002. This effort has been impacted by the stand-down and by support required for the accelerated MOX shipment; LANL believes it might be completed in October. Overall, the NNSA and LANL efforts are expected to be responsive to the Board letter.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 27, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 27, 2004

Tom Burns reported for duty here this week as a DNFSB site representative. Also this week, a site rep discussed observations on resumption activities with the University of California ES&H Panel, which was here conducting an on-site review.

LANL Resumption Status: LANL is progressing on overall resumption and will likely resume some moderate-risk non-nuclear operations early next week. Nearly all nuclear facilities have begun their management self-assessments (MSAs); LANSCE and TA-18 are conducting MSAs for their moderate risk activities (i.e., Level 2) and have yet to propose the MSA scope for their higher risk activities (i.e., Level 3). Most nuclear MSAs are expected to be done in mid-September and to be followed by a multi-week lab readiness assessment (LRA). Schedules are fluid. Barring major pre-start findings, nuclear facilities might individually resume operations in October or November, 3 to 4 months after the stand-down.

Integrated Safety Management (ISM): An apparent breakdown in the LANL interim work control process played a major role in the LANL management decision to stand down the lab (site rep weekly 7/16/04); therefore, the site reps have been closely monitoring MSA evaluations of ISM. Preliminary indications are that the interim work control process is incompletely or inconsistently implemented in many nuclear and non-nuclear facilities. Furthermore, while an improvement over that of a year ago, the interim process still needs work; LANL recognized this before the stand-down, but anticipated improvements have been delayed by the stand-down. The assessments should provide useful feedback in improving the process. Identifying and fully implementing these improvements warrants priority.

Authorization Basis (AB): Last week, LANL revised its operations requirements (LIR 300-00-03.1) to improve the process for updating and maintaining Authorization Agreements (AAs). The AAs list the AB documents that support NNSA's decision to allow a nuclear or high hazard facility to operate. Most LANL AAs are out-of-date and are expected to be updated as part of the resumption process.

Critical Experiments Facility (TA-18): In a letter dated 5/21/04, the Board identified issues that need to be addressed near-term to ensure continued safe operations in TA-18. Most of these issues focus on ensuring adequate controls for critical experiments with plutonium metal. On July 9th, TA-18 curtailed nearly all operations including those for critical assemblies (site rep weekly 7/16/04).

Last week, LANL provided the status: LANL has tentatively identified 11 engineered controls and 16 administrative controls that play a role in managing the risk of reactivity insertion accidents for the 5 critical assemblies; LANL intends to recommend to NNSA discontinuing implementation of the principal engineered control - the in-core temperature monitoring system (ITMS); LANL will review both the risks and controls as part of the Level 3 resumption process during the next few months. These actions are expected to be responsive to the Board's 5/21/04 letter. NNSA still needs to respond next month to a reporting requirement on ITMS from an earlier Board letter (7/9/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 3, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 3, 2004

Management: The New Mexico Environmental Department (NMED) has released for 30-day public comment a proposed, legally-enforceable consent order for LANL cleanup by 2015. The consent order arose from 2 years of negotiations, stemming from an NMED draft order issued in May 2002.

Resumption Status: LANL has binned the remaining resumption effort into 26 moderate-risk (Level-2) and 15 higher-risk (Level-3) activities. LANL has resumed none of the Level-3 and three of the Level-2 activities, mainly classified computing and some non-nuclear light-lab work. The Resumption Review Board (RRB) is now reviewing management self-assessment (MSA) reports for 7 more Level-2 activities, including limited TA-18 work. Schedule pressure on the MSA teams and the RRB is intense. That said, MSA teams are generally doing a thorough job identifying issues, and RRB feedback has led some MSA teams to revise and improve their reports. LANL expects the first four Level-3 readiness assessments (RAs) for nuclear activities to begin the week of 9/13 and to cover the tritium facility (WETF), radiography facility, waste and characterization operations, and packaging and transportation. Schedules are still fluid, and several RA schedules appear overly optimistic.

Integrated Safety Management: LANL continues to actively refine its draft integrated work management procedure, intended to replace the current interim process, and expects to issue the final procedure and begin training and implementation within a couple of months, at earliest. Most resumption MSAs should be done by then. LANL anticipates that these MSAs will confirm that the work control issues are due more to incomplete implementation than to the process; however, the final procedure and its implementation can be adjusted if the MSA results indicate otherwise.

Los Alamos Neutron Science Center (LANSCE): LANSCE has released its investigation report on two workers who discovered last March that they were working in an uncontrolled, unrecognized high radiation area and exited (site rep weekly 3/12/04). The report identifies inadequate implementation of work control as the root cause, and that lessons learned from similar previous events had not been incorporated. LANL is pursuing corrective actions, including evaluating engineered controls.

NNSA and LANL are considering re-categorizing LANSCE Lujan Center and 1L Target activities from Level-3 to Level-2, which would reduce the institutional scrutiny before resumption. While LANSCE management has been responsive to safety issues, LANSCE appears to also have many of the same risk indicators as other activities ranked at Level-3 (e.g., multiple tenants and customers; recent accidents or near-misses; and full range of hazards- radiological, electrical, high explosive). LANSCE would be the only LANL nuclear facility that does not receive the institutional scrutiny from a Level 3 RA. It is not intuitively obvious that this re-categorization is appropriate.

Plutonium Facility (TA-55): On Wednesday, TA-55 dropped an empty Type B shipping container while removing it from a shipping cradle. Operators properly stopped work. Damage was superficial. The operators had just dry-run placement of the container horizontally onto the cradle as part of a verification to support the MOX program (site rep weekly 8/13/04). The forklift operator then lifted the container and may have inadvertently released it when he intended instead to rotate it to vertical, due possibly to equipment failure. TA-55 found that the collocation of certain forklift controls increased potential for dropping the container (i.e., positive USQ) and is modifying the forklift.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 10, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 10, 2004

LANL Resumption Status: Schedules for the 9 or 10 LANL readiness assessments (LRAs) for higher-risk nuclear activities (Level 3) are slipping, and none are likely to begin next week. Schedules are still fluid; LANL is starting to plan on LRAs being about 3 weeks long, which is more consistent with the management self assessment (MSA) durations. LANL has resumed 6 of the 26 groups of moderate-risk activities (i.e., Level 2) and is close to authorizing resumption of another 6 (i.e., total 46%). This includes light labs, shops, classified computing, and limited TA-18 operations.

Quality of the Level 2 MSAs completed to date appears mixed; several MSA reports have been revised several times based on feedback from the LANL Resumption Review Board. Lessons learned are being fed back to the on-going MSAs to improve quality. The sequence of resumption is also starting to receive consideration; specifically, certain security, waste management, and health and safety operations need to start before most programmatic work. Developing and implementing a well-conceived sequence of resumption continues to warrant attention.

At this time, LANL has a plan but does not yet appear to have in place a systematic approach for managing and analyzing the issues being reported. Based on cursory analysis, many of these issues involve work control, training and qualification, and equipment and infrastructure. NNSA and LANL are acting on preliminary indicators of problems. For example, NNSA has directed LANL to establish an unreviewed safety question (USQ) review team because of USQ process issues. LANL has also proposed conducting a special cross-cutting LRA focused on the facility-program interface and the accountability for equipment maintenance because of the issues already identified in these areas.

Critical Experiments Facility (TA-18): TA-18 has completed a Level 2 MSA and been authorized to resume activities involving security category III/IV material. To address pre-start findings, TA-18 needs to receive the LANL Director's approval of a restart plan for resolving issues on control of material-at-risk. These issues led LANL to shutdown TA-18 operations on July 9th (site rep weekly 7/16/04). Once that plan is approved and closure verified, TA-18 intends to start packaging security category III/IV material for the first shipments to the Nevada Test Site Device Assembly Facility.

Los Alamos Neutron Science Center (LANSCE): The 1L Target operations and Lujan Center user programs at the LANSCE facility have been re-categorized from Level 3 to Level 2 (site rep weekly, 9/3/2004). Re-categorization of the 1L Target operations appears appropriate given the rigor of the redundant engineered controls that prevent the dominant accident scenario (i.e., tungsten target oxidation and dispersal). LANL documentation supporting re-categorization of the Lujan Center programs indicates that the hazards are commensurate with the Level 2 criteria; however, recent work control issues may warrant further institutional scrutiny.

Authorization Basis: LANL has proposed and NNSA has accepted an updated LANL nuclear facility list. Principal changes are: the TA-21 tritium facility (TSFF) has been down-rated to Hazard Category 3 (HC-3) for 3 years in preparation for D&D; the TA-50 Radioactive Liquid Waste Treatment Facility has been elevated to HC-2, although the supporting analysis has not been submitted; and the TA-54 Decontamination and Volume Reduction System (DVRS) has been elevated to a HC-2 for a 5 month period that starts when DVRS is released to perform TRU waste visual examination and repackaging.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 17, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 17, 2004

Nichols was here this week supplementing site rep coverage of LANL resumption activities.

Integrated Safety Management (ISM): LANL has released its investigation report on the laser-induced eye injury that occurred in a non-nuclear facility (site rep weekly 7/16/2004). The report identifies the primary causes as inadequate work control and non-compliance with safety requirements. The uncertainty introduced by the behavior aspect of this event contributed to LANL management's decision to shutdown operations, along with recognition that such behavior negates the integrated work management improvements that LANL has invested heavily in making during the last year (site rep weeklies 5/7/04, 10/17/03, 9/12/03). LANL is committed to implementing an improved work control process within the next few months.

LANL Resumption Status: Schedules for the 9 LANL readiness reviews (LRRs) for higher-risk nuclear activities (Level-3) continue to slip. TA-55 and CMR will likely be the first nuclear facilities to have LRRs. These will likely begin the week of Sep 27th and could be quickly followed by LRRs for the other nuclear operations. LANL's most optimistic estimate for finishing all 19 nuclear and non-nuclear LRRs is end of October and assumes the following: the management self-assessments (MSAs) were high quality; the MSAs identified a manageable list of issues; few new issues are found by the LRRs; and some LRR assessment activities can be paralleled.

Overall, most Level 3 MSAs have slipped because of evolving expectations and the experience-level of many MSA team members. Most MSA reports are expected into the Resumption Review Board (RRB) during the next two weeks. This will probably saturate the RRB, which continues to be the primary means by which LANL is ensuring uniform quality and consistency in the reviews. The shortest pathway to safe resumption requires the RRB to continue to thoroughly review these MSA reports and ensure that the MSAs were comprehensive in scope and identification of issues.

Because of mounting schedule pressure, NNSA and LANL intend to reduce the scope of the LRRs. Compared to the MSAs, the LRRs will focus more on management competency, personnel behavior, and integrated safety management. Breakdowns in these specific areas directly led to the decision to shutdown. The LRRs will also focus on validating issues identified during the MSAs. However, counter to standard practice for readiness assessments, the LRRs will not explore MSA conclusions in areas that the MSA teams deemed acceptable unless an LRR team discovers a new issue, which the LRR team will then pursue. NNSA and LANL are accepting the reduced scope because of the robust RRB review process and because of a degree of independence introduced into the MSA process by involvement of federal and LANL Performance Surety Division staff.

Training: NNSA is assessing training at its sites in response to a Board letter (7/9/03). NNSA intends to conduct its performance-based assessment at LANL as part of the LRRs. LANL is also preparing a corrective action plan in response to an earlier NNSA assessment (site rep weeklies 7/9/04, 7/16/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 24, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: T. D. Burns Jr. and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 24, 2004

Nichols was here this week supplementing site rep coverage of LANL resumption activities.

Resumption Status: Next week, LANL may start 3 or 4 of the 9 lab readiness reviews (LRRs) anticipated for nuclear facilities. The Resumption Review Board (RRB) has approved starting the Weapons Engineering Tritium Facility LRR and is reviewing the 3 management self-assessment reports for the CMR Building and the Plutonium Facility, including Pu-238 operations. LANL also revised its resumption plan this week. The changes include simplifying the classification-of-findings criteria. A condition of imminent danger, a violation of requirement indicating unknown or unanalyzed risk, or a newly discovered issue that would have stopped work before the stand-down are considered as potential pre-start findings. Such findings are required to have compensatory measures in place, and these are required to be verified by senior management before acceptance by the RRB.

Integrated Safety Management (ISM): LANL has issued an updated integrated work management process and plans to implement it by June 2005. Activities with new, deficient, or missing work control documents are expected to implement it by end of November. This action is responsive to the Board's letter of 9/13/04, which suggested LANL fully and aggressively pursue an improved process in parallel with resumption. Some changes in the process include increased emphasis on worker involvement and management accountability, particularly at the group level; a simplified, site-wide grading logic similar to that used for the resumption process; a job hazard analysis tool/database; clear subject matter expert involvement; and required training. As part of the resumption review process, NNSA has also informally observed that LANL facilities with some maturity in formality of operations have tended to demonstrate effective integrated work management. This week, LANL issued a Conduct of Operations Manual and institutional requirements long in development. LANL has committed to have demonstrable compliance with the applicable DOE order by September 2005.

Authorization Basis (AB): LANL has reported certification issues with sealed sources in two radiological facilities and has placed the sources in robust safes as a compensatory measure. LANL raised the issues after NNSA inquiries into the certification at another facility, including questions on source size, age, and compliance with current requirements (ANSI N43.6-1997). In April 2000, NNSA and LANL credited sealed-source certification and down-rated these facilities to radiological status. Considering the inventory without a certification exemption, these facilities appear equivalent to nuclear facilities (e.g., Hazard Category 2 or 3), and valid certification would appear equivalent to a safety-class or safety-significant requirement. Overall, NNSA and LANL may be well-served to periodically reevaluate the surveillances performed and the bases for acceptance of LANL radiological facilities.

Unreviewed Safety Questions (USQ): NNSA and LANL have identified issues with the LANL USQ process (site rep weekly 8/20/04). The DOE performance assurance office (DOE-OA) has also asserted that the applicable DOE guide is not compliant with the Nuclear Safety Rule (10 CFR 830) and consequently the LANL USQ process is not consistent with the Rule. LANL is revising its USQ process to address these issues. This is being done expeditiously to support the resumption process.

Tritium Facilities: As part of resumption reviews, LANL has identified AB compliance issues in TA-21 (TSFF). LANL intends to reduce TSFF's inventory and propose downgrading it to radiological status. TSFF will likely continue neutron tube target loading until after WETF starts up those operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 1, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 1, 2004

Keilers was at DNFSB-Headquarters in Washington D.C. Monday through Wednesday. Jordan and Burnfield were on-site this week augmenting site-rep coverage of resumption activities.

Resumption Status: Field work for the Weapons Engineering Tritium Facility (WETF) lab readiness review (LRR) is complete. The LANL Resumption Review Board (RRB) is currently reviewing management self-assessment (MSA) reports for TA-55 (including Pu-238 operations), CMR, LANSCE, the TA-8-23 radiography facility, the site services contractor (KSL), and moderate-risk TA-50 and TA-54 waste operations (including WIPP drum characterization). Pending RRB concurrence, LRRs for some of these activities – particularly TA-55 and CMR – may begin next week.

Critical Experiments Facility (TA-18): LANL has reported closure of the material-at-risk issues that led to the pause in most TA-18 operations on July 9th (site rep weekly, 7/16/2004). TA-18 has resumed handling Security Category III/IV material and is conducting an MSA for operations involving critical experiments and Security Category I/II materials. On Wednesday, TA-18 made its first shipment of nuclear material to the Nevada Test Site Device Assembly Facility. This shipment consisted of Category III/IV material. The evolution was not without incident. While entering TA-18, the transport truck severed a low-hanging low-voltage overhead line that was not installed to the proper height. Future shipments will require spotters to ensure adequate clearance until the facility raises the low-hanging lines. Lessons-learned will be promulgated lab-wide.

Authorization Basis (AB): On Monday, NNSA approved the revised LANL unreviewed safety question (USQ) procedure submitted last week (site rep weekly, 9/24/04). As a condition-of-approval, NNSA has imposed an interim policy on verification of safety control implementation. Under this interim policy either a readiness assessment or an operational readiness review shall be performed when a new documented safety analysis (DSA), technical safety requirement (TSR), or USQ does any of the following: identifies new safety-related equipment; significantly affects facility procedures; requires new training or retraining of facility personnel; or significantly modifies a facility's design baseline. Only the NNSA Site Office Manager has the authority to waive these requirements. Implementation details for the interim policy are to be developed.

TA-54 Waste Operations: During a recent resumption-related walk-down, NNSA observed approximately 1,000 Type 7A 85-gallon over-pack drums stacked three-high in one dome. The most recent AB for transuranic waste storage, approved in November 2003, precludes stacking these drums three-high because they are not certified for that drop height. The previous AB allowed stacking up to five-high. Confusion over the new AB's implementation schedule led the facility to conclude that the new AB requirements would not take effect until November 2004. Potential operational impacts due to space constraints and safety concerns with quickly moving a large number of drums have led to questions about the practicality of meeting the November deadline for un-stacking. LANL and NNSA are working on a path forward, which will likely involve accepting the current configuration in the short-term and committing to un-stacking the drums as a priority as space becomes available.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 8, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 8, 2004

Quirk was on-site this week augmenting site rep coverage of resumption activities.

Resumption Status: The LANL Director has approved resuming 46 % of the moderate and higher risk activities, including the first full nuclear facility resumptions: specifically for the Weapons Engineering Tritium Facility (WETF), the Los Alamos Neutron Science Center (LANSCE), and TA-50 and TA-54 moderate-risk waste operations. These facilities are using startup checklists or plans, mostly focused on formal work control and release, system alignments and operability, and collocated worker awareness.

The LANL Resumption Review Board (RRB) has concurred with 42 % of the higher risk activities moving forward into the lab readiness review (LRR) stage, including 4 of 9 groups of nuclear activities (i.e., 44 %). This week, the RRB concurred with LRRs commencing for the Plutonium Facility (TA-55) – except Pu-238 activities, the Chemistry and Metallurgy Research Building (CMR), and the Radiography Facility (TA-08). The TA-55/CMR LRRs will start next week, and LANL expects them to take 2 weeks. The RRB is currently reviewing the management self-assessment reports for Pu-238 operations, TA-18 critical experiments, and the site services contractor (KSL).

Overall, the quality of the management self-assessments (MSAs) being conducted is still mixed but improving. Nuclear facilities are self-identifying numerous issues and are generally firm in grading themselves; they are typically judging that one-fifth or more of the lines of inquiry are not satisfied. Some are reluctant to identify findings as pre-starts. The RRB continues to be the key element to ensure consistent quality of these reviews, including consistent identification of pre-starts.

Waste Operations: The TA-50/54 operations that are resuming include installation of the visual examination and repackaging glove-box in the Decontamination and Volume Reduction System (DVRS), as well as non-intrusive characterization of transuranic waste. To address pre-starts, these facilities have had supervisors trained on the new work control process and have tightened up both document control and work authorization. These resumptions are key steps toward LANL finishing the Quick-to-WIPP Program by October 2005, their current goal, and significantly reducing TA-54 risks.

Los Alamos Neutron Science Center (LANSCE): The majority of LANSCE pre-starts were related to work control. Although independently derived, LANSCE compensatory measures parallel those of TA-50/54. On a longer-term scale, LANSCE plans to resume user operations in the Lujan Center after addressing conduct-of-operations findings via a resource-loaded plan (site rep weekly 9/10/04).

Issue Management: LANL has established a senior-management-level Institutional Assurance Board (IAB). It will manage the laboratory's contractor assurance system including institutional issues, corrective actions and improvements, assessment of risk, assignment of priorities, and evaluation of effectiveness. All other lab assurance elements are subordinate to the IAB.

Authorization Basis: Because of the extent of issues already recognized with the LANL unreviewed safety question (USQ) process, LANL has proposed and NNSA has approved deleting review of USQ implementation from the scope of the nuclear facility LRRs. Instead, all LRR reports will contain an *a priori* institutional pre-start finding on USQ implementation and will reference the site-wide compensatory measures and the corrective actions currently being pursued to address these issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 15, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 15, 2004

Winters was on-site this week augmenting site rep coverage of resumption activities.

Management: LANL is splitting the Operations Associate Directorate into two parts: (1) Technical Services, and (2) Security and Facility Operations. The former will include functions such as performance surety, facility engineering, project management, health and safety, radiation protection, environmental protection, and operational efficiency. The latter will include waste operations, emergency response, security, facility support, and site planning.

Resumption Status: Lab readiness reviews (LRRs) for plutonium operations (TA-55, CMR) continue. The LRRs for Pu-238 operations and TA-18 critical experiments will likely begin next week, followed shortly by the LRR for TA-50/54 higher-risk waste operations. This week, one LRR team for a non-nuclear operation concluded that the prior management self-assessment (MSA) was incomplete, in spite of a well-prepared MSA report. The LRR team terminated their review and started a technical assist. While this is disappointing, it does demonstrate a level of integrity in the review process.

Critical Experiment Facility (TA-18): NNSA is overdue in submitting its report to the Board demonstrating that the safety-class in-core temperature monitoring system (ITMS) will operate reliably and effectively to prevent critical assemblies from overheating (ref: Board letter 7/9/03). NNSA and LANL are not pursuing ITMS because Security Category I/II operations at TA-18 will terminate in less than a year. This affects 4 of the 5 assemblies. The fifth, SHEBA, uses low-enriched uranium solution fuel and may continue to operate. SHEBA will require resolution of the ITMS-related issues, which could be as simple as a well-administered limit on plutonium sample size.

NNSA is delaying its response because of uncertainty in what critical operations are really required during the next year. The recent TA-18 MSA report describes operations management and resource issues. It appears to validate still-open concerns that were raised in a more recent Board letter (5/21/04). Because of these open issues, TA-18 appears to have limited near-term ability to support an expected broad range of complex operations including: early-move of Security Category I/II material, transition to Nevada Test Site, and critical assembly operations for experiments and training.

Radioactive Liquid Waste Treatment Facility (RLWTF): NNSA has approved mission need (i.e., Critical Decision 0) for an approximately \$60M RLWTF upgrade project. Since 1963, the RLWTF has collected, treated, and disposed of LANL radioactive and other liquid wastes. While construction has started on a new pump house and influent storage facility for the low-level streams, the larger upgrade project is key to ensuring continued reliability of the remainder of the facility, including those portions that process the higher-level transuranic waste streams from TA-55.

The upgraded facility is expected to be categorized as Hazard Category 2 (HC-2). The NNSA approval memo specifies that the preliminary functional classification of safety systems, the bounding accident scenarios, and other aspects of the facility safety basis be submitted and accepted by the NNSA Site Office authorization basis team as part of conceptual design and prior to LANL requesting approval of Critical Decision 1.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 22, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 22, 2004

R. Kasdorf was on-site this week augmenting site rep coverage of resumption activities.

Resumption Status: The LANL Director has approved resuming 56 % of the moderate and higher risk activity groups (i.e., 20 of 24 moderate risk; 4 of 19 higher risk; 24 of 43 overall). LANL is mid-way through reviewing and resuming nuclear operations. The Weapons Engineering Tritium Facility (WETF) has been approved to resume but still needs to resolve Operational Readiness Review (ORR) pre-starting findings from last Spring before starting up some activities. Certain TA-50/54 waste operations and the Los Alamos Neutron Science Center (LANSCE) were categorized as moderate risk and have also been approved to resume. The laboratory readiness reviews (LRR) for TA-55/CMR programs and infrastructure have completed field work. Reports should be completed next week. Two other LRRs began this week, covering TA-55 Pu-238 operations and TA-18 critical experiments and security category I/II operations. The Resumption Review Board (RRB) has accepted the management self-assessment (MSA) report for the TA-8 radiography facility, and its LRR should also begin soon. The RRB is reviewing MSA reports for both the site services contractor and TA-50/54 higher-risk waste operations. On-site transportation is still in the MSA phase.

Essential Activities: When the LANL Director suspended operations on July 16th, certain operations were deemed essential (i.e., Level-0) and were allowed to continue. The list of essential operations has been under change control since then. The LANL Resumption Plan requires that these activities be risk-categorized and reviewed in accordance with the plan. Because of programmatic pressure, LANL organizations are increasingly proposing certain activities be categorized as essential so that they can begin these activities before the resumption review and approval process is finished.

Two instances have occurred recently that may indicate less than adequate control of essential activities. In one case, an activity in a nuclear facility was deemed essential; however, the follow-on MSA identified pre-start findings – indicating a condition exists that is inconsistent with safe and secure operation. In the second case, a nuclear facility was preparing to recommend an activity as essential with the errant understanding that this designation would remove the activity from the scope of the on-going LRR. NNSA and LANL are increasing scrutiny of essential activities and have re-emphasized that no activity can proceed, essential or otherwise, until pre-start findings are resolved and that essential activities are not outside the scope of the resumption review process.

Issue Management: So far, the LANL resumption process has done a credible job of identifying both facility and institutional safety issues via the bottoms-up resumption review processes. However, actually realizing safety improvements from the stand-down investment will be fundamentally dependent on the laboratory's ability to manage the identified issues– i.e., systematically analyze the issues to develop achievable and effective corrective actions, prioritize these corrective actions in an integrated manner with other laboratory imperatives, and formally track the corrective actions to closure. Unfortunately, the laboratory's issue management processes remain ill-defined and incapable of substantively influencing institutional priorities. Expedited improvements appear warranted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 29, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 29, 2004

Resumption Status: LANL readiness review (LRR) teams submitted their reports to the Resumption Review Board this week for plutonium operations (TA-55/CMR) and will likely submit reports next week for both TA-18 security category I/II and TA-55 Pu-238 operations. An LRR has started for TA-50/54 higher-risk waste operations, and another should start next week for TA-8-23 radiography.

Plutonium Facility (TA-55): NNSA has approved an interim addendum (expires 3/30/05) to the TA-55 authorization basis (AB) to allow LANL to finish cleanup of the room contaminated with Pu-238 in August 2003. Cleanup of the room essentially stopped about 6 months ago because of AB issues. The approved addendum permits residue cans in filtered plastic bags to be transferred into either glove-boxes or 55 gal Type A drums with plastic drum liners and filters. Drum limits consider heat loading and material-at-risk. Until the residue is dispositioned, the drums will be stored on the floor in TA-55 in locations picked considering seismic and fire risks. The drums will also undergo periodic radiological and visual inspection. Over-packing will start after the LANL Director approves TA-55 resumption and is expected to take 2 months. In a generic sense, the interim AB addendum approach appears useful for facilitating focused, short-duration risk reduction activities lab-wide. As for TA-55, disposition of the corroding cans of Pu-238 residue and cleanup of this room would constitute a significant risk reduction, as discussed in the Board's letter of 9/13/04.

Critical Experiments Facility (TA-18): LANL has reported that TA-18 moved security category I material prior to fully resolving pre-start findings and to receiving resumption approval. Management misinterpreted the Director's approval of certain essential (i.e., Level 0) operations as having precedence over addressing pre-starts identified later that apply to security category I/II operations. The LRR team has also found that TA-18 has not fully adhered to their combustible loading surveillance procedure, including missing review steps by management and by a fire protection engineer. LANL reports that combustible load limits were not exceeded. Overall, while LANL is making some improvements, TA-18 operational staffing, management, and control do not currently appear commensurate with the risks of the proposed full range of operations (site rep weekly 10/15/04).

Radioactive Liquid Waste Treatment Facility (RLWTF): NNSA and LANL will likely need to decide within a few weeks on whether to allow the Plutonium Facility (TA-55) to transfer transuranic (TRU) liquid waste to the RLWTF and to allow the RLWTF to resume treating such waste. The site reps understand that TA-55 may begin to resume operations soon and that TA-55 caustic liquid storage is now nearly full. While the TA-55 tanks are contained within glove-boxes, it is poor practice to store this waste for an extended period. Low storage capacity may impact resuming both national security and nuclear material stabilization missions (i.e., Board Recommendations 94-1/00-1).

While TA-55 may have issues, the ability of the RLWTF to safely receive and treat TRU waste is questionable. For example, the caustic waste receipt tank leaked last year and has since been used only for direct transfer to avoid challenging the known leak-site (site rep weeklies 9/19/03, 10/24/03). Efforts to order a replacement tank have stalled during the last year due to still-unresolved authorization basis and engineering equivalence questions. Another example is a clarifier tank that has visible corrosion and un-characterized mechanical integrity (site rep weekly 7/30/04). It appears to be a potential single-point-failure for processing. If the clarifier leaked, the leakage would be contained within the building but would be radiologically challenging to clean up. TA-55 and RLWTF are developing a joint path forward to propose to the Resumption Review Board.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 5, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 5, 2004

Winters was on-site this week participating in the Quick-to-WIPP discussions. Martin, Nichols, and Von Holle were on site attending a high explosives conference.

Resumption Status: The Director has approved resumption of plutonium operations (TA-55/CMR, except Pu-238), as well as health, safety, and radiological services. TA-55 and CMR are planning a deliberate inventory and resumption effort during the next month. Overall, the LANL Director has approved resuming 63 % of the moderate and higher risk activity groups.

Quick-to-WIPP Program: This program involves shipping ~2,000 transuranic waste drums with the highest, most dispersable inventory to WIPP. LANL shipments to WIPP were suspended in Oct 2003. Characterization activities briefly resumed in July but were then suspended on July 16th as part of the LANL-wide stand-down. NNSA, LANL, DOE-EM, Carlsbad Field Office (CBFO), and the CBFO contractor met this week to determine a path-forward to quickly resuming compliant characterization and shipping, and progress was made. Key goals are to resume non-intrusive characterization shortly, achieve a full characterization rate of 60 drums per week by January, resume shipments no later than March, and complete the program in October. Continued close cooperation between multiple agencies is required for success. Since these actions address the highest-consequence nuclear accident postulated at LANL, it appears prudent for NNSA and LANL to consider categorizing Quick-to-WIPP activities as essential (i.e., Level 0). This hazard will likely persist after October 2005, since LANL anticipates a new round of recovering high-activity waste from underground. NNSA and LANL would be well-served to consider accepting higher short-term risks (e.g., seismic) to expedite efficiently shipping this waste to WIPP and thereby achieve timely overall risk reduction.

Tritium Facilities: The path forward for the one remaining TA-21 nuclear facility (TSFF) is ambiguous. LANL identified authorization basis (AB) issues during resumption reviews last month and indicated that an essential activity would be proposed near-term to remove 3 waste drums containing more than 90% of the facility's source term (site rep weekly, 9/24/04). This would reduce the radioactive inventory below the hazard category 3 threshold and thereby permit downgrading TSFF. To date, this has not happened; in fact, NNSA continues to press LANL to control the facility to a 1986 AB and to fully implement a new AB. It appears more appropriate to expedite removing the source and downgrading TSFF, based on this facility being slated for near-term closure.

Essential Activities: NNSA and LANL continue to have inadequate control of activities deemed essential (i.e., Level 0 – see site rep weekly 10/22/04). These activities are allowed to proceed prior to completion of the resumption review process and originally were just those necessary to keep facilities safe, stable, and secure. LANL is increasingly proposing other activities as essential based on programmatic drivers (e.g., Pu-238 fueled clads completion, TA-18 emergency response training). In at least one case, NNSA and LANL organizations bypassed the LANL Director approval and NNSA Site Manager concurrence for a proposed essential activity, which was subsequently suspended pending proper approval. NNSA and LANL have also not designated key risk-reduction activities as essential, such as TSFF source reduction, the Quick-to-WIPP Program, and Pu-238 room decon in TA-55. LANL has prepared guidance on re-designation but has not disseminated the guidance. More rigor in managing essential activities is necessary ensure the integrity of the resumption process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 12, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 12, 2004

Critical Experiments Facility (TA-18): LANL has completed the laboratory readiness review (LRR) of N-Division activities involving Category I/II materials, which includes TA-18 critical assemblies. This review identified significant operational issues including: lack of adequate staffing; weak level of knowledge of TSR requirements; superficial implementation of the integrated work management process; poor conduct of operations as evidenced by procedural compliance problems; and an overall low state of morale. These issues are similar to those previously identified in a May 2004 management self-assessment at TA-18 (site rep weekly 7/2/04).

N-Division management is scheduled to present their proposed path forward for addressing these issues to the Resumption Review Board next week. Previous presentations to LASO management indicated that N-Division is pursuing some positive initiatives to improve their operational capabilities. However, given the depth and breadth of the issues, it is uncertain whether necessary improvements can be achieved prior to the September 2005 deadline for cessation of Category I/II activities at TA-18.

Plutonium Facility (TA-55): The LANL Director has approved resumption of TA-55 Pu-238 operations. The LRR review of these operations identified several areas needing improvement, including: more timely repair of degraded equipment and revision of incorrect procedures; more rigorous management of on-the-job training; and more deliberate confirmation of readiness. On the positive side, the LRR team found that management effectively communicates information to workers and workers understand the importance of procedural compliance.

Deliberate resumption of Pu-238 operations is a key step for LANL to clean-up Room 201B, which was contaminated with Pu-238 in August 2003. LANL also intends to quickly finish 23 encapsulated fueled-clads to support the NASA New Horizons mission to Pluto. DOE has stated that the 23 fueled-clads are sufficient and that the new scrap recovery line is not needed to support the New Horizons mission (ref: Board letter 8/1/03). Given the progress of the MSA/LRR resumption process, an essential activity re-designation for the fueled-clad activity is no longer being pursued.

Radiography Facility (TA-8-23): TA-8-23 is a 1940s era building that is used for non-destructive testing of high-explosives and nuclear components. The current safety basis for this hazard category 2 facility is a 3 year-old justification for continued operations (JCO). TA-8-23 lacks seismic, confinement, and fire suppression features; however, the dominant hazard (a natural gas line) has been removed. Several attempts to update the safety basis have been unsuccessful. In April 2004, NNSA suspended TA-8-23 operations with explosive and tritium items due to lightening protection deficiencies and safety basis confusion. Efforts to recover from this suspension were superseded by the lab-wide stand-down on July 16th, 2004.

Last week, NNSA approved an interim path forward consisting of (a) rescinding the latest proposed safety basis (submitted in June 2004), (b) resolving all resumption review pre-start findings, (c) and restricting material-at-risk to 40 g Pu-239 equivalent (limits off-site consequences to 2 rem). Additionally, LANL has committed to cease operations if a new safety basis is not approved by March 2005.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 19, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 19, 2004

Andrews, Jordan, and White were here this week reviewing LANL resumption status.

Resumption Status: The LANL Director has approved resuming 67 % of the moderate and higher risk activity groups (i.e., 21 of 24 moderate risk; 8 of 19 higher risk; 29 of 43 total). Overall, the reviews have been rigorous, and the startups are proceeding deliberately. The resumption effort has improved LANL's management self-assessment (MSA) capability, but further improvement is still warranted and is receiving attention. Systematic analysis of review findings and development of corrective action plans are both about half-done. More emphasis on standardized resolution of local issues would be beneficial (i.e., take the best ideas from around the lab to develop common solutions). Where they fit, institutional issues are being captured in the Operational Efficiency Project; however, that project does not include nuclear material management (i.e., Recommendations 94-1/00-1), lab-wide corrective actions from the TA-55 Pu-238 uptake event (8/03), or lab-wide fire protection improvements. These other areas also warrant priority. Status of some nuclear operations follows:

Radiography Operations (TA-8-23): The LANL Director approved a limited resumption this week. Operations with explosives and tritium are prohibited until a lab readiness assessment confirms lightning protection and related issues are corrected. Operations involving greater than 40 g Pu equivalent are prohibited until safety basis deficiencies are addressed.

Critical Experiments Facility (TA-18): This week, TA-18 received "essential-activity" approval to begin packaging security category I/II material for shipment to Nevada Test Site and to TA-55. TA-18 has developed a plan to address the issues reported last week. While the plan appears promising, it would be prudent if performance metrics were established and if more progress were made before certain operations resumed, including critical experiments. NNSA and LANL are on this course.

Solid Waste Operations: The lab readiness review (LRR) team has completed field work and their report is imminent. Non-intrusive characterization activities to support the Quick-to-WIPP program should start in mid-December. The TRUPACT loading facility (TA-54 RANT) has seismic issues involving the roof-to-wall connections that need to be reconciled prior to resumption.

Plutonium Operations: TA-55 and CMR have approval to resume, including Pu-238 operations. They will complete material inventory next week. As a result of clean-out operations, TRU caustic solution storage is nearly full (~95 %), increasing pressure to discharge to TA-50 (RLWTF).

Liquid Waste Operations: After 14 months, RLWTF has received approval to procure but not yet install a replacement for the leaking caustic waste receipt tank. The delay is largely due to confusion on what constitutes a major modification requiring a preliminary documented safety analysis (PDSA). Because of material condition, RLWTF capability to receive and treat TRU waste is questionable.

Tritium Operations: WETF has resumed operations. TSFF will propose de-inventory as an essential activity, which could positively accelerate its re-categorization as a radiological facility.

Other Operations: LANSCE is proceeding toward deliberate resumption of Lujan Center operations. Activities involving the site support contractor (KSL) and on-site transportation are still under review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 26, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: T. D. Burns Jr. and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 26, 2004

Resumption Status: Most LANL nuclear operations have resumed to some degree, based on LANL verifying that pre-start findings are either corrected or have an adequate compensatory measure in place. On October 1st, LANL proposed and NNSA approved removing Unreviewed Safety Question (USQ) issues from the scope of the lab readiness review process based on the fact that problems with the USQ process were already well-known and corrective actions were underway (site rep weekly 10/8/04). As part of the corrective actions, NNSA directed LANL to establish a USQ review team that would mentor facilities and review new and existing USQs for adequacy. LANL and NNSA agreed to capture these issues as institutional pre-start findings for all nuclear facilities and cite the on-going corrective actions in the Operational Efficiency project as accepted compensatory measures.

In a November 19th memo, NNSA indicated that the current protracted schedule and uncertain funding for on-going corrective actions would place the USQ issue back as a local pre-start finding for every nuclear facility. While timely resolution of the USQ-related corrective actions is important, this new course does not reflect a balanced perspective of the relative safety risks, such as those discussed in the Board's letter of September 13th. NNSA and LANL need to carefully balance safety priorities and reach a sound consensus on the immediate actions, if any, for operating nuclear facilities and on the schedule and funding for the longer term corrective actions.

Critical Experiments Facility (TA-18): Two recent occurrences are indicative of TA-18 safety basis issues. First, LANL has self-identified that the CASA 3 combustible limits in the NNSA-approved Basis of Interim Operation (BIO) and the Technical Safety Requirements (TSRs) are five times higher than assumed in the safety analysis, as documented in a BIO appendix. LANL has taken action to reduce the CASA 3 combustible inventory to below the more conservative limit. Second, LANL has missed implementation plan milestones for transition to use of approved robust storage containers for non-metallic material-at-risk. LANL has also missed the annual in-service-inspection of such containers. LANL is placing these materials into TA-55 standard cans as a compensatory measure.

Conduct of Engineering: NNSA and LANL are overdue in responding to the Board's January 27th letter on LANL lack of implementation of DOE Order 420.1A, *Facility Safety*. LANL has included implementation within the scope of the institutional Operational Efficiency Project, which has increased its visibility but also delayed development of a resource-loaded schedule. LANL has made some progress within the last year, such as updating the engineering standards manual, a requirements document (site rep weekly 3/12/04). The NNSA Site Office has also issued a review procedure covering the interface between design and safety basis through conceptual design. However, LANL still lacks an institutionally-consistent systems engineering program, as well as institutional engineering procedures that standardizes practices to meet requirements. These would support safety system design and evaluation for both existing and new facilities (e.g., the CMR Replacement).

Also, for more than a year, NNSA and LANL have iterated on what constitutes a major modification that requires a preliminary documented safety analysis (PDSA). This has impacted several projects with safety implications, such as the RLWTF tank replacement discussed last week (14 month delay) and the CMR large vessel clean-out installation (11 month delay, site rep weekly 2/6/04). The latter will likely impact DOE meeting commitments to the Board under Recommendations 94-1/00-1.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 3, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 3, 2004

Hadjian and Jones were here this week observing LANL preparations to update the LANL-wide probabilistic seismic hazard analysis.

Plutonium Facility (TA-55): NNSA and LANL need to aggressively renew their efforts to address the findings from the Pu-238 Type B investigation of nearly a year ago (site rep weekly 12/19/03). This effort has stalled during the stand-down and is just now resuming. Some areas needing attention are: developing comprehensive requirements for safe stabilization, storage, and disposition of Pu-238 materials; completing the LANL comprehensive nuclear materials packaging and storage plan; and completing the preliminary LANL-wide inventory assessment of radioactive material outside an approved containment boundary. Regarding the Pu-238 contaminated room, LANL is preparing procedures to over-pack residues and complete the cleanup; however, starting up additional pyrolysis capability and disposing of stabilized residues may be delayed for up to a year, depending on how NNSA and LANL perceive the relative risks (e.g., seismic and building leak path issues vs extended storage of Pu-238 contaminated cheese-cloth and other residues in drums and glove-boxes in PF-4).

Critical Experiments Facility (TA-18): On Thursday, the LANL members of the Resumption Review Board (RRB) approved a division-level recommendation to restart TA-18 subject to completion and line management validation of all corrective actions for pre-start findings. The LASO member of the RRB withheld his concurrence with this approval recommendation. Though generally satisfied with the resumption plan, he indicated that he would withhold concurrence until (a) LASO has independently verified that the proposed corrective actions are both completed and effective, and (b) LANL has submitted and LASO has accepted a resource-loaded plan outlining proposed future TA-18 activities. Regarding those activities, the potential accident consequences of two of the five proposed critical experiments for FY05 have not been analyzed and may result in the need for Safety Class controls. An expedited effort to evaluate the potential accident consequences of the proposed critical experiments and demonstrate the adequacy of the associated controls is warranted and will be necessary to address the concerns raised in the Board's May 21, 2004 letter.

Emergency Exercise: On Wednesday starting at 6:45 AM, NNSA conducted a no-notice exercise that activated the LANL Emergency Operations Center (EOC). The scenario involved a transportation accident with injuries and a chemically reactive, toxic plume release. The NNSA team tentatively concluded that incident command, and event categorization and classification were properly executed; however, most other areas need work, including EOC communications, consequence evaluation, protective action confirmation, and HAZMAT response time. Many issues seen were already known from post-Cerro Grande fire reviews or other recent exercises, but they remain unresolved.

Tritium Operations: NNSA appears to have decided to transfer the neutron tube target loading (NTTL) mission from LANL to Sandia. The LANL Weapons Engineering Tritium Facility (WETF) has been preparing to receive the mission for years and is nearly ready. NTTL operations are currently performed in the TA-21 Tritium Science & Fabrication Facility (TSFF)— a 40 year old facility with legacy contamination from previous missions and an ill-defined safety basis. The transfer decision may extend operations in TSFF by more than a year. The path forward may warrant re-consideration due to the risks associated with continuing to run TSFF and the NTTL investment already made in WETF..

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 10, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 10, 2004

Malen, Plaue, and Tontodonato were here this week reviewing nuclear material management and other activities. Burns was off-site this week.

Resumption Status: The LANL Director has approved resuming 77 % of the moderate and higher risk activity groups (i.e., 24 of 24 moderate risk; 9 of 19 higher risk; 33 of 43 total). Considering nuclear operations, the LANL Resumption Review Board (RRB) has forwarded to the Director the recommendation that TA-18 fully resume following resolution of pre-start findings; NNSA has not concurred. The TA-50/54 lab readiness review (LRR) team completed field work on intrusive waste operations about 3 weeks ago and expects to submit its report today. LRRs for the site services contractor (KSL) and for on-site transportation are still open. The TA-21 tritium facility (TSFF) has a de-inventory plan but will need management support for this as an essential activity. NNSA has formally declared that the site-wide unreviewed safety question (USQ) issues constitute an open pre-start finding for every nuclear facility; LANL and NNSA have informally agreed to not let this impact operations, based on LANL's intent to address the issues on a timely basis (site rep weekly 11/26/04).

Critical Experiments Facility (TA-18): NNSA has established its own interim senior supervisory watch over on-going TA-18 security category I/II material operations (i.e., the Early Move Project). The watch consists of 3 federal site office assistant managers. The trigger events for this action were: (a) TA-18 conducting security category I/II operations last Friday without the LANL senior supervisory watch, counter to this activity's approval conditions; and (b) a TA-18 worker in respirator and protective clothing reclining on the floor in a controlled contamination area on Wednesday, also during a security category I/II operation. A few likely underlying causes for these issues are attitude, training/level-of-knowledge, unclear management expectations, and programmatic pressure to meet Early Move milestones, which have no schedule contingency. Overall, TA-18 operational control does not appear commensurate with the risks of either current activities or full resumption.

Plutonium Facility (TA-55): LANL determined this week that a TA-55 worker may have received an elevated Pu-238 uptake in June. The potential uptake was detected via a discretionary bioassay among personnel who were working in a Pu-239 lab-room that had one elevated fixed-head weekly sample (~150 DAC-hours, Pu-238). The glove-box work station below the sampler was found to have a glove with a pin-hole leak. There were no other indicators of a release, and the other workers in the room during this period were not found to have received an elevated dose. LANL is investigating.

Nuclear Material Management: NNSA and LANL need to apply more emphasis on finishing the corrective actions from the Pu-238 Type B investigation of a year ago; as is, the priority assigned to the TA-18 Early Move Project may overwhelm other areas needing attention. Constraints on transuranic waste operations are also skewing the risk reduction strategy toward packaging and storing materials over processing or discarding. These constraints include: (a) TA-50/54 not approved to resume; (b) TA-50 RLWTF material condition, as previously reported; (c) TA-54 above-ground inventory nearly at the safety basis limit; and (d) continued delay in LANL resuming WIPP shipments. As a result, TA-55 caustic liquid waste tanks are full, and the TA-55 PF-4 basement waste inventory is approaching control limits (e.g., in some areas, drums are double-stacked). Without action, TA-55 could become "waste-logged," which has both safety and national security mission implications.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 17, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 17, 2004

Resumption Status: About a quarter of LANL moderate and higher risk activity groups have not yet been approved to resume, including waste operations and site support contractor (KSL) activities. Many remaining activities have been deemed essential and have continued in parallel with resumption reviews. The formal process has been that line management proposes activities as essential after Resumption Review Board (RRB) concurrence. Also, when resumption reviews identify an applicable pre-start finding, essential activities have stopped until adequate compensatory measures are in place.

Based on recent events, formal control of the resumption process and of essential activities is eroding – a trend that needs to be reversed. Formal closure of RRB traveler actions would be beneficial. A systematic review of the many corrective action plans now being pursued for consistency, completeness, and effectiveness would also be worthwhile (site rep weekly 11/19/04). Unless such a review is done and acted upon, LANL may return to conditions existing at the time of the stand-down.

Radioactive Liquid Waste Treatment Facility (RLWTF): The Plutonium Facility (TA-55) is nearly waste-logged, which has mission and safety implications. The LANL Director and the NNSA Site Office Manager have approved the TA-50 RLWTF receiving and processing TA-55 transuranic liquid waste next week, as an essential one-time-only activity. This has safety implications for RLWTF (site rep weekly 10/29/04). TA-50 plans to mitigate risks by keeping the liquid level in the waste receipt tank below the known leak site and by-passing a corroding clarifier tank. While this may be acceptable, the RRB has not formally reviewed and concurred in this activity as essential, nor has the NNSA Site Office extended previous authorization basis approval to use the leaking waste receipt tank.

Site Support Contractor (KSL): LANL and KSL have aggressively inserted management into the KSL integrated work control process as a compensatory measure for an approved but failed compensatory measure involving checklists and training. LANL resumption reviews have found the checklists and training are ineffective - conditions that elsewhere led to suspension of activities deemed essential. The aggressive management steps appear to be the actions that should have been taken in the first place. These steps have not been formally reviewed and concurred in by the RRB as the compensatory measure. Furthermore, the failed compensatory measure is representative of the corrective actions being pursued by other LANL organizations (e.g., checklists or procedure changes that may not really address the issue). The effectiveness of such corrective actions is suspect.

Critical Experiments Facility (TA-18): TA-18 operations are suspended until LANL proposes and NNSA approves a credible, integrated, and resource-loaded plan for FY-05 activities. LANL intends to propose and have the plan in place by January 15th. Meanwhile, NNSA is requiring that the Site Office Assistant Manager for Operations concur in the plan-of-the-day and in the work release of all higher risk activities and all moderate risk activities involving nuclear material, except for emergency actions. NNSA intends to release only those activities required to ensure safety and security.

Chemistry and Metallurgy Research Building (CMR): On Wednesday, Wing 5 evacuated and LANL Hazmat team responded after potentially shock-sensitive dried perchlorates were found on a bottle in a storage cabinet. The NNSA facility rep and CMR raised concerns about the first response plan. After more information became available, Hazmat entered and successfully removed the hazard.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 24, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 24, 2004

Plutonium Facility (TA-55): Both the current (1996) and proposed (2002) authorization bases for TA-55 specify a safety-class passive ventilation confinement strategy, which is the subject of Board Recommendation 04-2. In April, the staff questioned the TA-55 analyses. Last Friday, LANL submitted to NNSA a re-analysis and concluded that the building leak path factor is 10 to 50 times higher than previously asserted and that neither passive nor active confinement modes can mitigate the potential off-site consequences to below evaluation guidelines. On Monday, NNSA directed LANL to immediately analyze other controls that can reduce the predicted consequences and to propose compensatory measures by January 7th. Timely resolution is needed to support continued operation.

There are number of other issues with the TA-55 1996-era authorization basis besides leak path factor, such as incomplete functional classification and no requirements for in-service inspections, storage container pedigree, and material-at-risk limits. Because of LANL resumption efforts and leak path factor re-analysis, the safety basis upgrade has been delayed another 6 to 8 months. A totally integrated upgrade with full resolution of leak path factor issues is preferred, but if not achievable in short order, a partial upgrade including compensatory measures for known weaknesses may be a better option.

Solid Waste Operations (TA-54): Risk reduction in TA-54 relies on shipping transuranic waste to WIPP, which stopped in October 2003 and is now not expected to resume until May 2005. The new safety basis, which is still being implemented, includes a material-at-risk (MAR) limit that is about 5.5 % above current inventory. It also requires that LANL ship the roughly 2,000 drums with the highest, most-dispersible inventory to WIPP by September 2004, which was missed. This is the Quick-to-WIPP Program. Earlier this year, LANL proposed October 2005 as the new Quick-to-WIPP completion target.

NNSA now believes that LANL and the WIPP contractor can realistically achieve only about 40 % of the intended WIPP shipments in FY-05 (i.e., 40 instead of 96 shipments). Furthermore, since May 2002 when the Quick-to-WIPP initiative began, TA-54 has received more waste, and the number of drums meeting the Quick-to-WIPP criteria has increased by about 800 to about 2,800 drums.

Further receipts by TA-54 will likely be constrained by the MAR limit until shipment rate improves. This has mission and safety impacts. NNSA is considering (1) allowing TA-55 to ship roughly 300 drums next month to TA-54 so that TA-55 can continue to operate, and then (2) constraining TA-55 direct-discard efforts that are underway in response to the Board's Recommendations 94-1/00-1 so that TA-54 can continue to operate. This course could adversely impact commitments made by the Secretary of Energy to the Board. The risk trade-offs of such a decision have not been evaluated.

High Efficiency Particulate Air (HEPA) Filters: TA-55 secured programmatic work in one room for about a week while investigating elevated fixed-head air samples. The likely cause is an infrequently used glove-box vent HEPA filter. On Monday, a transfer of transuranic caustic liquid waste from TA-55 to TA-50 RLWTF was stopped when a continuous air monitor alarmed in the TA-50 treatment room. No contamination was found, and nasal swipes of the four people in the room were negative. The alarm was attributed to a tank vent HEPA filter, which is being replaced. TA-50 and TA-55 are taking independent actions to address these issues. LANL would be well-served to pursue unified institutional action using guidance in the DOE nuclear air cleaning handbook (DOE-HDBK-1169-2003).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 31, 2004

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 31, 2004

LANL was closed this week, providing an opportunity for reflection on the year.

On July 16th, the LANL Director suspended all but essential operations, and LANL began a self-examination and resumption process. As of last week, the Director had approved resuming 77 % of the moderate and higher risk activity groups. Nuclear operations not yet approved to resume include TA-50/54 waste operations, the site services contractor, on-site transportation, TA-18 critical experiments facility, and TA-21 tritium facility (TSFF). LANL reports they have examined more than 3,000 operations and identified more than 2,000 safety-related corrective actions from this process.

A major challenge for LANL in the coming year will be to ensure that these corrective actions are consistent, complete, sustainable, and effective. Over the years, LANL has often identified valid issues, prepared corrective action plans that appeared credible, and then failed to execute. A recent example is the stalled TA-55 Type B corrective action plan, which began early this year. LANL studies of corrective actions from reportable occurrences illustrate the problem: most corrective actions are reactive, one-time, facility-specific responses; most target procedural changes or equivalent; few eliminate or substitute for the hazard; few specify new or modified engineered barriers; and few opt for institutional solutions. The level of sustained management commitment required to reverse this trend should not be underestimated.

Worker safety and work control issues contributed to the decision to suspend operations. In September, LANL issued a Conduct of Operations Manual, an updated integrated work management process, and a schedule to implement the latter by June 2005. In October, LANL corrected span-of-control problems by splitting the Operations Directorate and increased visibility and independence of key institutional functions including engineering, fire protection, and emergency management; however, NNSA and LANL continue to be reactive on emergent safety issues, such as TA-18's operational issues during the last year.

While the resumption reviews provided a shot-in-time perspective, the conditions that led to suspension could recur unless NNSA and LANL improve their assessment processes – including improving management's timely and accurate awareness of emergent operational issues. LANL assessment processes are not robust. The LANL Director has stated that he suspended operations because of a pattern of near misses in safety and security that created a fundamental lack of confidence in the lab's ability to conduct work without a major mishap. At the time of suspension, NNSA had an effective operational oversight process, but its effectiveness has sharply eroded due to resumption demands on staffing and to shifts in assignments and responsibilities. Most NNSA Site Office reporting of emergent safety issues now is informal and not amenable to systematic review. NNSA is currently attempting to rebuild its oversight processes, as well as verify corrective action closures. This will likely require increased staffing.

Regarding safety bases, within the last 2 weeks, NNSA has approved a LANL strategy for determining which proposed activities constitute a major modification requiring a Preliminary Documented Safety Analysis (PDSA). NNSA also clarified that interim safety bases employing safe harbor methodologies may be appropriate when the unreviewed safety question process is insufficient but a PDSA would be excessive. These are the most positive steps regarding safety bases taken this year. In most other areas, the safety basis issues discussed in the Board's letter of May 27th persist. Little progress is apparent on centralizing the safety basis function, improving quality of NNSA and LANL work, capturing a verified list of the safety bases, and updating aging safety bases (e.g., for plutonium operations – TA-55, CMR).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 7, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 7, 2005

Resumption Status: The LANL Director approved resumption for on-site transportation this week. The lab readiness review report covering TA-50/54 intrusive waste operations, a critical area, is still not submitted; field work was done about 7 weeks ago.

LANL has made progress on systematically analyzing several thousand institutional issues reported during the resumption reviews; this has led to identifying common problems that potentially require institutional action. However, LANL continues to struggle to formulate complete and effective corrective actions for both institutional and local (i.e., facility-specific) issues. Progress has been particularly slow on local corrective actions, and no mechanism is in place to ensure their integration and consistent quality. NNSA is justifiably concerned with the lab's slow apparent progress. LANL senior management is meeting weekly with NNSA to provide status and has committed to completing the resumption, including corrective action plans, by January 31st.

Federal Oversight: The NNSA Site Office has submitted to headquarters a facility representative (FR) staffing analysis. It indicates a need to increase the number of field-deployed FRs from 11 to 20, as well as permanently assign 2 team leaders and possibly 1 manager (these slots are temporarily filled now by 3 FRs). This would strengthen federal oversight of nuclear and other higher-hazard operations; introduce federal oversight into several dozen radiological and moderate hazard facilities that currently receive no regular federal oversight and little contractor independent oversight; and facilitate verification of closure of facility-specific corrective actions identified from resumption reviews. It does not include additional subject matter experts that may be needed to followup on LANL institutional corrective actions.

Integrated Safety Management (ISM): This week, the TA-50 Radioactive Liquid Waste Treatment Facility had an operator who was sprayed with treated waste water, and the TA-48 Radiochemistry Laboratory (RC-1) had a 17-year-old student who was nearly splattered by low-level tritium and xylene when a small vial shattered. The student was trained but was working alone. Radcon personnel responded but were not informed before entry of the operations in the room or of the presence of a chemical hazard; the emphasis was radiological, similar to the TA-55 toxic vapor event (site rep weekly 1/16/04). While both events had little direct safety consequence, NNSA and LANL reviews have found lessons that could improve implementation of the new integrated work management process.

Authorization Basis (AB): LANL is evaluating several recent instances of inadequate safety analyses or safety basis implementation including: (1) the leak path factor for the Plutonium Facility (TA-55) appears non-conservative, raising questions on the effectiveness of approved controls (site rep weekly 12/24/04); (2) the LANL Policy Office rescinded and then restored 30 lab performance requirements (LPRs) after it was determined that they are referenced in several nuclear facility safety bases; this is an example of institutional-level changes unwittingly affecting nuclear operations without analysis of the possible impact; (3) the TA-18 safety basis credits radiographers as being certified or qualified without defining the terms; this follows on confusion about TA-18 combustible loading inspections (site rep weekly 11/26/04); (4) questions have been raised about triple-stacking of transuranic waste drums in TA-54 and the height of conveyors used in non-destructive characterization of waste drums.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 14, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 14, 2005

Management: LANL has committed to resuming all operations by January 31st; a few operations are likely to remain to be resumed. In particular, LANL now expects to pursue a DARHT hydrotest in March as an essential activity. LANL is also under intense pressure to complete the TA-18 Early Move Project by September. Increased resources and emphasis on these activities may decrease both federal and contractor attention and oversight of nuclear operations.

Plutonium Facility (TA-55): TA-55 appears to be under increasing operational stress as a result of vault space limitations, waste-pathway constraints, the expected influx from TA-18 to support the Early Move Project, the current 1996-era inadequate safety basis, and now the emergent leak path factor issue (site rep weekly 12/24/04). The situation will be aggravated if, in the interest of time, TA-18 ships material to TA-55 in packaging that does not meet TA-55 packaging standards.

Last Friday, LANL proposed and NNSA approved a set of interim compensatory measures to address the leak path factor issue and directed LANL to aggressively begin identifying potential solutions using a cost-benefit approach. The risks associated with continued operation, however, need to be better understood. The approved compensatory measures focus on mitigating the consequences of a Pu-238 lab room fire, which was the single accident that LANL evaluated. While this addressed one accident scenario, it did not address other known scenarios with potentially significant consequences (e.g., basement waste fire, vault fire). Consequently, the approved controls are probably necessary but may be insufficient to address the full spectrum of potential accidents that could occur in TA-55.

NNSA and LANL have options that could aggressively reduce those risks. For example, the poorly containerized Pu-238 combustible residues in the room that was contaminated in August 2003 may now constitute a more significant risk than NNSA and LANL previously recognized; in fact, they may dominate the risk among main-floor operations. Deliberately but expeditiously cleaning up this room, packaging the residues, and pyrolyzing them would reduce risk. On the current course, starting up additional pyrolysis capability and disposing of these residues could be a year away (site rep weekly 12/3/04). Similarly, TA-55 is nearly waste-logged (site rep weeklies 12/17/04, 12/24/04). Addressing the obstacles to TA-55 transferring waste, including resuming WIPP shipments from TA-54, would also reduce risk.

Finally, TA-55 continues to operate under a safety basis that has been increasingly shown to be outdated. The safety basis support for TA-18 Early Move and for TA-55 resuming pyrolysis operations will compete for resources required to fully update the TA-55 safety basis. It may be advisable for NNSA and LANL to consider a partial update, together with an interim safety basis that specifically addresses the leak path factor issue.

Readiness Assessments: LANL needs to improve its management self-assessment (MSA) process. The lab readiness assessment (LRA) of TA-54 Area G safety basis implementation started and prematurely stopped this week, indicating a weak MSA; preliminary estimates are that it will be several more months before this safety basis is implemented and verified. An LRA for the Radiography Facility (TA-8-23) was completed this week, but the findings indicate another weak MSA.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 21, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 21, 2005

Winters was on site this week to discuss LANL-WIPP interaction.

Resumption Status: This week, the LANL Director presented to LANL his assessment of status: operational safety, security, and compliance have improved as a result of the resumption effort; they are now satisfactory; and they will continue to improve as a result of initiatives such as the Operational Efficiency Project and a new effort focused on behavior-based safety. The NNSA Site Office view is that LANL deserves credit for a largely successful resumption effort, completed in 6 months, that identified thousands of issues; however, it remains to be seen whether LANL can succeed at evaluating the issues systematically and at implementing consistent and effective longer-term corrective actions. Currently, LANL is running behind earlier expectations on both institutional and local corrective actions. NNSA is pursuing federal staff augmentation to improve federal oversight of these activities.

The site reps observe that LANL could increase its chances for success by following up on improvements to the LANL corrective action program suggested a year ago by an assist team from the Institute for Nuclear Power Operations (INPO); LANL could also establish an institutional body to ensure a consistent level of quality in the corrective actions. LANL is considering such initiatives.

Waste Operations: The Quick-to-WIPP program is intended to expeditiously ship the roughly 2,000 highest activity drums at LANL to WIPP and thereby reduce the risks associated with the highest consequence accident postulated at LANL in approved safety analyses; it would also provide much needed operating margin for both TA-54 Area G waste operations and the TA-55 Plutonium Facility.

LANL's last shipment to WIPP was in October 2003. Drum characterization resumed this month. LANL now expects to resume shipping drums in April 2005 and to complete Quick-to-WIPP in June 2006 – 21 months later than originally planned. There are a number of near-term actions needed for success, including: (a) complete and verify implementation of the Area G safety basis, which addresses the small to moderate risk accidents; (b) complete Operational Readiness Reviews and startup of the DVRS glovebox line; (c) install additional non-destructive examination capability; (d) establish a 2nd TRUPACT loading station. This effort has gone poorly since, at least, the LANL stand-down (7/16/04); the latest indicators are from the lab readiness assessment on safety basis implementation that terminated last week and the TA-50/54 resumption review report issued on January 10th. That said, the level of commitment seems to be increasing among DOE-EM (CBFO), NNSA, and LANL.

Authorization Basis (AB): LANL is pursuing the downgrade of two current nuclear facilities– the TA-8-23 Radiography Facility and the TA-21 Tritium Science and Fabrication Facility– to radiological status. This initiative is commendable from an overall risk-reduction perspective given that the age and condition of these facilities are less-than-ideal for continued long-term nuclear operations. However, the level of oversight by both LANL and the NNSA Site Office drops precipitously for facilities that are categorized as radiological. Increased attention to radiological facilities lab-wide appears warranted to ensure that residual risks are identified and addressed appropriately (site rep weekly 9/24/04).

NNSA Oversight: The Site Office facility operations group is implementing a periodic report system that should improve formal issue management on the federal side (site rep weekly 12/31/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 28, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 28,2005

Critical Experiments Facility (TA-18): Two recent reportable occurrences illustrate the continued problems at TA-18 regarding tracking and implementation of safety basis requirements. Specifically, a safety basis implementation plan milestone to characterize uranium solutions and an in-service inspection of the safety-class flood retention structure were not performed as required. The critique of the missed in-service inspection indicated that TA-18 had been inappropriately applying a 25% grace period to these activities. LANL is investigating whether the misapplication of grace periods is a lab-wide issue.

A previous non-compliance with compensatory measures has resulted in the suspension of TA-18 programmatic activities since mid-December. LASO is authorizing, on a daily basis, limited activities at TA-18 that support compliance with safety and security requirements. Commencement of programmatic activities has been contingent upon LANL's completion of an integrated and resource loaded operations plan that outlines how LANL intends to successfully execute these activities in a safe and compliant manner.

On Friday, LANL presented their operations plan for the Early Move programmatic activities. The projected completion date significantly exceeds the NNSA target date of September 2005. LASO has indicated that this plan provides sufficient information to justify resumption of Early Move activities, but that the schedule delays are unacceptable and that LANL needs to identify options to allow the NNSA target date to be met. LANL has committed to provide a revised plan by mid-March 2005. The fate of programmatic activities beyond Early Move and the degree of continued LASO involvement in work authorization for programmatic activities were not addressed.

Vital Safety Systems: LANL is pursuing standardization of its systems engineering program, applicable to both facility and programmatic work. While the contractor's program on the facility side has been moving forward, the programmatic side has evolved little and particularly needs more emphasis on adequate detachment between the systems engineering function and programmatic drivers. The NNSA safety system oversight program here is embryonic (similar to the LANL programmatic side) but has recently started to move forward.

Chemistry and Metallurgy Research Facility Replacement Project (CMRR): The CMRR project Critical Decision 1 (CD-1) package is currently being finalized for submission to the Deputy Secretary of Energy and the Energy Systems Acquisition Advisory Board. The estimated project cost is \$850M and encompasses both the primary nuclear facility and a supporting radiological laboratory. The scope for these facilities will meet the baseline project requirements but provide no mission contingency capability. Projected facility start-up is in late 2012. Completion and submission of the CD-1 package is awaiting LASO approval of the Preliminary Hazard Analysis and concurrence with the proposed location of radiological support laboratory; both of which are expected to be received by the first week in February. Project personnel are striving to submit the CD-1 package prior to the end of February to avoid approval delays associated with senior management turnover at DOE headquarters.

Radio-chemistry Laboratory (TA-48): On January 10th, a 19 year-old student dropped a wrench and shorted two batteries while working on a small un-interruptible power supply. Energy released melted one lead terminal and discolored another. LANL review of the event determined that work controls and training were inadequate (e.g., no integrated work document) and that institutional guidance on identifying the hazard class for this type of battery work is not definitive. This is the second safety-related event at TA-48 involving students working alone during the last 2 months (site rep weekly 1/7/2005).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 4, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 4, 2005

Resumption Status: LANL has largely completed site-wide resumption: operations have been assessed; numerous issues have been identified; pre-start findings (i.e., those indicating an unanalyzed risk or condition of imminent danger) have been addressed by either a compensatory measure or permanent solution. LANL is now moving, albeit slowly, into the longer-term corrective action phase.

Waste Operations: The LANL Director has approved resumption of TA-50/54 waste operations. The startup plan includes management field walk-down of procedures, documented resolution of issues, management presence for initial operations, and safety basis training for personnel. TA-50 transuranic liquid waste operations remain on hold pending caustic receipt tank replacement, expected in May.

Critical Experiments Facility (TA-18): On Friday, the LANL Director approved TA-18 resumption but without federal concurrence. NNSA has concurred in resumption or essential status for every other moderate or higher risk activity group, nearly 4 dozen total. Furthermore, for the first time since mid-December, TA-18 conducted operations Friday without federal concurrence in the plan-of-the-day.

LANL asserts that TA-18 pre-start issues have been addressed, except for LANL submittal and NNSA acceptance of an integrated, resource-loaded plan demonstrating TA-18 can safely and securely operate and meet priorities, particularly to be below the Security Category I/II threshold in September 2005 (i.e., Early Move). This deadline appears unachievable without extreme measures; LANL is concerned that the priority assigned to Early Move is impacting continued viability of TA-18 programs including the criticality safety and experiments program. NNSA asserts that the plan is necessary to ensure that TA-18 is focused on priorities and has adequate resources, supervision, and staff to conduct more than a few complicated operations without safety, security, or compliance issues arising; such issues have recurred at TA-18 and led NNSA to direct federal concurrence in daily operations (site rep weekly 12/17/04).

The site reps understand that LANL will conduct a readiness assessment per LANL requirements before resuming critical assembly operations and that LANL will formally resolve issues raised by the Board before conducting such operations with plutonium (i.e., those with Safety Class implications).

Plutonium Facility (TA-55): LANL has proposed and NNSA has approved additional compensatory measures to address vulnerabilities identified by the recent leak path factor re-analysis (site rep weekly, 1/14/05). LANL derived the new compensatory measures from a more complete evaluation of 18 postulated accident scenarios for TA-55. This drew upon the best information available, including process hazard analyses from the safety basis upgrade proposed in April 2002 but still unapproved. In parallel, LANL is pursuing clean up of the room contaminated with Pu-238 in August 2003 and restoring capability to pyrolyze and disposition combustible Pu-238 residues.

Authorization Basis: NNSA has directed LANL to upgrade the TA-55 Technical Safety Requirements (TSRs) by consolidating the controls from the following sources: unreviewed safety questions against the currently approved 1996 safety basis; hazard analyses from the proposed 2002 safety basis upgrade; analyses from the NNSA-LANL joint review team working on the safety basis upgrade; and the recent compensatory measures related to leak path factor. This TSR upgrade would enhance safe nuclear operations in TA-55 during the interim period before the full safety basis upgrade is completed.

The site representatives were at DNFSB-Headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 18, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 18, 2005

Matthews and Jordan were here this week reviewing Integrated Safety Management.

NNSA Management: The NNSA Site Office is reassigning for 120 days about a fifth of its workforce (i.e., 20 out of 110) to increase federal oversight of safety, infrastructure, laboratory corrective actions, and security. Details are in development, but it appears that most of the increase will be in facility operations and security oversight; other local federal functions will be cut-back. Properly establishing priorities and effectively matching redeployed workforce skills to actual oversight needs appear key to the efficacy of this initiative. The Site Office Manager intends to periodically evaluate effectiveness and adjust priorities and personnel accordingly.

Integrated Safety Management (ISM): LANL is beginning a long-term effort to improve their ISM implementation by training managers and supervisors in the Dupont "Safety Training Observation Program," also called STOP™. This training focuses on skills for observing and auditing workplace safety, reinforcing safe work practices, correcting unsafe acts and conditions. Emphasis is on management commitment and individual responsibility for safety. The management and supervisor training consists of 8 modules, a trial period, and a refresher module, all expected to take about 9 months. LANL then plans to roll out corresponding training for employees.

Critical Experiments Facility (TA-18): Last Wednesday (2/9/05), LANL resumed obtaining federal concurrence with what operations are conducted at TA-18 (site rep weekly 2/4/05). This week, LANL began to shift lead responsibility for all TA-18 operations to the Nuclear Materials and Technology (NMT) Division, which previously played only a support role at TA-18 and only in the Early Move Project. NMT brings significant operational and fissile material shipping/handling expertise to this effort; however, this reassignment by itself doesn't resolve apparent resource constraints, nor does it address competing mission priorities. The latter now not only includes long-term viability of the criticality safety program, but also potential impacts to other NMT missions. LANL plans next month to submit to NNSA a resource-loaded plan for TA-18 activities.

Authorization Basis (AB): LANL senior management has approved centralizing institutional safety basis authority, as NNSA and LANL described to the Board in August 2004 (site rep weekly, 8/20/04). This authority will fall within the Performance Surety (PS) Division. The objectives include ensuring that appropriate priorities are established, that AB documents adhere to an institutional standard of quality, and that adequate training is provided to safety analysts. Under this arrangement, individual safety analysts will meet institutional standards but remain within their respective line organizations.

Tritium Facilities: TA-21 (TSFF) is resuming neutron tube target loading operations as an essential activity; LANL plans to also conduct a lab readiness review per the resumption process. Planning continues for transferring this mission to Sandia. NNSA has also accepted a LANL proposal to remove tritiated waste from TSFF under a partially implemented safety basis. A proposal to downgrade TSFF to radiological status is expected by September 2005 (site rep weeklies, 12/3/04, 1/21/05).

Training: NNSA has completed a performance-based training assessment at LANL in response to a Board letter (7/9/03) on all NNSA sites (site rep weekly 9/17/04); the report is expected in March.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 25, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 25, 2005

Management: The NNSA Source Evaluation Board for the LANL contract competition is seeking authority to extend the current contract by 180 days (i.e., to nearly the end of March 2006). This is to allow (a) the successful bidder to propose a substantially equivalent benefits package, (b) NNSA to evaluate the package, and (c) current employees appropriate time to evaluate their options. A longer transition may increase uncertainty for some; on the other hand, if this is done right, it could reduce the very real potential for momentary worker distractions and lapses affecting safety during this period.

Integrated Safety Management: LANL managers responsible for plutonium, tritium, and radiography operations are beginning a sequence of courses on human performance elements, developed by the Institute of Nuclear Power Operations (INPO). The training is compelling in communicating its key points, including that even the best make mistakes; most human-factor-related events are due to latent organizational weaknesses; error-tolerant organizations focus on learning from such events rather than assigning blame; and such organizations develop processes with defense-in-depth against human errors.

Plutonium Facility (TA-55): Based on bioassays, TA-55 has identified four individuals who may have received possible Pu-238 uptakes while working in a Pu-239 lab room last June (site rep weekly 12/10/05); some gloveboxes in the room have legacy Pu-238 contamination. The most-recent dose estimates have central tendencies below 5 Rem CEDE. The estimates tend to decrease during followup bioassays.

The sequence of events is as follows. In June 2004, one of 52 fixed-head air samples in the room was high. A glove-box glove was found with a pin-hole leak. Nine employees working in the room submitted special bioassays. In July, another employee self-identified he had been in the room and submitted a kit. In December, bioassay results became available; reasons for the delay are being addressed. Initial results for the self-identified employee were high but dropped during followup sampling. Upon further review, TA-55 identified 28 people who were in the room during the week of the high fixed head sample. Initial bioassay results from this larger set have identified three other individuals who may have received a Pu-238 uptake. Detailed radiological surveys in the room have identified a capped copper vent line that had a small amount of loose Pu-238 contamination, which may or may not be the cause; the line runs under a glove-box line and is connected to Zone 1 ventilation. Other than the delay in bioassay analyses, LANL appears to have followed their procedures in responding to this event; however, the sparse workplace indicators (e.g., no positive nasal swipes) and the apparent lack of motive force to spread contamination are curious.

Waste Operations: During the last two months, TA-54 Area G has received transuranic waste drums from TA-55 (~1,400 Ci), temporarily alleviating TA-55 solid waste inventory issues (site rep weekly 1/14/05). LANL also appears on track to resume WIPP shipments in mid-April. One constraint may be NNSA and LANL achieving timely resolution of open safety basis issues involving the seismic capacity of the TA-54 RANT facility, which is used for loading TRUPACT shipping containers.

During the next seven months, TA-55 would like to ship another roughly 4,000 Ci to TA-54 to make vault space for TA-18 Early Move and to meet Secretarial commitments to the Board under Recommendations 94-1/00-1 (i.e., for direct discard of excess material). The constraint here was the TA-54 safety basis material-at-risk limit. NNSA has approved changes to the Technical Safety Requirements (TSRs) that credit robust packaging of sealed sources from the Off-site Source Recovery Program; these changes may provide sufficient operating margin for TA-54 to receive these shipments. This risk-balancing between TA-54 and TA-55 warrants continued close monitoring through this fiscal year and beyond.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 4, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 4, 2005

Bamdad, Jones, Jordan, and March were here this week reviewing fire protection, emergency response, TA-55 safety analyses, and CMRR project status. Also this week, NNSA, LANL, and the state of New Mexico signed a legally-enforceable consent order for environmental investigation and cleanup by 2015.

Fire Protection: At all but one LANL nuclear facility (TA-18), the highest-consequence nuclear accidents that NNSA and LANL have postulated involve fire. LANL has insufficient engineering staff to address fire protection issues, resulting in slow updates to fire hazard analyses (FHAs), incomplete action on FHA recommendations, and insufficient attention to timely and systematic analyses of trends. Furthermore, NNSA and LANL still need to address fire response staffing issues identified in a baseline needs assessment completed last June. A recent LANL reorganization and new management may elevate the visibility of fire protection issues and expedite LANL fully addressing these needs.

Critical Experiments Facility (TA-18): LANL is conducting Early Move activities and is considering uranium-based critical assembly operations without a clear authorization basis; NNSA appears to have informally accepted this situation. NNSA approved a TA-18 safety basis and its implementation plan in 2002 and amended both in 2003, assuming continued operation. During the last year, TA-18 has fallen behind on implementation, most notably for the safety-class temperature-based scram. Also, as part of implementation, TA-18 grayed-out sections of the technical safety requirements (TSRs) that were not yet implemented. These sections have not been updated, confusing operators on what is actually implemented and leading them to miss requirements, such as in-service inspections. LANL has not proposed nor has NNSA formally accepted the risk of TA-18 operating under these conditions.

Plutonium Facility (TA-55): TA-55 has no credible safety-class control to address a number of low-probability, high-consequence accident scenarios, since recent LANL analyses have shown the approved strategy based on passive ventilation is ineffective. This ought to be among the top 3 high-consequence nuclear safety issues at LANL, considering TA-55's enduring mission, its inventory and processes, its significant Pu-238 hazard, and its proximity to the public (site rep weeklies 12/24/04, 1/14/05, 2/4/05).

NNSA recently approved compensatory measures to address this; however, none of the compensatory measures qualify as safety-class, they are still being implemented, and they should not be relied on by themselves for an extended period. NNSA and LANL anticipate that within a month, LANL will propose and NNSA will take action on a set of interim TSRs that will address this and other known TA-55 safety basis issues for a longer period, such as a year. NNSA committed to specifying explicit functional classification, including safety-class assignments, and to specifying a time-limit for how long the interim TSRs are in effect. NNSA and LANL have struggled for years to correct TA-55 safety basis issues, and now the high priority assigned to TA-18 Early Move may interfere with timely resolution.

Longer term, NNSA and LANL may need to consider a suite of safety-class controls including active ventilation. Based on highly sophisticated analyses, LANL concluded that passive-mode building leakage is high and can vary widely (i.e., 20 to 70%). While the trends appear correct, the model is unrealistic and highly conservative. The selections of assumptions and possible solution strategies also

show a bias against considering active ventilation. For example, only 1 of 9 analytical cases presented had active ventilation; interpretation is difficult because this case also had time-limits on external door openings. This case was the most effective of those presented at minimizing building leakage (10%).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 11, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 11,2005

Feldman and Massie were here this week to discuss status of LANL support for the Pit Disassembly and Conversion Facility. Shackelford was also here observing NNSA sponsored training on specific administrative controls, conducted per a DOE commitment under Recommendation 2002-3.

Operational Efficiency (OE) Project: LANL intends that the OE Project would address many of the institutional post-start findings identified during the resumption reviews. Within the last week, NNSA and LANL have agreed to a OE project execution plan, and LANL has prepared a baseline. The project includes 8 main elements: safety, quality assurance (QA), software QA, conduct of engineering, safety basis, operations, environmental risk management, and training. LANL management appears dedicated to executing this multi-year program, which could systematically reduce a broad spectrum of LANL safety risks and address several issues raised by the Board.

Radioactive Liquid Waste Treatment Facility (RLWTF): Last Thursday (3/3), two workers were exposed for an hour to unexpectedly high airborne contamination levels. This may have resulted in Pu uptakes since the respirators they were wearing do not offer protection commensurate with the high airborne levels found after the job was done; bioassay results are expected next week.

The workers were cleaning up paint chips in an underground vault, in preparation for the leaking caustic tank replacement. Respirators were being used based on previously seen conditions in the vault. The radiological controls technician (RCT) conducting the exit frisks found contamination levels an order of magnitude higher than he expected on their respirator cartridges and several orders of magnitude higher than previously seen on the fixed head air sample, which was the only air monitoring conducted in the space. NNSA and LANL are pursuing questions regarding this event, such as the cause for this unexpected increase in airborne contamination level, the future use of engineered controls to minimize and monitor airborne contamination, and the level of subject matter expert review for these types of jobs. Careful followup is in order, including careful radiological characterization of the vault to determine the cause and best path forward for recovery.

Plutonium Facility (TA-55): This week, work has commenced on the recovery of Room 201B, which was contaminated with Pu-238 in August 2003 (site rep weekly, 2/4/2005). The contamination resulted from a breached residue can and led to a Type B uptake event. The current clean-up phase includes over-packing approximately 180 Pu-238 residue cans into filtered plastic bags and completing room decontamination. To date, 38 of the residue cans have been bagged (20%). Execution of the next phase of recovery, which entails over-packing the bagged residue cans into Type A 55 gallon drums with an additional filtered plastic drum lining, is contingent on a laboratory readiness review and is expected to begin in mid-April. This progress is encouraging and completion of these activities will significantly reduce the risk-profile at TA-55.

Unfortunately, progress on related institutional corrective actions associated with the Type B contamination event, including site-wide nuclear material packaging improvements, has not kept pace. These initiatives continue to languish as necessary resources have been redirected to support the TA-18 early move project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 18, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 18, 2005

LANL was closed Monday and Tuesday due to snow.

Management: NNSA intends by June 30th to verify that 100% of the pre-start findings from the LANL resumption reviews are either closed or have adequate compensatory measures in place. LANL management and lab readiness assessment teams performed a similar verification prior to resumption. Given the importance of fully resolving the pre-starts, this second-check appears worthwhile. Longer-term, NNSA intends to also confirm by sampling that local corrective actions are adequate.

Radioactive Liquid Waste Treatment Facility (RLWTF): Last Friday, LANL began a formal investigation into the two workers exposed to unexpectedly high airborne contamination (site rep weekly 3/11/05). The investigative team expects to report its findings in mid-April.

Chemistry and Metallurgy Research Building (CMR): Earlier this month, NNSA assessed the implementation of CMR safety system requirements by tracking from the 1998 basis of interim operation (BIO) down to system documentation and surveillance procedures. As part of this review, both NNSA and LANL found inconsistencies in the current safety basis, particularly for Wing 9 hot cell interlocks and contamination confinement features and for a ventilation functional test that is vaguely described in the BIO. LANL believes that they have met the intent of the safety basis and that the safety basis revision submitted last April for CMR will resolve these problems.

Unreviewed Safety Questions (USQ): LANL is reviewing all negative USQ determinations (USQDs) dating back to April 2001 in response to NNSA concerns on inadequate implementation of the USQ process at the lab (site rep weekly, 9/24/04). About 16 % (253) of the +1,500 negative USQDs in this set have been reviewed. Six of the reviewed USQDs (i.e., ~3%) appear to have been mis-characterized as negative and should have been positive. Common implementation problems identified so far include: poor understanding of the margin-of-safety concept; inadequate bases for answers to USQD questions; and re-cycling of previous USQDs without adequate consideration of their applicability to new situations. LANL expects to complete this review by early-July.

Waste Operations: NNSA has approved TRUPACT loading operations at the TA-54 RANT facility on an interim basis (site rep weekly, 2/25/05). This approval expires August 1, 2006 and is contingent upon implementation of several compensatory measures to address seismic vulnerabilities, including: additional bracing for facility equipment; in-situ testing of over-head appurtenances; and material-at-risk limitations. LASO indicated that a major factor in approving these operations was the significant risk-reduction benefit associated with removing high-curie waste drums from TA-54 to WIPP. With this approval, LANL anticipates commencing Quick-to-WIPP shipments by mid-April. To address the long-term viability of the RANT facility, LANL has indicated that they will initiate a project to make the permanent facility modifications necessary to eliminate identified seismic vulnerabilities.

Quality Assurance (QA): LANL has proposed and NNSA is now reviewing a lab-wide QA program and implementation plan. LANL does not have a DOE approved QA program and has reported this as a non-compliance with the QA provisions in the Nuclear Safety Management Rule (10 CFR 830).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 25, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 25, 2005

Burns was in Albuquerque at the Pantex Focus Meeting on Thursday and at Sandia on Friday.

Waste Operations: NNSA and LANL believe they are on track to resume WIPP shipments in mid-April. By resuming these shipments (suspended in Oct 2003), LANL would begin to reduce the risks due to the highest consequence nuclear accident postulated at LANL in approved safety analyses.

Authorization Basis (AB): NNSA and LANL have approved a new set of authorization agreements (AAs) that lists the applicable AB documents for nuclear facilities. LANL has committed to updating AAs within 30 days of AB changes. Management intends to annually approve a consolidated update, next due on 1/31/06. This addresses an issue in the Board letter and staff report of 5/27/04.

Conduct of Engineering: The LANL Engineering Practices Council (EPC) held its first meeting this week and is intended to serve as the institutional authority for establishing and maintaining consistent engineering processes, policies, and procedures. FY-05 goals include interim qualification of system engineers for all LANL vital safety systems (~90), and issuance of approved institutional engineering procedures in the following key areas: screening for engineering work, design change packages, management level determinations, engineering equivalency, design information development, post-modification testing, independent external design reviews, and design adequacy and back-fit analyses. An effective EPC could help LANL resolve issues in the Board letter and staff report of 1/27/04.

Chemistry and Metallurgy Research Replacement Facility Project (CMRR): NNSA has approved the CMRR Preliminary Hazards Assessment (PHA) in support of Critical Decision-1. Nine conditions of approval (COAs) were imposed, covering issues such as little evaluation of chemical hazards, non-conservative assumptions (e.g., airborne release fractions) for certain scenarios, questionable criteria for determining the significance of potential worker exposures, and defensibility of the proposed safety-class passive confinement strategy. NNSA agreed with LANL pursuing active ventilation as safety-significant at this stage, which is counter to Board Recommendation 04-2.

NNSA tasked the project to perform a detailed cost-benefit analysis between active and passive confinement and other control options, such as fire suppression. While NNSA acknowledged the difficulty in technically defending a passive confinement strategy, NNSA expressed concerns that active confinement may exacerbate certain scenarios resulting in unintended hazards and incurring excessive life-cycle costs. Citing a preference for preventive over mitigative and passive over active controls, NNSA indicated that a combination of fire barriers and fire suppression needs to be explored as an alternative safety-class control. The merits and significance of these concerns are unestablished.

Plutonium Facility (TA-55): NNSA has extended the interim AB approval for rm 201B cleanup, which would have expired next week (site rep weekly 11/12/04). Impact of new conditions of approval are unknown. These include NNSA approval of interim Technical Safety Requirements (TSRs) to address the leak path issue and LANL implementation of those interim TSRs applicable to the cleanup.

NNSA has released LANL to design and construct trailer storage pads and a weather cover to support TA-18 Early Move. NNSA designated the pads and trailer anchor system as safety-class, the trailer shelving system as safety-significant (seismic/wind performance category: PC-3), and the weather cover lightning protection system as defense-in-depth. NNSA plans to act on a LANL proposed interim safety basis for this operation after additional safety analyses are submitted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 1, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 1,2005

Plutonium Facility (TA-55): NNSA has clarified that conditions of approval issued last week are not intended to interrupt room 201B cleanup; this high-priority risk reduction activity is continuing.

NNSA and LANL need to establish the safety-class control(s) they intend to rely on in place of passive ventilation and thereby address a number of low-probability, high-consequence accident scenarios. LANL has proposed interim Technical Safety Requirements (ITSRs) to define the safety envelope until the final safety basis upgrade is done, which could be a year. The ITSRs are intended to address the leak path factor (LPF) issue in the short-term, as well as consolidate controls from the following: unreviewed safety questions against the currently approved 1996 safety basis; hazard analyses from the proposed 2002 safety basis upgrade; and analyses from the NNSA-LANL joint review team working on the safety basis upgrade (site rep weeklies 2/4/05, 3/4/05).

The LANL submittal included refined LPF calculations, intended to quantify relative performance of the existing active confinement ventilation system. The analyses indicate that with the west exit doors open and the east exit doors closed, wind tunnel effects are precluded and the active ventilation system limits facility releases to less than 0.02%; two orders of magnitude lower than the best case estimates for passive confinement. Given that the PF-3 administrative building completely encloses the eastern exit doors, this analysis appears to be a reasonable representation of the actual facility configuration.

Citing a lack of quantitative data on PF-3's effectiveness as a wind-block and uncertainties about the potential costs of equipment upgrades, LANL has chosen not to pursue active ventilation as a safety-class control at this time. Instead, LANL proposes a combination of process-specific design features and administrative controls as a safety-class defense. NNSA review and additional LANL studies are underway.

Management: The NNSA Site Office and LANL have increased emphasis on responding to the Board on several late commitments and reporting requirements. Within the last week, they have issued responses on conduct of engineering (Board letter 1 /27/04); identification of critical admin controls (Rec. 02-3, commitment 4.5); roles and responsibilities for weapons points-of-contact (Rec 02-2, commitment 4.3.2); and TA-55 ventilation backup power (DOE commitment, Pu ventilation system study report, 3/15/96). The staff is reviewing these responses. NNSA still owes responses on a training assessment, which is nearly done, and on TA-18 temperature-based scram systems, which is waiting on NNSA to decide what critical assembly operations are required in the remaining time.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL appears on track to complete in mid-April the investigation into the RLWTF high-airborne contamination event (site rep weekly 3/11/05). Preliminary bioassay results indicate that the two workers received measurable but low internal exposures; these will likely be below the reporting threshold (500 mrem).

Fire Protection: LANL is increasing staffing and funding in FY-05 and 06 to address fire protection issues, including beginning to address fire hazard analysis updates and planning a response to the fire department baseline needs assessment (site rep weekly 3/4/05).

Radiography Facility (TA-8-23): LANL has secured operations in TA-8-23 and will propose to NNSA that it be downgraded from a HC-2 nuclear to a radiological facility (site rep weekly 11/12/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 8, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 8, 2005

Keilers was off-site this week.

Management: The LANL Corrective Action Review Board (CARB) met for the first time last week. The CARB is intended to oversee and guide corrective action management processes for both local and institutional issues identified during the resumption reviews. It will report to the LANL Director, consist of several LANL senior managers and non-voting NNSA reps, and function similarly to the largely successful LANL Resumption Review Board (RRB). With sustained management commitment, the CARB could become the key mechanism for ensuring that laboratory corrective actions are consistent, complete, sustainable, and effective (site rep weekly 12/31/04).

Chemistry and Metallurgy Research Building (CMR): This week, NNSA rejected the safety basis upgrade (BIO and TSRs) for CMR submitted by LANL in September 2004. More than 75 significant comments were provided to LANL for resolution and NNSA believes that the time required to adequately address these comments will be extensive. Given the age of the current CMR safety basis documents (circa 1998), NNSA is uncomfortable with relying on these for an extended period of time while the final safety basis upgrade is revised.

Consistent with the approach taken recently at TA-55 (site rep weekly, 4/1/2005), NNSA has directed LANL to develop a set of interim TSRs to support operations until the final safety basis upgrade is completed. In developing the interim TSRs, LANL has been directed to draw upon the best available information, including all unreviewed safety questions and hazard analyses produced for CMR since 1999. Additionally, no controls from the current safety basis are to be eliminated or downgraded. The due date for submission of the interim TSRs is August 31, 2005.

HEPA Filter Program: LANL has initiated a high level review of the laboratory's processes for ensuring the quality of HEPA filters used in safety-related applications. The review is assessing protocols for procurement, storage, installation, testing, and disposal. There is currently no institutional program for managing safety-related HEPA filters, and preliminary results indicate that the formality of the disparate divisional programs is weak, especially regarding storage of filters prior to installation. LANL expects to complete the review and issue a final report before the end of the month.

Critical Experiments Facility (TA-18): Early move activities continue with NNSA approving work on a monthly basis. Overall operational performance has improved since Nuclear Materials Technology Division took custody of the facility (site rep weekly, 2/18/05). This week, an operations center has been established to improve facility work control and more formally track execution of safety basis requirements. Efforts to clarify the implementation status of the currently approved safety basis and identify the control set necessary to support early-move and anticipated programmatic activities are on-going (site rep weekly, 3/4/2005).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 15, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 15, 2005

Waste Operations: This week, LANL made its first transuranic waste shipment to WIPP since October 2003; it consisted of 19 Quick-to-WIPP drums. Near-term, it appears that LANL and the WIPP contractor may achieve 1 shipment per week; however, WIPP shipments could be delayed by a plethora of open safety basis issues. These waste operations lack an integrated risk evaluation. The most effective risk reduction mechanism available is to ship the waste (site rep weekly 12/5/03). NNSA and LANL could consider the limited remaining life of these operations and streamline the controls with the goal of optimizing overall rate of risk reduction.

Plutonium Facility (TA-55): In support of their review of the recently submitted interim Technical Safety Requirements for PF-4 (site rep weekly, 4/1/2005), NNSA has requested that LANL provide a backfit analysis within 90 days characterizing the cost/benefit implications of upgrading the current active confinement system to meet Safety Class requirements. NNSA expects this analysis to clearly articulate the cost differences between upgrading to Safety Significant and Safety Class, respectively. The usefulness of this analysis could be enhanced by first defining what the necessary and sufficient requirements should be for upgrading an existing system.

TA-55 has identified that several employees received measurable Pu-238 uptakes while working in a Pu-239 lab room last June and that one of these received 800 mrem 50-yr CEDE, exceeding the 500 mrem reporting threshold. Investigation continues (site rep weekly 2/25/05).

Facility Management: Many of last year's resumption reviews identified issues involving the roles and responsibilities for facility operations management, as well as needs for standardized tools and appropriate support for the facility management function. A LANL team has thoroughly studied these issues and, this week, made recommendations to LANL senior management. Squarely addressing these issues is necessary for success in the resumption followup; in fact, addressing these issues appears to be a prerequisite for the Operational Efficiency (OE) Project (site rep weekly 3/11/05).

Issue Management: LANL has observed a growing number of late corrective actions intended to respond to resumption review findings; appropriate management attention is being applied on reversing this trend. The LANL Corrective Action Review Board (CARB) is developing its strategy for providing the LANL Director independent assurance that these corrective actions were properly identified, implemented, and sustainable. With continued management support, the CARB could provide a stronger feedback mechanism between identified issues and their corrective actions than previously existed at LANL. Success also hinges on the distributed network of LANL issue management coordinators that will support the CARB in its activities.

Critical Experiments Facility (TA-18): LANL has submitted the start-up notification report (SNR) for resuming critical experiments with uranium on the Planet machine. The SNR requires documentation of the applicable safety controls for these experiments; resolution of issues identified in the Board's letter of July 9, 2003; an independent laboratory readiness assessment; and NNSA restart approval. This deliberate restart approach appears acceptable from a safety basis and operational perspective. From a programmatic priority perspective, LANL will also be required to demonstrate minimal impacts to the Early Move project prior to commencing Planet operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 22, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 22, 2005

Critical Experiments Facility (TA-18): NNSA-HQ issued correspondence to the LASO site manager and LANL director outlining the priorities relative to work at TA-18 for the remainder of this fiscal year. First and second priority are to be given to work supporting the Early Move (EM) and Critical Experiments Facility (CEF) projects, respectively. Third priority is given to high-importance programmatic work which includes the following criticality experiments: a uranium-based Planet experiment supporting the National Aeronautics and Space Administration's space reactor program, uranium-based experiments on Planet and Sheba supporting the DOE nuclear criticality training program, and an experiment on Comet supporting emergency response programs. NNSA-HQ reiterated the importance of the critical experiments and its expectation that they can be performed this fiscal year in concert with the higher priorities. LASO concurrence with all programmatic work will continue to be required to ensure impacts to EM and CEF are minimized.

Plutonium Facility (TA-55): On Tuesday, NNSA rejected the interim TSRs submitted by LANL on March 23, 2005. Though stating that this was one of the best safety basis documents submitted by LANL, NNSA indicated that several comments, primarily dealing with insufficient specificity in Limiting Conditions for Operation statements, needed to be addressed prior to approval. The rejection memorandum made no mention of the NNSA position regarding implementation of a safety-class active confinement ventilation system to address vulnerabilities associated with the previous passive confinement strategy (site rep weekly, 4/1/2005).

Plutonium-238 Operations: LANL priorities for TA-55 Pu-238 operations are (1) recover the room contaminated in August 2003 and (2) startup the full-scale aqueous scrap recovery line, preferably by late August 2005; LANL is rebaselining these efforts. Plans for the latter include full readiness verification, which would address a previous issue (site rep weekly 8/1/03). Progress on the former requires LANL to next verify compensatory measures are in place for getting residue cans into drums and out of the room. In parallel, DOE-NE is considering if low-inventory cans can be disposed as waste instead of retained to recover the Pu-238. This would be beneficial since about half the cans in the room (~120 of 238) plus about 20 others in the vault may qualify for WIPP. Many of the other cans are higher-inventory cans with rags and combustibles. These residues require pyrolysis, which is not expected to resume before October. Pyrolysis appears key for significant risk reduction since cans in this population also contain about half of the room's inventory by mass of Pu-238.

Integrated Safety Management (ISM): LANL has had several occurrences recently in non-nuclear facilities that indicate worker safety issues continue to warrant elevated management attention. These include uncontrolled electrical hazards and improperly assigned respiratory protection levels.

Radiography Facility (TA-8-23): NNSA has approved downgrading TA-8-23 from a hazard category 2 nuclear facility to a radiological facility pursuant to inventory restrictions limiting nuclear material to less than 0.5% of hazard category 3 thresholds (site rep weekly 4/1/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 29, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 29, 2005

Electrical Safety: LANL has had 3 or 4 electrical safety occurrences in each of the last 4 months. All have been from non-nuclear activities; recently, they involved subcontractors and lock-out tag-out violations. LANL has included improving the lock-out tag-out program as part of the long-term Operations Efficiency (OE) Project. NNSA has directed LANL to analyze the electrical safety situation and take decisive action within 7 days; if inadequate, NNSA stated it may impose a limited shutdown.

Quality Assurance: LANL has determined that personnel performing receipt inspections were deviating from procedure; at this time, it appears that material control, traceability, and segregation were preserved. Separately, LANL has identified a concern that personnel using measurement and test equipment having a limited calibration may have misunderstood the implications of the limited calibration and misapplied the equipment. LANL has done an initial survey of the use of such equipment and believes there are no major impacts. LANL is still investigating both these concerns.

Management: Except for hydrotests, NNSA has finished verifying that pre-start findings from LANL resumption reviews are either closed or have adequate compensatory measures in place (site rep weekly 3/18/05). On Wednesday, the NNSA team reported that they had agreed with LANL on closure status of 368 of 376 pre-starts (i.e., 98 %). Five of the eight open pre-starts are related to nuclear operations (e.g., TA-50/54/55); these specifically involve integrated work management and work control.

In the last two weeks, LANL has cut in half the number of late corrective actions intended to respond to resumption review findings; LANL expects a further one-third reduction within the next week (site rep weekly 4/15/05). During the next 2 months, LANL plans to make organizational changes intended to address findings involving operational roles and responsibilities. Addressing these issues appears to be a prerequisite for continued progress on the OE Project.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Friday, LANL briefed NNSA on results of its investigation into the 3/3/05 event involving workers at RLWTF exposed to unexpectedly high airborne contamination levels (site rep weekly 3/11/05). This event led to 4 workers receiving low-level Pu-239 uptakes; current dose estimates are all less than 50 mrem CEDE, which is 10 % of the DOE occurrence reporting threshold (500 mrem) and 1 % of the federal annual limit for rad workers (5 Rem).

LANL's investigation revealed work control weaknesses during an event that fortuitously had negligible health consequences. The investigation team concluded that the hazard analysis and the selection and implementation of controls were inadequate. Their report indicates that the direct cause was 2 inexperienced workers squeezing air out of bags of debris, creating a puff release that highly contaminated their protective clothing; then during doffing, contamination became airborne and was inhaled by 4 workers. The root cause was failure at multiple levels to recognize that this was a complex, non-routine job. The report indicates incomplete implementation of integrated work management: during planning, hazards were estimated rather than measured; work-scope and radiation hazards changed after the work control documents were prepared; the workers were not trained and qualified for the new work-scope; job suspension limits and engineered controls were not used; abnormal conditions during earlier vault entries were missed, including unexpectedly high radiological indicators; and the controls that were specified were incompletely implemented. A corrective action plan is expected in May.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 6, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 6, 2005

Management: UC has named R. W. Kuckuck as interim LANL Director, effective May 16th.

Waste Operations: Certain TA-54 waste characterization operations (i.e., high efficiency neutron counting and real-time radiography) currently require handling drums about 1.5 feet higher than their maximum certified drop height of 4 feet. Since the drums are a credited safety feature, LANL identified this as a potential inadequacy in the safety analysis and then implemented compensatory measures. LANL plans to resolve this by lowering the equipment to below the drum's certified drop height. NNSA has approved continued operations under the compensatory measures until no later than May 20; however, modifications to lower the equipment may not be complete until mid-June. Cessation of characterization for nearly a month would significantly hamper LANL's ability to ship waste to WIPP and does not appear to be in the best interest of overall risk reduction at the lab.

Radioactive Liquid Waste Treatment Facility (RLWTF): In response to the investigation reported last week, LANL is taking actions, such as: stop non-routine radiological work in the affected division pending review for and correction of integrated work management deficiencies; review related work to determine if the resumption startup plan was effectively implemented; ensure the facility's perspective of the event is heard and evaluated; and review the investigation report to identify higher-tier management concerns and the state of compliance with the worker radiation protection rule (10 CFR 835). LANL's actions appear appropriate. LANL should be commended for a thorough investigation.

Electrical Safety: As a result of events discussed last week, LANL held a mandatory 2-hour training session this week; it was effectively given. LANL is also increasing the electrical safety training opportunities for its work force. Electrical safety will likely continue to challenge LANL because of the large site-wide electrical work-scope and the age and condition of facilities.

Plutonium Facility (TA-55): To expedite removal of security category I/II nuclear materials from TA-18, NNSA has approved temporary staging of these items in three safeguarded (SST/SGT) trailers at TA-55 prior to completion of the trailer tie-down pads. NNSA is requiring that the staged items be in certified DOT Type B shipping packages and that the storage duration be limited to seven months.

Critical Experiments Facility (TA-18): NNSA has approved the start-up notification report (SNR) for uranium-based critical experiments on the Planet machine (site rep weekly, 4/15/05). LANL is using a deliberate approach to resume this operation, which includes a management self-assessment (MSA) that started this week. An independent laboratory readiness assessment is scheduled for the week of May 16. The first operation is currently expected during the week of June 13.

Issue Reporting: High-reliability organizations have processes that reward the discovery and reporting of errors (ref: DNFSB/TECH-35, Dec 2004). LANL has improved at self-identification and reporting of issues in the last few years. For example, the PAAA system has become one of the most effective systems at LANL for identifying and tracking closure of nuclear safety issues; LANL internally reviewed more than twice as many issues for PAAA applicability in 2004 than in 2001 (i.e., 343 vs 151); comparing the same years, the percentage of PAAA reports resulting from assessments instead of occurrences increased from 4 % to 66 %. Recent feedback (e.g., on the RLWTF investigation) does not positively reinforce this trend; instead, it could lead to suppression of reporting and thoroughly investigating issues, making it ultimately more difficult to identify and correct safety issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 20, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 20, 2005

Management: On Thursday, NNSA issued the request for proposal for the next LANL contract (site rep weekly 2/25/05). Key dates are: proposals due - July 19; contract awarded - December 1; contract begins - June 1, 2006. The new contract would run 5 to 20 years. Maximum annual fee that could be earned may jump nearly an order of magnitude compared to the current contract (\$8.7M vs \$79M).

Chemistry and Metallurgy Research Building (CMR): CMR had a contamination release to a lab room last Thursday (5/12) that may result in Pu-239 uptakes by one to four workers; preliminary bioassay results will be available in a few weeks. The workers were introducing bag-out material into a glovebox line when contamination was detected on a worker's gloves; within minutes, the continuous airborne monitor alarmed, and the workers evacuated. The workers were in anti-C's but were not in respirators. Followup actions taken were appropriate. CMR is reviewing the event for lessons learned, including adequacy of procedures and controls and applicability to other operations.

Chemistry and Metallurgy Research Replacement Facility Project (CMRR): On Wednesday, the Deputy Secretary approved Critical Decision 1 (CD-1 – start of preliminary design) for CMRR, as well as CD-0 for CMR decontamination and decommissioning. NNSA owes the Board a briefing within 30 days of CD-1 approval on the rationale for using a design-build approach and on its plan to ensure adequate NNSA and LANL technical staffing for preliminary design (ref: Board ltr, 2/24/05).

Critical Experiments Facility (TA-18): Early Move activities appear to be on track to de-inventory TA-18 to below the Security Category I/II threshold in September. This is receiving high priority.

The management self-assessment report for Planet uranium-based critical assembly operations is in preparation. Tentatively, there are several pre-start findings; the most challenging pre-starts involve clarifying the safety basis to avoid operator confusion (site rep weekly 3/4/05). Clarifying the safety basis warrants priority if the limited scope of Planet operations envisioned are to occur safely, deliberately, and within the time remaining. This ought to be achievable.

Emergency Management: Several assessments during the last year have identified issues with LANL emergency management (ref: site rep weekly 12/3/04). LANL is also implementing the National Incident Management System (NIMS). NNSA and LANL met this week and have developed a path-forward to address the issues and to verify progress during upcoming emergency exercises.

Waste Operations: LANL is proposing continued use of conveyors for moving a single drum at a time during certain characterization activities; the conveyors place the drum at 5 to 7 feet elevation, which is above the drum maximum certified drop height of 4 feet (site rep weekly 5/6/05). By December, LANL intends to lower the characterization equipment (i.e., trailers) as the permanent solution. Acceptance increases the likelihood LANL can keep transuranic waste shipments to WIPP on schedule. These shipments are LANL's principal mechanism for reducing the risks associated with the highest consequence nuclear accident postulated at LANL in approved safety analyses.

Tritium Facilities: TA-21 (TSFF) has reduced its tritium inventory to below the Hazard Category 3 nuclear facility threshold; subject to NNSA verification, it will be downgraded to a radiological facility. Neutron Tube Target Loading operations continue pending transfer of that mission to Sandia.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 27, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 27, 2005

Jordan and Plaue were on site this week reviewing startup preparations for the new Pu-238 aqueous scrap recovery line. Burns is off-site until the week of June 13th.

Pu-238 Operations: The schedule leading to startup of the new Pu-238 aqueous scrap recovery line is: LANL readiness assessment (RA) starts next week; NNSA RA would be in July; and startup would be in August. As discussed in the Board's letter of August 1st, 2003, Pu-238 is the dominant source term in TA-55 glove-box operations, and any future upset involving Pu-238 in this unique facility could adversely affect the health and safety of the public, the workers, and the environment, as well as national security. For perspective, LANL analyses indicate that inhaling one or two 2-micron diameter particles of Pu-238 oxide (i.e., about the ICRP default size) results in 0.5 Rem CEDE dose. Aqueous processing of Pu-238 is a particular concern since it results in more particles of respirable size than nearly all other operations; this increases the potential consequences from certain upsets.

NNSA and LANL have worked for years to develop appropriate controls for this increased hazard; some issues remain. The LANL RA team appears qualified and independent (4 of the 9 members are from SRS); it plans to examine both closure of previous Board issues and readiness. NNSA's RA team is undefined, and NNSA's level of commitment to a thorough federal review is unclear at present.

Following startup, TA-55 may have to operate the new line at the advertised sprint rate (8 kg/yr) for two years if they are to meet customer needs. For relief, they intend to also run the manually-intensive bench-scale line to produce about 3 kg/yr through 2007. Both a fast, early operating tempo for the new line and the extensive use of bench-scale for production would have significant safety implications.

Plutonium Facility: NNSA has approved two new Hazard Category 2 nuclear facilities at TA-55: (1) the safeguarded trailer pad and cover to support TA-18 Early Move for 5 years and (2) a metal shed (PF-185) to store unirradiated mixed oxide fuel within shipping containers for 4 years. Accident analyses indicate that both have unmitigated off-site consequences below the evaluation guideline.

NNSA is requiring that Operational Readiness Reviews (ORRs) be done before these two storage facilities start up. This is driven by NNSA's designation that these are new facilities. NNSA envisions that the ORRs will be done in June. The TA-18 Early Move Project had planned to be using the pad on June 1st and may be delayed. The mixed oxide fuel is already at LANL in another facility; that facility will be outside its safety basis on June 30th when the shipping container certification expires, unless the shed is authorized and in use.

The late decision to require these ORRs has led to safety concerns for other activities: (1) attention has been diverted and resources have been pulled away from the thorough startup review needed for the higher risk Pu-238 scrap recovery line – this is particularly true for the NNSA RA oversight of the scrap recovery line startup; (2) this action increases programmatic pressure on both TA-18 Early Move and on Pu-238 scrap recovery line startup, creating conditions that are more conducive to human fallibility and potential accident precursors. These were both challenging projects before and are now more challenging if the current schedules are to be maintained.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 3, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 3, 2005

Integrated Safety Management: LANL's integrated work management (IWM) process probably has the greatest potential of any LANL initiative to directly improve day-to-day worker safety, including worker safety in nuclear facilities (site rep weeklies 10/31/03, 1/16/04, 5/7/04, 9/24/04). LANL Audits and Assessments (AA) examined IWM implementation in Nov 2003, Jun 2004, and Mar 2005. Most recently, AA reports seeing some improvements, but there is still a persistent wide range in implementation. Furthermore, 47 of 97 (48 %) of workers interviewed do not believe the process improves safety. LANL management is committed to the IWM approach, but progress has lagged (e.g., guidance and training development). It is worthwhile for LANL to press ahead, particularly on IWM process improvement and training. Any training ought to reiterate the problems that IWM is intended to solve; this might best be done by a discussion of previous accidents (e.g., those cited in previous site rep reports) and how the IWM process, if properly used, might have prevented them.

Training: NNSA has completed its assessment of LANL performance-based training and provided the results to LANL. At this point, LANL's institutional training issues are well-understood, but they permeate the entire laboratory (e.g., IWM implementation). They include: insufficient training staff; weaknesses in management/supervisor training and instructor training; weak job/task analysis, which is key to using a systematic approach to training; ineffective training materials; and no defined process for systematic evaluation of training programs in nuclear facilities. LANL intends to address these issues under the multi-year Operational Efficiency (OE) Project; this will be a massive task.

Plutonium Facility (TA-55): The LANL readiness assessment (RA) for the new Pu-238 scrap recovery line began this week on schedule; the NNSA RA team leader and team remain undefined. NNSA had a uniquely well-qualified team leader selected to review the new line, but he has been reassigned to lead the NNSA operational readiness review for the trailer pad discussed last week.

In December 2004, TA-55 identified that several employees received measurable Pu-238 uptakes last June while working in a Pu-239 lab room (site rep weekly 4/15/05). LANL has thoroughly investigated this event to determine the point of origin, including reviewing 13 months of fixed air sample results (i.e., roughly 62,000 data points). This event appears well understood; appropriate actions have been taken; and the effort has provided a useful investigative tool for future events.

Fire Protection: For most LANL nuclear facilities, fire dominates the high-consequence end of the risk spectrum. NNSA and LANL rely on installed fire protection systems and on LANL and Los Alamos County emergency response personnel to mitigate consequences of a nuclear facility fire.

NNSA has directed LANL to discontinue efforts to establish a long-term contract with Los Alamos County for fire response services. Since 1997, LANL has maintained service via short-term contracts; this has impacted development of a long-term strategy on fire response staffing and resource needs. In mid-2004, LANL completed a Baseline Needs Assessment (BNA) that discussed these needs. Lack of a long-term contract is a likely root cause of many of the BNA issues. It is unclear now how NNSA intends to address these issues, which affect LANL's ability to respond to a nuclear facility fire.

Waste Operations: LANL has made 8 WIPP shipments since mid-April, shipping a total of 134 drums, including 100 from the Quick-to-WIPP set. Characterization activities using conveyors continue (site rep weekly 5/20/05). Prohibited item removal is the rate limiting step at present.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 10, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 10, 2005

The Board and a staff team were here this week reviewing LANL nuclear activities.

Waste Operations: LANL has shifted responsibility for nuclear waste operations to the associate director who is already responsible for critical assembly, plutonium, and tritium operations. This consolidates most of the responsibilities at that management-level for nuclear operations and processes – particularly, from the point of waste generation through the point of waste disposition. On-site transportation, and LANSCE are still in different directorates; these are the exceptions. Potential disadvantages include possibly more challenging span of control and possibly fewer institutional “checks and balances” between the waste generation and disposition points. Potential advantages include increased rigor and operational experience applied to waste operations and possibly more focused planning and support for overall LANL nuclear infrastructure.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL has developed a corrective action plan in response to its investigation into the March high-airborne contamination event at the RLWTF (site rep weekly 5/6/05); it includes both facility and institutional actions. Key facility elements are: resumption of non-routine radiological work after a management walk-down and approval that adequate controls are in place; a similar management verification for elevated-risk routine work; and establishment of a Facility Operations Safety Committee (FOSC) that will execute a due diligence process for explicitly defining and authorizing work and ensuring adequate controls are in place.

During the next few months, RLWTF faces four major challenges: (1) improving work control based on lessons learned; (2) receiving and treating TA-55 transuranic acid waste in a room with degraded systems – Room 60, as well as treating waste already in the RLWTF acid receipt tank; (3) switching over to new transfer lines from TA-55; and (4) replacing the leaking caustic waste receipt tank and thereby providing TA-55 about a year of operating grace while Room 60 is upgraded. LANL is emphasizing the role of the expert-based FOSC to ensure these activities are conducted safely.

Integrated Safety Management (ISM): Besides the facility-specific actions discussed above, LANL has identified institutional actions in response to the March high-airborne contamination event. These actions are to be completed by September 30th. Some of the key actions include:

- improving the stop work process to accommodate a broader range of situations - the goal is to simplify and incentivize stop work actions as a key element of the ISM program
- performing additional reviews of work practices, including peer-to-peer review for immediate work control improvements and broader recommendations for work control tools and training
- improving integrated work management based on last year’s resumption reviews and other lessons learned – including addressing special work permits and clarifying control hierarchy and importance of conservative hazard assessment and assumptions in work planning
- increasing subject matter expert (SME) involvement in work planning, as well as ensuring appropriate assignment of experienced supervisors, SMEs, and workers to higher-risk jobs
- implementing more consistent radcon practices, and improving compliance with the occupational radiation protection rule (10 CFR 835)

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 17, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 17, 2005

Hadjian was on site for a workshop supporting the LANL seismic hazard analysis update.

Waste Operations: This week, NNSA approved a set of interim compensatory measures for waste characterization operations (site rep weekly, 5/20/05). At issue were characterization activities employing conveyers that place waste drums above their maximum certified drop height. Specific compensatory measures include material-at-risk limits, railings on the sides of the conveyers, and sand bags beneath the conveyers to limit potential drops to less than four feet.

This approval is positive from an overall risk-reduction standpoint, since it will allow shipments of TRU waste to continue to WIPP without delay; these shipments are LANL's principal mechanism for reducing risks associated with the lab's highest consequence nuclear accident postulated in approved safety analyses.

Authorization Basis (AB): While there have been some improvements made in the last year, LANL nuclear facilities are still operating with aging safety bases. For example, the safety bases for the Chemistry and Metallurgy Research Building (CMR), the Plutonium Facility (TA-55), and the Radioactive Liquid Waste Treatment Facility are 6, 8, and 9 years old, respectively. Other factors, besides age, also contribute to uncertainty about the state of safety bases for LANL nuclear facilities, such as: weak document control, extensive use of conditions of approval (COAs) in federal correspondence (ref: Board ltr 1 /31/05), and varying approaches to verifying COA implementation.

The NNSA Site Office with Service Center support has assembled the relevant correspondence between January 2004 and March 2005 in an attempt to verify COA implementation for this period and to develop a useful database. This NNSA team has determined that NNSA issued about 800 COAs during this 15 months. Furthermore, the team is finding that many COAs are not actionable as written and need to be translated into operational terms; this is becoming a sizeable effort that could have been avoided if there was closer coordination between those responsible for safety basis and operations. The NNSA team hopes to achieve verification of these COAs by end of September.

Readiness Verification: Programmatic pressure is beginning to result in some compromises in operational readiness reviews (ORRs) and readiness assessments (RAs). LANL completed the management self-assessment (MSA) last week and the ORR this week for the TA-55 safeguarded trailer pad. The NNSA ORR may start Friday and finish next Tuesday. While this is a low complexity activity, the MSA report indicates that the state of the operation when LANL ORR began was not commensurate with expectations set in the applicable DOE standard (STD-3006). For example, procedures were still draft, operator training was incomplete, disposition of some non-conformances in the pad were open, an AB change needed to be approved, and a fire protection exception remains open. These should not be difficult issues to resolve, but it appears that the verification process is being used more as an assist than an assessment, counter to the intent of the DOE startup order (Order 425.1C). Hopefully, the upcoming ORR on the TA-55-185 shed for mixed oxide fuel containers and the upcoming RAs for the TA-55 Pu-238 scrap recovery line and the TA-18 critical assembly restart will be more deliberate.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 24, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 24, 2005

Keilers is off-site until the week of July 5th.

Authorization Basis: NNSA has approved the laboratory implementing requirements (LIRs) for facility categorization (LIR 300-00-05), nuclear facility safety bases (LIR 300-00-06), and non-nuclear facility safety bases (LIR 300-00-07). These documents clearly outline the expectations for LANL safety analyses and should help improve the quality, consistency, and efficiency of laboratory efforts to establish acceptable safety envelopes for nuclear and other hazardous activities. Approval of these documents is a key milestone in support of safety basis improvements under the Operational Efficiency project.

Quality Assurance (QA): LANL has completed its investigation of impacts associated with potential misapplication of equipment that received only limited qualification from the central calibration laboratory (site rep weekly, 4/29/2005). The investigation concluded that there were no significant impacts to safety or product quality resulting from these application errors. One non-conformance regarding tardy out-of-tolerance notifications from the calibration laboratory was cited as well as several noteworthy practices. A final report is to be issued shortly.

Plutonium Facility: Upon issuance of the contractor operational readiness review (ORR) report, the NNSA ORR commenced for the TA-55 safeguarded trailer pad on Tuesday (site rep weekly, 6/17/05). Key issues from the contractor ORR include: a necessary but still unapproved fire protection exemption, inconsistency between the safety basis and the fire hazards analysis, inadequate start-up plans, and inadequate management understanding of the readiness review process. NNSA intends to complete the ORR and have the pad operational by July 1st; one month later than the original target date. The overall TA-18 relocation schedule has been maintained by re-sequencing material moves, with materials destined for the vaults now preceding materials destined for the trailers.

The contractor ORR for the TA-55-185 shed envisioned to support storage of mixed-oxide (MOX) fuel containers has been postponed until late summer (site rep weekly, 5/27/05). Approval for the current storage location will expire on June 30th with the shipping container's certification. LANL intends to move the containers to the basement of PF-4 by early next week for temporary storage; they will then be moved to TA-55-185 when it becomes available.

Critical Experiments Facility (TA-18): LANL continues to pursue closure of management self assessment (MSA) findings related to resumption of uranium-based critical experiments on the Planet machine. Open MSA pre-start issues include: organizational roles and responsibilities are ill-defined, the safety basis controls have not been clearly established, and operator training is not complete. Commencement of the laboratory readiness assessment is on-hold pending NNSA approval of the plan of action, which is contingent upon further progress on closing MSA issues. Given the resumption delays to date, one of the planned criticality operations for Planet has been cancelled (criticality engineer training) and the other is in jeopardy (NASA space reactor experiment).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 1, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 1, 2005

Radioactive Liquid Waste Treatment Facility (RLWTF): The Interim Safety Basis for caustic tank removal and replacement activities was approved by NNSA this week. It is contingent upon several prerequisite actions being completed; the most significant of which is emptying the collocated acid tank. The equipment necessary to process the acid waste is in less-than-ideal condition and several mitigative options are under evaluation. Execution of any of the options will require Resumption Review Board approval. Currently, LANL believes they can obtain the necessary approvals and complete the caustic tank replacement by early fall.

Plutonium Facility: NNSA has completed their Operational Readiness Review (ORR) for the TA-55 safeguarded trailer pad. The final ORR report is in preparation and will not be issued until next week. Numerous pre-start findings were identified, including: inadequate review of industrial hazards, shortcomings in emergency management, insufficient basis for excluding criticality accident alarms, and an unresolved fire protection exemption. Resolution of these issues will delay start-up of the pad beyond NNSA's July 1 startup goal (site rep weekly, 6/24/05). NNSA HQ has indicated they intend to verify closure of select pre-start issues prior to authorizing operations to commence.

Conduct of Engineering: The NNSA site office completed a safety system oversight review of the systems engineering program at the TA-16 Weapons Engineering Tritium Facility (WETF). The review focused on system engineer training and qualification, configuration management, and surveillance. The team found that although the system engineers were knowledgeable and actively pursuing their qualifications, they should be allowed more time on the floor to monitor their systems. Configuration management processes for programmatic equipment were found to be good, but similar processes for facility equipment were disjoint and confusing. No findings were noted with regard to the surveillance program; however, the team did observe that the facility was slow to respond to previously identified in-service inspection issues.

Authorization Bases: This week, NNSA approved LANL's latest revision to their nuclear facilities list (Rev. 6). This list is intended to capture all hazard category 2 and 3 facilities at the laboratory and identifies their numbers as 18 and 10, respectively. These numbers include the relatively static environmental remediation sites.

Chemistry and Metallurgy Research Facility (CMR): In light of uncertainty regarding the number and implications of suspect welds in facility safety and support systems, NNSA has mandated that LANL reduce the allowable material-at-risk (MAR) in CMR from 20.2 kgs of plutonium equivalent to 9 kgs. This reduction significantly lowers the potential unmitigated accident consequences postulated in the facility safety basis; but not below the evaluation guideline of 25 rem. Although the suspect welds call into question the reliability of the credited safety features (fire suppression and ventilation), NNSA has decided to accept the residual risk of continued facility operations subject to near-term implementation (by July 12th) of the new MAR limits.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 8, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 8, 2005

Plutonium Facility (TA-55): The NNSA Site Office believes that preparation of the new safeguarded trailer pad needs to be further along and that another readiness review cycle is needed before startup; this appears appropriate. While the NNSA operational readiness review (ORR) discussed last week was thorough, the facility was clearly not ready, and the nature and number of pre-start findings for what ought to be a straight-forward activity are a major concern.

For example, the NNSA team observed that program drivers and schedule pressure completely dominated safety oversight; NNSA operational oversight was particularly not evident; criticality safety issues exist, such as lack of justification for not having criticality alarms; emergency response personnel left a mock injured person unattended in a mock contamination area for 25 minutes while responding to a simulated spill; and construction and installation of additional trailers was incomplete at the time of the ORR and represents an unanalyzed hazard outside the safety envelope. By any standard, these findings constitute an unacceptable condition for starting operations and possible indicators of other undiscovered significant issues. NNSA and LANL appear to have rushed to declare readiness and push through the verification process. It's clear that the readiness verification process was used as an assist in getting ready, which is counter to applicable DOE requirements. There were indicators of this evolving condition (site rep weekly 6/17/05).

Readiness Assessments (RA): The TA-55 pad ORR is not the only recent case where programmatic pressure has been allowed to compromise the effectiveness of the readiness verification process. The recent LANL RA on the new TA-55 Pu-238 scrap recovery line also identified a large number of findings and observations (i.e., 72, including 29 pre-starts); this is unexpected from an operation that has had previous RAs and has been preparing for startup for years. For both the pad and the new line, management prematurely declared readiness to proceed. This trend ought to be reversed.

Integrated Safety Management (ISM): There continue to be indicators that the LANL Integrated Work Management (IWM) initiative may need tuning and is neither fully nor consistently implemented (site rep weekly 6/3/05). Also, in April, NNSA completed a verification that pre-start findings from the LANL resumption reviews were either closed or have adequate compensatory measures in place (site rep weekly 4/29/05). The largest category of the roughly 400 pre-starts involve ISM (32 %). The site reps observe: (1) it's vital that LANL follow up on the transition of compensatory measures to final closure – based on discussions, LANL management understands this; (2) LANL did not present nor did NNSA review closure of the ISM-related pre-starts against consistent criteria. As a result, the state of IWM implementation may have been accepted for some organizations when a similar state was rejected for others, resulting in a misleading impression of the state and consistency of implementation.

The site reps believe that LANL could tighten up feedback and thereby ensure continuous improvement, as well as full and consistent implementation of the IWM process; this might include increasing senior management involvement, further empowering the Integrated Work Management Committee (IWMC), and increasing the frequency of floor-level assessments of implementation – both locally and by the institution – to ensure performance matches institutional expectations.

Chemistry and Metallurgy Research Building (CMR): In May, the site reps reported on a contamination event involving four workers in CMR (site rep weekly 5/20/05). Bioassay results indicate that the exposures were less than 1 % of the federal annual limit for rad workers (5 Rem).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 15, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 15, 2005

Plutonium Facility (TA-55): In April, NNSA rejected the Interim Technical Safety Requirements (ITSRs) submitted by LANL for TA-55. The intent of the ITSRs is to consolidate the best available control set for TA-55 operations pending completion of the final Documented Safety Analysis upgrade (site rep weekly, 4/22/05). NNSA and LANL also indicated that the ITSRs would capture the safety-class control strategy for addressing passive confinement vulnerabilities identified last December. The Board has clearly stated its position (re: Board letter 5/31/05) that a reasonable upgrade of the existing active confinement ventilation system is the preferred safety-class alternative.

LANL has revised the ITSRs to address previous NNSA comments and resubmitted them for approval. In general, the latest ITSRs represent an improved set of controls, derived from the most recent analyses, and captured in a single document; this is a positive. However, the ITSRs eschew the active confinement ventilation system as a safety-class control and continue to rely on a collection of administrative controls and process specific design features to compensate for the passive confinement vulnerability; this is disappointing. The recently completed LANL cost-benefit analysis for potential TA-55 ventilation system upgrades (site rep weekly, 4/15/05) concludes that a full upgrade of the ventilation system is impractical (i.e. \$352 M), and that improvements to either the passive confinement system or select glovebox and fire suppression equipment are preferable, as a long-term solution, to more focused ventilation system upgrades.

The NNSA position regarding the proposed safety-class control strategy and potential upgrades to the active confinement ventilation system remains undeclared pending completion of their on-going review of the ITSRs. NNSA is expected to finish their review before the end of the month.

Unreviewed Safety Questions (USQs): LANL has completed its review of all negative Unreviewed Safety Question (USQ) determinations dating back to April 2001 (3/18/05). The review was performed in response to NNSA concerns about potentially inadequate implementation of the USQ process at the lab. Of the 1,263 negative USQ determinations reviewed, 20 (~1.6%) were found to be mis-characterized that should have been positive. Statistically, the results do not indicate a systemic failure of the USQ process at LANL; however, the specific safety implications of the 20 incorrect determinations are still under review. As an on-going quality control measure, LANL's central safety basis office will continue to review, on a sampling basis, negative USQ determinations from May 2005 forward.

Waste Operations: LANL's transuranic (TRU) waste shipments to WIPP are the principal means for LANL to reduce risks associated with the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 4/15/05). Unfortunately, several safety basis and operational issues have arisen that call into question the safety envelope supporting waste operations. It is imperative that NNSA and LANL expeditiously correct these deficiencies to ensure the proper controls are being implemented to support safe and efficient execution of these critical risk-reduction activities

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 22, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 22, 2005

Jordan and Shackelford were on-site this week to review training and qualification programs at both LANL and LASO. Keilers was off-site Wednesday and Thursday to attend the NNSA workshop on activity-level work planning and control with Burnfield.

Critical Experiments Facility (TA-18): LANL has revised their path forward for resuming uranium-based critical experiments on the Planet machine in response to shifting NNSA priorities and lessons-learned from the recent readiness verification failure for the TA-55 safeguarded trailer pad. Resolution of outstanding safety-basis issues (e.g. impacts of local control station removal, uncertain structural capacity of Planet's upper fissile material holding plate, and approval of new material-at-risk limits) will now be obtained prior to recommencing any readiness verification reviews. Once these issues are closed, LANL intends to perform a second management self-assessment and an independent lab readiness assessment to verify readiness. LANL intends to perform sub-critical prerequisite activities (e.g. hand-stacking measurements) to minimize the time needed to complete the planned uranium-based experiments. These prerequisite activities are scheduled to begin next week.

Radioactive Liquid Waste Treatment Facility (RLWTF): NNSA and LANL recently convened an independent technical review of the RLWTF replacement project. The review team's report identified several potential improvements, including robust segmentation of certain facility operations to isolate potentially higher source-term materials from lower source term materials. Specifically, the review team suggested that higher source term materials be removed using simple settling and filtration techniques in a robust below-grade cell upstream of the main purification facility and that only lower source-term supernate be forwarded on for more complex processing in the purification facility. This recommendation appears sensible from both a safety and economic perspective; the higher hazard materials would be localized in a simple and robust enclosure with minimal manipulation and the more complex purification facility would only be required to process lower hazard materials. Further exploration of this approach appears warranted.

Readiness Assessments (RA): In response to the failed readiness verification process for the TA-55 safeguarded trailer pads (site rep weekly, 7/8/2005) and the NNSA operational readiness review finding that adequate LASO safety oversight was not evident, the LASO Manager convened an independent review by personnel from the NNSA Albuquerque Service Center. This review found the following issues at LASO contributed to failed process: approval of the level of readiness review required was not coordinated between the assistant managers for safety and operations, and no formal site office procedures are in place to ensure future coordination; integration of safety, security, and program imperatives occurred below the site office manager level and was not well balanced; and inadequate resources were provided to support a successful readiness process in the time allotted by the aggressive schedule. These findings appear to be specific manifestations of more general problems associated with informal site office processes, poor coordination between assistant managers, integration of competing imperatives at too low a level in the organization, and inadequate resources. Timely resolution of these problems is necessary to ensure that LASO is capable of providing effective safety oversight.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 29, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: T. D. Burns Jr. and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 29, 2005

Am-241 Contamination Event: On Monday, LANL determined that a staff member in the Sigma Complex (TA-3-66 – a radiological facility) had become contaminated with Am-241 eleven days earlier while unpacking vials of uranium nitride from TA-55. During the period that contamination was undetected, the employee unknowingly spread contamination both in the facility and off-site, including his home. LANL is pursuing surveying and decontamination activities both on and off-site, including surveying the nearly two hundred people who work in Sigma and their work-spaces. As of Thursday, about a dozen people were placed on special bioassay monitoring; initial bioassay results should be available in mid-August. LANL has secured affected areas and is initiating an investigation.

Critical Experiments Facility (TA-18): Also on Monday, LANL determined that the fissile content of four recently re-packed 110 gal drums had not been reviewed by the criticality safety group and that these drums exceeded the criticality limit by factors of up to 2.25. This was discovered during a criticality review to support shipping the drums. Local posting refers to guidance given elsewhere for the type of material involved. There are similarities between this event and problems observed during simulated fissile material handling for the TA-55 pad ORR (site rep weekly 7/8/05); together, they indicate issues with procedure clarity, training, supervision, and oversight of fissile material handling.

Federal Oversight: Ineffective assessment processes – both federal and contractor – contributed to the decision last summer to suspend LANL operations (site rep weekly 12/31/04). The resumption reviews provided breadth-and-depth perspective on the state of operations; however, the quality of that picture will decay with time without a mature contractor assessment system. To compensate for this, NNSA had planned to increase federal staffing at LASO by 20 % in FY-06, including increased field presence by facility reps and subject matter experts. Those plans have been cancelled. LASO now plans to rely highly on a mature contractor assurance system that currently does not exist at LANL and that will take some time to develop regardless of the outcome of the contract competition. The federal approach to oversight of LANL now appears counter to the reality that challenges are growing; LANL is a unique national institution in transition, particularly from the standpoints of mission, safety, security, infrastructure, business practices, and the unprecedented contract change.

Radiological Facilities: Since 1997, NNSA has approved downgrading more than a dozen nuclear facilities to radiological facility status, including at least two facilities where NNSA credited ANSI source encapsulation as permitted by the applicable DOE standard (STD-1027). From review of the available information for these two facilities (TA-35-2, TA-35-27), it is not clear that these sources would maintain their integrity at end of life in a major facility fire, which could result in unanalyzed on-site and off-site consequences. If these were designated as nuclear facilities, LANL would be required to develop and implement engineered and administrative controls to address such scenarios; this same rigor appears warranted for these radiological facilities. Furthermore, the level of oversight by both LANL and LASO drops precipitously for facilities that are categorized as radiological. Increased attention to radiological facilities lab-wide appears warranted to ensure that residual risks are identified and are addressed appropriately (site rep weeklies 1 /21/05, 9/24/04).

Administrative: This is the last weekly report for Burns, who is leaving the federal service and relocating to the Washington D.C. area. It has been an honor to work for the Board and a privilege to serve at LANL.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 5, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 5, 2005

Am-241 Contamination Event: In response to the inadvertent contamination release reported last week, LANL has addressed off-site contamination and has implemented adequate radiological controls in the Sigma Complex (TA-3-66). Contamination spread occurred via contact and not airborne suspension; with each contact, the levels transmitted dropped one-to-two orders of magnitude. Contamination beyond secondary-contact is very low and likely non-detectable by standard techniques.

Within Sigma, LANL is controlling access to contaminated areas, which include two offices, a lab room, and a shop. LANL has put in place continuous air monitoring in selected areas, monitoring of personnel upon building exit, and daily surveys of high-traffic areas, all of which indicate the controls are effective. Whole body counts on the primary individual involved indicate a low-level uptake; more definitive bioassay results should be available in a few weeks. LANL is investigating the event.

Waste Operations: LANL's transuranic waste shipments to WIPP are the principal means for LANL to reduce risks associated with the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 7/15/05). Since April when shipments resumed, LANL has made 17 shipments for a total of 347 drums – of which around 200 (60 %) are from the higher-activity Quick-to-WIPP set – and the shipment rate has doubled from about 1 per 8 days to 1 per 4 days on average.

This has happened in spite of operational issues, such as poor safety basis implementation and inconsistent disciplined operations. For example, the Area G safety basis was suppose to be implemented in Summer 2004; Area G prematurely terminated a verification assessment on safety basis implementation in January 2005, and it has never been completed. There are also indicators of issues in the LANL resumption review report for waste operations, dated 1/10/05 (site rep weekly 1/21/05). In light of LANL reports of new evidence of problems, the LASO Manager has requested the LANL Director to justify continued operation of the TA-50/54 waste facilities by next Thursday (8/11/05).

Plutonium Facility (TA-55): Last Thursday (7/28/05), NNSA approved a set of interim technical safety requirements (ITSRs) for TA-55 that expire in one year. The ITSRs are intended to consolidate controls from: unreviewed safety questions against the currently approved 1996 safety basis, hazard analyses from the proposed 2002 safety basis upgrade, and compensatory measures approved in February to address the passive ventilation confinement vulnerability (site rep weekly 7/15/05). Key controls are to be implemented and verified within 90 days, with the remainder within 11 months. NNSA and LANL expect few TSR changes will be required when the full safety basis upgrade is finished in about a year.

LASO is reviewing the cost-benefit analysis for ventilation upgrades and remains skeptical of the cost effectiveness of the currently understood full upgrade to safety-class. LASO questions whether the system, as-is, even meets safety-significant requirements and has directed LANL this month to recommend prioritized low-cost upgrades that will improve ventilation reliability and reasonably reduce risk. LASO also tasked LANL to propose improvements to fire suppression and to high-risk glove-boxes within the next few months and to replace Pu-238 glove-box HEPA filters within the next year.

Authorization Basis: LANL is no longer pursuing the use of the TA-55-185 shed to store mixed-oxide fuel shipping containers and the temporary use of the TA-54 Decontamination and Volume Reduction System (DVRS) to repackage transuranic waste drums (site rep reports 6/24/05, 5/27/05, 6/11/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 12, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 12, 2005

DOE Independent Oversight Review: This week, the DOE Office of Independent Oversight and Performance Assurance (DOE-OA) had a team on site preparing for an in-depth review in October; based on anticipated scope, this review should provide a good indicator of the status of corrective actions that were developed in response to last year's resumption reviews.

NNSA Type B Accident Investigations: Next week, NNSA will start two Type B investigations per DOE Order 225.1A into (a) the loss of contamination control in TA-3-66 (Sigma) involving TA-55 items, and (b) the acid inhalation injuries in TA-48 RC-1, discussed below. LANL investigative efforts will shift to assisting the federal teams. Both Type B investigations are to be done by Sep 30th.

Radiochemistry Laboratory (TA-48 RC-1): On June 16th, two RC-1 post-docs received potential chemical overexposures when mixing acids without appropriate ventilation. Both exhibited immediate symptoms. One recovered shortly while the other had continuing symptoms and was hospitalized for six days in late July. The LANL Medical Director and LANL management were informed of the event on August 3rd, nearly seven weeks after the event, and LANL reported it to NNSA. Both RC-1 and the LANL division that runs RC-1 have a history of operational issues, often involving students or post-docs (e.g. site rep weeklies 1/28/05, 9/17/04, 8/1/03, 1/10/03, 6/28/02). The LANL Director has reemphasized to the work force that employees have the right and responsibility to stop work for unsafe conditions. This event is the subject of one of the Type B investigations.

Integrated Safety Management (ISM): Both the TA-55/Sigma and RC-1 events illustrate that LANL has not fully and consistently implemented the Integrated Work Management initiative. As discussed in the Board's letter of July 21st, this initiative has the greatest potential of those within the Operational Efficiency Project to directly improve worker safety. The RC-1 event particularly indicates issues with stopping work when presented with unsafe conditions, prompt reporting of problems, and focusing on learning from events. Overcoming such issues is key to LANL evolving to a high-reliability organization as described in DNFSB TECH-35, Dec 2004.

Until LANL achieves that state, NNSA and LANL have to rely on assessments and oversight to detect and correct problems. The majority of NNSA and LANL institutional oversight now focuses on nuclear and high-hazard facilities and their implementation of NNSA approved safety bases, which is important; line management at the group, division, and associate-director levels is held responsible for oversight of low-to-moderate hazard facilities, like Sigma and RC-1, and that oversight is inconsistent in effectiveness at best. Within the latter class of facilities, the site rep observes that oversight drops precipitously for facilities that are downgraded from Hazard Category 2 or 3 to radiological status (site rep weekly 7/29/05). Sigma was downgraded in March 2001. RC-1 was downgraded in June 2003.

Decommissioned Facilities: This week, the site rep toured part of the TA-21 plutonium facility, which has been in surveillance and maintenance status since the early 1980's. With the exception of a few lab benches, the rooms are empty. Essential services are maintained, including fire suppression, and combustible content is low. Residual contamination is fixed under the floor cement covering and under wall and ceiling paint; there is extensive paint peeling in some areas. Water intrusion is evident both from spots in the ceiling and around many concrete support columns; the water intrusion is extensive enough that it could be an indicator of incipient structural issues. LANL has prepared budget estimates and, subject to funding approval, intends to begin removing the TA-21 plutonium and tritium facility structures starting in FY-07.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 19, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending August 19, 2005

Weapons Engineering Tritium Facility (WETF): On Wednesday (8/17), WETF suspended programmatic operations due to emergent questions on (a) whether WETF was operating under an NNSA approved set of technical safety requirements (TSRs) and (b) whether WETF had correctly used the LANL unreviewed safety question (USQ) process to determine if facility modifications required NNSA approval. The former question has been resolved; the latter remains under review.

Waste Operations: LANL has responded to NNSA's request to justify continued operation of the TA-50/54 waste facilities (site rep weekly 8/5/05). Overall, LANL has increased emphasis on conduct of operations and on management walk-downs and reviews as a start for long-term improvements.

Actions taken so far appear appropriate. Among these, LANL: (a) assessed key areas such as life safety, pressure safety, fire suppression, drum integrity; (b) secured some activities due to deficiencies found in assessments; (c) continued other activities with compensatory measures such as time and temperature restrictions for workers in personnel protective equipment, air quality verification before work in normally unmanned spaces, increased communication on status of activities, and increased support by external operations experts; and (d) established an expert-based Facility Operations Safety Committee (FOSC) that reviews work planning and controls for liquid waste operations. LANL plans to expand the FOSC reviews to cover all waste operations. LANL also has assessments underway to determine extent of condition for safety basis implementation issues involving waste operations.

Plutonium Facility (TA-55): While TA-18 Early Move activities are proceeding, the related path-forward for the TA-55 safeguarded trailer pad still appears open (site rep weekly 7/8/05). On August 9th, the LASO Manager proposed to NNSA Headquarters (NA-10) a path forward for readiness review and startup. The proposal does not require redoing the readiness assessment process (i.e., ORRs) but instead focuses on thorough federal and contractor followup on the known issues. While commitment to rigorous closure has been expressed, many details are missing. NA-10 action is forthcoming.

Critical Experiments Facility (TA-18): The path-forward is still open for the remaining Planet and Comet experiments, including defining the readiness assessment needs and considering whether to perform the experiments later in Nevada instead (site rep weekly 7/22/05). On August 15th, LANL proposed to NA-10 retaining required parts at TA-55 and performing the experiments in TA-18. It has been longer than a year since critical assembly operations. The Comet and Planet experiments are expected to take 10 to 20 days and 18 to 36 days, respectively. A detailed baseline is due by Sep 30th.

Chemistry and Metallurgy Research Building (CMR): In late 2003, LANL determined that some welding processes used on site may not have complied with national consensus codes, and in April 2004, LANL began a program to ensure appropriate quality in new welds and to screen accessible existing welds in nuclear facility safety systems (site rep weeklies 3/26/04, 4/26/04). As part of that screening, CMR identified 1,221 suspect welds – the most by far in any LANL nuclear facility. Since May 2005, LANL has had a team of system engineers and welding experts (including certified weld inspectors) inspect and evaluate for service the suspect welds and select other welds in CMR; results, including photographs, are documented in an extensive database. Out of about 2,000 welds evaluated, CMR found 28 unacceptable welds and one missing beam clamp. CMR has issued non-conformance reports on these deficiencies to begin disposition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 26, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending August 26, 2005

Waste Operations: Last Friday (8/19), the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRRF) suspended its glovebox operation due to an employee concern that an air-operated tool in use could pressurize the glovebox and cause a release to the room; LANL has also found that the vacuum on this box is marginal, even with the air tool disconnected, and is working toward resolution. WCRRF repackages transuranic waste drums to support the Quick-to-WIPP program, which is key to LANL long-term risk reduction (site rep weekly 8/5/05); it's in heavy use because of the high fraction of legacy drums found with prohibited items during real-time radiography. The suspension illustrates a key challenge for NNSA contractors, which is to appropriately address the entire risk spectrum of potential upsets from low to high consequence.

Weapons Engineering Tritium Facility (WETF): Last Wednesday (8/17), LANL line management suspended WETF programmatic operations, as reported last week. On Thursday (8/25), LANL line management documented the concerns and their resolution and authorized resumption. Lack of annual safety basis updates and a major change in the LANL unreviewed safety question (USQ) process last September contributed to confusion (site rep weekly 3/18/05); the technical safety requirements (TSRs) and the safety basis for WETF are 2 and 3 years old, respectively. Also contributing is the fact that many USQs involve modifications and only address the end-state but not the interim states that may actually be higher risk; this is an institutional issue. LANL is performing a back-look on WETF USQs.

Lessons learned from this event include the need for clear formal communication when suspending and resuming nuclear operations, particularly what management-level suspended operations, what specifically were the problems causing suspension, what will be the criteria for resumption, and what level of readiness review will be required to verify that the originating problems were corrected.

Plutonium Facility (TA-55): On Thursday, TA-55 had a criticality safety limit violation involving a 2 % exceedance of fissile material passing through a glovebox; the problem was found and reported by those involved, which is positive. Line management has suspended TA-55 and TA-18 special nuclear material movements and is implementing a corrective action plan with clear resumption criteria.

NNSA Oversight: Safety oversight by the NNSA Site Office (LASO) is increasingly hampered by several factors, including an imbalance of experience and authority within LASO management and the lack of a formal concurrence process that would provide LASO management a balanced perspective and unity-of-purpose before decisions are made. These are longstanding issues (e.g., site rep weeklies 3/29/02, 8/23/02), but their safety significance is increasing at this time of transition. Recent symptoms include the premature declaration of readiness for the TA-55 pad ORR and the two ORR pre-start findings on federal oversight (site rep weekly 7/8/05); these findings indicated a lack of a demonstrable oversight program for the pad and a lack of active counterbalance between program and operations or other safety personnel. Events since then indicate the problems persist, resulting in a loss of focus.

Another limiting factor is inadequate field presence; for example, the number of deployed, qualified facility reps (7) has dropped by about a third in the last year and is now about a third of that projected to be required in the most recent LASO facility rep staffing analysis (20 - see site rep weekly 1/7/05). Experienced federal management, adequate experienced staff, focused attention, and balanced perspective all appear to be key through contract transition, and they all warrant attention.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 2, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 2, 2005

Fire Protection: LANL has submitted to the NNSA Site Office a strategy to address fire protection deficiencies and achieve site-wide improvements, as requested by a Board letter dtd 5/31/05. It includes proposals for increasing staffing, addressing the Baseline Needs Assessment, and completing site-wide fire alarm system replacement via a budget line item. LANL requested comments by Sep 9.

Plutonium Facility (TA-55): LANL has recommended to NNSA the following prioritized upgrades to improve ventilation reliability and reduce risk (site rep weekly 8/5/05): complete installation of a new diesel generator; design and install switchgear upgrades and a new uninterruptible power supply; replace confinement doors and certain aging components in the facility control system; and reinforce internal ventilation ductwork to meet current seismic requirements. Portions of these upgrades are included in the TA-55 Reinvestment Project. LANL is also finalizing a re-analysis of accidents that rely on building confinement ventilation as the primary control. Results are expected shortly.

NNSA HQ (NA-10) is the startup authority for the TA-55 safeguarded trailer pad and has approved a path-forward for startup (site rep weeklies 7/8/05, 8/19/05). Key elements include NNSA Site Office (LASO) verification of readiness to start, and NA-10 and NNSA Chief of Defense Nuclear Safety (CDNS) review of issue closure packages. NA-10 is also requiring NA-10 & CDNS review and NA-10 approval of LASO corrective actions and plans for addressing federal oversight deficiencies.

Waste Operations: Transuranic waste repackaging in the TA-50 Waste Characterization, Reduction, and Repackaging Facility (WCRRF) remains suspended due to glovebox concerns; timely resolution is needed to support LANL risk reduction (site rep weekly 8/5/05). This has evolved into a safety basis issue since (a) the potential to pressurize the glovebox is an unanalyzed accident; (b) isolating air supply to prevent the accident constitutes a modification and a new control; and (c) glovebox vacuum is marginal in the event of a breach. WCRRF's safety basis is poor; it consists of a 5-year-old hazard analysis and interim technical safety requirements. NNSA has also directed that WCRRF shut down within 1 or 2 years; therefore, extensive facility or safety basis upgrades may not be worthwhile.

Los Alamos Neutron Science Center (LANSCE): Portions of LANSCE are designated as hazard category 3 (HC-3) nuclear facilities, and LANSCE operates under a multi-part safety basis that is more than 4 years old and intended to comply with both nuclear facility and accelerator safety requirements (site rep weekly 1/9/04). NNSA recently disapproved a LANL recommendation to consolidate the safety basis and operate LANSCE solely to the accelerator safety requirements in the applicable DOE Order (DOE O 420.2B). NNSA asserts that this order's exclusion of accelerators from the Nuclear Safety Management Rule (10 CFR 830) is inappropriate for LANSCE since LANSCE's radioactive inventory exceeds the HC-3 threshold and may even exceed the HC-2 threshold. The path-forward for LANSCE to achieve an updated set of necessary and sufficient safety basis controls is uncertain.

TA-21 Tritium Facility: NNSA has approved downgrading the TA-21 Tritium Science and Fabrication Facility (TSFF) from Hazard Category 3 to radiological. Neutron Tube Target Loading continues pending transfer of that mission to Sandia, after which TSFF will begin decommissioning.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 16, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 16, 2005

Waste Characterization, Reduction, and Repackaging Facility (WCRRF): NNSA has approved interim safety basis requirements (e.g., worker respiratory protection, increased airborne monitoring) for resuming repackaging of transuranic waste in WCRRF (site rep weekly 9/2/05); this resumption is essential to achieve the Quick-to-WIPP Program risk reductions. The NNSA Site Office has declared it is the restart authority and will approve restart based on a LANL management self-assessment.

Plutonium Facility: In addition to ventilation upgrades previously discussed (site rep weekly 9/2/05), LANL plans on refining accident analyses by January with the goal of showing a passive confinement strategy works; modeling refinements include ramp vs step airborne release, explicit material-at-risk partition for Pu-238 powder vs sintered-form, refined wind boundary conditions from a computational fluid dynamics code. If this fails, LANL plans to quantify potential passive confinement upgrades in February, and if those prove insufficient, consider the following options in this order in March: an active aerosol removal system at PF-4 exits; fire suppression upgrades; further ventilation upgrades. It is unclear how this aligns with DOE's implementation plan for Board Recommendation 04-2.

Pu-238 Operations: On Thursday, LANL, NNSA, and the staff had a video-teleconference on the status of aqueous recovery startup and corrective actions from the August 2003 contamination event. LANL is making progress in dispositioning some legacy Pu-238 residues as waste, but resumption of pyrolysis is now projected to slip into next year. Pyrolysis warrants priority since it is an essential risk reduction step for the large remaining inventory of combustible residues (site rep weekly 4/22/05).

Emergency Response: LANL is radically changing its Emergency Operations Center (EOC) processes and procedures to implement the National Incident Management System (NIMS) per Presidential Directive HSPD-5. While there is much to be done, progress is evident in recent training activities and drills compared to the exercise last December (site rep weeklies 5/20/05, 12/3/04).

Conduct of Engineering: Under the Operational Efficiency (OE) Project, LANL has established an institutional engineering program, including setting up an active Engineering Practice Council, formally training and qualifying ~25 systems engineers (including oral boards), and developing an institutional manual and procedures that are now under senior management review. In FY-06, LANL plans to begin improving engineering records for vital safety systems using the new procedures.

Quality Assurance (QA): Under the OE Project, LANL is on-track by December to issue 9 of 15 key institutional QA procedures and to close the site-wide welding potential inadequacy in safety analysis (PISA). The 9 procedures involve audits, assessment, commercial grade dedication, suspect counterfeit items, graded approach, non-conformance reporting, supplier evaluation, and procurement quality. LANL believes that the 6 remaining procedures would benefit from input from the new contractor; these include calibration, inspection and test, document control, and records management.

Safety Basis: The safety basis sub-project is one of the more deeply challenged efforts under OE to achieve its goals, including ensuring sufficient qualified staffing, and establishing and verifying safety basis document control. LANL now plans to complete its OE safety basis commitments and to independently assess technical safety requirement implementation in nuclear facilities by May 31st.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 23, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 23, 2005

Von Holle was on site this week attending the LANL energetic materials review.

Plutonium Facility (TA-55): The NNSA Site Office (LASO) has endorsed the LANL plan to refine accident analyses and try to justify a passive confinement strategy by January 2006 (site rep weekly 9/16/05); NNSA emphasized LANL continuing plans to reduce material-at-risk limits, to seismically upgrade the 60 % of glove-box supports that have not already been upgraded to safety-class, and to provide safety-class containers capable of withstanding fire, explosion, puncture, and crushing. The challenges, besides the analyses, are significant; for example, the widely used TA-55 standard container (i.e., the Hagan can) has elastomer seals that will likely fail and leak during a major fire.

Waste Operations: LANL's transuranic waste shipments to WIPP are the principal means for LANL to reduce risks associated with the lab's highest consequence nuclear accident postulated in approved safety analyses. Since April when shipments resumed, LANL has made 36 shipments for a total of about 800 drums – of which 362 (45%) are from the higher-activity Quick-to-WIPP set. LANL has also increased emphasis on conduct of operations and on management walk-downs and reviews as a start for long-term improvements (site rep weekly 8/19/05).

Last Wednesday (9/14/05), LANL provided LASO a roughly 2-year \$20M integrated plan to move nuclear waste operations from its current ad-hoc mode to an efficient, unified, disciplined operation. Key elements include improving organizational management and worker culture and training by December, improving infrastructure and safety basis implementation by September 2006, and revitalizing operations by early 2007. This Wednesday (9/21/05), LASO provided LANL its recent "for-cause" assessment of safety systems supporting waste operations. It concludes that safety basis requirements generally are inadequately identified, implemented, and fulfilled; specific findings are sweeping and involve safety bases, USQ process, requirement flow-down, fire protection, configuration management, and safety system surveillance, testing, and maintenance.

Many of the issues from the LASO assessment were previously recognized (e.g., site rep weekly 8/5/05) and could be addressed within the LANL plan. One course would be for LANL to evolve the plan based on review of specific LASO findings, establish clear metrics and milestones, and, with full LASO support, expeditiously execute the plan and reduce risk in a timely and balanced manner.

NNSA Oversight: LASO has nearly completed its verification of the TA-55 safeguarded trailer pad startup readiness (site rep weekly 9/2/05); the verification process so far has been ad-hoc but thorough. However, last Friday (9/16), LASO proposed to NNSA headquarters (NA-10) a pad fire protection exemption without obtaining concurrence from LASO staff responsible for safety basis and for fire protection. The exemption request is on hold; LANL is working with LASO to resolve remaining technical issues, which involve new hazards and controls not recognized when the exemption request was generated. LASO's weak concurrence process is a recurring issue (site rep weekly 8/26/05). Furthermore, 5 of 10 LASO technical managers have not completed the Senior Technical Safety Manager (STSM) qualification, nor are compensatory measures apparent (ref: DOE response to Board Recommendation 93-3, *Improving DOE Technical Capability*). This aspect, coupled with the last year's turnover of LASO technical managers, may be further weakening local federal oversight.

Sigma Complex (TA-3-66): On Monday (9/19/05), Sigma reimplemented personnel exit surveys and other controls, based on Am-241 contamination found in uncontrolled areas (site rep weekly 8/5/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 7, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 7, 2005

Plutonium Facility (TA-55): On Wednesday (10/5), the NNSA Site Office (LASO) submitted issue closure packages to NNSA Headquarters (NA-10) and recommended startup of one trailer on the safeguarded trailer pad. This follows LASO and LANL resolution of open trailer fire protection issues early last week and NA-10 approval of the trailer fire protection exemption last Wednesday (9/28).

Last Friday (9/30), LASO approved startup of TA-55 enhanced external security measures before completion of formal verification that safety basis controls for these measures were in place; startup was nearly immediate to support secretarial-level security commitments made in 2003. The LANL management self-assessment (MSA) started in earnest this Monday (10/3) and was completed Thursday (10/6). The LANL readiness assessment (RA) is expected to start and finish next week.

Startup before verification creates a vulnerability that in this case was avoidable: the MSA previously began on Sep 12th with ample time, but then aborted two days later while LASO reconsidered the level of readiness review – resolved on Sep 28th. During this period, LANL recognized a new major accident scenario, complicating matters, and appropriately proposed TSR modifications on Sep 27th. LASO approved these on Sep 29th. When LASO approved startup on Sep 30th, LASO also restricted LANL from implementing some of the enhanced security measures, apparently due to lingering safety concerns. At present, the controls look adequate for the current security measures, but the expedited process used was less than satisfactory and increases the probability that something was missed.

Critical Experiments Facility (TA-18): LANL has completed characterization and packaging of material requiring Security Category I/II; there are few of these items remaining to be shipped, and they will be shipped once NA-10 authorizes startup of the TA-55 safeguarded trailer pad.

LANL has stopped work on Comet and is shifting attention to preparing SHEBA to resume delayed-critical operation and to start burst-mode operation; LANL's ability to successfully conduct these operations at TA-18 is subject to appropriate planning, priority, and support. Looking ahead, the future for DOE criticality training and experimental capability is the proposed Critical Experiments Facility (CEF) at the Nevada Test Site. The Energy Systems Acquisition Advisory Board (ESAAB) met this week to consider Critical Decision-2 for the CEF Project; the outcome is unknown.

Sigma Complex (TA-3-66): On Monday (10/3), a Sigma employee driven by program requirements singlehandedly removed a heavy press from a hood, surveyed it with a meter, and found it lightly contaminated with depleted uranium. He then attempted decon, tagged the press as radioactive, and moved it into a corridor where a radcon tech found it on Wednesday. LANL is investigating. Sigma is one of a class of facilities that receives little federal and contractor oversight; such oversight might detect vulnerabilities without relying on events such as this to flag issues (site rep weekly 8/12/05). This particular event would likely have received little attention except for increased contractor sensitivity due to the Am-241 Type B investigation underway. It warrants study since it reveals multiple work-control issues, some of which appear traceable to latent organizational weaknesses.

Chemistry and Metallurgy Research Building (CMR): CMR is inventorying and removing legacy hazardous chemicals and, this week, found three containers of shock-sensitive material. LANL Hazmat responded, and the containers are being deliberately and safely dispositioned.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 14, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 14, 2005

Jordan was on site this week augmenting site rep coverage.

DOE Independent Oversight: The DOE Office of Independent Oversight and Performance Assessment (DOE-OA) is here this week and next inspecting NNSA & LANL management programs for environment, health, and safety; a major focus of their inspection is status of corrective actions developed in response to last year's resumption reviews. They return in mid-Nov to validate findings.

Waste Operations: Based on a LANL management self-assessment, NNSA has approved restart of examining and repackaging of transuranic waste in the TA-50 WCRR Facility; this is an essential step for LANL to move forward on the Quick-to-WIPP risk reductions (site rep weekly 9/16/05).

Plutonium-238 Operations: By Oct 31st, LANL expects to complete decontamination of the room that was contaminated in August 2003. Currently, four cans in the room await packaging; the remainder (~234) have been packaged for eventual shipment to WIPP via Area G or for eventual stabilization (e.g., pyrolysis) and disposition (e.g., aqueous recovery) within TA-55.

DOE-NE (Nuclear Energy) and LANL currently expect LANL to resume bench-scale and start up full-scale aqueous recovery operations in Nov 2005 and Feb 2006, respectively. NNSA is requiring that "applicable" TA-55 interim TSRs first be implemented for both lines to address the building leak-path issue; it appears appropriate for NNSA and LANL to formally agree on specifically which new TSR controls must be implemented and verified as a pre-start for these operations. Some of the other steps required to support full-scale startup are: (a) resolution of remaining questions on effectiveness of safety basis controls (e.g., hydrogen generation); (b) closure of pre-start findings and definition of path-forward for post-starts from the LANL June 2005 readiness assessment (RA); (c) final LANL & NNSA RAs, covering also applicable interim TSRs; and (d) opening safe disposition pathways for residues and waste, preferably including the pyrolysis pathway (site rep weeklies 9/16/05, 5/27/05).

NNSA Type B Accident Investigations: NNSA has completed its investigation into the TA-48 acid inhalation injuries; the investigation into the Am-241 release continues (site rep weekly 8/12/05). Among conclusions from the former are that the acid injuries resulted from mixing and using acids outside a functional hood; those involved did not believe that a reportable accident had occurred; management did not ensure that workers recognized the full extent of hazards or that the workers were trained in the work control process or that the workers followed institutional practices; the workers' drive to accomplish research took priority over housekeeping, even though both had equivalent hazards; by reducing oversight and field presence, the NNSA Site Office (LASO) lost an opportunity to gauge the LANL integrated work management process; LASO followup on previous investigations has not driven LANL to establish a robust line management assessment program; LASO followup has also been slow, indicating weak NNSA commitment to using feedback to drive improvements.

Management: The LANL Institutional Assurance Board (IAB) and the Nuclear Safety Executive Board (NSEB) have been increasingly effective; LASO participation with these boards has dropped, which is unfortunate. The IAB does change control for the Operational Efficiency Project, while the NSEB reviews closure of PAAA corrective actions. LANL staff presentations before the NSEB also provide a uniquely useful and succinct analysis on the state and direction of LANL nuclear operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 21, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 21, 2005

Rosen was on site this week for the annual plutonium surveillance and monitoring conference.

DOE Independent Oversight: The DOE Office of Independent Oversight and Performance Assessment (DOE-OA) has completed their on-site review of NNSA and LANL; the site expects the first draft report for factual accuracy review by Nov 4th. Preliminarily, DOE-OA found resumption-related corrective actions in general and integrated work management (IWM) implementation in particular to be lagging from where they ought to be at this stage; also, both federal and contractor assessment systems, including issue management, warrant improvement. The DOE-OA team received full cooperation. Based on the review's thoroughness, the team's report ought to provide a well-substantiated snap-shot of the site's condition as the site prepares for contract transition.

Plutonium Facility (TA-55): LANL has completed a readiness assessment (RA) on implementation of safety basis controls for enhanced external security measures at TA-55 (site rep weekly 10/7/05). There were no pre-start findings; the 4 post-start findings and 5 observations focus on sustainability of controls such as vehicle speed limits.

Fire Protection: On Oct 3rd, LANL submitted to LASO an improved integrated plan to address fire protection issues and achieve site-wide improvements, as requested by a Board letter dtd 5/31/05 (site rep weekly 9/2/05). The plan covers staffing, fire hazard analyses, the 2004 emergency service baseline needs assessment, county fire dept contract, fire alarm system replacement project, and wild-land fire management. LANL based the plan on benchmarks with other DOE sites (e.g., SRS, LLNL) and plans to increase fire protection program funding in FY-06 by 50 % above the FY-05 target.

Nuclear Material Stabilization: During this week's conference, LANL reported that they continue to be on track to achieve the accelerated risk reduction committed to by the Secretary in DOE's latest LANL implementation plan for Recommendations 94-1/00-1 (7/23/04). Specifically, in the last two years, LANL has achieved 56 % of the overall risk reduction that is to be done by end of CY 2009. Within the last year, LANL has stayed on track by emphasizing robust packaging; processing has been limited by the long-term suspension of transuranic liquid waste receipts by the TA-50 Radioactive Liquid Waste Treatment Facility – RLWTF (site rep weeklies 7/1/05, 10/29/04). Eventually, some of this material will have to be unpackaged, processed, and repackaged or otherwise dispositioned; LANL currently expects this to take another two years (i.e., through CY 2011).

On Sep 7th, LANL submitted to NNSA a revised project execution plan for Board Recommendations 94-1/00-1. The plan accounts for impacts of the LANL-wide suspension and acknowledges that the RLWTF issues and the priority assigned to TA-18 Early Move Project have profoundly affected execution. One implicit assumption appears to be achieving increased throughput of transuranic waste within LANL and from LANL to WIPP. Specifically, in April 2005, LANL established that TA-55 will need to ship about 7.5 kCi of transuranic waste to Area G per year over 3 years; actual shipments in FY-05 from TA-55 to Area G and from Area G to WIPP were about half and about a quarter of that amount, respectively. Without improvement, the current trend could impact both mission and nuclear material stabilization activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 28, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 28, 2005

Dwyer, Jordan, Shields, and Tontodonato were on site this week reviewing preparations for contract transition. Elliott was also on site this week with an NNSA criticality safety review team.

LANL Contract Transition: Transition is scheduled for Dec 1st, 2005 to May 31st, 2006. Success requires close interaction between NNSA, the incumbent management team, and the in-coming management team, which NNSA will identify by Dec 1st. The in-coming team was required to submit a transition plan as part of their bid package, but it is not available now. The NNSA Site Office (LASO) is embargoed from discussing transition with LANL until released by the Source Evaluation Board. LANL management is planning for transition based on their best judgement of what's required.

NNSA Oversight: LASO has issues that hamper effective oversight and is not ready to manage contract transition or the new contract (e.g., site rep weeklies 9/23/05, 8/26/05). To get ready, LASO plans to enter a 3-month strategic pause in parallel with the first half of contract transition (i.e., Dec 2005 - Feb 2006), during which LASO would perform an organizational reboot by re-analyzing staffing needs, re-engineering key processes, and formalizing policies, procedures, training, and qualification. Detailed planning for the pause will occur during the next 2 to 3 weeks.

LANL would continue to operate during the pause, but LANL processes require LASO interaction and oversight. The first 3 months of contract transition is especially pivotal to ensuring not only that the new contractor starts out right but also that management and personnel stay focused on continued safe operation. LASO plans to have a small "continuity team" (e.g., ~10-20 people) focused on essential interaction. LASO also intends to rely on increased LANL oversight to compensate for decreased federal oversight during the pause, which would include cutting back on most deployed facility reps. LANL oversight and assessment processes unfortunately also have issues, and LANL appears inclined to wait and let the new contractor make improvements. Overall, it does not appear that NNSA has analyzed and understood the risks and the required risk mitigation associated with this pause, nor does it appear that corporately NNSA has systematically evaluated alternatives to the pause, such as bringing in an external federal assist team to facilitate LASO improving operations at this critical juncture.

TA-18 Early Move Project: Last Friday, NNSA approved startup of the TA-55 safeguarded trailer pad, and this week, TA-18 was de-inventoried to below Security Category I/II levels. A security-led inventory verification is underway to support a security downgrade decision. TA-18 is planning for SHEBA restart in delayed-critical mode and for a few other activities with sufficient fissile material to warrant criticality safety evaluations and formal development and implementation of controls.

On the pad startup, resolution of contractor-side issues from the June Operational Readiness Reviews are well-scrubbed, but resolution of federal-side issues are not apparent (site rep weekly 7/8/05); NNSA would benefit from a causal analysis of the latter focused on identifying systemic problems.

Chemistry and Metallurgy Research Replacement Facility Project (CMRR): Last Friday, the Deputy Secretary approved the performance baseline and construction start (Critical Decision 2/3) for the radiological lab / utility / office building (RLUOB), with scheduled completion in January 2010.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 4, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 4, 2005

Anderson, Burnfield, Jordan, and Von Holle were on site this week reviewing the status of LANL initiatives on integrated work management and conduct of engineering.

Waste Operations: LANL transuranic waste shipments to WIPP are the principal means for LANL to reduce risks associated with the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 9/23/05). Rate of shipment dropped from 9 truckloads per month in September to 1 per month in October due to the priority DOE has assigned to shipments from Idaho (~80/month). NNSA expects LANL shipments to resume at a rate of 1 per week later this month.

Integrated Work Management (IWM): The staff team observes that, within the Operational Efficiency (OE) project, the safety element, which builds on the IWM initiative, still has the greatest potential to directly improve worker safety, as discussed in a Board Itr to the NNSA Administrator (7/21/05); this is also the only effort at LANL that can eventually address work planning and control commitments made by the Secretary in DOE's implementation plan for Board Recommendation 04-1.

While significant progress has been made, implementation remains incomplete and is hampered by lack of consistent and continuously visible support by both NNSA and LANL senior managers as a high priority, lack of consistent understanding of the process at all levels, and insufficient availability of qualified mentors and subject matter experts (e.g., RCTs, IH). Although not always apparent, LANL has worked hard on this initiative; there have been at least four major revisions of the IWM procedure in the last two years; these were necessary, but the turnover frustrated the workforce. The lack of common understanding of the process is closely linked to broad issues at LANL in developing effective institutional training, which LANL is separately working. The limited availability of subject matter experts may be exacerbated if process changes are made that require more documentation but thereby reduce on-floor time and reinforce the opinion of many that this is primarily a paper process.

A common factor in each of the major accidents and near-misses at LANL during the last two years has been the human performance element, and LANL now has at least four loosely-coupled pilots underway to test implementation of best practices (e.g., INPO). This "test before implementation" approach is prudent, but integration will be needed. This effort is encouraging and appears key to LANL evolving into a high-reliability organization as described in DNFSB TECH-35, Dec 2004.

Conduct of Engineering: This OE element has shown the greatest improvement during the last two years of any of the eight OE sub-projects: two years ago, LANL had some groups with self-developed partially structured approaches to engineering tasks, but no institutional program (Board Itr 1 /27/04); now, there is an institutional program focused on high hazard and nuclear facilities with a good start at developing and implementing standardized approaches and with a small cadre of formally trained and qualified system engineers. There is also growing recognition among those directly involved with engineering that if these new approaches had been taken by some past LANL projects, then startup and life-cycle costs would have been substantially reduced. That said, senior management attention is warranted to ensure sustainability and further progress; challenges include: sustaining procedure and training development; establishing clear and formal linkage to other lab-wide processes (e.g., QA, IWM, USQ); moving out smartly on a multi-year technical baseline reconstitution (only about 3 % funded in FY-06); and logically evolving applicability into lower hazard and radiological facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 11, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 11, 2005

Independent DOE Oversight: The DOE Inspector General Office has started a review of the TA-18 mission relocation effort, including the TA-18 Early Move and the NTS Critical Experiments Facility projects. Also, the DOE Independent Oversight and Performance Assessment Office (DOE-OA) was here this week and expects to issue a report on their review in December (site rep weekly 10/21/05).

LANL Operations: Last Monday (10/31), LANL began to implement a new operations management structure focused on consolidating operations authority and thereby addressing several major issues identified during last year's resumption reviews (site rep weeklies 9/9/05, 4/15/05). There are three key elements: the RDL – the single individual assigned authority, accountability, and ultimate responsibility for a facility and its compliance with its safety basis; institutional support organizations (ISOs), which set the standards and provide the RDL and RDL staff the tools, training, and other resources to be successful; and the responsible line managers (RLMs), who are responsible for ensuring work is done within the compliance envelope jointly and formally set with the RDL.

Chemistry and Metallurgy Research Building (CMR): On Wednesday, CMR declared a potentially inadequate safety analysis (PISA) because the locations of some safety-class fire suppression risers do not match safety basis descriptions; this could affect required actions if a riser becomes inoperable. The cognizant system engineer found the problem during a walk-down. CMR is requiring operations manager approval before securing any risers and has started the unreviewed safety question process.

Pu-238 Operations: NNSA and LANL are considering conducting a set of operational readiness reviews (ORRs) before startup of the new aqueous scrap recovery line; LANL is also reassessing the closure of several pre-start findings from LANL's June readiness assessment; schedule impacts are not yet known. Effort to resume the bench-scale operation near-term continue (site rep weekly 10/14/05).

NNSA Site Office (LASO) Strategic Pause: LASO has targeted starting its 3-month strategic pause on Nov 21st, provided planning is complete (site rep weekly 10/28/05). Objectives of the pause have shifted more to requirements and staffing analysis and to office process development, and less to training and qualification. With few exceptions, LASO management and key staff are now totally focused on planning the pause down to the level of developing improvement plans for each LASO sub-organization and for each federal employee; this already appears to be affecting federal management of the laboratory, as well as requiring increased LANL management attention.

As for direct nuclear facility oversight, LASO currently anticipates 4 deployed facility reps during the pause, compared to 9 deployed now and to 20 required per the last analysis (site rep weekly 1/7/05). LANL is assembling a team of ~10 operationally experienced contractors to backfill for some federal oversight functions now expected to lapse; some of these contractors were assisting certain nuclear facilities with implementing challenging safety bases; implementation may now slip further behind.

Without close attention, other efforts with significant nuclear safety implications may also be affected, such as: reducing Area G transuranic waste inventory, resolving the Plutonium Facility (TA-55) leak-path issue, implementing interim TSRs at TA-55, reducing the multi-year safety basis backlog, ensuring thorough and rigorous readiness reviews, and keeping the Chemistry and Metallurgy Research Building (CMR) replacement project on track to support eventual CMR decommissioning.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 18, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 18, 2005

Emergency Exercise: LANL responded to hazardous material found off-site Wednesday morning and then conducted its annual emergency exercise Wednesday afternoon, including activating the Emergency Operations Center (EOC). The scenario involved a simulated accident between a vehicle and an acid-loaded tanker with accompanying injuries and a toxic plume release over the town-site.

Based on activities the site rep observed, emergency response showed marked improvement compared to training drills conducted earlier this year and a no-notice exercise conducted last December (site rep weeklies 9/16/05, 12/3/04). Coordination in the EOC between NNSA, LANL, and Los Alamos County was close and commendable; this is an essential element for LANL emergency response due to the proximity of LANL facilities to the public. Considering nuclear facilities, while the probability of a major accident and off-site release is low, further pre-planning appears needed to ensure timely and effective community protective actions, including resources to implement those protective actions.

Fire Protection: On Nov 8th, LASO forwarded to NNSA headquarters (NA-10) the LANL integrated plan to address fire protection issues in the Board's letter of May 31st (site rep weekly 10/21/05). LASO expressed concerns with (a) the pace of implementing improvements until the new LANL contract is in place, (b) LANL fire protection staffing and progress on fire hazard analyses, (c) LANL use of the exemption request process, (d) lapse in forest thinning funding, and (e) the incompletely understood path-forward to finish site-wide fire alarm system upgrades.

Of particular concern are delays in completing the scope of the partial site-wide fire alarm system upgrades in LANL plutonium facilities (TA-55, CMR); the delays have been attributed to lag-time for accompanying safety basis changes. These upgrades are intended to correct long-standing problems in alarm signal transmission (site rep weeklies 1/17/03, 9/28/01), and they become even more important as LANL transfers fire department dispatch to the newly established EOC joint dispatch center.

NNSA Site Office (LASO) Oversight: The LASO 3-month stand-down to prepare for contract transition starts Monday (11/21); NNSA's contract announcement is expected the following week (12/1), which will start the 6-month contract transition. During the first half of contraction transition (Dec 2005 - Feb 2006), federal oversight at LANL will be cut to one-third of current levels and consist of a 31-person continuity team, including 4 facility reps and 3 subject matter experts, supplemented in some manner by the NNSA Service Center. LANL will also step up operational oversight by 8 to 10 people during this period. The LASO Manager will meet daily with his principal staff to assess emergent needs and shift personnel as deemed necessary (site rep weeklies 11/11/05, 10/28/05).

The scale and timing for the stand-down is unfortunate since it coincides with the first 3 months of contract transition; the federal role during this period will be pivotal to (a) setting expectations for the new contractor management team and (b) ensuring the LANL workforce, understandably anxious about the future, stays focused on continued safe operation. The daily LASO Manager meeting appears to be the key risk mitigation since the composition of the LASO continuity team was established ad hoc. At this time, the deliverables, the specs for deliverables, and the opportunities to accelerate LASO preparation for transition are incompletely defined. LASO also appears to need substantial external assistance to efficiently achieve the key objective of the stand-down – develop sound processes for managing the new contract – since the new contract will be radically different from the old one (e.g., fee determination) and is outside the experience of many LASO personnel.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 25, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 25, 2005

Waste Operations: LANL has resumed transuranic waste shipments to WIPP at the rate of one per week; shipments last Tuesday (11/15) and this Monday (11/21) were the first two made since Oct 6th (site rep weekly 11/4/05). Overall, NNSA and LANL have shipped about one-fifth of the roughly 2,000 higher activity drums that constitute the Quick-to-WIPP population. The site rep is skeptical that NNSA and LANL can meet the safety basis requirement to ship the remaining drums from this set by June 2006; limiting factors appear to be the throughput constraints on both the TRUPACT loading facility (RANT) and the visual exam and repackaging facility (WCRR), as well as possibly the availability of WIPP trucks.

Management: NNSA stated this week that it will delay the LANL contract selection announcement that was scheduled for Dec 1st. Separately, the NNSA Site Office (LASO) started its partial stand-down on Monday (11/21). Some preparations were not yet complete, such as (a) identifying and having on-board supplemental federal support (e.g., from the NNSA Service Center); (b) increasing contractor oversight; and (c) setting up reporting processes to efficiently provide management daily perspective on emergent safety issues that might require immediate attention.

Transportation: Last week, NNSA reported results of a federal readiness assessment (RA) performed in October on LANL's implementation of its nuclear transportation safety basis, which was approved in Nov 2002; the companion LANL RA was completed in May 2005. The NNSA RA team concluded that, in general, the technical safety requirements (TSRs) are adequately implemented, but there are some deficiencies in select safety management programs including fire protection, quality assurance, and configuration management. A LANL corrective action plan is due next month.

Quality Assurance (QA): Also last week, LASO approved the LANL quality assurance program (QAP) and its implementation plan and placed them under change control; this action fulfills the requirement within the Nuclear Safety Management Rule (10 CFR 830) for a DOE approved QAP. Much needs to be done to fully achieve and validate implementation: as part of the Operational Efficiency (OE) Project, LANL continues to be on track to issue 9 of 15 institutional QA procedures by end of December, as discussed in site rep weekly 9/16/05; the 6 remaining procedures are still on hold based on the expected benefit from input by the new contractor management team.

Maintenance: LANL is not in compliance with the DOE nuclear facility maintenance management order (DOE O 433.1); LASO and LANL have recently increased emphasis on bringing LANL into compliance by mid-2006. Key DOE O 433.1 requirements include submitting and receiving DOE approval of a maintenance implementation plan (MIP) and updating the MIP biennially; establishing performance metrics; identifying consensus standards; and integrating the program with other safety programs (e.g., safety basis, integrated safety management). LANL submitted an institutional MIP in June 2005, and it awaits NNSA action. LANL expects nuclear facilities to submit annual plans in December to support implementation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 2, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 2, 2005

Management: After extensive review, the LANL Corrective Action Review Board (CARB) this week concurred with comments on the resumption corrective action plan for Los Alamos Neutron Science Center (LANSCE) – the first nuclear facility to reach this milestone. The CARB now is reviewing plans for six divisions, including those for the site services contractor (KSL), the Chemistry Division, and the Weapons Engineering Tritium Facility (WETF). The CARB reviews are LANL’s primary mechanism to ensure corrective actions are consistent, complete, and sustainable across the institution.

Nuclear Safety Oversight: As reported last week, the NNSA Site Office (LASO) started its partial stand-down, involving about two-thirds of its staff, before preparations were complete. Status of those preparations is as follows:

- On Friday (11/25), LASO issued a procedure for managing emergent issues that would have been worked by “paused” federal staff; such issues will now be triaged by LASO senior staff and assigned an owner if deemed essential. The procedure has lists of the baseline essential activities and the 31 continuity team members; assignment of roles and responsibilities for the baseline activities is not stated but assumed to align with prior assignments of team members.
- Subject to LANL senior management approval, LANL has plans and is poised to embed 8 operationally experienced people as institutional oversight within LANL nuclear and higher hazard facilities; this team would report findings daily to LANL management.
- External federal support has been discussed, but none appears to be on site at this time.

Plutonium 238 Operations: On Thursday (12/1), LANL began a readiness assessment (RA) on resuming the bench-scale aqueous scrap recovery operation, as well as implementing interim technical safety requirements specific to bench-scale (site rep weeklies 10/14/05, 8/5/05); the NNSA facility rep at TA-55 is observing. In parallel, LANL is improving planning and scheduling of Pu-238 operations, centered on starting up the full-scale aqueous recovery line and addressing the large residue backlog.

On Sep 30th, LANL submitted for NNSA approval a process hazard analysis for residue pyrolysis and bench-scale hydroxide precipitation; these are essential operations for reducing risks from the legacy Pu-238 residues and from new residues that will be created by the bench-scale recovery operation when it starts. Most of the legacy residues are now in containers (e.g., slip-lid cans) within plastic bags with filters; the bagged containers have been placed on shelves in storage cages that are due for seismic upgrades. The plan had been to store bagged containers in drums, but the need to do that was obviated by DOE designating ~60 % of the cans as transuranic waste, and they have been removed. While the remaining cans have been inspected and show no exterior damage, internal degradation is likely occurring and drives the need for timely disposition. NNSA action appears to be the next step on the critical path for residue disposition but also appears to be impacted by the LASO pause.

Waste Operations: On Wednesday (11/30), LANL discovered that an improperly vented transuranic waste drum had been shipped from TA-54 storage to the TA-50 inspection facility (WCRRF). The drum had a metal clip between the drum body and lid instead of a vent filter in the lid; the clip created a vent path that prevents gas buildup but is unfiltered. To prevent recurrence, LANL is improving procedures and operator training, as well as looking for indicators of other such drums in storage.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 9, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 9, 2005

Plutonium Facility (TA-55): TA-55 is LANL's largest and most complex nuclear facility by most metrics and is currently operating under a 9-year-old safety basis and a new set of interim technical safety requirements (iTSRs) that are still being implemented. The iTSRs include compensatory measures for TA-55's dominant nuclear safety issue, which is the still-open question on effectiveness of the passive confinement strategy in the event of a major accident (site rep weekly 9/23/05). It's likely that final resolution will involve some combination of confinement ventilation, fire suppression, containerization, glove-box upgrades, material-at-risk limits, and specific administrative controls.

While their report is still draft, the recent DOE Office of Independent Oversight (DOE-OA) review at LANL raises questions on the TA-55 ventilation and fire suppression systems, as well as safety basis. LANL has actions underway that may address many – but perhaps not all – of these specific issues over time; these actions include the TA-55 Reinvestment Project, the LANL conduct of engineering technical baseline reconstitution, and the LANL efforts in response to Board Recommendation 04-2 on active confinement. Given (a) the importance of NNSA and LANL reaching timely resolution on confinement strategy and (b) the potential impacts on that resolution from these issues, it may be appropriate for NNSA to initiate a focused safety system oversight (SSO) review at TA-55 soon after the DOE-OA report is finalized, which is expected before the end of the month.

Nuclear Safety Oversight: The NNSA Site Office (LASO) partial stand-down continues (site rep weekly 11/25/05). LASO is working on a procedure to integrate federal activities during the 3-month pause, which has now been underway 3 weeks. LASO also appears poised to shift staff to address a growing backlog of LANL safety basis proposals requiring federal action; the backlog grew from 7 to about 30 during the first two weeks of the pause. The NNSA Chief of Defense Nuclear Safety (CDNS) office had 2 people on site this week focused on TA-18 and TA-55 operations; several NNSA Service Center managers were also on site Thursday to discuss future Service Center support for LASO.

On the contractor side, LANL has embedded 8 people in facilities as institutional oversight; their first weekly report to LANL management is due today and will be discussed with LASO next Tuesday.

Training: As part of the Operational Efficiency (OE) project, LANL has assessed most of its lab-wide courses (~600) and determined that the majority of course-providers have not used the systematic approach to training required by the DOE nuclear training order and LANL policy. This standard approach has five sequential steps: analyze needs; set objectives; develop materials; deliver training; and evaluate effectiveness. Full implementation would not only strengthen sustainability of many resumption-related corrective actions but also address concerns among many on the need for more meaningful and effective training. LANL plans to develop a prioritized list of courses needing improvement within the next few weeks and have a schedule for course revisions by mid-February.

Critical Experiments Facility (TA-18): Last Friday, NNSA (NA-10) approved Critical Decision 2, the performance baseline, for the Nevada Test Site critical experiments facility (CEF). Scope includes 4 of the 5 assemblies at TA-18; SHEBA is excluded. Scheduled completion is 1st Quarter FY 2010.

Am-241 Contamination Event: Last week, the LASO Manager signed the report on the NNSA Type B investigation into the inadvertent contamination release that occurred in July 2005 (site rep weeklies 8/12/05, 7/29/05). NNSA release of the report is expected shortly.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 16, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 16, 2005

Plaue was on site this week augmenting site rep coverage.

Emergency Response: The NNSA emergency operations office (NA-43) observed the NNSA Site Office (LASO) and LANL emergency exercise last month and has issued a report. It indicates that, while some areas need more work, overall performance was substantially improved compared to that observed in the exercise a year ago (site rep weeklies 11/18/05, 12/3/04).

Criticality Safety: Per LANL request, NNSA (NA-117) recently performed at LANL one of its first formal criticality safety program reviews in the complex (site rep weekly 10/28/05). The NNSA team's report states that they observed no ongoing unsafe operations from a criticality safety perspective; however, their observations indicate that the LANL program is expert-based, under-staffed, incompletely documented, infrequently assessed, and managed informally and at too low a level; overall, the program is not demonstrably compliant with applicable national consensus standards.

The NNSA team made several specific recommendations that it suggested should be implemented within 3 months to provide a formal basis for continuing operations. These recommendations center on reviewing all ongoing fissile material operations and ensuring that an explicit criticality safety analysis exists for each, that the controls developed are implemented in postings and procedures, and that appropriate configuration management is in place for all explicit and assumed engineered controls. The team asserted that, while it seems unlikely that an undiscovered hazard exists, these recommendations should be implemented expeditiously. LANL is evaluating the team's report and recommendations.

Nuclear Safety Oversight: LANL and LASO seem to be at-odds on federal access to day-to-day observations by the new LANL oversight team, but urgent discoveries would probably be quickly reported. The LANL team is still coming up to speed and has been focused on facility-entry training and introductions to operations management, such as the RDLs - several of which are also new to their positions under the new ops management structure (site rep weekly 11/11/05). Overall, the federally imposed "LANL oversight team strategy" appears to be a force-fit solution that still is developmental and that still incompletely compensates for reduced federal oversight during the LASO stand-down..

Plutonium-238 Operations: LANL is still waiting on LASO action on a process hazard analysis for residue pyrolysis, which is a key risk reduction step (site rep weekly 12/2/05); action appears delayed by the LASO stand-down. Also, LANL has finished a readiness assessment of the bench-scale aqueous recovery operation. Pre-start findings included addressing glove-box housekeeping and demonstrating safety-related component quality-level; post-start findings included improving operator knowledge of the chemical processes so that they can recognize and respond to abnormal conditions.

Critical Experiments Facility (TA-18): LANL is waiting on LASO action on a Nov 10^h proposal to decommission the 4 critical assemblies that are to move to Nevada; this appears perhaps delayed by the LASO stand-down. Decommissioning disables certain safety features required by the TA- 18 safety basis, but this looks acceptable since these machines have been de-fueled and will no longer operate at TA-18. Timely action is needed to support the Nevada Critical Assembly Facility (CEF) project, which is the key element to sustaining the national criticality safety training and experimentation program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 23, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 23, 2005

Martin and Rauch were on site Tuesday augmenting site rep coverage.

LANL Contract: On Wednesday (12/21), DOE announced that Los Alamos National Security LLC (LANS) has been selected as the next management and operations contractor for LANL, effective June 1st, 2006. The LANS partnership includes University of California, Bechtel, Washington Group Intl, and BWX Technologies. Initial contract term is 7 years, with potential for extensions to 20 years.

Waste Operations: NNSA and LANL continue to have difficulty in achieving efficient transuranic waste operations, although efficient waste operations and shipment are key to addressing the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 9/23/05). NNSA and LANL anticipate increasing to 2 shipments per week in early January and to 4 shipments per week in the Spring and thereby finish shipment of the -2,000 higher activity waste drums in the Quick-to-WIPP set by June 30th, 2006. There are challenges: for example, this schedule likely requires LANL to go to multi-shift (24/7) characterization, which increases worker risks if incorrectly done. NNSA has directed LANL to provide in January specific recommendations to improve efficiency.

Am-241 Contamination Event: NNSA now plans in mid-January to release the report and to brief the site on findings from its Type B investigation into the July 2005 release (site rep weekly 12/9/05). LANL has been taking actions based on what it knows of the issues. The NNSA briefing and report are needed to ensure that proper corrective actions are being taken with appropriate priority.

Plutonium Facility (TA-55): Monday morning, nine workers promptly evacuated the TA-55 vault following a continuous air monitor (CAM) alarm; appropriate immediate actions were taken, including securing the scene. The release was predominantly Pu-239. Five workers had positive nasal smears (-90 dpm max); three workers had contamination on gloves or booties consistent with later floor surveys (20k dpm max). Initial dose estimates should be available in January.

The workers were inventorying containers. Due to this event, TA-55 has secured material movements outside glove-boxes, and LANL has started an investigation, which is proceeding deliberately. TA-55 identified and triple-bagged a suspect container and another nearby similar container on Wednesday and radiographed these containers on Thursday. Further investigation and recovery will occur after Jan 1st

Pu-238 Operations: The readiness assessment (RA) for the bench-scale aqueous recovery operation has two open pre-start findings: (1) show compliance with quality requirements for safety-class ball-mill jars, and (2) resolve a material discrepancy on the as-delivered jar lids - the lids are aluminum instead of stainless steel, which is the material specified in the safety basis.

NNSA approved interim bench-scale operations in May 2004 based on several controls, including stainless-steel jar lids, and bench-scale operated briefly with the discrepant lids before the July 2004 lab stand-down. In July 2005, NNSA approved designating the jars and lids as safety-class in the interim technical safety requirements (iTSRs); this is one of the compensatory measures for the passive confinement strategy issue. TA-55 recently found the discrepancy while verifying the iTSRs applicable to bench-scale. Based on this and other issues, TA-55 management has put a hold on bench-scale startup, pending an independent formal causal analysis of the RA findings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 30, 2005

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 30, 2005

The laboratory was closed this week, providing an opportunity for reflection.

LANL is in a transformation. In the long term, the contract decision last week will eventually reshape the lab and conceivably the entire nuclear weapons complex. In the short-term, this decision ended one period of uncertainty for the workforce while ushering in another. The safety implications of personnel distraction during this period have LANL management's attention.

There has been tremendous activity since the lab-wide stand-down of July 2004 and throughout this year. Indicators of LANL progress included: • resuming nuclear operations safely and deliberately within 6 months; • identifying several thousand issues during resumption and quickly addressing about 400 such issues that were deemed an unanalyzed risk or imminent danger; • establishing the Corrective Action Review Board (CARB) as an independent quality check on actions taken on the approximately 2,000 non-institutional issues found during resumption; • consolidating line responsibility for most nuclear operations at the associate director level, and consolidating operations authority with a few key individuals - the RDLs; • making substantial progress on the Operational Efficiency (OE) Project, which is intended to address weaknesses in key institutional functions, such as training and quality assurance; • resuming transuranic waste shipments to WIPP after an 18-month hiatus, and by year's end shipping about one-fifth of the roughly 2,000 higher activity drums that constitute the Quick-to-WIPP set - these shipments are key to addressing the lab's postulated highest-consequence nuclear accident; • developing and starting implementation of interim technical safety requirements (iTSRs) for the Plutonium Facility (TA-55) - these are key to continuing safe operation of TA-55 under the 9-year old safety basis and to compensating for the still-open confinement strategy question, which is TA-55's dominant nuclear safety issue; • recognizing emergent safety concerns and briefly suspending nuclear operations on at least four occasions in four separate nuclear facilities.

The key criticism may be the slow pace. The DOE Office of Independent Oversight (DOE-OA) recently summed this up well: to paraphrase - resumption-related corrective actions in general and integrated work management (IWM) implementation in particular are lagging from where they ought to be; also, both federal and contractor assessment systems, including issue management, warrant improvement (site rep weeklies 11/4/05, 10/21/05, 12/31/04). The contract competition likely hindered progress, since the commitment needed to some long-term fixes will also require long-term ownership.

On the federal side, NNSA oversight of LANL was reactionary and steadily deteriorated this year. DOE-OA also summed this up well: NNSA is not always performing effective oversight that drives continuous improvement in integrated safety management, in the contractor assessment system, and in other areas; recent efforts have focused on NNSA Site Office internal organizational matters and would benefit from management and organizational stability and increased headquarters support. The issues with NNSA oversight were best-illustrated by some of the problems that arose during the TA-18 Early Move Project, particularly with the TA-55 pad startup process (e.g., site rep weekly 7/8/05). While the Early Move Project achieved its FY-05 objectives, it adversely impacted many safety initiatives, such as nuclear material stabilization, criticality safety improvements, and TA-55 confinement strategy resolution. In the case of the TA-55 pad, programmatic priorities dominated startup to the point that restoring balanced priorities nearly derailed the Early Move Project. While LANL has taken some actions, NNSA has apparently done little to study and avail itself of lessons learned from this project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 6, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 6, 2006

Contract Transition: NNSA is scheduled to brief the Los Alamos Alliance LLC team today on their unsuccessful bid; more details on LANS transition plans should be available 10 days after this brief.

Federal Oversight: The NNSA Site Office (LASO) is 7 weeks into a 14-week stand-down to prepare for the June Pt contract transition (site rep weekly 11/25/05). In the last month, the 8 federal staff assigned to the authorization basis (AB) group have resumed their duties in order to address a growing backlog. Also, the 3 facility reps (FRs) assigned to WETF, LANSCE, and DARHT are beginning to attend plan of the week/day meetings to increase federal awareness of the higher hazard activities occurring in those facilities; their part-time coverage (15 %) supplements 4 other FRs who are deployed full-time, primarily in plutonium and waste operations (TA-55 and TA-50/54). As a result of these shifts, LASO now has 37 people total working on continuity of LANL operations; the number directly involved with safety oversight has increased from 10 to 15 (i.e., 4 FRs, 8 AB staff, 3 SMEs).

LASO now has 88 internal and 19 external federal staff assigned to preparing for contract transition (107 total), although it doesn't appear that all are full-time. They are divided into 16 teams. While reports have inconsistencies, it appears that these teams are running about 3 weeks behind the baseline schedule on average. Most teams still expect to be done by Feb 28"; however the business model team and the contract transition team now expect to finish in mid-April and end of May, respectively.

Plutonium Facility (TA-55): TA-55 continues to radiologically characterize and to plan recovery from the Pu-239 contamination released into the vault on Dec 19^h (site rep weekly 12/23/05). Initial dose estimates for personnel involved are low (e.g., 10 - 50 mrem CEDE range, which is two orders of magnitude below the annual federal limit). Material movements outside glove-boxes remain restricted.

Based on contamination surveys and radiographs, the source appears to be an archival oxide sample from the early 1980s; the sample was packaged in a plastic screw-lid jar within a plastic bag, both within a taped, slip-lid can; the inner jar and bag failed, releasing powder into the can; the vinyl tape around the lid circumference then possibly failed, causing the release. TA-55 has triple-bagged this container and another similar container, but records indicate that there could be several dozen similar containers in the vault, including about a dozen that are near-identical. Some of these containers were on a list to be repackaged near-term as part of LANL response to Board Recommendations 94-1/00-1, but clearly this effort needs higher priority. A recovery plan is expected to be available next week.

TA-55 Confinement Strategy: This week, NNSA disapproved LANL-proposed performance criteria for safety-class plutonium containers because the criteria did not account for a eutectic-induced failure mode for plutonium metal in stainless steel packaging at above 400 C. NNSA had requested the criteria last September as part of developing a path-forward for the TA-55 confinement strategy issue (site rep weekly 9/23/05). The LANL proposed criteria are based on 10 accident scenarios, mostly involving Pu-238 containers. It's not clear that LANL considered all applicable Pu-239-related scenarios (e.g., vault fire) or whether these criteria will contribute in a readily justifiable manner to addressing the confinement strategy question; the picture is incomplete, particularly due to questions on pedigree of current Pu-238 and Pu-239 packaging. LANL owes refined accident analyses to NNSA this month that hopefully will focus future actions for the confinement issue (site rep weekly 9/16/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 13, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending January 13, 2006

Jordan was on site this week augmenting site rep coverage.

Plutonium Facility (TA-55): Thursday evening (1/12), LANL placed TA-55 in standby (Mode 2) and established a 2 hour roving fire watch due to suspected failure of a 17-year-old fire alarm system component that is no longer made. Last year, NNSA designated this system as safety-significant as one of the compensatory measures for the confinement strategy issue. LANL plans to eventually replace the system as part of the TA-55 reinvestment project. On Friday (1/13), NNSA approved LANL's proposed path-forward, which involves modifying the system and testing at least one alarm device in each of the roughly 200 zones before removing the fire watch and returning to operations.

In addition to the above, LANL continues its deliberate investigation and recovery planning for the vault contamination of Dec 19th. Followup on suspect packaging has led to checking containers in CMR and TA-35(TA-55). LANL also appears on schedule to submit by Jan 31st its refined analysis of the passive confinement strategy (site rep weeklies 9/16/05, 9/23/05).

DOE Independent Oversight: The DOE Office of Independent Oversight (DOE-SP-40, formerly DOE-OA) has issued their final reports on their October assessment of LANL and the NNSA site office (LASO); previous summaries apply (site rep weeklies 10/21/05, 12/9/05, 12/30/05). The final report on LANL emphasizes needs for: • clarifying the direction, expectations, and accountability for implementing the integrated work management (IWM) initiative; • establishing a systematic approach to address longstanding issues on the TA-55 safety basis and vital safety systems; enhancing and effectively implementing the lab's corrective action management process. The next steps are for NNSA to forward the report to LANL and for LANL to prepare a corrective action plan.

Criticality Safety: The site rep understands that a LANL plan to respond to last month's NNSA criticality safety assessment report is imminent (site rep weekly 12/16/05). The NNSA team recommended that LANL within 3 month review all ongoing fissile material operations and provide a formal basis for continuing these operations, with emphasis on ensuring that an explicit criticality safety analysis exists for each, that the controls developed are implemented in postings and procedures, and that appropriate configuration management is in place for all explicit and assumed engineered controls. Due to the extensive number of such operations (~700 in TA-55 alone), LANL plans to focus efforts before March 8th on reviewing documentation with assistance from outside experts and on correcting identified deficiencies; on-the-floor reviews would follow. While concerned about the completeness of this effort, NNSA has indicated that this is an acceptable path-forward.

Critical Experiments Facility (TA-18): The site rep understands that the effort to resume SHEBA operation remains under-funded and has decreasing priority; the probability of success appears very low based on the low priority and the similar but unsuccessful attempts last year to restart Planet and Comet. Furthermore, there are informal reports that the Nevada Test Site Device Assembly Facility (DAF) is under-funded for FY-06 and may be placed in warm-standby in March; if this does occur, it will likely impact transferring remaining TA-18 material, now at TA-55, to DAF and timely starting up operations in DAF that would support the national criticality safety research and training program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 20, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 20, 2006

Plaue was here this week augmenting site rep coverage and reviewing nuclear waste operations.

Federal Oversight: The NNSA Site Office has resumed facility rep coverage for the Weapons Engineering Tritium Facility (WETF) because of a new operation scheduled to start in February.

Plutonium Facility (TA-55): On Monday, TA-55 completed fire alarm system repairs and resumed operations. On Thursday, TA-55 resumed normal material moves that use robust packaging; other material moves outside glove-boxes remain restricted due to the Dec 19" vault contamination event.

Integrated Safety Management (ISM): Last Tuesday (1/10), the Radio-chemistry Lab (TA-48 RC-1) had a radiation meter saturate, later attributed to procedure violations; the event was reported on Thursday (1/12) and contentiously critiqued on Friday (1/13). RC-1 has had similar events in the past; they will likely continue until more constructive feedback and improvement mechanisms are in place.

Waste Operations: Efficient waste operations and shipment are key to addressing the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 12/23/05). LANL has decided to forgo 24/7 waste characterization and instead adopt a promising extended shift approach suggested by the work-force; even so, LANL expects the Quick-to-WIPP set of higher activity drums will not be shipped before October - 3 months later than the current commitment.

The site rep believes that, due to future receipts and underground inventory recovery, the risk reduction from Quick-to-WIPP may no longer be as great as NNSA once perceived (site rep weeklies 12/24/04, 11/5/04); the risk may remain high until Area G is nearly de-inventoried, now projected for early 2012. Better goals now may be to sustain and improve operations and maximize efficiency. LANL has started an aggressive improvement effort that has merit and is based on best practices at other sites (e.g., SRS). NNSA could actively support this effort, including accepting some short-term risks (e.g., seismic) to maximize efficiency; these short-term risks appear similar to those accepted for CMR.

Pu-238 Operations: Preparations continue for resuming bench-scale aqueous recovery near-term and starting up the full-scale line later this year. One bench-scale issue is that it will increase the current sizeable inventories of residues and liquid wastes, both of which do not have operating disposition pathways. The liquid waste pathway relies on RLWTF TRU operations not expected to resume until mid-2006. The residue pathway relies on pyrolysis startup and new packaging standards, related to longstanding, still-open NNSA and LANL corrective actions from a Type B investigation (Dec 2003).

On full-scale, LANL now intends to have engineered, normally-open vents for several tanks and thereby address hydrogen generation; this will require NNSA approval of new safety features. LANL now also believes that ion exchange operations will be needed soon after startup; this will require addressing shortly several other open safety issues cited in a Board letter of Aug P', 2003.

Chemistry and Metallurgy Research Replacement Facility Project (CMRR): Vendor design work on the rad lab/utility/office building (RLUOB) is highly restricted until LANL approves the vendor's quality assurance plan and audits his quality program. The NNSA Site Office has requested and LANL is preparing lessons learned from how the RLUOB quality requirements and standards were invoked.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 27, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 27, 2006

Am-241 Contamination Event: On Tuesday (1 /24), the NNSA Type B investigation team leader briefed LANL management on the findings on the Am-241 release of July 2005. The team concluded that the onsite and offsite responses provided adequate protection of the workers, the public, and the environment and that the direct cause was repeated handling of highly contaminated items without any radiological controls. The site rep will report further on this next week (site rep weekly 12/23/05).

DOE Independent Oversight: On Wednesday (1 /25), the NNSA Site Office (LASO) requested LANL to respond to the recent report by the DOE-SP Office of Independent Oversight and to provide a corrective action plan (CAP) for identified deficiencies (site rep weekly 1/13/06). Because of the similarity in institutional issues, LANL is developing an integrated CAP, expected in March, that will address the DOE-SP report, the Am-241 contamination event, and the TA-48 acid vapor inhalation injury event (site rep weekly 10/14/05). On the DOE-SP report, the site rep believes that the issues asserted on TA-55 vital safety systems warrant a timely, focused, and objective examination because of their potential impact on resolution of the confinement strategy issue (site rep weekly 12/9/05).

Plutonium Facility (TA-55): TA-55 has visually inspected and taken swipes on the exterior of the approximately 100 containers in the vault with characteristics most like the one that leaked on Dec 19th; they have found no indications of other failed packaging, including no discernable increase in contamination levels (e.g., CAMs). The plan for these containers during the next few weeks is to introduce them in small groups into a glovebox line for repackaging. Subject to the results of comprehensive surveys, limited vault operations with compensatory measures may resume next week.

Radioactive Liquid Waste Treatment Facility (RLWTF): The TA-50 transuranic (TRU) liquid waste processing system is in marginal condition (e.g., site rep weeklies 7/1/05, 10/29/04, 7/30/04). Near-term, LANL plans to resume operating the existing system in order to process current backlogs of TA-50 and TA-55 acidic solutions and to de-inventory the TA-50 existing equipment. By mid-2006, LANL intends to replace the TA-50 leaking caustic waste receipt tank, by-pass existing equipment, and install new equipment. To support near-term operations, LANL plans to invoke new operational controls for confirming system integrity and rapidly detecting and responding to leaks.

The TA-50 pump house and influent storage facility construction project is struggling. Although the expected source-term is low, NNSA designated this as a Hazard Category 2 nuclear facility in 2004 and designated several safety-significant systems, such as the structure (PC-2) and liquid confinement system (site rep weekly 2/6/04). In September, LANL took over management of construction. The below-grade concrete structure appears largely in place now, and the storage tanks are being delivered. Last week, an NNSA independent project review (IPR) team identified about a dozen concerns with the project; their final report is expected in a few days. This week, NNSA and LANL began a quality assurance review focused on the steel and concrete construction because of questions raised during the IPR team review. Based on what is known now, NNSA and LANL are considering actions, up to and including suspending the project until the issues are further understood and a path-forward is defined.

Critical Experiments Facility (TA-18): This week, NNSA approved releasing the hold on decommissioning the four critical assemblies that are to move to Nevada (site rep weekly 12/16/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 3, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 3, 2006

Anderson was here this week and will be here next week augmenting site rep coverage.

Plutonium (Pu) Facilities: Since at least 1999, the Pu storage standard (DOE STD-3013) has identified a potential for container failure due to a Pu metal and iron eutectic at about 400 °C and has stated that storage in stainless steel containers appears acceptable up to 250 °C. Recently, NNSA and LANL have begun to rely on container integrity to address fire scenarios and the TA-55 confinement strategy issue; however, LANL analyses for several nuclear facilities indicate temperatures in the range of 400°C to 600 °C or higher for unmitigated fires involving moderate combustible levels.

This week, LANL declared a potential inadequacy in safety analysis (PISA) for several nuclear facilities, including TA-55, due to the eutectic issue (site rep weekly 1/6/06); compensatory measures include identifying storage locations that have Pu metal and ensuring combustible loading reviews are current. Separately, LANL has slipped their proposal for resolving the TA-55 confinement strategy issue to March 31^d to allow time for an independent technical peer review; impact on DOE's ability to meet the Secretary's commitments under Board Recommendation 04-2 is unclear at this time.

Am-241 Contamination Event: The Type B investigation report discussed last week captures in one place a number of longstanding NNSA and LANL issues, such as the observation that radiological facilities receive insufficient independent oversight. Some of the needs identified include: facilities ensuring that radiological hazards are appropriately communicated, LANL institutionally ensuring that the integrated work management (IWM) initiative is consistently applied, the NNSA site office (LASO) expanding its oversight to radiological facilities, and NNSA headquarters setting oversight expectations for LASO (site rep weeklies 11/4/05, 9/23/05, 8/12/05, 7/29/05, 7/8/05).

Radiological Facilities: Since 1997, NNSA has approved downgrading more than a dozen LANL nuclear facilities to radiological status; in a few cases, NNSA and LANL credited ANSI source encapsulation or DOT special form packaging when downgrading, as permitted by DOE STD-1027. Without these exclusions, these facilities would be considered nuclear facilities (Hazard Category 2 or 3) and would have analyses done and controls implemented per the Nuclear Safety Management rule (10 CFR 830 subpart B) to prevent or mitigate accidents such as fires. Because of these exclusions, some of these facilities have radioactive inventories comparable to nearby Hazard Category 2 or 3 nuclear facilities but much less rigor in oversight and in development and implementation of controls.

On Wednesday (2/1), NNSA disapproved excluding both Pu metal and oxide items from the inventory sums for LANL radiological facilities categorized using the DOE STD- 1027 exclusion; NNSA cited the eutectic issue for metal items and the lack of justification for oxide items; this appears to reverse the previous downgrade decisions and to make 10 CFR 830 subpart B applicable to these facilities.

The site rep observes that, based on review of the references cited in DOE STD-1027, the technical basis for the prior exclusions seems insufficient to ensure that a fire in a downgraded facility will not result in a significant on-site or off-site release. Specifically, with the possible exception of the DOT Type B containers and ANSI Class 5 and 6 sealed sources, it appears that the required container testing would not demonstrate package integrity under a representative unmitigated fire scenario (e.g., 400 °C to 600 °C or higher). This may have implications to other DOE sites (site rep weekly 7/29/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 10, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 10, 2006

Anderson was here this week augmenting site rep coverage.

Radiological Facilities: LANL has put materials in a safer configuration due to concerns that eutectic formation might breach containers during a fire; another concern is that the encapsulation credited by DOE STD-1027 may also be ineffective in a fire. Analysis is underway to better define the concerns.

Integrated Work Management (IWM): LANL management attention has increased on improving IWM implementation and pursuing human performance initiatives (site rep weekly 11/4/05). Some of last year's pilots, such as IWM mentors, appear successful and are embraced by the workers; increased management presence on the floor and focused walk-arounds have also been effective. However, it is unclear right now how far and fast improvements can be driven before contract transition on June 1st.

Authorization Basis (AB) Verification: The NNSA Site Office (LASO) is struggling and lacks internal consensus on the level of federal and contractor verification required following AB changes, particularly following AB updates for on-going activities. Such changes are not explicitly included in the DOE startup and restart order (O 425.1C). For their part, LANL is developing an implementation validation review (IVR) process that seems based on proven best-practices at other sites.

Plutonium Facility (TA-55): Vault recovery from the Dec 19th contamination event continues (site rep weekly 1/13/06). TA-55 is moving suspect containers out of the vault and into glovebox lines for inspection and repackaging. This week, work slowed when one bulged inner can and one rusted-to-failure inner can were discovered and when concerns were raised on potentially pyrophoric contents in other cans; these represent abnormal conditions that warrant special attention. In other areas, a PF-4 evacuation drill last Thursday (2/2) revealed issues in emergency response and in drill simulation and control; the drill was complicated by contamination found on clothing for two PF-4 workers. TA-55 also reported last week that a sliding door between two glove-boxes fell and momentarily pinned a worker's gloved hand without injuring the worker; as a result, TA-55 is looking for those systems that need frequent repair and that should be placed in a routine scheduled maintenance program.

Pu-238 Operations: TA-55 management has authorized resumption of the bench-scale aqueous scrap recovery operation based on completion of a lab readiness assessment, on closure of pre-start findings, and on verification of implementation of applicable interim technical safety requirements (site rep weekly 1/20/06). Material condition of this operation has greatly improved in recent weeks. Actual startup is expected next week using a deliberate startup plan and under increased oversight.

Chemistry and Metallurgy Research Building (CMR): CMR reported this week that a Wing 5 worker found a high level of localized Am-241 contamination on the side of his hand. The contamination was removed with tape; nasal swipes were negative; the source is being investigated.

Lightning Protection: Several nuclear facility ABs cite lightning protection as performing a nuclear safety function. LANL is investigating questions on completeness of recent system inspections, including making a judgement on system operability in each nuclear and high hazard facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 17, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending February 17, 2006

Nuclear Safety Oversight: The NNSA Site Office (LASO) is within two weeks of the end of its 14-week stand-down to prepare for the June 1st contract transition (site rep weeklies 1/6/06, 11/25/05). Preparations for the stand-down were incomplete when it began, including establishing compensatory oversight mechanisms. LANL has since embedded 8 operationally experienced people as institutional oversight within the nuclear and higher-hazard facilities, and LASO has renewed its own oversight mechanisms and increased its staffing dedicated to continuity-of-operations by 20 % (i.e., to 37). Both these efforts started from scratch in early December and have grown in effectiveness during the last two months, based on the quantity and quality of operational data now being reported.

Separately, NNSA appears poised to accelerate dependence on the contractor assurance system (CAS) at LANL after the June 1st contract transition. Few details are available now on the new contractor's CAS proposal or on the CAS implementation schedule. It is also unclear how accelerated federal dependence on CAS would be consistent with recommendations on federal oversight that were made during the two recent NNSA Type B investigations and the DOE-SP Independent Oversight review (site rep weeklies 2/3/06, 12/30/05, 10/14/05).

Fire Protection: LASO has not yet formally tasked LANL to develop an updated fire protection strategy, as committed to by NNSA to the Board in a letter dated Jan 12th; the site rep believes that a near-term update of LANL's status on executing its current strategy would be more beneficial – particularly for wildfire – and that a strategy revision should be deferred until after contract transition.

Criticality Safety: By March 8th, LANL expects to finish the documentation review of its on-going fissile material operations and to finalize a criticality safety improvement plan that addresses issues identified in NNSA's Dec 2005 criticality safety assessment report (site rep weekly 1/13/06). LANL reported this week that they are about 80 % complete reviewing analyses and procedures for about 600 operations; of those completed, about 10 % (44 operations) have warranted a walk-down for further evaluation and about 5 % (22 operations) have warranted putting compensatory measures in place.

Plutonium Facility (TA-55): Pu-238 bench-scale aqueous recovery operations resumed this week. Separately, the vault recovery operation has been curtailed in order to ensure that hazard identification and controls are adequate for addressing abnormal containers; recovery should resume next week. Overall, vault decontamination appears essentially done, except perhaps for the shelf that held the container that failed on Dec 19th. The key steps now are to address suspect containers and to establish confidence that controls will be adequate for future handling and storage operations based on current knowledge of containers and their contents. Longer term, increased emphasis on stabilization and packaging (i.e., Recommendations 94-1/00-1/05-1) appears warranted to prevent recurrence.

Waste Operations: On February 7th, NNSA formally approved Critical Decision 0 (CD-0) for a new Hazard Category 2 transuranic waste facility that would be capable of processing and shipping about 1,000 drums per year after TA-54 shuts down, which is expected in 2012 per the Consent Order. Total project cost is not to exceed \$40 M. Bounding accident scenarios, safety system functional classification, and to the extent possible, all other aspects of the facility safety basis are to be defined as part of conceptual design and before CD-1, which is scheduled for the 2nd quarter of FY-07.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 24, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 24, 2006

Hunt was here this week augmenting site rep coverage.

Plutonium Facility (TA-55): LANL has placed TA-55 in standby (Mode 2) and established a continuous fire watch due to an emergent concern over operability of sprinkler heads. Extent of condition and path-forward are still being determined; initial projections are that programmatic operations may remain suspended for several weeks. The facility has begun to containerize material that is now in glove-boxes and thereby increase the margin-of-safety during a possible extended suspension. LANL is also considering whether similar concerns may apply to other LANL facilities.

The concern arose when engineering personnel were walking down the system and found that up to about half of the sprinkler heads in some rooms have paint or corrosion, which could compromise functionality of fire suppression. TA-55 fire suppression is designated safety-significant now and is being considered for re-designation as safety-class in response to the building confinement strategy issue. During this suspension, TA-55 intends to also pursue resolution of other issues, such as those identified in last year's NNSA criticality safety assessment and the DOE-SP review.

Waste Operations: On Friday, the TA-54 TRUPACT loading facility (RANT) suspended operations due to a potential inadequacy in safety analysis (PISA) involving the minimum specified riser pressure for the fire suppression system. While this suspension may be short-term, it also interferes with transuranic waste shipments from LANL to WIPP, which are key to addressing the lab's highest consequence nuclear accident postulated in approved safety analyses (site rep weekly 1/20/06).

Fire Protection: Fire scenarios dominate the high-consequence end of the risk spectrum for LANL nuclear facilities. LANL is working on corrective actions to address weaknesses in the institutional fire protection program in response to a Board letter of May 31st, 2005. The issues discussed above highlight the importance of strengthening the institutional program and oversight in this area.

Critical Experiments Facility (TA-18): TA-18 activities are dwindling and consist mostly of finishing the Early Move Project and staging sources from the Off-Site Source Recovery Program; in particular, the possibility of restarting SHEBA is remote, and planning for its decommissioning has begun. People are leaving, the customer-base is shifting elsewhere, and resources are decreasing to run TA-18 as a Hazard Category 2 nuclear facility. New focus on timely closure appears warranted.

Radiological Facilities: NNSA has concurred with LANL that there is no plutonium-oxide eutectic issue for encapsulated sources; restrictions are still in place for plutonium-metal sources. A related concern – on whether encapsulation credited by DOE STD-1027 would maintain integrity in an unmitigated fire – is apparently not being pursued, at least not locally (site rep weekly 2/3/05).

Radioactive Liquid Waste Treatment Facility (RLWTF): Last Friday (2/17), TA-55 transferred their acid liquid waste inventory to the RLWTF acid waste receipt tank. Next week, RLWTF expects to begin a management self-assessment on resuming transuranic waste operations in order to process the liquid waste backlog and de-inventory systems before planned upgrades (site rep weekly 1/27/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 3, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 3, 2006

Jordan, Owen, Schapira, and Tontodonato were here this week reviewing status of contract transition.

Fire Suppression: LANL has determined that about a third of the 2,100 sprinkler heads in TA-55 and about an eighth of the 4,600 heads in CMR have some issue that may compromise functionality; a few other LANL nuclear facilities are also affected to lesser extent. Upon review, NNSA and LANL have also concluded that the riser pressure in TA-54 RANT facility is adequate (site rep weekly 2/24/06).

TA-55 continues in stand-by and plans to replace all the sprinkler heads on the main floor (~970) and all the suspect heads in the basement this month and then to return to normal operation. The new lab-room heads will have a lower actuation temperature than current heads and generally should respond faster and reduce the release during a fire. LANL also intends now to address a long-standing issue involving low flow to a few hydraulically remote lab-room heads (site rep weekly 4/4/03). CMR has terminated normal operations for lab-rooms with suspect heads and established fire watches. Many of the CMR suspect heads appear to be in non-lab-room spaces, such as the filter towers; by focused repairs using available stock, CMR replaced many of the suspect heads in lab-rooms this week.

TA-55 Confinement Strategy: LANL has completed its refined analyses of confinement strategies (site rep weeklies 9/23/05, 9/16/05). LANL asserts there are two dominant accident scenarios: a major earthquake and a Pu-238 lab-room fire. For the former, LANL proposes completing current plans to seismically upgrade glove-box supports as safety-class. For the latter, LANL proposes retaining several existing controls plus installing a new safety-class door midway down the corridor that runs adjacent to the Pu-238 lab-rooms; the door is being designed now and may be installed this month.

For the Pu-238 lab-room fire, LANL needs to demonstrate about a factor of 75 reduction in leakage by either an engineered or administrative safety-class control. LANL proposes the following controls (factor of reduction is provided in parenthesis): current passive confinement features, such as exterior doors that are assumed closed within 5 minutes, based on refined wind boundary conditions (x4.8); the new mid-corridor door (x2.6); current Pu-238 lab-to-corridor doors, closed within 1 minute (x2.5); Pu-238 containerization and material-at-risk reduction (x2.0). The analyses assume a 10-minute ramp release from glove-boxes in a fire (x1.2) and safety-class combustible controls. Building exit training for workers and short-response sprinkler heads also increase margin. Ventilation, fire suppression, and fire alarm systems remain safety-significant with upgrades anticipated to improve their reliability.

Pu-238 Operations: It is not yet clear that LANL's confinement analyses adequately consider all scenarios, including Pu-238 scenarios. TA-55 has a significant Pu-238 residue inventory, much of it combustible and some of it in poor containers (e.g., slip lid). Opening a disposition pathway has slipped for years; pyrolysis is now suppose to start in July and stabilize these residues by early 2007.

Pu Containers: It is unclear how LANL's confinement analyses address scenarios with Pu outside glove-boxes. TA-55 has about 10,000 items; 60 % are in standard cans that may be thermally limited; 40 % are in weaker non-standard cans; 9 % have additional risk attributes; and 1 % are an elevated risk and have been moved to a glove-box or over-packed. Relatedly, TA-55 has deconned and down-posted the vault from a contamination area; respirators are still required when handling non-standard cans.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 10, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending March 10, 2006

On Thursday, LANL, NNSA, and the Board's staff had a video-teleconference on the design effort for the CMR Replacement Project's radiological lab/utility/office building (RLUOB).

Authorization Basis (AB): The NNSA Site Office (LASO) has chosen to allow the nuclear facility authorization agreements (AAs) to expire and has directed LANL to come up with another system. The AAs list the AB documents that support NNSA allowing a nuclear or high hazard facility to operate; they were updated more than a year ago as a pre-start requirement for LANL resuming such operations; they are a key compensatory measure for several LANL nuclear facilities (e.g., TA-55) that are operating with safety bases that are 7 to 10 years old (Board ltr 5/27/04, site rep weekly 3/25/05). Maintaining these old ABs typically requires 3 to 5 LANL proposals and NNSA actions per week; this pace makes it difficult keeping AAs current, but they seem essential to AB configuration management.

Criticality Safety: On Wednesday (3/8), LANL submitted results of its documentation review of 564 fissile material operations, as well as its criticality safety improvement plan that is intended to address issues from a recent NNSA NA-117 assessment (site rep weekly 2/17/06). During its review, LANL identified 64 operations (i.e., 11 %) that warranted a high-priority walk-down; of these, LANL considered 24 (4 %) warranted immediate action: 19 involved TA-55 transfer (i.e., drop) boxes where the justification for limits was not immediately apparent; 4 involved machining or sample-prep boxes where the operation had been slightly altered without a criticality review; 1 involved ensuring back-flow prevention in an acid feed line. While the remaining operations were considered acceptable, LANL raised lower-tier issues with more than half the contractor evaluations and approval actions; nearly all these cases were from documentation generated prior to mid-2003. LANL's improvement plan includes detailed walk-downs of the remaining 500 operations this year; the plan is under formal change control, and any changes are subject to concurrence of the LASO senior safety advisor.

Federal Oversight: LASO has exited its 14-week stand-down preparing for contract transition (site rep weeklies 2/17/06, 11/25/05). While some improvements were made, such as establishing a records control center, many prior problems persist, such as ineffective processes to address differing opinions, to find balanced perspective, and to achieve unity-of-purpose before decisions are made; the problems are particularly acute at the organizational interface between safety-basis and operations.

Based on its own staffing analyses, LASO suffers from an insufficient number of technically-qualified staff to perform nuclear safety oversight: only 4 of 8 LASO managers in senior technical safety manager (STSM) positions have STSM qualification; 3 of the 5 safety analysts are fully qualified, compared to about 15 needed per responsible LASO management; 3 of 16 facility reps (FRs) are fully qualified – they are deployed at 3 of the 27 LANL nuclear facilities (TA-55, CMR, and LANSCE) – it is not apparent when and how LASO plans to establish qualified FR coverage for the remainder; 6 of 7 safety and health experts appear fully qualified for their positions, compared to about 30 needed to support nuclear and non-nuclear oversight. LASO has no full-time criticality safety expertise on site, which seems inconsistent with the scale of LANL fissile material operations. LASO has essentially no funding available this year for hiring or training staff and thereby beginning to alleviate this condition.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 17, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 17, 2006

Contract Transition: Los Alamos National Security (LANS) LLC started their due-diligence facility walk-downs this week with CMR; they expect to complete a sampling of facilities by mid-April.

Federal Oversight: The NNSA Site Office (LASO) has started to reinvent itself again. NNSA has decided to move immediately at LANL into a two-year pilot of its new oversight model, which will rely heavily on LANS's still-undefined contractor assurance system. NNSA asserts that this model will not affect federal nuclear safety oversight; however, it is unclear now how NNSA, for the purposes of its oversight, intends to categorize the lower hazard nuclear facilities (i.e., the radiological facilities), nor is it clear how NNSA will ensure adequate federal oversight of shared institutional safety programs, such as fire protection, quality assurance, training, and work control. The next step appears to be for LASO to prepare an implementation plan by July 1st (site rep weekly 2/17/06).

Fire Protection: Fire scenarios dominate the high-consequence end of the risk spectrum for LANL nuclear facilities. Recent attention has focused on code-discrepant sprinkler heads (site rep weekly 3/3/06). TA-55 remains in standby and is on track to finish its planned sprinkler head replacements by the end of this month; this is being closely managed. CMR has consulted with the LANL fire protection group, has reduced the set of heads requiring immediate replacement from about 600 to about 90, and has replaced these heads, tested the system, and returned to normal operation.

Chemistry and Metallurgy Research Replacement Facility (CMRR): On Thursday (3/16), LASO concurred in a CMRR nuclear safety strategy to guide the preparation of the preliminary safety basis, which is due in draft in August. During a review two years ago, the Board's staff suggested the need for such a set of NNSA-approved guiding principles for the purpose of driving early and explicit communication and consensus on safety considerations affecting the design (site rep weekly 4/2/04).

The approved safety strategy is essentially a reiteration of the LANL preliminary hazard analysis (PHA) and the LASO safety evaluation report of a year ago (site rep weekly 3/25/05). The strategy reasserts the following as safety-class: passive building confinement, long-term storage containers, fire barriers, fire suppression (including detection), long-term vault, building structure, and glove-box supports; active ventilation would be safety-significant. While the NNSA approval letter asserts that the strategy paper's logic is both technically and fiscally sound, the technical justification consists of references to expert opinion and to the PHA of a year ago, and cost considerations are not mentioned.

A classic issue is for a DOE site to declare a set of systems as safety-class or safety-significant, and then fail to follow up on the engineering, procurement, operability, and maintainability commensurate with that quality level. Institutionally, LANL's intent has been to address this via conduct of engineering and quality assurance initiatives; however, how these initiatives will interface with the CMRR project is not clear. The suite of safety systems preliminarily selected for CMRR also exceeds that for TA-55 PF-4, even though the latter is involved with higher hazard operations; some of these controls may be appropriate to consider for back-fit into TA-55, while others may prove difficult to implement in a technically justified manner from an engineering and operations perspective.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 24, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 24, 2006

The Board and a staff team were here on Tuesday and Wednesday reviewing LANL nuclear activities. On Wednesday evening, the Board held a public hearing and meeting on LANL contract transition.

Management: The Corrective Action Review Board (CARB) is starting their review of the quality and sustainability of the TA-55 and CMR corrective actions from the 2004 resumption reviews; this is one of several reviews of higher-hazard activities that the CARB hopes to complete before the June 1st contract transition. The CARB continues to provide a stronger feedback mechanism between identified issues and their corrective actions than previously existed at LANL – in spite of the fact that most CARB members are also highly involved with transition and their other management duties.

Plutonium Facility (TA-55): TA-55 expects to complete the sprinkler head replacements today. Related modifications, post-maintenance testing, and resolution of NNSA conditions of approvals continue, and the facility expects to resume full operations (i.e., Mode 1) during the week of April 3rd.

LANL has proposed and NNSA has approved conducting NFPA standpipe flow testing before operations resume. This will require routing fire hoses through open building confinement doors for a total of four 8-hour periods. LANL plans to seal the doorways with heavy plastic and thereby maintain differential pressure. LANL also plans to station personnel at the standpipe valves and at the open doors, who can quickly secure the testing and the doors if directed by the person-in-charge.

Radioactive Liquid Waste Treatment Facility (RLWTF): Last week, a decontamination crew in proper protective equipment re-entered the underground tank vault that was the scene of the high airborne contamination incident of a year ago (site rep weekly 3/11/05). Planning for this re-entry has been extensive, in support of the planned replacement of the caustic waste receipt tank in this vault.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 31, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 31, 2006

Integrated Work Management (IWM): The LANL Director addressed the lab this week on safety-related lessons learned so far during his 10-month tenure. He emphasized that LANL continues to deliver top-level work in spite of distractions and transition-related stress; that procedures have to be followed, particularly for nuclear operations; that the integrated work documents, which capture activity-level hazards and controls, set the boundaries for bench science; that the new IWM process is necessary but not sufficient – it cannot be separated from the worker being involved in the process and thinking through the activity; and that it is constructive for people to report safety lapses and issues.

Criticality Safety: Last week, LANL organizations reported two separate criticality infractions: one involved an 11% mass and volume exceedance for an archival solution sample; the other involved an unevaluated geometry for a set of metal items that were within mass limits. Both reports resulted from heightened sensitivity of workers to criticality safety. As part of its criticality safety improvement plan, LANL plans to complete walk-downs of medium-priority processes, as well as drafts of new institutional criticality safety policies and procedures in May (site rep weekly 3/10/06).

Waste Operations: Efficient transuranic (TRU) waste operations and shipment are key to addressing LANL's highest consequence nuclear accident postulated in approved safety analyses. LANL has nearly completed characterizing the set of about 2,000 higher-activity drums in the Quick-to-WIPP program and has shipped about 860 of these drums to WIPP (i.e., 43 %); the extended-shift approach suggested by the workforce has been remarkably successful at acceleration. LANL is currently making up to 4 shipments per week, with a near-term potential to move to 7 shipments per week.

This progress is at risk due to DOE budget issues. During a Citizens Advisory Board meeting this week, NNSA and LANL stated that the FY-06 legacy waste disposition budget is being cut 28 % (i.e., from \$51M to \$37M) and that this will likely result in suspending prohibited item disposition in the WCRR Facility after the Quick-to-WIPP drums are completed in April and suspending other characterization operations in July. This is unfortunate: stopping and restarting operations is grossly inefficient compared to maintaining a steady pace; LANL has also found that a large fraction of legacy drums have items prohibited by WIPP, removing these items has tended to be rate-limiting, and safely resuming operations in aging, marginal facilities such as WCRR is difficult and time-consuming.

The basis for these funding decisions rests on the perception that shipping the 2,000 Quick-to-WIPP drums will significantly reduce the safety risks associated with LANL TRU waste operations; however, the risk reduction from Quick-to-WIPP may not be as great as NNSA once perceived (site rep weekly 1 /20/06). LANL now has roughly 25,000 drums containing more than 140 kCi above ground. By 2012, LANL expects to generate new waste and retrieve buried waste, resulting in about 50,000 drums in total that will need to be characterized and shipped. During much of this period, the total above-ground inventory is likely to remain comparable to the current level, and while the average radioactivity per drum is low, there will likely continue to be a set of drums that constitute a risk comparable to those in the Quick-to-WIPP set for some time. At the very least, a more detailed evaluation of the risks incurred from these decisions is needed; based on what is known now, the chosen course appears counter to both sound business practice and sound risk-based decision making.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 7, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: V. Anderson
SUBJECT: Los Alamos Report for Week Ending April 7, 2006

Keilers was off-site this week. Anderson was on site providing site rep coverage.

Plutonium Facility (TA-55): This week, TA-55 closed the remaining open items associated with replacing about 1,200 sprinkler heads and returned to normal operation. TA-55 management abruptly placed the facility in standby six weeks ago after a fire protection engineer reported issues with sprinkler heads that might compromise their ability to function as intended (site rep weekly 2/24/06). The facility then entered an intense period of developing engineering work packages, mustering qualified work force, installing scaffolding, replacing the questionable basement sprinkler heads and all the main-floor sprinkler heads, installing other upgrades, and completing post-maintenance tests.

Radiation Protection: It was discovered this week that a maintenance subcontractor employee working on sprinkler head replacement in TA-55 had not given the appropriate baseline bioassay samples prior to performing work that required enrollment in LANL's bioassay program.

Chemistry and Metallurgy Research Replacement Project (CMRR): In February, LANL completed a quality assurance (QA) supplier evaluation of the vendor for the rad lab/utility/office building (RLUOB) and conditionally approved the vendor proceeding into preliminary design (site rep weekly 1/20/06). The RLUOB – a radiological facility – is the first project for this vendor that contractually requires compliance with the nuclear quality assurance standard NQA-1; therefore, success will require close monitoring as the vendor develops and demonstrates its QA program.

Radioactive Liquid Waste Treatment Facility (RLWTF): The TA-50 pump house and influent storage facility construction project has been struggling but has made improvements and fully resumed construction activities last week (site rep weekly 1/27/06). LANL review of the project's quality assurance program concluded that it is largely effective, and the previously identified construction issues appear correctable. While there are significant challenges, including approval of a budget reprogramming, a path-forward seems to exist.

Critical Experiment Facility (TA-18): LASO was notified last week that substantial quantities of legacy beryllium were being stored in Warehouse 1 at TA-18. LANL conducted surveys of Warehouse 1 and CASA 1 at TA-18 to determine the extent of beryllium contamination throughout the facilities, and found that the majority of the floor in Warehouse 1 exceeds the threshold values for classification as a beryllium contamination area. Although beryllium worker training had not been required for entry to Warehouse 1, all employees assigned to work there were trained as beryllium workers. LANL is now working to identify a path forward for the beryllium stored in the warehouse and associated contamination removal so that Warehouse 1 can return to normal operations.

Contract Transition: Los Alamos National Security, Inc. (LANS) completed their due diligence facility walk-downs this week (site rep weekly 3/17/06). LANS will now pursue roll-up of and development of a path forward for issues identified during the conduct of the walk-downs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 14, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 14, 2006

Plaue was here this week augmenting site rep coverage; Deplitch was on site Wednesday for the 90 % design review of the Planet control system for the NTS (DAF) Critical Experiments Facility.

Waste Operations: LANL's highest-consequence postulated nuclear accident scenario involves transuranic waste. This week, LANL reported several waste storage domes having large fabric tears; per the 2003 authorization basis (AB) – which has never been fully verified as implemented – this constitutes a degraded safety-class system. For worker safety, LANL has restricted access to one ripped dome. For perspective, the domes are 9 to 19 years old, compared to a 10-year suggested life, and both NNSA and LANL recognized dome degradation as an issue in 2003. When approving the AB, NNSA observed that, given the lack of effective safety systems (e.g., the domes), removal of the material-at-risk by shipment to WIPP is the only way of reducing the potential offsite consequences.

DOE, NNSA, and LANL are now on a pathway that will likely slow WIPP shipments after the Quick-to-WIPP campaign is completed. Due to DOE budget issues, LANL is slowing disposition of items prohibited by WIPP and is continuing to plan on suspending these operations in early May. No further operations are planned in the key facility for this – WCRRF – through the remainder of FY-06 and possibly longer, except for conducting periodic surveillance of essential equipment and making a modification to increase glove-box differential pressure (site rep weeklies 3/31/06, 9/16/05).

At times during the Quick-to-WIPP campaign, LANL was finding that 90 % of the legacy drums had items prohibited by WIPP that required disposition in WCRRF; with great effort, LANL increased WCRRF through-put to ~75 drums/week; it's now less than half that. Based on current information, suspending WCRRF operations seems inconsistent with timely and efficiently shipping transuranic waste to WIPP and thereby addressing one of LANL's most significant nuclear safety issues.

Pu-238 Operations: LANL's second-highest-consequence postulated nuclear accident scenario involves Pu-238 operations in TA-55, and it is exacerbated by the building confinement strategy issue. Recently, more restrictive material-at-risk controls have been proposed as part of a new confinement strategy; refinement is needed to ensure that these controls are clear and operationally effective. Separately, NNSA has approved a process hazard analysis (PrHA) for pyrolysis and for hydroxide precipitation; these are key operations for addressing the significant Pu-238 inventories in combustible residues and in liquid wastes, respectively (site rep weeklies 3/3/06, 1/20/06). Pyrolysis is scheduled to restart in July; liquid waste solidification is also being considered. LANL is also poised to submit to NNSA a substantially revised PrHA for the full-scale aqueous scrap recovery line; this revision is intended to address issues from the Board's letter of Aug 1st, 2003; the improvements look promising.

Federal Oversight: While LANL's recent efforts to address TA-55 fire suppression issues and resume operations were noteworthy, federal oversight fell below prior levels for a resumption of this importance. Last Friday, NNSA management deferred to LANL on adequacy of closure of related NNSA conditions-of-approval. Also, NNSA management directed the sole fully-qualified facility rep (FR) at TA-55 to focus on his paperwork backlog instead of monitor the contractor's decision-making process leading up to resumption; the FR did review resumption documentation. For several years, TA-55 has had only one fully-qualified FR, although by most metrics it warrants two or three.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 21, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 21, 2006

Contract Transition: Forty days remain under the UC contract. LANL has almost finished its integrated corrective action plan (ICAP) for the two recent Type B investigations and the DOE-SP review. LANL has also triaged the findings from the LANS due-diligence facility walk-downs; several findings indicate persistent weaknesses that parallel those that led to the 2004 lab suspension; LANL is pursuing several findings needing near-term attention (site rep weeklies 3/31/06, 1 /27/06).

Based on discussions, the site rep understands the following: LANS intends to address remaining findings after the June 1st transition, including mapping institutional issues from the walk-downs and the ICAP into an expanded Operational Efficiency (OE) Project; NNSA has directed LANS to provide a report on the walk-downs by May 1st and provide their plan for an expanded OE project by June 1st.

Solid Waste Operations: The DOE Carlsbad Field Office (CBFO) has assigned a "work-off team" to review LANL transuranic waste operations during the next few months, identify improvements, and assist LANL in developing a new legacy waste disposition baseline, due in mid-May. While encouraging in the longer-term, this does not alter the impending suspension of waste characterization this summer and the eventual drop in shipments after the Quick-to-WIPP campaign is finished.

Liquid Waste Operations: The transuranic liquid waste processing system in the Radioactive Liquid Waste Treatment Facility (RLWTF) is in marginal condition (site rep weekly 2/24/06). The facility has completed a readiness assessment to resume operating this system, including demonstrating procedures for confirming system integrity and for rapidly detecting and responding to leaks. Operations will likely resume next week.

Separately, NNSA has requested LANL to provide alternatives to fully upgrading the system, given the limited remaining facility life; these are also expected next week. There are tradeoffs to consider; one option is to capture more source-term upstream in TA-55, which has more robust safety systems, and thereby reduce the source-term and the operational load on the degraded systems in the RLWTF.

Authorization Basis (AB): NNSA and LANL have made little progress in the last two years on updating nuclear facility ABs; these documents capture the analyses, requirements, and controls that are the foundation for safe nuclear operations (ref: Board letter 5/27/04). For example, the safety analyses for the Chemistry and Metallurgy Research Building (CMR), the TA-55 Plutonium Facility, and the RLWTF are 8, 10, and 11 years old, respectively. TA-55 does have interim technical safety requirements (iTSRs) that were approved last year, but the iTSRs expire this summer. Also, last August, LANL proposed iTSRs for CMR and a new AB for RLWTF; these still await NNSA action.

Federal Oversight: As a result of the aging AB situation, LANL needs to propose and NNSA needs to evaluate and act upon several AB submittals per week to support continued safe nuclear operations. The ability of the NNSA Site Office (LASO) to support the status quo - much less to make progress on the aging AB backlog - has been marginal for some time (site rep weekly 3/10/06). During the next few weeks, LASO is losing several key safety analysts, which will likely exacerbate the problem.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 28, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 28, 2006

Anderson, Bamdad, Jones, Jordan, and Kasdorf were here this week reviewing the CMRR Project.

Waste Operations: Last Friday (4/21), DOE restored funding, thereby allowing LANL to continue transuranic waste characterization and avoid a drop in WIPP shipments after the Quick-to-WIPP campaign is finished. It seems appropriate for DOE, NNSA, and LANL to further study and more explicitly consider the safety risks associated with LANL transuranic waste in future budget decisions.

This week, NNSA approved: (1) changes to material-at-risk limits for the TRUPACT loading facility – RANT – that align the drum limit with the WIPP acceptance criteria; (2) continuing to operate RANT through July 2007 without seismic upgrades; and (3) loading cemented drums into TRUPACTs using a mobile loader outside the RANT building. These drums came from solidifying sludge at the Radioactive Liquid Waste Treatment Facility (RLWTF) and have low-activity. These actions generally support improving the shipping rate (site rep weeklies 4/14/06, 1 /20/06).

Chemistry and Metallurgy Research Facility Replacement Project (CMRR): The staff team that was here this week observed that the CMRR nuclear safety strategy document is a step-forward, but it's implementation needs more engineering involvement (site rep weekly 3/17/06). Design is an iterative and evolutionary process, and this project's design is clearly still evolving.

Essentially, the safety analysts, who developed the strategy, still need to define clear functional requirements for safety systems during upsets (i.e., more specific than “fire-resistant,” “impact-resistant,” and “no material release”); the engineers and designers still need to select applicable codes and standards and develop designs that clearly meet those requirements; both parties – the safety analysts and the engineers – need to work continuously and closely together to develop a satisfactory design. One area warranting attention is ensuring plutonium confinement during and following a design basis earthquake, including ensuring adequate safety system reliability and redundancy.

Fire Protection: On Tuesday (4/24), the NNSA Site Office (LASO) and LANL provided NNSA headquarters an updated status of LANL fire protection improvements (ref: Board ltr 5/31/05, NNSA ltr 1/12/06). Ensuring adequate staffing of contractor fire protection engineers and of fire-fighters remain central unresolved issues. In June, LANL plans to complete the scope of the partial site-wide fire alarm system upgrades in LANL plutonium facilities, which is positive (site rep weekly 11/18/05). Last week, LANL imposed outdoor work restrictions due to growing wild-land fire concerns.

Lightning Protection: Several LANL nuclear facilities rely on their lightning protection systems to perform a safety function; concerns with functionality of these systems were the subject of Board correspondence in 2002 and 2003. On Apr 6th, LASO provided LANL a report on a federal lightning protection assessment that was performed in October 2005; LASO's primary concern was timely correction of deficiencies found during inspections. In response to the federal review and their own reviews, LANL has centralized inspections, improved trending and tracking, and obtained the services of external certified inspectors; senior management attention this year on lightning protection has started to make a difference, but there is still much to be done (site rep weeklies 2/10/06, 6/4/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 5, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending May 5, 2006

Contract Transition: Twenty-six days remain under the UC contract. While LANS's top-level management and the basic operations structure are evident, it is less clear what are the key mid-level positions, who will be the key occupants, what are their qualifications, and how will LANS ensure confidence in its overall ability to control nuclear operations on and immediately following June 1st. LANS has observed LANL operations; however, LANS has not yet demonstrated readiness to analyze and control operations on a daily basis. One perspective is that DOE frequently and safely changes contracts across the complex; also, the LANS management team has extensive experience from other sites. However, DOE has not changed this contract since inception; this is probably DOE's most complex site; and few LANS senior managers have direct experience controlling LANL operations.

Much of LANS's mid-level management structure seems fluid until at least May 15th, when employee responses to offer letters are due. During that week, LANS management intends to internally review the closure of transition activities, including adaptation or modification of institutional procedures, status of outstanding issues and pre-existing conditions, and internal certification of closure of each contractually required transition area. The following week, LANS reports on closure status to NNSA and to its Board of Governors. On May 30th, NNSA reviews closure validation.

Radiological Facilities: Radiological facilities have lower source-terms and receive significantly less federal and contractor oversight than the Hazard Category (HC) 2 or HC-3 nuclear facilities, even though radiological facilities have been more prone to mishaps in the last two years (site rep weekly 2/3/06). This week, LANL reported that TA-54 Area L – a radiological facility – has received from off-site about 20 metric tons of depleted uranium (DU), which exceeds the HC-3 lower threshold (13 metric tons). LANL is de-inventorying Area L to below the HC-3 threshold and is conducting an extent-of-condition review focused on inventory tracking.

Aircraft Overflights: In 2003, LANL declared an unreviewed safety question (USQ) involving flights through LANL's restricted airspace. NNSA and LANL then implemented a compensatory measure involving explicit analysis and approval of each overflight. Over time, the fidelity of this compensatory measure has decreased. LANL recently submitted to NNSA a standalone safety basis and control set for overflights. LANL asserts that the probability of an accidental aircraft crash into a nuclear facility is small, assuming overflight activity remains about the same as during the last decade and that helicopter flight-paths are controlled. NNSA action is forthcoming.

Plutonium Facility (TA-55): NNSA has approved a process hazard analysis for assembling radiation test objects (RTOs) at unspecified locations in PF-4. Conditions of approval include: a limitation of one fissile item per activity, which will be a STD-3013 container if the item is oxide; a criticality safety evaluation for each configuration and location; a dedicated transient combustible inspection; a fire watch; and a readiness verification. RTO assemblies were previously conducted at TA-18, and the operational lessons learned from TA-18's last RTO operation should be helpful. That said, the potential for interaction with other PF-4 operations appears high and conducting a meaningful readiness verification appears difficult without a permanent assigned location. These activities appear challenging and important enough to warrant a dedicated location and a thorough readiness review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 12, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr., LANL Site Representative
SUBJECT: Activity Report for Week Ending May 12, 2006

The site representative was at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 19, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending May 19, 2006

Authorization Basis (AB): LANL now has about four dozen AB submittals at the NNSA Site Office for action, and LANL and NNSA are starting to lose track of them, including LANL's most recent recommendations for the TA-55 confinement strategy issue. On the positive side, NNSA's operational staff (FRs) are increasingly involved in federal review of proposed safety basis controls.

Contract Transition: Preparations continue for the June 1st contract transition from UC to LANS. LANS has rolled out its mid-level operations management structure, which evolved logically from the current LANL responsible division leader (RDL) structure. Their basic facility model consists of a facility operations director who will oversee mostly-matrixed functional managers for operations, maintenance, engineering, security, safety and health, waste services, and other support functions.

For the nuclear facilities, LANS has populated this management structure with an appropriate balance of new and incumbent staff, who are to complete an interim qualification process by June 1st and to achieve full qualification within 6 months. LANS is also preparing a deliberate operations plan that involves a detailed review of all on-going work within the first two months, as well as expectations that new work will be reviewed for full compliance with the integrated work management (IWM) process and that management will be engaging the workforce and observing operations.

Integrated Safety Management: Last Friday (5/12), a TA-55 pipe-fitter became contaminated (10k dpm) when he was sprayed by low-activity water while cutting an acid liquid waste line that had been flushed. The pipe-fitter was in anti-Cs and a respirator but not the waterproof acid suit required by procedure. Others involved, including safety personnel, did not interdict. The assigned supervisors were not present because they lacked respirators. While this event had minimal safety consequences, it seems to be a near-miss since the line could have had higher-activity acid waste. As a result, TA-55 suspended non-routine crafts work and held lessons-learned sessions with crafts and supervisors. TA-55 also intends to perform a causal analysis to identify further corrective actions.

TA-55 has been leading the lab in evolving a human-performance perspective on operational issues, which would apply here (site rep weekly 2/25/05). Most such events are due to latent organizational weaknesses. In this case, work-scope growth, schedule pressure, difficult work conditions, and fatigue seem to have created an environment rich in pitfalls, increasing the probability that someone was going to make an error with safety consequences; also, the waste lines are normally locked out, and the presence of water indicates a system configuration control issue. High-reliability organizations focus on learning from such events and on developing processes with defense-in-depth against errors. TA-55 seems to be on that track and needs to successfully apply these principles, particularly given TA-55's backlog of crafts work, due in part to the recent unscheduled sprinkler replacement outage.

Radioactive Liquid Waste Treatment Facility (RLWTF): Friday morning (5/19), a RLWTF tank leaked about 1,500 gal of low-activity water to a sump from where it was automatically pumped to another tank. Personnel entered the room to investigate and then within minutes evacuated when the continuous air monitor (CAM) alarmed. Preliminary data indicates no radionuclide uptakes; bioassay results will be available within 2 weeks. The cause of the leak is under investigation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 26, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 26, 2006

Anderson was here this week augmenting site rep coverage.

Criticality Safety: LANL determined this week that a nuclear facility was staging liquid plutonium residues for shipment at a location with posting that prohibited storage of hydrogenous fissile material. The event serves to re-emphasize the importance of LANL following up on its commitments in the recent criticality safety improvement plan (site rep weekly 3/31/06).

Contract Transition: This week, LANS briefed their Board of Governors and NNSA on their readiness to run LANL starting June 1st. While having concerns, LANS asserts that they are ready; their transition plan is complete; key personnel are in place; and they have working relationships in place between their management team, the work force, the community, and the customer.

Authorization Basis (AB): Most of the pre-existing conditions that LANS has identified involve operations, and several of those involve AB issues, such as the state-of-compliance with the Nuclear Safety Management rule (10 CFR 830). Particular concerns are the LANSCE safety basis, which is a piecemeal set of documents that expire in August, and the TA-55 safety basis and interim technical safety requirements; the last are not fully implemented and expire in July (site rep weekly 4/21/06).

LANS considered that the lack of configuration control of the list of AB documents, as evidenced by inaccurate and expired authorization agreements, constituted a pre-start condition for transition (site rep weekly 3/10/06). After several iterations, LANL submitted and NNSA approved last week updated authorization agreements for the Hazard Category 2 nuclear facilities.

Integrated Safety Management: On May 16th, LANL submitted to NNSA an integrated corrective action plan (ICAP) for the two recent Type B investigations and the DOE-SP review (ref: site rep weeklies 2/3/06, 1/27/06, 1/13/06, 11/4/05, 10/4/05). Key elements of the ICAP involve integrated work management (IWM); behavior based safety; oversight and assessment processes; radiological protection; safety basis; conduct of engineering; vital safety systems; and configuration management. The ICAP was developed by teams consisting of line managers and institutional subject matter experts, increasing the likelihood that the actions would be both achievable operationally and effective at addressing root causes. Both the current and the incoming LANL Directors have endorsed the plan. Schedules and resources for most actions are unspecified and left to LANS to establish.

Federal Management: NNSA's response is not evident to Type B and DOE-SP findings involving federal management, several of which have nuclear safety implications. Also, one Type B observation was that the NNSA Site Office has been ineffective at managing both federal and contractor corrective actions from prior Type B incidents, such as the August 2003 Pu-238 release with uptakes; some of those actions remain incomplete. As an example, the site rep observes that DOE, NNSA, and LANL still seem to lack clear assignment of funding and oversight responsibilities and effective cradle-to-grave management processes for Pu-238 operations (JON 12). NNSA appears challenged to identify and implement federal corrective actions, as well as oversee contractor corrective actions to closure.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 2, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 2, 2006

Contract Transition: Los Alamos National Security LLC began managing operations on Thursday.

Waste Operations: On Tuesday (5/30), Area G had a drum-drop event, resulting in 5 dented drums but no radioactive release and, fortuitously, no injuries. Specifically, a forklift operator picked up two pallets of heavier-than-expected drums from a three-pallet-high stack; while backing up, the forklift started to tip forward; 7 of the 8 drums slid off, fell to the ground, denting one drum in an adjacent row. Follow-up actions appeared appropriate. Opportunities for improvement include labeling heavier drums, better training of workers, and increasing focus on immediate actions for such events.

Pajarito Laboratory (TA-18): On May 23rd, NNSA headquarters (NA-10) announced its intent to accelerate transfer of Defense Programs activities out of TA-18 by 18 months (i.e., by Oct 1st, 2006) and not fund TA-18 infrastructure beyond FY-06. Feasibility to complete the transfer within the next four months is unclear right now. TA-18 has slid into limbo since its security downgrade last October; it still has a significant inventory of radioactive and other hazardous materials that warrant clear ownership and close management attention (site rep weeklies 10/28/05, 2/24/06, 4/7/06).

Legacy Nuclear Materials: LANL has a substantial legacy inventory throughout, particularly in TA-18, the plutonium facilities (TA-55, CMR), and waste storage (TA-54 Area G). This inventory drives the public and worker risks from LANL nuclear operations; it has nearly saturated storage for some facilities; its timely disposition affects not only safety but the lab's national security mission.

Several of LANL's highest-consequence postulated nuclear accident scenarios involve transuranic waste stored at Area G, which is near capacity. For example, the safety analysis approved in 2003 assumes that, without mitigation, a large earthquake would cause drums containing about 24 % of the Area G radioactivity to rupture without fire, leading to calculated off-site doses warranting about 2 to 3 orders of magnitude of mitigation. This week's drum-drop event illustrates that the drums are generally robust and that the safety analysis is conservative; however, the degree of conservatism is uncertain – particularly whether it constitutes 2 to 3 orders of magnitude. Updated analyses are due this month but are unlikely to improve the risk picture. Shipments to WIPP remain the primary mechanism for risk reduction.

TA-55 appears near capacity, pending more trailer startups on the safeguarded trailer pad, a temporary solution. It has unmitigated scenarios with calculated off-site consequences similar to Area G's. The highest involve Pu-238 lab room fires, exacerbated by an uncertain degree of building confinement. TA-55 has hundreds of grams of Pu-238 residues, some intermixed with combustibles in poor containers within gradually degrading plastic bags, stored in the room that was contaminated in Aug 2003; these conditions are similar to those assumed going into the worst-case accident scenarios.

TA-55 also has roughly 4,000 items in non-robust containers; these constitute a handling risk for the worker (e.g., the Dec 2005 vault contamination), and they could fail during a major accident. While TA-55 is pursuing more robust packaging, radiochemical stability is an issue, and processing has been postponed due to TA-50's transuranic liquid waste treatment problems. TA-55 would like to dispose of more residues, including the Pu-238 residues, with minimum handling and processing. This would likely require an unprecedented degree of coordination between NNSA, DOE-EM, LANL, and the WIPP contractor to establish optimum waste acceptance criteria, and a safe and efficient program.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 9, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending June 9, 2006

Jones and Jordan were here this week reviewing CMRR and augmenting site rep coverage, respectively.

Plutonium Facility (TA-55): TA-55 has declared a potential inadequacy in the safety analysis (PISA) for Pu-238 residues in higher-loaded containers because of the potential for hydrogen generation if the residues are hydrogenous and the potential for acid generation if the bagging is polyvinyl chloride. Movement of the containers has been restricted, and they will be repackaged on a priority basis.

Chemistry and Metallurgy Research Facility Replacement Project (CMRR): This week, LANL began the formal review process of the first-phase deliverables for the preliminary nuclear facility design. Both the systems engineering approach and the document review process are state-of-the-art, but both require experienced and qualified personnel for the effort to be successful. It remains unclear how NNSA will obtain the resources for the federal review, especially for safety analyses.

Operational Efficiency (OE) Project: While details are sparse, it appears that LANL (LANS) has assigned each of the OE sub-projects and related safety programs (e.g., maintenance) to an associate director and has committed to NNSA to have institutional policies and procedures in place for each by Oct 1st. To support this, LANL has consolidated responsibility for some safety programs at the division level; the new centralized safety basis and training divisions seem particularly promising.

Following Oct 1st, LANL would close out the OE Project, and further evolution of each safety program would be managed and funded through the assigned associate director and his organization. One disadvantage of this is loss of visibility into whether previously identified issues have been addressed and whether these programs have become truly effective. Presumably, the LANL contractor assurance system will provide that insight; it is also sparsely defined now but suppose to be mature by Oct 1st.

Conduct of Engineering: Conduct of engineering is typical of the safety programs within the OE Project. LANL intends that this program apply to both facility and programmatic work and has enlisted Bechtel to compare LANL policies and procedures with those of Savannah River Site and Bechtel. Success hinges on close coordination among, at least, four associate directorships that are separately responsible for engineering, maintenance (including system engineers), operations, and training. The envisioned improvements seem likely to increase efficiency and to facilitate incorporating safety into designs affecting programmatic work. So far, this appears promising.

Federal Oversight: The NNSA Site Office (LASO) continues to struggle with ensuring adequate oversight of nuclear operations (site rep weeklies 4/21/06, 3/10/06). The safety system oversight (SSO) program, which was viable before the LASO stand-down last November, now appears defunct. The facility rep (FR) program is down to 2 of 12 FRs being fully qualified, with a third nearly qualified; they are deployed at LANSCE, CMR, and RLWTF; LASO is again reviewing its FR staffing needs against DOE STD-1063 criteria. LASO still has no apparent plans to bring a criticality safety expert on site full-time, which is illogical given the scale of LANL fissile material operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 16, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 16, 2006

Andersen, Hadjian, Jones, and Rizzo were here this week reviewing CMRR geotechnical information.

Chemistry and Metallurgy Research Building (CMR): This afternoon, a researcher making space in a Wing 5 hood inadvertently spilt an unknown liquid that spontaneously ignited. The researcher extinguished the fire. LANL emergency personnel responded, and the situation appears under control.

Plutonium Facility (TA-55): Last Friday (6/9), a KSL worker sustained first and second degree burns on one hand due to a malfunction of a soldering torch; he was working under a glove-box in a Pu-238 lab room and was wearing cotton anti-Cs and rubber gloves. KSL suspended work using this type of torch and is investigating the event, including the personal protective equipment requirements.

Also last week, LANL proposed that TA-55 continue to operate under the interim technical safety requirements (iTSRs) until the new safety basis is completed. When approving the iTSRs, NNSA required that they expire on July 28th, 2006. The iTSRs – which are still not fully implemented – capture compensatory measures to address the passive confinement issue discussed below, as well as other needed controls identified since the last safety basis approval in 1996 (site rep weekly 8/5/05).

Recommendation 04-2: In 2004, the Board recommended that DOE disallow reliance on passive confinement and require an active confinement ventilation system for defense nuclear facilities with the potential for radiological release. For Hazard Category 2 facilities, such as TA-55, the Board stated an expectation that these systems would be categorized as safety-class or safety-significant, depending on a conservative application of DOE-approved methodology, and that they would be designed and maintained to function during abnormal and accident conditions. The Secretary accepted this in March 2005. The Board subsequently accepted DOE's implementation plan (IP).

In accordance with the IP, DOE has developed confinement ventilation performance criteria and a structured evaluation process. It involves teams identifying gaps between the ventilation system, the criteria, and the safety basis; reviewing potential upgrades using a structured cost-benefit approach; and recommending to the Program Secretarial Officer those upgrades needed to enhance ventilation reliability under normal and accident conditions. DOE has committed to pilot the process with TA-55.

In a parallel but uncoupled effort, NNSA and LANL have doggedly pursued refining their analyses to justify TA-55's passive confinement strategy, in spite of Recommendation 04-2 observations on the credibility of such analyses. Last August, NNSA expressed doubt that TA-55's ventilation system meets even safety-significant requirements (site rep weekly 8/5/05). In March, LANL observed that neither passive nor active ventilation confinement is sufficient and proposed a series of controls (site rep weekly 3/3/06). LANL's conclusion that active confinement is ineffective is counter to their calculations of a year ago and is based on subsequent model tuning. NNSA has not yet acted on LANL's recommendations, which focus on installing a safety-class door in the corridor adjacent to the Pu-238 lab-rooms, developing safety-class containers, and seismically upgrading glove-box supports.

Perhaps, a convergent course might be for the site to implement LANL's proposed controls, to fully engage in the 04-2 pilot, and to pursue the ventilation reliability upgrades that are thus identified (related reports: 12/24/04, 3/4/05, 4/1/05, 7/15/05, 9/2/05, 9/16/05, 9/23/05, 12/9/05, 4/14/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 23, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 23, 2006

Plaue was here this week augmenting site rep coverage.

Weapons Engineering Tritium Facility (WETF): Last Friday (6/16), WETF had a tritium release to a room while workers were leak-checking secondary containers. The workers evacuated the room, and the tritium (less than 100 Ci total) was exhausted via an approved stack until Wednesday when workers in bubble suits found and fixed the source. Health consequences appear minimal (e.g., micro-rem range to the public). WETF had a similar room release in 2003 (site rep weekly 4/18/03).

Chemistry and Metallurgy Research Building (CMR): The facility's and the emergency response team's immediate actions for last Friday's hood fire were appropriate overall; the event also offers lessons learned. As followup, CMR suspended both facility and programmatic operations on Monday, conducted sweeps for unidentified legacy materials, and resumed operations in most rooms by Thursday. Other facilities have begun sweeps. LANL has started a formal investigation.

Waste Operations: Area G has several hundred transuranic waste drums with no clear disposition path because their contents exceed the WIPP drum limit (80 Ci) and the LANL repackaging facility (WCRRF) safety basis limit (56 Ci). The 2003 Area G safety basis indicates: these drums range up to 760 Ci; in total, they constitute more than 25 % of the Area G transuranic inventory but only about 1 % of the number of drums; of the 3 dozen analyzed accident scenarios, about half have predicted unmitigated off-site consequences exceeding 100 rem (CEDE), and about a third of these are due to these drums.

The choke point for disposing of these drums is WCRRF and its safety basis limit, which is driven by seismic scenarios. WCRRF is LANL's only asset with WIPP-certified capabilities for visual examination and repackaging drums with greater than 0.5 Ci. WCRRF was running well earlier this year, in spite of issues with glovebox ventilation and its 6-year-old safety basis. LANL plans to upgrade WCRRF ventilation this summer and to submit a safety basis revision this fall. LANL is also considering using CMR for drum repackaging because of its higher limits, but CMR also has seismic concerns.

Plutonium 238 Operations: TA-55's Pu-238 residue inventory is a major nuclear safety challenge (site rep weekly 6/2/06). For perspective, if designated as waste and packaged to typical Area G drum levels (i.e., 6 Ci/drum), this inventory's total volume would correspond to about a decade's worth of transuranic waste shipments from TA-55 and to about an eighth of the current number of drums in Area G.

LANL and the WIPP contractor have negotiated a tentative path-forward for Pu-238 debris waste that will allow loading drums to the WCRRF limit, 56 Ci. Paradoxically, pyrolysis of the combustible residues would generate a safer, more chemically inert ash but that material form is currently classified not as debris but as homogenous waste without an approved WIPP pathway (site rep weekly 1/20/06).

For debris waste, the tentative path-forward will require TA-55 to open containers, split the contents, and repackage residues into drums, and for WCRRF to later open, empty, and visually confirm the contents of some of the drums. There are significant handling risks involved; it would be advantageous to only have to do these steps once, preferably combined into a single WIPP-certified operation in TA-55, which would require increasing priority and coordination. LANL and WIPP are working on the path forward.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 30, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 30, 2006

Recommendation 04-2: On Friday (6/30), the staff held a teleconference with DOE and NNSA headquarters and the site on the scope and path-forward for the TA-55 pilot (site rep weekly 6/16/06).

Radioactive Liquid Waste Treatment Facility (RLWTF): On Tuesday (6/27), two workers were injured at the pump house and influent storage facility construction site. The workers were hit by a stairwell segment that was being lifted by a crane and slipped its rigging. LANL immediately suspended hoisting and rigging operations and has been releasing such operations on a case basis. LANL has also launched an investigation. One of the workers remains in critical condition.

Integrated Safety Management: Last week, LANL management reviewed safety-related occurrences during the first 3 weeks of the LANS contract and concluded that their rate and severity are greater than expected. Starting last Friday (6/23), each level of management has taken roughly a day to review the events and to brainstorm corrective actions. LANL management intends to thereby solicit input from all levels of the lab and roll it up to senior management for action in early July.

The NNSA Site Office (LASO) has forwarded to headquarters the LASO and LANL corrective action plans from last year's DOE-SP audit and two Type B accident investigations (site rep weekly 5/26/06). LASO observed that the LANL plan lacks completion dates and that headquarters' corrective actions remain undefined. For their portion, LASO closed several Type B identified needs for expanding federal oversight by citing the conceptual NNSA oversight pilot, which contrarily involves contracting federal oversight. LASO intends to validate closure of LANL corrective actions semiannually.

Waste Operations: LANL will likely curtail transuranic waste shipments to WIPP next week because of an issue found last week with head space gas samples for several hundred debris drums that had been accepted for shipment. The issue involves composite gas samples drawn from multiple waste streams, instead of the required single waste stream, and then sent to Idaho for analysis.

LANL is analyzing the risks of 3 alternatives to address the high-activity drums discussed last week:

- TA-50 WCRR Facility – this facility is WIPP compliant and operational but restricted to 56 Ci by inventory limits in its 6-year-old safety basis; operations involve one air glove-box that will get a ventilation upgrade; WCRR requires drums to be trucked over on-site roads from TA-54.
- TA-54 DVRS Facility – this facility has an inerted glove-box and could be made operational relatively quickly; NNSA imposed more restrictive requirements on it than on WCRR, and it does not meet some requirements, such as redundant nitrogen supply. DVRS is close to drum storage, improving efficiency and reducing on-site transportation risks; however, the glove-box interferes with DVRS down-sizing waste now in ~300 plywood crates, its intended purpose.
- CMR Wing 9 basement enclosures – Wing 9 has two rooms with separate filtration that were used at one time for WIPP waste studies but are now not operational and would need a glovebox (on order); while Wing 9 appears more robust than the other options, it may not be; this option would require trucking drums to near the center of LANL's main population area.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 7, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 7, 2006

Site-wide Environmental Impact Statement (SWEIS): NNSA has issued a draft SWEIS; NNSA's preferred alternative is to expand operations, including achieving an 80 pit/year manufacturing rate.

Plutonium Facility (TA-55): NNSA has extended the interim Technical Safety Requirements (iTSRs), which LANL expects to have fully implemented this month (site rep weekly 6/16/06).

Authorization Basis: LANL is not compliant with the Nuclear Safety Management rule (10 CFR 830) because of the state of the nuclear facility safety bases; NNSA and LANL have made little progress since May 2004 when the Board issued a letter on this topic (e.g., site rep weeklies 4/21/06, 6/17/05). Last Friday (6/30), NNSA informed LANL that it expects LANL to remedy the lack of current, compliant safety bases during the next year and then to comply with the rule, including submitting high-quality annual updates; NNSA also expects LANL to manage the safety basis workload, including considering the severe constraints on federal safety basis expertise.

Operational Efficiency (OE) Project: Last week, LANL confirmed its intent to internalize the OE safety initiatives and to close the OE Project by Oct 1st. In early 2005, OE was envisioned as a multi-year effort to systematically reduce a broad spectrum of safety risks; it was the product of some hard lessons learned before and during the LANL stand-down of 2004. Since then, the scope has decreased to mainly include defining necessary resources and developing plans and procedures; implementation of many initiatives was postponed due to contract transition (site rep weeklies 6/9/06, 3/11/05).

The new LANL management intends to close OE after achieving a set of intermediate milestones; their perspective is that operational efficiency should be a way of doing business rather than a project. In parallel, LANL has launched a new project to develop an "integrated scientific-methodology-based" approach to operations, maintenance, engineering, and training. While the signals are mixed, this appears to include stepping back and considering whether program and facility work should once again be planned and executed via separate processes; this would be counter to conclusions of several NNSA and LANL accident investigations since 2002. LANL intends to have the "integrated programs" defined in September, with resource-loaded implementation plans to follow.

Feedback and Improvement: While the new LANL management has done well at issue discovery and rediscovery (e.g., critiques), they have yet to substantively improve issue management, operations, and safety. Some examples are: • last week's suspension and partial resumption of hoisting and rigging operations were informally promulgated and controlled, causing some confusion; lessons learned from prior LANL suspensions remain unaddressed (e.g., site rep weekly 8/26/05); • on Thursday (7/6), TA-55 personnel self-reported a criticality safety infraction, which led to a brief suspension of operations on Friday; such infractions are a recurring issue and the subject of a lab corrective action plan (site rep weekly 3/10/06); • last Tuesday (6/27), the Sigma Complex (TA-3-66) received a potential internally contaminated package from TA-55 that was not what was expected; there are parallels to the Am-241 contamination event of a year ago, also the subject of a corrective action plan (site rep weeklies 2/3/06, 5/31/06); • LANL has postponed their readiness assessment for starting up more trailers on the TA-55 safeguarded trailer pad because findings from the startup of the first trailer a year ago remain open (site rep weeklies 7/8/05, 10/7/05). A common theme here, which applies lab-wide, is the continuing need for followup on known issues and corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 14, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 14, 2006

Accident Investigations: LANL has competent teams conducting separate investigations on the RLWTF construction accident and the CMR hood fire; the investigations are expected to be done by July 28th and Aug 16th, respectively (site rep weeklies 6/30/06, 6/23/06). The former meets criteria in DOE Order 225.1A *Accident Investigations* for a federal Type B investigation; NNSA has chosen to grant an exception rather than conduct an investigation; federal oversight of the LANL investigation consists of the NNSA project manager who is responsible for the RLWTF construction project.

Federal Oversight: On June 30th, the NNSA Site Office (LASO) submitted to headquarters its implementation plan for the two-year pilot of the new oversight model. The plan reiterates the pilot's objectives and guiding principles while providing few specifics: it discusses the high reliance on the LANL contractor assurance system, the need for risk-based prioritization of federal oversight, the need to consider unique concepts for headquarters interface, and the expectation that LASO management and staff will dedicate at-least half their time to the pilot. Many key questions remain open (site rep weekly 3/17/06). In the coming weeks, LASO intends to define the oversight concept and a new organization structure to support completing implementation of the pilot by Oct 1st.

Waste Operations: Transuranic waste shipments from LANL to WIPP remain suspended, not only because of the head space gas sampling issue but also an emergent concern that internal packages in debris drums may shift and thereby permit exterior radiation levels to exceed the WIPP contact limit, 200 mrem/hr (site rep weekly 6/30/06). Limited shipments may resume for non-debris waste forms.

Pajarito Laboratory (TA-18): The Chemistry and Metallurgy Research Building (CMR), Wing 9, has begun to receive and store uranyl nitrate solutions from TA-18 and is scheduled to complete receipts of both nitrate and fluoride solutions (e.g., SHEBA fuel) in September. CMR anticipates a roughly one-year campaign to convert all these solutions into oxide (site rep weekly 6/2/06).

Management: LANL is phasing out the Corrective Action Review Board (CARB) on Aug 1st, and intends to replace it with a new issue management process still under development. The CARB was established in 2005 as an independent quality check on actions intended to address the roughly 2,000 non-institutional issues found during the LANL stand-down and resumption (site rep weekly 4/8/05).

The CARB has only partially lived up to its potential. In late May, with the looming Jun 1st contract transition, the CARB reported the outcome of its reviews covering plutonium and tritium operations (i.e., NMT and ESA Divisions). The CARB observed that NMT had developed a reasonable path forward but had made insufficient progress to allow the CARB to complete its review; NMT resources were a particular concern. For tritium operations, the CARB generated comments but did not complete its review process before contract transition. Upon contract transition, NMT and ESA ceased to exist; the CARB suggested its input be passed onto the new owning divisions. The CARB is now wrapping up reviews of waste operations and the site services contractor (KSL), but these are also expected to be incomplete, similar to those for NMT and ESA. While key data is being archived and LANL management has expressed commitment to followup, their mechanism to do so is not yet apparent.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 21, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending July 21, 2006

Chemistry and Metallurgy Research Facility Replacement Project (CMRR): The project intends to use an interim seismic ground motion spectrum to support structure and component design for the next few months while the site-wide probabilistic seismic hazard analysis (PSHA) is finalized. Last month's staff review found that the PSHA and CMRR site characterization efforts were using different inputs (e.g., shear wave velocities, damping curves). While the project believes that the interim spectrum is conservative, timely resolution of differences would reduce programmatic risk.

Plutonium Facility (TA-55): TA-55 has concluded that they need to improve their glove-box glove program, based on the rate of glove failures and the informality of current glove change-out criteria.

TA-55 is also close to full implementation of the interim technical safety requirements (iTSRs), with a few exceptions that will require NNSA approval; lab verification is scheduled for early August. The key exceptions involve longstanding issues: (1) highly loaded cans of Pu-238 non-hydrogenous residues are still in the room that was contaminated in Aug 2003; (2) non-robust containers are still in use in the vault. TA-55 recently moved their higher-loaded cans of Pu-238 hydrogenous residues into a glove-box line and is still requiring respirators for vault work. Full resolution warrants priority.

Waste Operations: This week, LANL resumed characterization of transuranic debris waste and made two shipments to WIPP, consisting of non-debris waste (i.e., OSRP sources). Separately, LANL has withdrawn the proposed RLWTF safety basis submitted last September because of concerns with the submittal's adequacy; RLWTF operates now under a 1995 safety basis and 1999 iTSRs.

LANL is struggling with many issues involving transuranic waste storage, repackaging, and shipment: the fabric on safety-class storage domes is ripped; the strength of safety-class banding is questionable; some of the +20,000 safety-class drums above ground have excessive weight (i.e., greater than 1,000 lb); many of the drums will need to be repackaged, but the single repackaging facility – WCRRF – is several miles from the drums and is not authorized to repackage the roughly 300 drums that exceed 56 Ci because of seismic concerns; the single shipping facility – RANT – is not authorized to load a TRUPACT above about one-fifth of the TRUPACT radioactivity limit, also because of seismic issues.

At this point, neither NNSA nor LANL seems to understand and to be considering the relative risks of alternatives to address these issues – particularly, whether it is appropriate to take actions to address a seismic vulnerability that may also slow shipments. The risk picture is complicated because the half-dozen relevant safety bases used assumptions that differ, sometimes by an order of magnitude or more; however, they all seem to indicate that the risk is high until most drums are shipped. With a concerted effort, it ought to be possible to safely and compliantly ship the drums within a few years.

Radiological Facilities: LANL has determined that a small Pu source was brought into a radiological facility, in conflict with NNSA conditions of approval for that facility, and that the facility had lost configuration control of its material-at-risk tracking system. It's positive that these issues are being found, but they are not likely limited to this facility; as evident from last year's two Type B investigations, such facilities receive little oversight (site rep weekly 2/3/06, 10/14/05, 8/12/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 28, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 28, 2006

Plutonium Facility (TA-55): LANL has not yet proposed and NNSA has not yet approved a path-forward to address eight discrepancies in the interim technical safety requirements (iTSRs) that were approved a year ago. The site rep reported on the two most significant issues last week; the other six involve primarily errors in the iTSRs. The iTSRs are supposed to be implemented July 31st, and without formal resolution and approval, the basis for continuing operations appears uncertain.

Waste Operations: LANL has proposed but NNSA has not yet approved continuing to operate the TRUPACT loading facility – RANT – to an older version of its TSRs until mid-December. RANT's authorization to operate to the older TSRs expires July 31st, and RANT is not prepared to operate to the new TSRs. The new TSRs were intended, in part, to mitigate seismic concerns by further restricting the inventory, but they also reduce efficiency of waste shipments to WIPP. Since March 2005, NNSA has intended for RANT to receive seismic upgrades or shutdown. LANL has apparently not been pursuing the upgrades since last Fall, NNSA has not monitored the issue since last Fall when it dropped its SSO oversight, and the issue remains open (site rep weeklies 4/28/06, 3/18/05).

Los Alamos Neutron Science Center (LANSCE): LANL has proposed but NNSA has not yet approved continuing LANSCE operations under the current five-part safety basis through Aug 2007, as well as using updated nuclear data to calculate the 1L Target radioactive inventory. The current LANSCE safety basis, now ~5 years old, expires Aug 31st, and using old data, the target inventory is predicted to exceed a radionuclide-specific safety basis limit on Aug 9th, necessitating shutdown. Even using the new data, this safety basis limit will likely drive target replacement within a year, which may or may not be the best decision from an overall risk perspective (site rep weekly 9/2/05).

Weapons Engineering Tritium Facility (WETF): WETF has one of the newer LANL safety bases (2002), and its implementation was verified via ORR in 2004. Safety analyses show that unmitigated consequences from postulated WETF accident scenarios are about an order of magnitude lower than for TA-54 and for TA-55, but WETF still warrants safety-class controls to protect the public.

In letters in 2002 and 2003, the Board questioned the efficacy of WETF lightning protection as safety-class. In early 2004, NNSA responded by directing LANL to upgrade safety-class containerization and fire barriers, and to reevaluate WETF accident scenarios, including lightning, in the next safety basis update. While WETF has made some safety improvements, such as moving inventory into ASME-pedigree containers, NNSA and LANL management have allowed the fire barrier upgrade to slip. In 2005, NNSA disapproved a proposed safety basis update because of USQ discrepancies and passed up an opportunity to reassert the need for the fire barrier upgrade that would improve public safety. LANL expects to resubmit a safety basis update in November (site rep weekly 3/5/04).

Management: Either NNSA or the contractor should have persevered on the WETF upgrade and should have averted the artificial crises discussed above for TA-55, RANT, and LANSCE, but neither did. LANS recognized before Jun 1st the looming TA-55, RANT, and LANSCE deadlines. NNSA could have taken appropriate actions before Jun 1st, but NNSA's attention has been elsewhere. As a result of late awareness, NNSA has relinquished opportunities to exert federal authority in these cases. Collectively, these cases illustrate the slip in nuclear safety oversight here in the last two years.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 4, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 4, 2006

Broderick, Elliott, and Plaue were here this week reviewing criticality safety and TA-55 upgrade plans.

Authorization Basis: NNSA has approved LANSCE operating under its current safety basis until August 2007 and the TRUPACT shipping facility, RANT, operating under its older technical safety requirements (TSRs) through this month. For TA-55, LANL has declared a potential inadequacy in safety analysis on the interim TSR issues and plans to request NNSA approval of interim TSR changes.

Institutional Safety Programs: LANL management has acknowledged a \$200M shortfall in its FY-07 budget (i.e., ~10 %); the impact on necessary improvements to safety programs is uncertain. For example, the Operational Efficiency (OE) Project, which ends Oct 1st, identified that \$7.4M over 3 to 5 years is required to execute the OE-generated plan for technical baseline reconstitution of vital safety systems in nuclear facilities; FY-06 funding for this was \$0.2M. Similarly, the OE-related plan to systematically address about 600 institutional training issues identified during the last 3 years is estimated to cost \$44M and take 4 years; resolving these training issues appears fundamental to LANL improving other safety programs, such as work control, conduct of operations, and criticality safety. Currently, neither LANL's priorities for these improvements nor NNSA's intentions to contractually incentivize the improvements is clear; their overall priority may be decreasing.

Criticality Safety: Criticality safety is one of the LANL safety programs for which NNSA and LANL's intentions are unclear and the priority may be falling. The DOE Facility Safety Order 420.1 requires that nuclear operations satisfy the requirements of the ANSI/ANS nuclear criticality safety consensus standards, unless otherwise approved by DOE. NNSA's on-site review last Oct reported that the program was not demonstrably compliant with these standards (site rep weekly 12/16/05).

While LANL has completed high and moderate priority walk-downs of fissile material operations, LANL is falling behind on its criticality safety improvement plan, intended to bring the LANL program into compliance with the standards; the schedule is undefined now due to budget issues. For example, it's unlikely that LANL has sufficient criticality safety staff to complete the walk-downs, resolve issues, and implement the other ANSI/ANS program elements, including conducting annual oversight reviews of several hundred fissile material operations; on-site criticality staff is about half that estimated just to sustain the status quo and a quarter of that estimated to drive the improvement plan to completion in FY-07. The NNSA Site Office still lacks full-time federal expertise to provide oversight of the program. While these issues persist, NNSA and LANL are accepting higher risk than would be accepted in nuclear industry practice (site rep weeklies 3/31/06, 3/10/06, 2/17/06, 1/13/06).

Tritium Operations: LANL is moving out TA-21's remaining tritium operations and preparing to start up some higher-activity tritium operations in a TA-16 radiological facility. While the total inventory is less than a tenth of the Hazard Category (HC-)3 threshold, it seems more appropriate from a safety perspective to transfer the operations to the new radiologically-vacant WETF wing (Bldg 450), which has better safety features and has been maintained to HC-2 standards. In 2004, NNSA withheld approval of Bldg 450 startup due to WETF configuration management issues, since shown to exist at all the LANL nuclear facilities. These lab-wide issues motivated the conduct of engineering initiative and the technical baseline reconstitution discussed above (site rep weeklies 9/2/05, 7/9/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 11, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 11, 2006

Bamdad, Broderick, Kupferer, Plaue, Rauch, and Von Holle were here this week reviewing LANL support of Pantex; Bamdad, Broderick, and Plaue also reviewed TA-55 confinement analyses/strategy.

Pajarito Laboratory (TA-18): The first critical assembly (Planet) has been moved out for refurbishing and shipment. LANL has also proposed a new baseline for TA-18 transition; it includes relocating Off-site Source Recovery Program (OSRP) storage to TA-55 (11/06), transferring solutions to CMR (11/06), dispositioning the solutions (8/07), de-inventorying TA-55 safeguarded trailers (2/07), and downgrading TA-18 from hazard category 2 to a radiological facility (2/07) (site rep weekly 7/14/06).

Authorization Basis (AB): High quality safety bases are needed to provide reasonable assurance that nuclear facilities can operate safely in a manner that adequately protects workers, the public, and the environment, as required by the *Nuclear Safety Management* rule, 10 CFR 830. The attached table summarizes the state of LANL AB development, implementation, and verification. Nearly every facility has AB-related issues affecting both mission and safety. Overall, in spite of significant effort, NNSA and LANL have been unable to update a single AB since the Board letter of May 27th, 2004 on this topic; 10 CFR 830 requires AB's be reviewed and updated annually (site rep weekly 8/20/04).

On-Site Transportation: LANL has proposed and NNSA is reviewing an updated transportation safety document (TSD), which would be the first LANL AB update in three years. The current TSD requires that vehicle drivers are government-UC vice LANS employees. Before contract transition, NNSA approved extending the current TSD until Sep 28th to allow LANL to propose changes.

Waste Operations: LANL has shipped about 14 kCi out of Area G in the last four years, including about 11 kCi so far in FY-06. This would constitute about 10 % of the Area G inventory, but it does not reflect receipts from TA-55 and CMR; those receipts were comparable to the shipments made through April 2006, which is the last receipts data available to the site rep.

LANL transuranic waste operations are an example of where AB-related issues are affecting mission and safety; a balanced risk perspective isn't apparent. In the last two months, rate of shipments has dropped (i.e., 15 in June, 7 in July) due to non-AB characterization issues involving debris waste. To make progress, LANL has been shipping non-debris waste – specifically, high-activity OSRP sources in pipe over-pack containers. As a result, while the rate of drum shipments has been cut roughly in half, the curie shipment rate has doubled. To address NNSA seismic concerns, LANL is now quickly implementing new technical safety requirements that will limit the shipping facility's throughput for high-activity drums (site rep weeklies 7/28/06, 7/21/06).

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF has drained the acid waste receipt tank and processed that stream, in preparation for replacing the leaking caustic receipt tank. This was the first transuranic waste processing at RLWTF since late 2004; the facility systematically found and addressed several issues before starting this evolution (site rep weeklies 4/21/06, 12/17/04).

LANL Hazard Category 2 and 3 Nuclear Facilities	Safety Basis age (years) ^a	Relative Inventory ^b	Status and Remarks
Radioactive Liquid Waste Treatment Facility (TA-50-1)	11	2	TA-50-1 is 43 years old, is in marginal condition, and is scheduled to be replaced in 2011. Its technical safety requirements (TSRs) are 7 years old.
Plutonium Facility (TA-55)	10	6,000	TA-55 has a 1-year-old set of interim TSRs that are a stop-gap measure for several nuclear safety issues. LANL is to propose a new safety basis in Sep 2006.
Chemistry and Metallurgy Research Facility (CMR)	8	4,000	CMR is 54 years old, is in marginal condition, and is scheduled to be replaced in 2013. Current safety analyses only evaluated operations to 2010.
Los Alamos Neutron Science Center (LANSCE)	4 to 6	less than 1	LANSCE is an accelerator that NNSA is requiring to operate as a nuclear facility because of its inventory. NNSA recently extended its 5-part safety basis to Aug 2007.
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	5	50	TA-50-69's safety basis consists of a 5-year-old hazard analysis and interim TSRs. It is in marginal condition and is LANL's only operating nuclear facility for repackaging transuranic waste, now stored at Area G.
Weapons Engineering Tritium Facility (WETF)	4	70	WETF's safety basis is implemented and was verified in 2004. Fire barriers still need upgrades; Bldg 450 startup for radiological operations remains unresolved.
Critical Experiments Facility (TA-18)	4	900	LANL expects to de-inventory TA-18 and to recommend downgrading it to a radiological facility in early 2007.
On-site Transportation	4	–	The transportation safety document expires Sep 28 th ; NNSA is reviewing a proposed update.
Area G Transuranic Waste Storage (TA-54)	3	3,000	Safety basis implementation has yet to be verified, which is scheduled for Sep 2006. Area G's transuranic waste is to be shipped off site by 2012 to support Area G closure in 2015.
Radioactive Nondestructive Testing Facility (RANT)	3	70	RANT is LANL's sole transuranic waste shipping facility; because of seismic issues and confusion on its TSRs, NNSA has authorized operations until Aug 31 st .
Nuclear Environmental Sites	2	–	These are inactive underground sites; the safety basis has implications for compliance with the state's consent order.
Safe Secure Transport Facility (TA-55)	1	60	This facility is used for special nuclear material storage and was originally authorized for use until 2010.

Notes: a 2nd column is the number of years since the NNSA safety evaluation report that approved the contractor's documented safety analysis, based on the May 2006 authorization agreement and the October 2005 nuclear facility list.

b 3rd column is the maximum radioactivity assumed in safety analyses, measured in units of the Hazard Category 2 threshold in DOE STD-1027.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 18, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 18, 2006

On Wednesday, the staff held a video-teleconference with the NNSA site office on the oversight pilot.

Federal Oversight: On Oct 1st, the NNSA site office intends to increase federal presence at facilities with postulated accidents having predicted high off-site consequences (e.g., TA-54, TA-55) and to rely on LANL's developmental contractor assurance system to monitor less hazardous facilities and worker safety. Federal oversight of institutional safety programs is still being defined.

Accident Investigations: LANL's investigation of the June 30th construction accident at RLWTF is complete. While the report has not been released, it appears that the identified root causes center on lack of management's awareness of unsafe conditions and behaviors at the job-site; lack of implementation of the Integrated Work Management (IWM) process; lack of flow-down and enforcement of LANL requirements upon subcontractors; and lack of review of subcontractor history for safety issues. NNSA has accepted LANL's conclusions (site rep weeklies 7/14/06, 6/30/06).

Integrated Safety Management: LANL is investigating another serious safety event, which occurred last Friday (8/11). A subcontractor contacted 480 V while drilling a self-tapping screw into a non-nuclear facility's motor control center; the subcontractor luckily escaped injury. There are apparent parallel issues between this event, the June 30th accident, and prior LANL accidents and near-misses.

The Board observed last year the importance of the IWM initiative for improving worker safety, as well as the need for workers, supervisors, and safety professionals to understand the process and to be involved in its implementation (Board ltr 7/21/05). Progress stalled before contract transition. LANL is now exploring whether and how to change the IWM process. When considering changes, it would be worthwhile for LANL to explicitly consider the logic and trade-offs for each process step, since the current process reflects hard lessons learned found during several investigations since 2001.

Authorization Basis (AB): Both LANL and NNSA rely on subcontractors to, respectively, prepare and review safety analyses; in recent years, both have increasingly relied on one subcontractor to do both functions. It's unclear that NNSA and LANL are adequately ensuring appropriate independence.

Plutonium Facility (TA-55): TA-55 has declared that the interim technical safety requirements are fully implemented, although NNSA and LANL have not closed on the prior reported issues (site rep weekly 7/28/06). TA-55 has also lost power and ventilation a half-dozen times since June 1st, causing PF-4 evacuation; NNSA is still reviewing a March AB package for improving ventilation reliability.

Waste Operations: For budgetary reasons, LANL has curtailed the integrated plan developed last Fall to make nuclear waste operations more unified, efficient, and disciplined; NNSA approved the plan in May 2006, and it is part of the authorization agreement for waste operations (site rep weekly 9/23/05).

Pajarito Laboratory (TA-18): TA-18 has curtailed nuclear operations because a procedural change last April specifying criticality safety limits was never finalized; LANL asserts that operations have been within the limits, which have not changed recently. Operations should resume next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 25, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending August 25, 2006

Anderson, Ogg, Plaue, and Winters were here this week reviewing legacy nuclear materials and transuranic (TRU) waste operations. This is part of a series of staff reviews focused on developing an integrated perspective of LANL's current and future nuclear operations and their safety implications.

NNSA and LANL envision dramatic increases in material through-put and operating tempo for the Plutonium Facility (TA-55) during the next six years, including an order-of-magnitude increase in pit production (~80 pits/yr), a Pu-oxide campaign to provide startup feed for the Savannah River Sites's new mixed oxide fuel plant (~80 kg/yr), and a Pu-238 heat-source campaign (~9 kg/yr). NNSA and LANL are also planning to complete roughly two billion dollars of nuclear facility investment by 2014, including an analytical chemistry and material characterization lab (CMRR), a radioactive liquid waste treatment facility (RLWTF), a TRU waste processing and shipping facility, a pit radiography facility, and TA-55 programmatic, security, and facility upgrades. By 2022, NNSA intends to consolidate such plutonium operations at an unspecified DOE site, as part of the new NNSA vision for the 2030 Complex.

While process knowledge exists, synthesis for the next decade's objectives is largely lacking, particularly for support functions (e.g., residue and waste processing). Pre-conceptual studies on pit manufacturing options are the most mature of studies contemplated and are based on recent TA-55 experience. The least desirable option from a safety perspective involves concurrently modifying rooms while conducting operations; this may become the choice by default without NNSA close engagement, not now evident.

Longstanding infrastructure problems have also allowed plutonium residue and TRU waste inventories to grow to where they impact both mission and safety, virtually ensuring failure unless addressed as a priority. For example:

- half of LANL's 9,000 nuclear material containers are non-standard and suspect.
- the 1960s-era RLWTF is a potential single point failure; it has not processed significant TRU liquid waste from TA-55 in two years.
- as a result of RLWTF issues, TA-55 has been unable to process residues, is now near its residue storage capacity, and is within 6 months of having to curtail pit operations unless resolved.
- LANL expects RLWTF TRU processing to resume during the next 18 months, starting in November, and needs it to ramp up to 2 to 5 times its previous throughput.
- LANL has been slow to pursue options (e.g., CLEAR line) to capture more source term at TA-55, the more robust facility, and thereby reduce the load on RLWTF.
- TA-55 needs to remove 30 to 60 contaminated glove-boxes within the next few years to make space for new equipment, but LANL has no capability now for large item size reduction.
- LANL has 50,000 TRU waste drums to ship to WIPP by 2010; shipment rate is limited by facility authorization basis and material condition issues; hundreds of higher activity drums still have no approved pathway off-site.
- TA-55 is nearly three decades old and at a point when equipment needs to be upgraded or replaced; however, NNSA is delaying and scaling back the TA-55 reinvestment project.

These problems are linked to some of LANL's most fundamental nuclear safety issues. For example:

- resolution of the TA-55 confinement strategy issue may depend on TA-55 reinvestment project upgrades that are now being delayed or are unscheduled (e.g., ventilation, fire protection).
- the off-site risk from TA-54 TRU waste drums remains high until nearly all the drums are shipped, according to DOE approved accident analyses.
- the LANL comprehensive nuclear materials packaging and storage plan – which was developed in response to the 2003 Pu-238 Type B investigation and the 2004 Secretary's 00-1 implementation plan – is still draft and unapproved by NNSA (ref: Secretary's ltr 7/23/04); this plan is a key element in LANL systematically and safely addressing its large plutonium residue backlog.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 1, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 1, 2006

On Wednesday, the staff held a video-teleconference with LANL on institutional safety programs.

Plutonium Facility (TA-55): LANL now expects to propose the upgraded TA-55 safety basis in early November; it will retain primary reliance on passive confinement as safety-class. Next week, LANL starts the confinement ventilation evaluation, per DOE's 04-2 implementation plan and assuming ventilation is safety-significant; the evaluation is due in mid-November. The selection as safety-significant is based on analyses that used non-physical assumptions and that may have considerably under-estimated confinement ventilation effectiveness (ref: Board ltr 5/31/05, site rep weekly 6/16/06).

Waste Operations: LANL resumed transuranic (TRU) debris waste shipments to WIPP last week. LANL has also proposed a safety strategy that involves using the WCRR drum repackaging facility and the RANT shipping facility to remediate and ship the above-ground higher activity drums off-site in 2007 and to support shipping the remainder of the 50,000 drums off-site during the next 4 years. The 325 above-ground higher activity drums (56 Ci or greater) constitute about 50 kCi, which is a third of the current above-ground TRU waste inventory; there are another ~300 higher activity drums with 90 kCi below ground. LANL expects to propose RANT and WCRR safety basis upgrades in October and the Area G safety basis update toward the end of 2006 (site rep weekly 7/21/06).

Integrated Safety Management: As a result of 3 near-misses, LANL held a series of employee and subcontractor meetings last week focused on electrical safety; the emphasis is on work planning and work control from the Integrated Work Management (IWM) process, particularly the roles of the person-in-charge, the plan-of-the-day, and management review and work release (site rep weekly 8/18/06). LANL has also been steadily working to improve its lock-out tag-out program and, more recently, has pursued issues with control of cranes with maintenance and inspection discrepancies.

Institutional Safety Programs: On Aug 17th, LANL submitted to NNSA an updated integrated corrective action plan, in response to last year's two Type B investigations and DOE-SP review; the plan includes developing a lab-wide IWM implementation improvement plan in January 2007. LANL has also assigned clear responsibilities for institutional safety programs to associate directors and has reiterated its commitment for achieving mature programs. Key elements include (a) an integrated set of manuals for operations, engineering, training, and maintenance, and (b) the facility operations directors as the lab's agents for consistent implementation of the institutional safety programs.

While the scope of the effort has been well studied (e.g., by the Operational Efficiency Project), the cost and implementation schedule remain undefined due to the FY-07 budget situation; LANL expects better definition in the next 4 to 8 weeks (site rep weeklies 8/4/06, 7/7/06, 6/9/09, 5/31/06, 4/21/06).

Contractor Assurance System (CAS): LANL expects the LANS Board of Governors to take action by Sep 12th on a proposed CAS description. This week, 2 LANS corporate assess/improve/modernize (AIM) teams were on site reviewing electrical safety, and nuclear and high hazard operations.

Conduct of Engineering: LANL has assigned a site chief engineer and is developing a network and procedures for the independent design authority function, which has not existed here in recent years.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 8, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 8, 2006

Radioactive Liquid Waste Treatment Facility (RLWTF) Upgrade Project: This week, NNSA approved with comments the preliminary hazard analysis, submitted in April, for a new hazard category 2 (HC-2) RLWTF, which would replace the current 43-year-old facility in 2010. The schedule is to complete preliminary design in mid-FY-07, final design in mid-FY-08, construction in mid-FY-10, and decontamination and decommissioning of the current facility in FY-12. Total project cost range is \$82M to \$104M. Size is ~21,000 ft². Current acquisition strategy is design-bid-build.

The dominant public hazards are chemicals used for pH adjustment (i.e., HCl and NaOH solutions); the design basis radioactive inventory (Am-241) is under 200 Ci, which is about four times the HC-2 threshold; this is one to three orders of magnitude lower than the radioactive inventories in other LANL HC-2 nuclear facilities. LANL assumes that TA-55 will start up and operate the CLEAR line and thereby reduce the new facility's source term most of the time to under 20 Ci. LANL's proposed initial functional classification includes no safety-class systems and has building structure, vehicle barriers, lightning protection, certain chemical and radioactive systems, and a natural gas seismic shut-off valve as safety-significant. The building and systems would be performance category 2 (PC-2). NNSA disagreed that the functional classification was complete and requested further evaluation, particularly of active confinement ventilation, which was proposed as defense-in-depth.

Waste Operations: NNSA and LANL continue to search for a path-forward for the high-activity transuranic waste drums reported last week; discussion focuses on whether to use the TA-54 DVRS Facility or the TA-50 WCRR Facility for repackaging these drums (ref: site rep weekly 6/30/06). The site rep believes that either facility could work for the high-activity drums and both will eventually be needed for drum repackaging. Given the activity levels (150 Ci avg, 750 Ci max), appropriate additional controls (e.g., respirators) and contingency planning appear key regardless of the selection.

Criticality Safety: An NNSA Service Center review of several of LANL's recent criticality safety evaluations has raised questions, particularly on their completeness as justification for the control set for fissile material operations. One root cause may be insufficient qualified staff to systematically accomplish the growing workload and drive the LANL criticality safety program to a state that meets DOE requirements and applicable national consensus standards (site rep weekly 8/4/06).

Federal Oversight: On Sep 1st, the NNSA Site Office provided headquarters an initial management system description for the two-year federal oversight pilot; it indicates that • federal oversight of nuclear operations will be transactional based on a graded approach; • it will rely on the contractor assurance system (CAS) to target areas needing more specific oversight; • it will include those institutional programs that nuclear facilities depend on for safe and secure operations; • non-nuclear operations that have the potential to release radiological or chemical constituents to the public will also receive federal transactional oversight. The model has the potential to increase federal oversight in facilities with postulated high-consequence accident scenarios but relies on CAS to find and respond to precursors in lower hazard facilities that have been problematic. It might be worthwhile for LASO to develop maturity metrics that guide improvements during the pilot; one useful metric would be the state of qualification of federal staff and team leaders being assigned to new positions.

Chemistry and Metallurgy Research Facility (CMR): LANL's accident investigation report for the June CMR hood fire is late and is undergoing LANL management review (site rep weekly 7/14/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 15, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 15, 2006

Gwal, Layton, March, and Matteucci were on site this week reviewing electrical and fire protection systems and programs, both site-wide and facility-specific for CMRR, TA-55, and WETF.

Infrastructure: The LANL preliminary FY-07 budget for nuclear infrastructure and operations appears, in some cases, to be less than the FY-06 budget and roughly a third of the estimated need; this could propagate longstanding declining trends in infrastructure that affect nuclear safety. The next test is how NNSA and the new LANL management reconcile the budget issues, and specifically, how they evaluate the mission vs infrastructure trade-offs. It is unclear how NNSA and LANL could achieve their long-term nuclear mission objectives without starting in FY-07 to substantively address longstanding issues with infrastructure and safety programs (site rep weeklies 9/1/06, 8/25/06, 8/4/06).

Fire Protection: The postulated highest consequence nuclear accidents at LANL are fire-related. It is unclear that LANL has adequate fire-fighting capability to respond to a nuclear facility fire, based on NNSA's long-term lack of a fire department contract with the county and lack of resolution of issues identified in a 2004 baseline needs assessment. LANL has made some progress in other areas, such as hiring 2 fire protection engineers in FY-06, and intends to hire 2 more in FY-07, subject to funding. LANL has also split the fire marshal and fire engineering functions to provide more independence and is working on fire hazard analysis updates for TA-55 and CMR (site rep weeklies 4/28/06, 6/3/05).

Plutonium Facility (TA-55): In 1996, the Board's staff noted that TA-55 lacked standard electrical analyses that are essential to ensuring personnel safety, as well as safe and reliable power (ref: Board letter and staff report 12/5/96). In 1997, LANL had a subcontractor complete these calculations. However, it seems little was subsequently done with the subcontractor's recommendations. LANL is now updating key analyses and expects them to be done in November; it's advisable for LANL to also fully and expeditiously evaluate the associated vulnerabilities and address the prior recommendations.

Electrical Systems and Safety: LANL has power grid infrastructure upgrades that are underway and that are improving the stability and reliability of site power, which is positive. On the electrical safety program, LANL has demonstrated vision in the last decade and has made major contributions to the DOE program, such as the DOE Electrical Safety Handbook; however, several LANL reviews have indicated that no real improvement has occurred in the last 3 years in the rate and severity of electrical safety mishaps; there also appears to be a strong linkage between electrical safety problems and broad weaknesses in implementation of the integrated work management (IWM) process. Current efforts are focused on improving program requirements (e.g., lock-out tag-out), improving oversight and training for subcontractors and students, and working toward more uniformity in program implementation.

On-Site Transportation: NNSA has disapproved LANL's proposed upgraded transportation safety document (TSD); NNSA asserts that the TSD did not demonstrate equivalence to federal regulations for on-site hazardous material shipments that use non-equivalent containers (site rep weekly 8/11/06).

Management: The LANS Board of Governors has approved the LANL contractor assurance system description, which now goes to NNSA; negotiations on FY-07 performance based incentives continue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 22, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 22, 2006

Recommendation 04-2: The on-site team has transmitted its preliminary evaluation of TA-55's confinement ventilation to the Independent Review Panel (IRP) Chairman. The team considered 24 accident scenarios and explored five in detail that seem to benefit most from active ventilation: a seismically-induced multi-room fire, two Pu-238 room fires, a vault fire, and an ion exchanger thermal excursion. Preliminarily, the team concludes that one particular ventilation subsystem by itself might be capable of maintaining building negativity during an upset and be a worthy candidate for safety-class; the subsystem's functionality depends on avoiding smoke plugging HEPA filters; seismically upgrading glove-boxes is also key, particularly those with furnaces or other fire initiators. The team has scheduled 2 weeks for IRP review and intends to complete its evaluation by mid-November.

Plutonium Facility (TA-55): TA-55 has assigned a location and has conducted a location-specific readiness review for assembling radiation test objects (RTOs), an activity formerly done in TA-18. LANL is also conducting a readiness assessment for starting up more trailers on the TA-55 safeguarded trailer pad and thereby addressing storage constraints. In August, NNSA approved LANL's proposed TA-18 transition baseline, which includes emptying the trailers in February 2007 and completing TA-18 material shipments in August 2008 (site rep weeklies 8/11/06, 7/7/06, 5/5/06).

Pu-238 Operations: During roughly the last year, TA-55 has reduced the Pu-238 material-at-risk in the room that was contaminated in Aug 2003 by about 40 %, primarily by packaging lean residues for WIPP shipment and entering richer residues into the glove-box lines; about 500 g of residues remain.

Weapons Engineering Tritium Facility (WETF): WETF's safety posture is highly dependent on tritium inventory limits, safety-class containers and fire barriers, and its combustible control program. During the last two months, LANL has imposed compensatory measures and addressed about 400 possibly discrepant penetrations in WETF fire walls, which have a 1-hr rating. LANL is currently not pursuing upgrading select fire walls to 2-hr rating because of interferences and estimated costs that are an order-of-magnitude higher than those of 2003. WETF reviewed its combustible control program with the Board's staff last week; while the program's technical basis seems weak, its implementation is strong. WETF intends to revisit the combustible controls and the potential fire wall improvements when submitting its safety basis upgrade, tentatively expected later this year (site rep weekly 7/28/06).

Emergency Exercise: LANL conducted its annual emergency exercise on Wednesday (9/20). The scenario involved an Area G drum impact, spill, and dispersal; a subsequent unrelated nearby wild-land fire; and contaminated personnel with injuries. Protective actions appeared prompt and appropriate; however, radiological monitoring data needed to bound the release seemed excessively delayed. NNSA participated in the exercise. LANL and the LANS corporate partners are largely responsible for formal evaluation of the exercise, which is forthcoming.

Federal Oversight: NNSA has resumed conducting safety system oversight (SSO) reviews at LANL. Reviews in August and September focused on safety systems for LANSCE and for nuclear waste operations, respectively. Reports are forthcoming (site rep weekly 6/9/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 29, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr., LANL Site Representative
SUBJECT: Activity Report for Week Ending September 29, 2006

The site representative was at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 6, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending October 6, 2006

LANL briefed Bader (Board Member), Keilers, and Martin on LANL's Reliable Replacement Warhead (RRW) design on Wednesday. Bader, Martin, and Rauch also had informal discussions with LANL on pit manufacturing options. Martin and Rauch attended a LANL energetic materials review.

Chemistry and Metallurgy Research Building (CMR): On Monday (10/2), the CMR fire protection engineer determined that flash-over could occur from one wing to the opposing wing across the spinal corridor and that this possibility is not addressed in the current CMR safety basis; the facility implemented compensatory measures, including a fire watch. On Wednesday, CMR secured the fire watch based on nearby combustibles being reduced to below a new calculated flash-over limit.

Management: Effective this week, LANL rolled out their contractor assurance system (CAS), and the NNSA Site Office (LASO) began their oversight pilot. Within the last two weeks, LANL has also established an institutional management review board (IMRB) to oversee the lab's new issue and corrective action management system (ICAM) and to prioritize institutional issues and corrective actions. All three of these efforts currently have low maturity, which is not unexpected. LANL has been developing the CAS since Jun 1st and intends to implement and improve the system in a deliberate manner during the next two years; the LASO pilot is on the same schedule.

For example, LANL is deploying better software for tracking performance and managing issues; CAS is highly reliant on line managers properly using these tools, establishing their own metrics, performing objective self-assessments, and faithfully following up on issues; this is the foundation of CAS. LANL line managers have performed these functions inconsistently and often poorly in the past, and LANL is starting to train managers now on how best to perform these functions in the future. For LASO, the oversight pilot depends on CAS being successful and accessible to federal oversight. LASO has also deployed more staff in nuclear facilities and has increased the pool of people assigned as subject matter experts; however, their relevant training and experience is generally low.

Institutional Safety Programs: LASO has forwarded to DOE HS-1 a new update of LANL's integrated corrective action plan that was prepared in response to last year's two Type B investigations and the DOE-OA review (site rep weekly 9/1/06). LASO recommends approval and delegation of authority to LASO for change control; LASO referenced processes it used to follow up on previous Type B investigations. The site rep observes that LASO has been unsuccessful in driving Type B corrective actions to closure, such as those still open from the Aug 2003 Pu-238 release.

This week, LANL closed the Operational Efficiency (OE) Project, which has been LANL's mechanism during the last two years for improving institutional safety programs. LANL asserts that 90 % of the OE milestones have been met and independently verified (i.e., 138 of 153). The remainder involve integrated work management (5), lock-out tag-out (1), quality assurance (1), vital safety systems (1), and training (2). LANL has assigned responsibility for followup to particular associate directors and has committed the IMRB to monitoring implementation.

Formality of Operations: LANL plans to issue an integrated set of manuals for operations, engineering, and maintenance by Oct 31st, review requirement applicability and identify gaps by mid-December, and issue a training manual and integrated implementation plans in January 2007.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 13, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 13, 2006

Waste Operations: Last Friday evening (10/6), LANL suspended Area G operations due to high contamination levels found on the bottom of one transuranic waste drum in Dome 33 (i.e., up to 0.5 M dpm alpha). Immediate actions were extensive and appropriate. Dome 33 was isolated, and work areas outside Dome 33 were released later that evening. The drum was over-packed, and access to Dome 33 has been restricted while the affected area is decontaminated. The drum breach appears recent, possibly within the prior week. No environmental, safety, or health impacts resulted.

This was a worker safety issue, but there are public safety implications. LANL appropriately suspended operations to protect the workers because the contamination extent was initially unknown. However, to protect the public, LANL depends on most drums maintaining integrity in the event of a major earthquake or other extreme upset. Due to Area G's proximity to the site boundary, LANL may be unique among DOE sites in designating drums as safety-class; however, many LANL drums are similar to this one, which was retrieved after more than a decade from underground storage and had indeterminate integrity. LANL plans to review Area G's risks and controls in its safety basis later this year and hopes to ship Area G's transuranic waste to WIPP by 2010, which is the ultimate resolution.

Chemistry and Metallurgy Research Building (CMR): Per an NNSA request, CMR resumed fire watches this week for rooms that could be potentially susceptible to flash-over across the spinal corridor during a fire. LANL intends to request NNSA approval to remove restrictions following an independent review by the LANL Fire Marshal. LANL is also considering longer-term solutions.

Pajarito Laboratory (TA-18): LANL defueled SHEBA this week, which is TA-18's last remaining critical assembly. TA-18 is storing the ~120 L of fuel solution in 20L carboys within 55 gal drums, pending shipment to CMR for storage and treatment. LANL plans to remove all of TA-18's security category III/IV nuclear material by Nov 30th, downgrade TA-18 to a radiological facility in Feb 2007, and place TA-18 into a surveillance and maintenance mode by Apr 1st, 2007 (site rep weekly 8/11/06).

Plutonium Facility (TA-55): On Sep 17th, NNSA concurred with a LANL proposed safety-significant (PC-2) switchgear modification that will increase TA-55 electrical power and confinement ventilation reliability and improve nuclear safety; the LANL proposal was submitted to NNSA in phases between Jan and Mar 2006 and has been in the works for several years. When completed, the modification will automatically close breakers to restore off-site power, if available, and will automatically transfer loads to a diesel generator if off-site power is not available. This would help minimize confinement ventilation upsets, such as those that occurred frequently this past summer (site rep weekly 8/18/06).

Authorization Basis: When a potential inadequacy in safety analysis (PISA) is discovered, the Nuclear Safety Management rule (10 CFR 830) requires contractors to place or maintain nuclear facilities in a safe condition, notify DOE, perform a USQ determination, and submit to DOE an evaluation of the safety of the situation prior to removing any operational restrictions. LANL currently has a plethora of PISAs; however, NNSA and LANL are exercising insufficient formality in tracking PISAs, and in maintaining and removing operational restrictions due to PISAs; driving PISAs to closure seems to lack priority. The site rep understands that NNSA and LANL are working to correct this situation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 20, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending October 20, 2006

The staff, NNSA, and LANL held a video-teleconference on LANL TRU waste operations on Thursday.

Accident Investigations: Last week, LANL management signed the accident investigation report for the June CMR hood fire. LANL has also issued a corrective action plan (CAP) for the June RLWTF construction accident; the CAP focuses not only on implementing integrated work management (IWM) but also on improving span-of-control, training, and execution of safety oversight by first line supervisors, managers, and safety professionals (site rep weeklies 9/8/06, 7/14/06).

Transuranic (TRU) Waste Operations: LANL has modified the WCRR repackaging facility to ensure reliable glovebox vacuum, a worker safety improvement (site rep weekly 10/14/05). NNSA and LANL have also converged on a path-forward for shipping the 325 highest-activity drums above ground in Area G to WIPP by Spring 2008; these drums contain about a third of the current above-ground inventory (i.e., ~50 kCi). By Oct 30th, LANL will propose updated safety bases for WCRR and RANT (the shipping facility) that support one year of high-activity operations. By Jan 2007, LANL will also propose a longer-term strategy for addressing large TRU-contaminated items, now stored in Area G in plywood boxes, as well as the remaining high-activity packages (~90 kCi, 300 Ci avg), which are to be retrieved from underground storage starting in FY-08 (site rep weekly 9/8/06).

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL is planning to replace the leaking caustic waste receipt tank during a weekend in November; preparations appear extensive, including the use of a mock-up to prove out processes and procedures (site rep weekly 8/11/06).

Plutonium Facility (TA-55): NNSA has not acted on LANL's proposed resolution of discrepancies in the interim technical safety requirements, which LANL declared implemented in August; the key issues involve: • non-robust nuclear material containers used in the vault, which was contaminated in Dec 2005; • Pu-238 residues still stored in the room that was contaminated in Aug 2003. Both of these are linked to still-open NNSA and LANL corrective actions in response to the Aug 2003 Pu-238 uptakes. Particularly, while WIPP recently approved new TRUCON codes and while LANL has disposed of some Pu-238 residues, NNSA and LANL have made little progress in developing packaging standards and addressing the remaining Pu-238 residues, some of which are intermixed with combustibles in poor containers within gradually degrading plastic bags (site rep weekly 6/2/06).

Los Alamos Neutron Science Center (LANSCE): On Sep 13th, LANL informed NNSA that, pursuant to a DOE General Counsel determination, LANSCE is excluded from the Nuclear Safety Management rule (10 CFR 830) and its PAAA provisions; the Occupational Radiation Protection rule (10 CFR 835) and accelerator order (DOE O 420.2B) apply (site rep weeklies 7/28/06, 9/2/05).

Institutional Safety Programs: On Sep 27th, LANL issued updated requirements for hazardous energy control for worker safety (i.e., lockout/tagout); this was a key open item from the now-closed Operational Efficiency (OE) project; the need for the update has been recognized for years and was highlighted by several recent near-misses. LANL plans to develop relevant training and modify subcontracts by Dec 1st, train workers by Feb 2007, improve hands-on training starting in Mar 2007, and revise facility-specific procedures by Aug 2007 (site rep weeklies 9/15/06, 9/1/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 27, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending October 27, 2006

Waste Operations: Last week, Area G discovered one 55-gal drum and 37 85-gal drums that are unvented; the safety basis requires drums to have filtered vents to prevent flammable gas buildup. Area G has equipment but no authorized process for venting drums and is developing a path forward.

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF continues to prepare to replace the leaking caustic waste receipt tank during November. Yesterday, ultrasonic inspection determined that the existing tank's side wall is structurally adequate but that the tank top has indications of weaknesses that may affect load path during lifting. LANL is reviewing the situation.

Chemistry and Metallurgy Research Building (CMR): CMR is continuing fire watches and has proposed a Justification for Continued Operation (JCO) to address wing-to-wing flash-over potential.

LANL's investigation report on the June hood fire indicates that it was due to a spill of a pyrophoric liquid, most likely tri-ethyl aluminum, from a cylinder that originated in TA-21 (DP Site) sometime in the past and was probably moved first to TA-54 and then to CMR; the cylinder's actual history is unknown; it was incorrectly assumed to contain uranium hexafluoride. Causal factors that LANL identified center on control of chemicals and incomplete implementation of integrated work management (IWM) – two longstanding issues at the laboratory (site rep weekly 6/16/06).

Criticality Safety: NNSA's team of criticality safety experts was on site this week to determine the status of the LANL criticality safety program. As of Oct 1st, LANL has walked down and triaged about half the lab's 564 fissile material operations, including all those considered to be high or moderate risk; while walk-downs of the remaining ~300 lower risk operations have slowed, LANL considers that they constitute no serious safety issues. Separately, the NNSA Site Office has assigned a competent individual responsibility for the LANL program and hopes to accelerate his qualification.

The NNSA team's preliminary conclusions are that criticality safety risks here are now well understood and are being well controlled using interim processes, as opposed to the situation a year ago; the strong field presence of LANL experts and the new database of interim criticality safety documentation appear noteworthy; LANL has much to do to establish a compliant program, which could take 2 to 3 years; that said, budgetary decisions made within the last week increase the lab's criticality safety program funding by about 20 % for FY-07, which is encouraging. The NNSA team expects to issue a report in November, and LANL expects to issue an updated schedule for corrective actions in December (site rep weeklies 9/8/06, 8/4/06, 3/10/06, 1/13/06, 12/16/05).

Radiological Facilities: The site rep understands that LANL is considering moving sources from TA-18 to TA-35-2/27 in the near future to support downgrading TA-18 from a Hazard Category 2 (HC-2) nuclear facility. In 2000, TA-35-2/27 was downgraded from HC-2 to a radiological facility by crediting encapsulation for roughly 1 kCi of sealed sources (i.e., 20 times the HC-2 threshold). As discussed in a Board letter (6/26/06), the technical basis for automatically crediting encapsulation to contain nuclear material during a fire is questionable; exacerbating this situation by increasing the inventory without further analysis and controls may be ill-advised (site rep weeklies 2/3/06, 7/29/05).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 3, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 3, 2006

Management: NNSA and LANL have agreed upon and issued a performance evaluation plan, which includes performance based incentives (PBIs) for implementing conduct of operations, engineering, and maintenance, as well as improving the safety bases, criticality safety, and readiness reviews.

Institutional Safety Programs: Last Friday (10/27), LANL forwarded to NNSA new institutional manuals for conduct of operations, maintenance, and engineering in accordance with the PBIs. Implementation plans are expected in January. NNSA intends to review performance quarterly. LANL has also established a conduct of operations performance index, based on occurrence reports and criticality safety infractions, that will serve as a metric for measuring improvement.

Authorization Basis (AB): Last Thursday (10/26), LANL proposed an updated on-site transportation safety document to NNSA. LANL expects to propose updated safety bases for the Plutonium Facility (TA-55) and the transuranic waste repackaging facility (WCRR) today and for the transuranic waste shipping facility (RANT) next week (site rep weekly 8/11/06). Also, NNSA has accepted a LANL re-analysis of the off-site airborne release from postulated accidents at 13 nuclear facilities; the re-analysis used current dispersion methodology and accounted for LANL shrinkage due to land transfers. The changes are within 30 % of previously approved results, except for LANSCE as discussed below.

Plutonium-238 Operations: LANL has concluded that the remaining residues in the room that was contaminated in August 2003 ought to be disposed of as transuranic waste without further processing (e.g., pyrolysis). LANL and the WIPP contractor have also converged on disposal criteria for these residues, as well as other Pu-238 solid wastes, that appear to minimize handling and operator risk while maximizing drum loading (i.e., up to the 80 Ci WIPP limit; site rep weeklies 10/20/06, 6/23/06).

Weapons Engineering Tritium Facility (WETF): WETF has addressed discrepant fire wall penetrations and is close to securing from compensatory measures imposed in August; LANL has also identified a slight overstress condition (5 %) in precast concrete ceiling beams during a fire, but asserts it is acceptable based on the assumed safety factors and the low probability of a fire concurrent with the assumed snow load. WETF is now in the midst of a major ventilation upgrade that includes installing hoods and task exhaust points, improving worker safety (site rep weekly 9/22/06).

Los Alamos Neutron Science Center (LANSCE): The current LANSCE safety basis (2000) predicts unmitigated off-site consequences of 18 rem from a postulated steam reaction with the activated 1L tungsten target; more recent studies indicate that the reaction products would deposit near the target, limiting the airborne release to the outside. In the re-analysis discussed above, LANSCE saw a factor of 5 increase above the current safety basis predictions due to proximity to East Jemez Road. NNSA has requested LANL to expeditiously reevaluate off-site consequences due to LANSCE accidents.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 10, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 10, 2006

Brett Broderick reported for duty here this week as a DNFSB site representative. Merritt and Plaue were also here this week reviewing NNSA and LANL nuclear safety oversight and operations.

Plutonium Facility (TA-55): TA-55 has increased operating tempo and is close to demonstrating a six pit per quarter surge capacity, either this quarter or next. Longer term, LANL intends to accelerate and complete a legacy pit production run by FY-09, then shift to building a Reliable Replacement Warhead (RRW) demonstration unit in 2010 and a first production unit in 2012. The maintenance tempo has also increased for upgrading equipment and is moving to an extended-hour work schedule, likely requiring extended-hour infrastructure support (e.g., site emergency services). Programmatic pressure is increasing on RLWTF receiving transuranic liquid waste by February 2007, on TA-55 processing, repackaging and consolidating residues, on LANL streamlining waste & excess glove-box disposition, and on LANL shipping excess plutonium to Savannah River Site (site rep weekly 8/25/06).

Chemistry and Metallurgy Research Building (CMR): TA-55's pit manufacturing depends on CMR providing analytical chemistry; future use of Wing 9 is also being considered. However, CMR is five-decades-old, and over-sized for the mission; near-term operational cuts are being considered, although CMR is increasingly difficult to maintain; an update to the 1998 safety basis is at least a year away.

In 1998, NNSA accepted the risk of CMR operation to 2010 but the replacement facility (CMRR) is not expected to be operational until 2013 or later. LANL did complete a CMR upgrade project in 2002, but otherwise, there has been little focused study since the 1998 decision of the risks associated with extending CMR operation past 2010; such a study appears warranted to enable risk-informed decision-making among the mission options and the alternatives to continuing CMR operations.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL expects to replace the leaking caustic waste receipt tank next weekend (11/18) using the existing two lifting lugs. This week, LANL determined that the tank top is structurally sound after removing paint in spots that interfered with previous ultrasonic measurements. LANL intends to inspect, load cycle, and then reinspect the existing lugs and their welds before removing the existing tank. The tank replacement is on schedule, but TA-55's programmatic needs to process a multiple-year residue backlog may drive RLWTF to subsequently treat transuranic waste before RLWTF's deteriorated treatment systems are upgraded.

Federal Oversight: On Oct 1st, the NNSA Site Office (LASO) began their oversight pilot. The week before, an external NNSA team concluded that LASO is prepared to implement the pilot, but it also identified significant gaps; for example, only 4 of the 26 people on the three integrated oversight teams (IOTs) are fully qualified: two facility reps (RLWTF, CMR), one safety analyst, and one project manager; only one IOT team member has unescorted access to TA-55 plutonium operations (PF-4).

Since Oct 1st, pivotal LASO management positions have become vacant, such as the SES Technical Deputy Manager, the Operations Assistant Manager, and the Senior Technical Advisor; several other key positions are temporarily filled. LASO's intent is • to have the Technical Deputy assume the Senior Technical Advisor responsibilities and not fill the latter position; • to compete the other key positions, subject to headquarters approval; • to self-assess the pilot in March; • to prepare for a Chief Defense Nuclear Safety review of the pilot, originally scheduled for January but now proposed for May.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 17, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 17, 2006

Authorization Basis (AB): Within the last two weeks, LANL has proposed to NNSA updated safety bases for TA-55, the transuranic waste repackaging facility (WCRR), and the transuranic waste shipping facility (RANT). Resolution of several of LANL's most significant nuclear safety issues are linked to these submittals (e.g., site rep weeklies 9/1/06, 8/11/06, 6/16/05, 12/9/05, 8/5/05).

Chemistry and Metallurgy Research Building (CMR): NNSA has approved a justification for continued operation (JCO) for potential wing-to-wing flash-over across the spinal corridor during a fire; CMR has secured roving fire watches; LANL has ordered fire doors for affected rooms. Also, on Tuesday, a CMR worker discovered contamination on his right palm, measured at ~11k dpm alpha and believed to be legacy Pu-238; nasal smears were negative; the worker has been decontaminated.

Weapons Engineering Tritium Facility (WETF): This week, NNSA concurred with LANL removing compensatory measures for safety-class fire wall discrepancies; LANL asserts that all fire walls credited in the safety basis have been repaired to a 1 hour rating and meet code requirements.

WETF continues ventilation upgrades and discovered this week that a mis-communication led workers to partially impair the safety-class lightning protection system before low lightning conditions were confirmed, a safety basis requirement. While questions persist on WETF lightning protection's effectiveness as a safety-class defense, adequate control of the human element is still needed to ensure functionality of any safety-class system intended to protect the public. WETF is overdue for a safety basis update and a re-examination of its safety system functional classification, now not expected until late FY-07 (site rep weeklies 11/3/06, 9/22/06; Board letters 8/19/03, 8/6/02).

Plutonium Facility (TA-55): Thursday afternoon (11/16), TA-55 curtailed work in PF-4 and personnel performed an orderly exit after acidic liquid backed up from the closed transuranic acid waste line into two pump rooms and then seeped into three adjacent rooms. As a precaution, LANL emergency response and hazardous material organizations responded. The TA-55 spill response team reentered and determined that the chemical hazard was minimal and the radiological hazard was readily manageable. The spill (estimated at 10 gal) was cleaned up, and normal operations resumed Friday. These small pump rooms are normally controlled as contamination and airborne radioactivity areas; they have a history of radiological and material condition issues that TA-55 is investigating.

Parajito Laboratory (TA-18): LANL has shipped the remaining TA-18 fissile solutions to CMR for disposition. NNSA has also approved a safety basis for storage of Off-site Source Recovery Program (OSRP) sources in a TA-55 transportainer and has approved startup of 3 more trailers (4 total) at the TA-55 secure trailer pad; these actions open the pathway for removing the remaining TA-18 nuclear materials and provide relief to the TA-55 vault, which has been storing TA-18 materials.

The TA-55 transportainer is limited to ~250 Ci, consisting of OSRP sealed sources in pipe-overpack containers meeting WIPP requirements. The trailers are limited to ~3,100 Ci and rely on the trailers, the pads, and external anchorage as safety-class features; containers, shelving, internal anchorage, and the pad slope are safety-significant; material-at-risk and combustible inventory limits are the key admin controls; dispersible Pu (e.g., powders, liquids) is prohibited. Both the transportainer and the trailers will likely be in use for several years (site rep weeklies 10/13/06, 9/22/06, 8/11/06, 7/7/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 24, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 24, 2006

Andersen was here this week attending a CMRR design status meeting.

Fire Protection: Most of the postulated highest-consequence nuclear accidents at LANL involve fire. LANL may not have adequate fire-fighting capability to respond to a nuclear facility fire, particularly if fire fighters are simultaneously responding to a fire elsewhere at the laboratory or the town-site.

The DOE Facility Safety order (DOE O 420.1B) requires DOE sites to implement an acceptable fire protection program with specified features; these include preparing a baseline needs assessment (BNA) that establishes the minimum required site fire-fighting capabilities and updating the BNA at least every 3 years. NNSA and LANL completed a BNA in 2004 that has languished and likely no longer reflects current conditions, such as the expanding TA-55 mission and the new National Security Science Building. The 2004 BNA also did not clearly set the minimum required site fire-fighting capabilities since LANL – possibly uniquely among DOE sites – relies on county fire-fighting resources and the 2004 BNA focuses on mixed needs. NNSA and LANL ought to expeditiously update the BNA and thereby clearly establish LANL's current and future fire-fighting needs (ref: Board letter 5/31/05).

Radioactive Liquid Waste Treatment Facility (RLWTF): Last weekend, LANL smoothly replaced the leaking caustic waste receipt tank and moved it to TA-54 Area G; system restoration has started. The tank developed the leak in September 2003, and its material condition has resulted in numerous safety and programmatic issues (e.g., site rep weeklies 9/19/03, 11/19/04, 4/29/05, 6/10/05, 3/24/06).

After removal, LANL determined that the tank was lighter and more heavily contaminated with Am-241 than expected; this has led to questions on disposition and on adequacy of the transportation procedures used. Other than that, this operation appears to have been well planned and well executed due to increased formality of operations and management attention applied during the last 18 months.

Plutonium Facility (TA-55): On Tuesday (11/21), a new spring-loaded sample holder ejected a small piece of plutonium metal from a hood that then bounced off a worker's anti-Cs and fell to the floor; the three workers in the room evacuated; the continuous airborne monitor alarmed; one worker had positive nasal smears, indicating a potential uptake; bioassay of affected workers is underway.

It appears that the new sample holder did not receive adequate scrutiny as a new potential hazard before being placed in use, which raises questions about work planning, authorization, and readiness determination. This operation is also incompletely described in the applicable safety basis process hazard analysis. TA-55 plans to conduct cold testing of the new sample holder before resuming the operation.

Quality Assurance: The NNSA Site Office discovered this week that LANL has issued and is implementing a new Quality Assurance Plan (QAP) in advance of NNSA approval. The Nuclear Safety Management rule (10 CFR 830) requires the QAP receive federal approval; NNSA Site Office review is underway. The proposed QAP, submitted on Sep 8th, reflects the LANS organization and is intended to incorporate requirements from the latest DOE Quality Assurance order (DOE O 414.1C).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 1, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 1, 2006

The Board and a staff team were here this week reviewing LANL activities.

Management Systems: Both the LANL contractor assurance system (CAS) and the NNSA Site Office (LASO) oversight pilot began on Oct 1st. Maturity of both is low and not expected for 2 to 3 years; NNSA is highly dependent on CAS being transparent and providing the necessary feedback to support sound decisions and ensure safe operations. LASO nuclear safety oversight is also limited by key management vacancies and insufficiently trained and qualified staff; LASO intends to have qualified facility reps in all the nuclear facilities by mid-2007 (site rep weeklies 11/10/06, 10/6/06).

Institutional Safety Programs: LANL safety programs, such as integrated work management (IWM), have persistent weaknesses. In recent weeks, LANL issued an integrated formality of operations plan to improve four key programs – operations, engineering, maintenance, and training. In January, LANL intends to issue facility-specific implementation plans for these, as well as a lab-wide improvement plan for IWM. LANL expects the improved IWM process to be implemented by September 2007.

Authorization Bases (ABs): LANL has had difficulties updating ABs, selecting viable controls, demonstrably implementing controls, and consistently analyzing accidents to support risk-informed decision making. LANL has committed to updating all the nuclear facility safety bases in FY-07, except CMR, which is planned for FY-08. LANL has also issued a safety basis improvement plan that emphasizes selection and implementation of demonstrably viable operational and engineered controls.

Transuranic Waste Operations: Area G risk is dominated by ~320 high-activity drums that collectively contain about 50 kCi, which is about third of the current above-ground TRU waste inventory; there are another ~300 high-activity drums below ground with about 90 kCi that LANL intends to start retrieving next year. LANL has proposed new safety bases for the key facilities needed to process and ship the above-ground high-activity drums to WIPP; however, at this point, NNSA and LANL still lack a common understanding and acceptance of the risk tradeoffs involved.

Plutonium Facility (TA-55): TA-55, so far, is on track to meet FY-07 commitments, but LANL staffing and infrastructure, both within and outside TA-55, can not clearly support and sustain the increasing tempo; LANL recognizes the needs for integrated planning and scheduling, which is underway. Pu-238 operations also receive much less support than weapons plutonium operations, although the former dominates TA-55's risk profile. For example, the Pu-238 residues in the room contaminated in August 2003 pose about a quarter of the risk due to TA-55 packaged materials. LANL has committed to addressing these residues by mid-2007, which is positive; however, NNSA and LANL have delinquent institutional commitments from that event, indicating a loss of priority.

Chemistry and Metallurgy Research Building (CMR): NNSA and LANL have not evaluated the risks associated with continued CMR operation past 2010, even though they expect the CMR replacement facility (CMRR) will not be operational until 2013 or later (site rep weekly 11/10/06). LANL is now starting to evaluate the safety implications of post-2010 operations, as well as pursue shifting people and operations out of the three most vulnerable wings during the next two years.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 8, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 8, 2006

Transuranic (TRU) Waste Operations: In discussions with LANL this week, NNSA management communicated that they are inclined to reject the proposed safety bases for two key facilities needed to process and ship about 300 high-activity TRU waste drums to WIPP. Based on their partially completed reviews, the NNSA review teams believe that the proposed safety bases over-rely on specific administrative controls over engineered systems and have quality issues, such as low specificity of functional requirements for the few declared engineered safety systems. The site reps observe that the issues seem to arise less from document quality and more from a lack of shared understanding and agreement of the risk tradeoffs involved in key safety basis decisions.

Unmitigated Risk Perspective: Several of LANL's highest-consequence postulated nuclear accident scenarios involve TRU waste stored at Area G. The Area G safety basis that NNSA approved in 2003 posits about three dozen accident scenarios that have unmitigated offsite consequences ranging from 1 to 1,800 rem (CEDE); predicted offsite consequences for about half the scenarios exceed 100 rem.

Several high-consequence scenarios involve about 300 high-activity drums (greater than 56 Ci) that lack an approved disposition pathway; these drums constitute about 2 % by number but about a third by activity of the total above-ground inventory (i.e., 50 kCi of 150 kCi). Without mitigation, small fires or spills involving small numbers of these high-activity drums lead to predicted off-site consequences of about 100 rem or greater. The general population of drums (~ 4 Ci average) can also induce high offsite consequences but only during less-probable large fires or a major earthquake.

LANL has proposed safety bases for processing the high-activity drums in the WCRR facility and shipping them from the RANT facility, thereby opening a disposition pathway that eliminates the risks associated with these high-activity drums. This would require NNSA to accept operations involving an order-of-magnitude more activity in these facilities than previously accepted, but only for the time required to process and ship 2 % of the drums. Without mitigation, large fires or a major earthquake involving these facilities with these inventories are postulated to cause building collapse and result in high offsite consequences (i.e., 50 rem for WCRR, 500 rem for RANT, compared to 1,000 rem for Area G); this corresponds to about 20 % higher risk from WCRR and RANT operations, but it supports achieving a significantly greater risk reduction in Area G for a broad range of accident types.

Mitigation Perspective: Area G has few creditable safety-class engineered systems, mainly just the containers; it is an extrapolation to assert that these systems will provide the two or three orders of magnitude of mitigation necessary to address the postulated accident scenarios. NNSA observed in 2003 that, given the lack of safety systems, removal of material-at-risk is the only way of reducing the potential offsite consequences; therefore, NNSA imposed a requirement to ship about 2,000 higher-activity drums by Sep 2004. This stalled due to a lack of an approved pathway that persists today.

Similar to Area G, WCRR and RANT have few creditable high-pedigree engineered systems that address fire and seismic scenarios. In August, LANL proposed a strategy that involves high reliance on compensating administrative controls; the key strategic assumption was that NNSA could accept short-term increased risk in WCRR and RANT to achieve a much greater and timely risk reduction in Area G. Since Nov 3rd, NNSA has been reviewing the proposed safety bases from a context appropriate for continuous, long-term operations, as opposed to one considering relative risks; this has created conditions for rejection rather than for continued engagement supporting timely resolution of issues.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 15, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending December 15, 2006

Transuranic (TRU) Waste Operations: NNSA has terminated reviews of the proposed safety bases for two key facilities needed to process and ship high-activity TRU waste drums to WIPP. NNSA has committed to provide LANL rough sets of representative comments from the curtailed reviews and to deploy a two-person team to liaison between NNSA and LANL during the document revision process.

In parallel with the safety basis revisions, LANL is completing engineering work packages for natural gas line removal and for fire suppression and seismic/structural upgrades in one of the key facilities – the WCRR repackaging facility. The site reps understand that these modifications are intended to align the systems with their descriptions in the safety basis revision; the modifications appear relatively small in scope but large in benefit in improving the facility's safety posture. For example, the structural modifications, which may start and complete next month, increase assurance that the building meets performance category 1 (PC-1) and possibly even PC-2 requirements; this is positive.

There may be other such opportunities, but as discussed last week, there are risks associated with continuing delay. It is advisable for NNSA and LANL to quickly but deliberately examine the suite of available safety systems for these two facilities, aggressively pursue straight-forward high-benefit upgrades, and equally aggressively pursue reaching agreement on compensating administrative controls when no straight-forward upgrade exists.

Recommendation 04-2: LANL has completed its evaluation of the TA-55 PF-4 confinement ventilation system; it included a cost-benefit analysis of 11 potential backfit options that could improve building confinement during bounding fire and seismic accident scenarios; NNSA site office action on the evaluation is pending (site rep weeklies 9/22/06, 9/1/06, 12/9/05).

The study asserts that upgrading confinement ventilation to safety-class would be costly and would be insufficient to mitigate all accidents considered, particularly a seismically-induced fire. While several options potentially address all the scenarios, a combination of two options—glovebox seismic support upgrades already planned (\$20M) and ventilation bleedoff subsystem modifications (\$5M)—was identified as the most cost-effective; the bleedoff subsystem modifications would focus on providing safety-significant active confinement during fires. The study concluded that this combination would drive mitigated consequences for most accidents to 0.1 rem CEDE or below and would reduce the mitigated consequence for a seismically-induced fire from about 174 to 15 rem CEDE.

Plutonium Facility (TA-55): Weaknesses in the TA-55 electrical distribution system leave the facility vulnerable to power loss from even minor grid transients. Nineteen transient events have impacted the facility over the past six months, ten of which led to significant operational interruptions. These events cause unplanned interruption of hazardous work; they adversely affect the operability of facility safety systems, particularly confinement ventilation; and while the transient lasts milliseconds, orderly recovery typically takes about 2 hours. Near-term, the facility is pursuing installation of a power conditioner and/or capacitor bank to reduce sensitivity to short duration transients. Longer-term, planned switchgear upgrades are intended to automatically transfer key loads to a backup diesel generator when offsite power is interrupted or lost (site rep weeklies 10/13/06, 4/2/04).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 22, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 22, 2006

Andersen, Hadjian, and Kimball were here Monday to attend a review of the site-wide probabilistic seismic hazard analysis (PSHA) update. LANL was closed on Wednesday due to snow.

Seismic Criteria: The LANL PSHA update has slipped and is now projected to be done next month. When completed, the seismic design loads are expected to increase over those that have been used since 1996; for example, Performance Category 3 (PC-3) peak ground acceleration tentatively increases by about 50 % – from 0.34 g to 0.52 g. The Chemistry and Metallurgy Research Building Replacement (CMRR) Project anticipated the increase and has been using consistent higher design loads since July (site rep weekly 7/21/06). The impact on existing facilities remains to be determined.

Criticality Safety: On Thursday (12/21), NNSA approved LANL's proposed updated criticality safety program improvement plan, which is intended to address issues from NNSA's Oct 2005 assessment during the next 3 years. LANL asserts that the 3 year time frame is acceptable because the laboratory has established that adequate safety margin exists and that an interim configuration management protocol is in place. NNSA is also still finalizing a report from their Oct 2006 assessment, which preliminarily concluded that criticality safety risks here are now well understood and are being well controlled using interim processes, as opposed to the situation a year ago (site rep weekly 10/27/06).

The LANL plan discusses accomplishments to date, including issuing an institutional policy and manual, reviewing 564 fissile material operations, and walking down most of the operations; the remaining 'low risk' operations are scheduled to be walked down by Mar 2007, about 3 months later than the original schedule. The next phase focuses on bringing practices and documentation into compliance with the new policy and manual. The scope is large but risk-prioritized; the largest part involves generating more than 110 new criticality safety evaluations (CSEs) for current operations that are missing CSEs, upgrading more than 50 technically deficient CSEs, and correcting roughly 170 CSEs that have other issues. LANL is planning staff augmentation in FY-07 to support this.

Chemistry and Metallurgy Research Building (CMR): CMR has a Cm-244 source in Wing 9 floor hole storage that has an order of magnitude more activity than that in the rest of CMR combined. The CMR safety basis (1998) assumes floor storage is robust and therefore excludes this source from material-at-risk (MAR) controls; if the MAR controls applied, the source would exceed the facility limit by an order of magnitude. A shielded cask is available to support disposition but cannot be used due to unresolved floor loading issues linked to a longstanding potential inadequacy in safety analysis (PISA). Prudence dictates timely action given the source's size and CMR's age-related issues.

Software Quality Assurance: A LANL investigation determined that ineffective implementation of the institutional software quality assurance (SQA) program was a shared root cause in three recent reportable occurrences. These events included 2 MAR limit violations at TA-54 Area L and the introduction of a prohibited item at the TA-3 Nonproliferation and International Security Center; each event involved deficiencies in safety-related software. To address institutional issues, LANL is revising SQA policies and procedures and requiring new division-level implementation plans to drive compliance. The investigation report also recommended the identification of a single MAR-tracking software program to replace the four separate systems currently in use across the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 29, 2006

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 29, 2006

The laboratory was closed and Broderick was off-site this week. Normal operations resume Jan 2nd.

Plutonium Facility (TA-55): On Dec 13th, several people were taken to LANL occupational medicine and one person was taken to the Los Alamos Medical Center because they had pre-existing respiratory conditions that could be aggravated by the chemical used for HEPA filter testing, done the previous evening. The chemical (dioctyl sebacate, DOS) has been used for such testing for a decade; it is similar to mineral oil and, while mildly irritating, has not been considered a health risk. TA-55 is pursuing increased employee notification before testing and potential changes to the tests to aerosolize less DOS.

Nuclear Material Stabilization: LANL has reported that about 630 kg of plutonium (Pu) have been stabilized since mid-2004 by repackaging for interim storage or disposal; LANL has thereby met 3 commitments due this month for stabilizing half of its Pu within the scope of the Secretary's 00-1 implementation plan (ref: DOE letter 7/23/04). The site reps observe: • while repackaging improves the safety posture, eventually much of this Pu will need to be chemically stabilized and repackaged again; • LANL still lacks large vessel clean-out capability; • LANL still lacks a comprehensive site-wide nuclear material packaging and storage plan – a key element described in the 00-1 implementation plan for LANL addressing its current large Pu residue backlog (site rep weekly 8/25/06).

Authorization Basis: NNSA has approved with comments LANL's 3-year safety basis improvement plan. The plan involves developing 10 CFR 830 compliant safety bases for all the nuclear facilities (except possibly CMR) during the first year, and then implementing the annual update requirement for nuclear facilities and completing hazard categorization of other hazardous facilities during the next two years. NNSA comments involved assumptions, project risk planning, and inventory control in less hazardous facilities. The plan emphasizes the linkage between safety basis and engineering and thereby could increase assurance that designated safety systems will demonstrably and reliably perform their safety function – a longstanding issue (ref: Board letter 1/27/04, site rep weekly 8/11/06).

Readiness Assessments: LANL conducts roughly two dozen reviews each year to confirm readiness for startup of new or modified nuclear operations and to verify implementation of new safety basis requirements. The LANL reviews have been inconsistent in quality and effectiveness; most issues arise from misunderstandings of the review's purpose, insufficient preparation, and premature declaration of readiness (e.g. site rep weekly 7/22/05). There have been few comparable federal reviews during the last five years, and to the site reps' knowledge, there were no such federal reviews in 2006.

In November, LANL issued a readiness review improvement plan to be completed during the next few months. Key elements include using separate processes for assessing startup readiness and safety basis implementation (already implemented and similar to that used at other sites, site rep weekly 2/10/06); strengthening the management self-assessment (MSA) process; improving training of readiness coordinators and other involved personnel; improving planning and scheduling; and improving coordination with the NNSA site office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 5, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 5, 2007

Federal Oversight: An NNSA Chief Defense Nuclear Safety (CDNS) team is on site next week to examine the NNSA Site Office oversight pilot and the Contractor Assurance System (CAS) interface.

Pajarito Laboratory (TA-18): This Spring, LANL plans to propose downgrading TA-18 from a Hazard Category 2 (HC-2) nuclear facility to a radiological facility, based on segmentation of the remaining radioactive inventory. Specifically, 3 transportainers will be used to store large pieces of natural and depleted uranium that are packaged for shipment to the Nevada Test Site; they would constitute 3 segments; the remainder of TA-18 would constitute a fourth segment. TA-18 would then be managed in a surveillance and maintenance mode until disposition plans are finalized.

Chemistry and Metallurgy Research Facility Replacement (CMRR) Project: The LANL subcontractor responsible for the design and construction of the Radiological Laboratory and Utility Office Building (RLUOB) submitted the final design to LANL on January 2nd; LANL intends to complete its review of the package this month and expects to approve it, following comment resolution, by mid-March. The RLUOB, a radiological facility limited to about 0.5 Ci inventory, is expected to have about 19,500 ft² of laboratory space, provide offices for 350 personnel, and contain a consolidated training facility and incident response center. Project management is briefing NNSA headquarters next week on the status and direction for the separate CMRR HC-2 nuclear facility.

Transuranic (TRU) Waste Operations: Area G currently has about 20,000 TRU waste containers with 131 kCi above ground (including ~15 kCi OSRP sources); there is a comparable inventory below ground, plus TA-55 waste receipts, that are currently all within the scope of the Area G closure effort.

The 2003 Area G safety basis identifies about 3 dozen postulated accident scenarios with unmitigated off-site consequences ranging from 1 to 1,800 Rem CEDE. A third of these scenarios involve small numbers of high-activity drums that currently have no approved disposition path (site rep weekly 12/8/06). The remainder involve large numbers of drums of average activity; the average activity has been increasing with time and now stands at about 6 Ci/drum. LANL expects to reassess the risks and submit an updated Area G safety basis to NNSA in the coming months.

Area G has few creditable engineered safety features; therefore, to reduce risk, NNSA advocated in 2003 expeditiously shipping higher-activity drums to WIPP. Since then, LANL has shipped about 5,300 drums (22 kCi), predominately with average activity; about 3,000 drums (18 kCi) were shipped last year; Area G has also continued to receive 300 or more drums per year from TA-55. The rate-limiting steps are repackaging drums to remove WIPP prohibited items and shipping drums; both are running at roughly 200 drums per month. There were short periods during the last year, when LANL was able to repack and ship waste at rates twice or more the average; however, these were not sustainable.

At current rates, these risks will persist for many years. Assuming the drum rejection, certification, and shipping rates experienced during the last 15 months, it will take roughly 8 years to certify and ship the current aboveground inventory (i.e., 2015) and another 8 years to address the belowground and TA-55 waste inventories (i.e., 2023). Improving on the rates will require a shared understanding of the risks, more appropriate prioritization, and a more concerted effort by the principal parties – NNSA, DOE-Environmental Management, LANL, and the WIPP contractor – than applied in the past.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 12, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 12, 2007

Federal Management and Oversight: NNSA announced this week the temporary assignment of a new Los Alamos Site Office (LASO) Manager, effective Feb 5th; he will be the sixth LASO Manager assigned since the site rep office was established here in August 2001. NNSA management continues to fully support the two-year LASO oversight pilot, which has challenges (site rep weekly 11/10/06).

The NNSA Chief of Defense Nuclear Safety (CDNS) team on site this week split their efforts between waste operations, as discussed below, and an examination of the pilot. The pilot's current state and key challenges appear well understood; management acknowledged that additional technical resources are expeditiously required for the pilot's success. The CDNS biennial review is scheduled for May.

Criticality Safety: There are inconsistencies between the LANL institutional criticality safety manual (ISD 130), issued last July, and a general TA-55 administrative procedure for nuclear criticality safety, revised last October; LASO and LANL acknowledge the latter needs to be improved. In a larger sense, LASO and LANL have agreed upon a plan to improve LANL's criticality safety program during the next 3 years (site rep weekly 12/22/06). Accelerating reestablishment of an active Nuclear Criticality Safety Committee to provide semi-independent institutional oversight would be helpful.

Transuranic Waste Operations: Last month, NNSA and LANL stalled on developing a path forward for the high-activity drums, disposition of which is funded by DOE-EM (site rep weekly 12/8/06). Last week, NNSA management directed CDNS to examine the risks and viability of starting to disposition these drums within weeks, in response to budgetary pressure from DOE-EM.

This week's CDNS review concluded that this is viable. Subject to headquarters agreement, CDNS will lead the effort and will pursue jointly with LASO and LANL a notional path-forward that involves developing a resource-loaded project plan by the end of January, developing a safety basis in February, completing limited facility improvements in March, completing procedures, training, and a joint federal-contractor readiness assessment in April – to support startup by end of April.

Notionally, the safety basis would consist of the draft documents submitted two months ago, a set of additional conditions and controls, and an ad-hoc list of other documents describing safety program and system enhancements, all captured in an authorization agreement. Since this safety basis and the joint readiness assessment are not consistent with DOE rules and orders, CDNS plans to process exemption requests to the Nuclear Safety Management rule (10 CFR 830) and the DOE startup order (DOE O 425.1C). Separately, LASO and LANL would develop 10 CFR 830 compliant safety bases for the affected facilities that would be reviewed, approved, and implemented after the April startup.

Chemistry and Metallurgy Research Building (CMR): On Monday (1/8), an operator sustained a puncture wound while performing glovebox operations in CMR. This event appears to be prompting a reexamination of the hand tools used in CMR gloveboxes and the controls and PPE implemented to provide worker protection. A systematic review could enhance safety and help prevent recurrence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 19, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 19, 2007

Deplitch and Goff were on site this week to observe a criticality assembly control system design review.

Operations: While core activities such as pit manufacturing are meeting targets, support operations and safety programs are increasingly strained to meet commitments within budget. For example: • extended-hour operations at the Plutonium Facility (TA-55) are now the rule rather than the exception but are not clearly supportable by institutional services, such as emergency response; • management has appropriately increased focus on reducing Area G transuranic waste inventory – e.g., extended-shift waste repackaging started this week in WCRR – but management has reduced focus on receiving TA-55 waste; as a result, TA-55 is accumulating waste and may need to slow down Pu-238 residue disposition, one of TA-55's most important risk reduction activities; • TA-55 is accumulating solutions that the Radioactive Liquid Waste Treatment Facility may need to process before upgrading its deteriorated systems; the alternative, retention in TA-55, also has issues; • unvented drums found in Area G in October still lack a path-forward; • several nuclear facilities have shortages in system engineers; • maintenance and worker qualification databases are marginally supported; • the institutional training program is underfunded and unlikely to make substantial progress this year on correcting longstanding training issues that were a contributing cause for the LANL 2004 stand-down.

Chemistry and Metallurgy Research Building (CMR): CMR is an example of conditions described above. To support pit manufacturing, CMR worked extended hours this week to recover from an analysis backlog caused by infrastructure issues that impacted programmatic equipment. The CMR operational staff has been cut by 16 % since October; losses include systems engineers (now at a quarter of estimated need), work planners, radcon technicians, waste services, and maintenance crafts. On the present course, CMR may need to begin to secure some operations in response to random equipment failures within weeks or months. This run-to-failure approach for CMR has been considered before and rejected; deliberate well-planned reduction of operational footprint is preferred. LANL has recently identified a need to extend CMR lifetime notionally to 2016; sharply reducing facility maintenance now is inconsistent with lifetime extension (site rep weekly 12/1/06).

Contaminated Wounds: Two events have occurred: • LANL has launched an investigation into the CMR puncture wound reported last week; it is to be completed by Feb 20th; NNSA is considering the need for a federal Type B investigation, per DOE Order 225.1A, *Accident Investigations*; CMR has taken actions to control the scene and to address already apparent problems. • On Wednesday (1/17), a TA-55 pit machinist was scratched and became contaminated while working in a glovebox; the wound count is positive; TA-55 has curtailed pit manufacturing work and is reviewing operations. CMR and TA-55 are also re-examining their glovebox glove integrity programs, which have weaknesses but are a key component in several facilities (e.g., WCRR) for worker radiological safety.

Criticality Safety: On Wednesday, a TA-55 worker reported a 20 % over-mass condition on a shelf of a cart. The room was secured; the condition was evaluated and corrected per LANL procedures. LANL's review of the event found problems with postings and with operator interpretation of which had over-riding precedent: the room posting or the cart posting. Underlying these problems are weaknesses in operator training and in implementing the Criticality Safety Officer program; these are focus areas for the criticality safety program improvement efforts (site rep weekly 12/22/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 26, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: Chuck Keilers and Brett Broderick, LANL Site Representative
SUBJECT: Activity Report for Week Ending January 26, 2007

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 2, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 2, 2007

Keilers was off-site this week.

Contaminated Injury Investigation: A laboratory sponsored Type B-like investigation into two recent contaminated wound incidents began this week (site rep weeklies 1/19/07, 1/12/07). The Associate Director for Nuclear and High Hazard Operations is leading the eight-person investigation team that includes four participants from LANS corporate parent organizations, including Washington Group International and BWX Technologies. During the initial interview phase, the team is split, with one half investigating the Chemistry and Metallurgy Research Facility event and the other half, the Plutonium Facility event. A draft report and findings are scheduled to be presented to lab management on 2/23/07.

Formality of Operations: The conduct of operations, engineering, and maintenance components of the Formality of Operations project have moved from the development to execution phase. Last week, LANL management approved implementation plans designed to close gaps between the new institutional manuals and the existing policies and procedures. Facility Operations Directors (FOD) are now responsible for executing these plans, which should serve to standardize and improve performance lab-wide. Progress will be assessed quarterly and tied to contractual performance based incentives. Conduct of training is the fourth element of the Formality of Operations initiative and is critical for enabling and sustaining success in the other areas. The training manual was issued this week, and FODs will perform gap analyses and revise implementation plans accordingly.

The need for timely, effective implementation of Formality of Operations is underscored by the events that prompted the investigation discussed above and warrants continued close management attention.

Transuranic (TRU) Waste Operations: The Chief of Defense Nuclear Safety (CDNS) was on-site this week to finalize the Project Management Plan for dispositioning 229 high-activity transuranic waste drums stored above ground at Area G (site rep weeklies 1/12/07, 12/15/06, 12/8/06). The plan targets approval to begin repackaging high-activity drums in the Waste Characterization, Reduction, and Repackaging (WCRR) facility on Apr 30th; the short (3-month) WCRR preparation phase drives the need for an exemption-based safety basis and readiness review strategy. To meet the Apr 30th target date, LANL is revising the existing draft safety basis for WCRR, with input from LASO and CDNS, and plans to reissue it later this month. The Project Management Plan assumes that a safety evaluation report approving the safety basis cannot be prepared in this period, so an exemption to the DOE readiness review order (O 425.1C) will be proposed. A LANL Readiness Assessment and NNSA Operational Readiness Review are then planned for April; assuming readiness is demonstrated, an exemption to the Nuclear Safety Management rule (10CFR830) will also be proposed to allow startup of Hazard Category 2 nuclear facility operations without an approved rule-compliant safety basis. NNSA HQ (NA-10) will serve as the Authorizing Authority for the exemption requests and facility startup.

The Project Management Plan's scope excludes 5 above-ground drums with activity greater than 300 PE-Ci that contain combustible debris and 60 sludge drums that cannot currently be processed in WCRR. These drums will be addressed in a later campaign to disposition underground high-activity waste.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 9, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 9, 2007

NNSA, LANL, and the staff held a video-teleconference on the CMRR Project on Wednesday.

Federal Management: A temporary NNSA site office manager, technical deputy manager, and senior safety advisor arrived this week and are expected to be on-station for 4 to 6 months until permanent assignments are made. These are key federal positions that strongly influence LANL nuclear safety.

Transuranic (TRU) Waste Operations: The quantity of material-at-risk (MAR) is a key assumption in accident analyses and is usually a key control for ensuring that a facility's operating state is within the bounds assumed in the analyses. LANL TRU waste facilities control MAR based on the waste generator's data, which is the best data available but often has large measurement uncertainties. In a recent case, the WCRR repackaging facility removed a WIPP-prohibited item from a drum that was initially believed to contain 48 % of the WCRR MAR limit (56 Ci), based on generator data, but later determined to exceed the WCRR MAR limit by 12 %, based on WIPP certification data – an increase by a factor of 2.3. LANL analysis of ~6,500 drums shows that the WIPP certification data averages about 30 % higher than the generator data and can be much greater for individual cases. NNSA and LANL are considering the implications on accident analyses and control selection.

Plutonium Facility (TA-55): The Plutonium Facility has resumed more than 90% of glovebox operations after standing down in mid-January in response to a contaminated injury that punctuated a string of less-severe glove breaches (see site rep weekly 1/19/07). TA-55 management took actions to identify and address worker safety issues associated with glovebox work and instituted a deliberate process for resuming operations. These actions included mandatory use of more puncture-resistant inner gloves; execution of formal walkdowns to identify and eliminate or otherwise better control hazards; temporary use of an independent safety observer for certain operations with a higher potential of injury; and plans for periodic walkdowns for certain operations deemed to have high potential risk.

Radioactive Liquid Waste Treatment Facility (RLWTF) Replacement Project: LANL plans to replace the existing RLWTF with a new facility by 2011. NNSA approved proceeding with a single Hazard Category 2 nuclear facility in June 2006, as part of Critical Decision 1. Based on expected life cycle cost savings, LANL subsequently proposed a new multiple-facility approach, in which TRU operations would be housed in a dedicated processing facility and an influent vault, as nuclear facilities, and low level waste operations would be conducted in a separate radiological facility.

NNSA asserts that the best course is to proceed with the original single-facility concept. The NNSA position is that the potential life cycle cost savings are not compelling enough to justify the programmatic risks unless certain actions are taken to mitigate these risks. NNSA is allowing LANL to pursue the multiple-facility concept, provided LANL meets several conditions, including planning on reducing the TA-55 liquid TRU waste stream and factoring this into the new RLWTF design. A LANL response detailing their path forward is due by Feb 15th.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 16, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 16, 2007

Anderson, Matteucci, Plaue, and Shuffler were on site this week reviewing TA-55 aqueous operations.

Contract Modification: On Jan 25th, NNSA and LANL added the updated DOE orders for emergency management (DOE O151.1C, 11/2/05) and facility safety (DOE O420.1B, 12/22/05) to the contract.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL has completed installation of the new caustic waste receipt tank and expects to complete system testing and begin receiving TA-55 transuranic liquid waste starting next week. LANL also now intends to propose that RLWTF process its transuranic waste inventory in May before starting to upgrade its deteriorated systems; this would increase TA-55's ability to process residues before RLWTF completes its first phase of upgrades. Last year, after a multi-year hiatus, RLWTF ran a transuranic waste campaign using the existing systems and a rigorous contingency planning and startup process (site rep weeklies 11/24/06, 8/11/06).

Electrical Safety: In recent weeks, LANL has had several electrical safety related events. A programmatic 208-volt lathe in a nuclear facility was damaged upon startup because it was wired to 480-volts. The ground wire shorted in a field-installed-plug for a programmatic laser in a nuclear facility, causing an arc. The 480-volt bus entering a non-nuclear facility overheated, causing a burning odor, due to improper installation by a subcontractor. Another subcontractor was working on an energized 480-volt panel with proper protective equipment but without an integrated work document.

In each case, appropriate recovery actions were taken, including stop work, and no injuries resulted. For these events, the causes are well understood and could be addressed by previously identified corrective actions. Near term, the LANL Chief Electrical Safety Officer (ESO) has recommended that facility ESOs take suspect and unapproved electrical equipment out of service until inspected. Longer term, LANL intends to issue and implement new lab-wide requirements for electrical equipment and for subcontractor management, as well as pursue the conduct of engineering initiative.

Issue Management: LANL is late on many of the corrective actions from the June 2006 RLWTF construction accident and has not yet systematically developed corrective actions for the June 2006 CMR hood fire (site rep weekly 10/20/06). LANL also appears to be falling behind on issuing Price Anderson (PAAA) noncompliance reports; three were issued this week for the longstanding non-compliant quality assurance program and for emergency management and fire suppression issues identified before June 2006. NNSA has established a performance based incentive involving corrective actions; however, other than occasional facility rep involvement, NNSA does not appear to be actively monitoring and advocating progress on corrective actions.

The LANL Institutional Management Review Board is exercising formal change control on lab-wide corrective actions (e.g., scope, schedule) and is learning from these experiences and improving its processes; this is a key element of the evolving contractor assurance system (CAS). The accident investigation for the CMR and TA-55 contaminated puncture wounds is expected to be done by Feb 26th and will provide LANL an opportunity to demonstrate improvement (site rep weekly 2/2/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 23, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 23, 2007

T. Davis was here this week augmenting site rep coverage.

Transuranic (TRU) Waste Operations: The Chief of Defense Nuclear Safety was on-site this week, working with LANL and local NNSA personnel on the development of a safety basis for repackaging high-activity drums under a temporary exemption to the nuclear safety management rule (10 CFR 830). LANL's objective is that this safety basis would be compliant, only lacking a federal safety evaluation report, which NNSA and LANL expect will follow at a later date (site rep weekly 2/2/07).

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF is close to receiving its first transfer of TRU liquid waste from TA-55 to the new caustic tank; this is the first of several milestones toward LANL re-establishing reliable TRU liquid waste processing capability.

Unvented TRU Waste Drums: Last October, Area G discovered about three-dozen drums that are unvented, a condition which violates the Area G safety basis since it could result in flammable gas buildup (site rep weekly 10/27/06). LANL segregated the drums. This week, LANL had a hazardous material response team confirm that the segregation was adequate and that the drums are not showing indications of pressure buildup. Area G has equipment but no authorized process for drum venting.

While NNSA and LANL waste management have been fully occupied with addressing the Area G high-activity drums and restoring RLWTF receipt capability, it has been four months since the unvented drums were identified; this seems an inordinately long period without a formal contractor analysis of the risk and the adequacy of interim controls and a formal federal risk acceptance. LANL is close to submitting to NNSA a justification for continued operation for the unvented drums.

Decontamination and Volume Reduction System (DVRS) Facility: LANL lacks capability to size reduce and disposition roughly 650 oversized TRU waste items that are either stored now at Area G or expected to be generated by 2010, mainly from TA-55; many of the existing items are in fiberglass reinforced plywood boxes. Recently, facility management barred receipt of newly generated oversized items because of the lack of a disposition path and commitments made to complete TRU waste shipments from Area G by 2010. This mainly impacts TA-55's efforts to remove large excess contaminated items (e.g., gloveboxes, pencil tanks) and thereby make space for TA-55 modernization.

To reconstitute this capability, LANL plans to restart the DVRS in May for a 4-month campaign as a radiological facility and then to upgrade DVRS and start it up as a Hazard Category 3 nuclear facility in Feb 2008. DVRS started up in 2002 as a radiological facility for this purpose. In 2004, LANL curtailed DVRS operations due to lack of funding. In 2005, LANL modified DVRS by installing a glovebox that was intended to be used for a five-month campaign to repackage high-activity drums; this campaign never started. More recently, the DVRS glovebox was reconsidered for repackaging high-activity drums but was not selected. LANL intends to remove the DVRS glovebox within a few months as a prerequisite for restoring large-item size reduction capability (site rep weeklies 11/10/06, 6/30/06, 9/19/03, 8/23/02).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 2, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 2, 2007

Broderick was off-site this week.

Price Anderson Enforcement Letter: NNSA has sent the former LANL contractor (UC) a preliminary notice of violation for the March 2005 Pu uptakes, the July 2005 Am-241 contamination event, and the Oct 2005 DOE-OA review findings (site rep weeklies 2/3/06, 1/27/06, 4/29/05). In May 2006, LANL (UC) issued an integrated corrective action plan (ICAP) to address related needs involving integrated work management; behavior based safety; oversight and assessment processes; radiological protection; safety basis; conduct of engineering; vital safety systems; and configuration management. The new LANL contractor (LANS) updated and committed to the ICAP in Sep 2006.

The site reps understand that LANL has embedded the ICAP corrective actions in the new issue management system (LIMITS), which is part of the contractor assurance system (CAS); however, LANL management does not appear to have an explicit mechanism in place for closely monitoring ICAP progress and quickly focusing attention on lagging elements of the ICAP when they arise.

Nuclear Infrastructure: LANL has a fiscally-driven imbalance between TA-55's needs to send and TA-54's ability to receive, certify, and ship transuranic (TRU) waste; this has mission and safety implications (site rep weekly 8/25/06). TA-55 has a significant backlog of plutonium residues that either need to be processed by TA-55 or shipped via TA-54 to WIPP for disposal. On several occasions, the Board has advocated disposal (e.g., Board ltr 11/21/01), and TA-55 has increasingly pursued disposal, particularly for higher-risk residues (e.g., Pu-238). However, TA-54 has its own challenges, such as a consent order commitment to close Area G by 2015; this requires shipping the aboveground and retrievable belowground TRU waste inventory to WIPP within the next 3 to 5 years. As of mid-2006, this inventory stood at about 300 kCi in about 43,000 drum-volume-equivalents.

To relieve the bottleneck, an alternate course under discussion involves TA-55 establishing interim capability to certify and ship newly generated TRU waste to WIPP in near-real-time, thereby decoupling TA-55 from TA-54 while avoiding a waste buildup in TA-55. Although initial investment would be needed, this course could expedite both TA-54 de-inventory and TA-55 residue disposition, leading to earlier risk reduction and enhanced mission performance for both operations.

Chemistry and Metallurgy Research Building (CMR): The following are noteworthy: • Two Wing 2 workers on Monday recognized intermittent alarming hand probes as an abnormal condition and called a radiological controls technician (RCT); the RCT discovered a contaminated probe and a glovebox glove with greater than 1 M dpm alpha (possibly legacy Pu-238); appropriate actions were taken, and no spread of contamination resulted; • CMR has reported 2 toxic-gas stainless-steel bottles that did not meet safety basis administrative controls, indicating a safety program lapse; the bottles are being stored in fume hoods pending proper disposition; • CMR is poised to begin installing new fire doors on wing entrances to the spinal corridor, thereby addressing the wing-to-wing flash-over concern; the effort has been delayed while NNSA and LANL negotiated a safety basis interpretation for all the CMR fire doors; NNSA and LANL would be well-served to formally capture the safety basis interpretation so that the safety basis accurately reflects the facility's nuclear safety requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 9, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 9, 2007

Federal Oversight: The acting NNSA Los Alamos Site Office (LASO) Manager presented his plan this week for adjusting the site office organization. The plan focuses on defining and staffing the long term site office management structure, ensuring facility representative coverage for nuclear facilities and placing additional emphasis on expeditious completion of training and qualification efforts for site office personnel. This plan also dissolves the 3 existing integrated operating teams (IOTs) with all currently deployed personnel returned to their parent organizations within the site office to focus on training and qualification. Two new IOTs (one for defense programs facilities; one for environmental management facilities) will be created and staffed as qualified personnel become available.

Contaminated Injury Investigation: Last week, the investigation team separately briefed LANL and NNSA management on the two contaminated wound incidents that occurred in January (site rep weeklies 2/2/07, 1/19/07, 1/12/07).

On Jan 8th, a CMR Wing 2 glove-box worker pierced a finger with a screwdriver while attempting to pry free a plutonium specimen from an epoxy mount. He was working alone. He withdrew his arms from the glove-box gloves, went into the next room to phone for assistance, and reached someone on his fourth attempt, who notified the CMR operations center. Radiological assistance arrived, and the worker was escorted to medical within an hour. LANL medical first excised the wound and then began chelation after 5 hours. Intermittent treatment continued for several weeks and reduced but did not eliminate the embedded activity. LANL expects a preliminary dose estimate in about 4 months.

On Jan 17th, a TA-55 machinist scratched his wrist on a lathe bit while donning a cotton glove over a glove-box glove. Per their training, personnel evacuated the room, and a radiological control technician assisted the machinist in donning a respirator before he withdrew his arms from the glove-box. The machinist was deconned and taken to LANL medical within two hours. The wound count slightly exceeded the guidance level for chelation, which began after 5 hours. Treatment continued for 2 days. Since the activity was close to the skin's surface, it was readily excised and eliminated.

Management responded as follows: Jan 11th – the responsible CMR group leader directed a review of operations involving sharp objects; Jan 17th – the responsible TA-55 division leader paused operations pending a review of sharp objects; Jan 19th – the responsible TA-55 associate director formally directed actions to enhance glove-box safety; Jan 20th – the responsible CMR associate director paused CMR glove-box operations; Jan 22nd – the LANL Director appointed a joint investigation team.

LANL's investigation identified several causes, which are similar to those of past events: • personnel did not follow procedures; • management expectations and supervision were inadequate; • management ineffectively responded to precursors; • some LANL managers lack the experience and training required to ensure that daily work is performed safely, while others with such experience are ineffectively used; • the CMR work was expert-based vice procedure-based; • the TA-55 work involved a hazard (the cutting bit) that management didn't eliminate or remove. The team also observed a lack of formality and consistency in the medical response. Schedule pressure and a perception of "mission over safety" had apparent roles. LANL is developing corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 16, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 16, 2007

Transuranic Waste Operations: LANL is past mid-way and largely on track to upgrade the waste repackaging facility (WCRR) and start remediating high-activity drums by May 1st (site rep weekly 2/23/07). This has been an intense, closely-managed campaign. Key milestones include: complete the safety basis review, procedures, and physical upgrades (e.g. seismic, vehicle barriers, transportainers) by Mar 31st; complete operator training (already started) by Apr 6th; complete the management self-assessment (MSA) and a separate contractor assessment in parallel, and federal and contractor readiness declarations by Apr 13th; complete the NNSA operational readiness review (ORR), which will have LANL-funded contractor participants, by Apr 26th; close findings and start up by May 1st.

May 1st startup is not assured; there are substantial parallel activities and a high reliance on NNSA approving exemptions to the startup order (DOE O425.1c), the facility safety order (DOE O420.1B), and the nuclear safety management rule (10 CFR 830) within the next few weeks. The startup order exemption involves accepting the parallel nature and rigor of the contractor readiness reviews. The facility safety order exemption involves accepting lack of fire suppression for concrete vehicle barriers and metal transportainers. The 10 CFR 830 exemption involves proceeding in advance of NNSA issuing a safety evaluation report (SER); NNSA expects to issue the SER in April and expects LANL to deliberately implemented it, possibly but not necessarily by May 1st.

Plutonium Facility (TA-55): This week, TA-55 transferred caustic and acid liquid waste to the Radioactive Liquid Waste Treatment Facility (RLWTF) – the first such transfers since RLWTF completed its tank replacement outage (site rep weekly 2/23/07). The transfers were delayed because of configuration management and other issues at TA-55. After the transfers, TA-55 discovered localized contamination near transfer line connections in the basement, which is under investigation.

Los Alamos Neutron Science Center (LANSCE): On Mar 7th, a LANSCE worker alarmed the personnel contamination monitor (PCM) while exiting a contaminated area; a radiological control technician (RCT) responded but then left to support other operations, expecting a 2nd RCT to assist the worker; the worker decontaminated himself, processed through the PCM without alarm, and left the site. Due to mis-communication, there was no RCT followup. The next day, an RCT detected residual contamination on the worker's left wrist before he was scheduled to reenter the contamination area. As a precaution, a radiological assessment team deployed and found no contamination in the worker's vehicle or home. LANL is investigating the event, which released no contamination but has commonalities with the July 2005 Am-241 contamination event (site rep weeklies 7/29/05, 2/3/06).

Quality Assurance: This week, NNSA approved the LANL Quality Assurance Program, as submitted on Mar 2nd in accordance with the Nuclear Safety Management rule (10 CFR 830). NNSA expects LANL to implement compensatory measures and to submit a monthly status report until the plan is fully implemented (site rep weekly 11/24/06).

Weapons Engineering Tritium Facility (WETF): WETF resumed normal operations this week after completing a major ventilation upgrade (site rep weekly 11/3/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 23, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 23, 2007

Plutonium Facility: This week, TA-55 declared a TSR violation and stood down operations when gas cylinders were found to lack the multiple restraints required by a specific administrative control (SAC). The existing wording of the SAC lacked specificity and could be interpreted as requiring every vessel containing pressurized gas in the facility to have dual restraint, regardless of the volume and working pressure. NNSA approved a Justification for Continued Operations to clarify the applicability of the restraint requirement on Thursday, after which TA-55 resumed normal operations.

Additionally, on March 8th, NNSA approved a Preliminary Documented Safety Analysis for an interim radiography capability at TA-55 that relies on extending PF-4 safety and support systems, including confinement ventilation and fire suppression. This capability, scheduled for startup in October 2007, will reduce the need for offsite Pu shipments and substantially increase pit manufacturing efficiency.

Integrated Corrective Action Plan (ICAP): LANL is late on several ICAP corrective actions, which were developed in response to the 2005 DOE-OA review and two NNSA Type B investigations. For example, LANL informed the Board last November that an improved integrated work management (IWM) process would be implemented by September but that is now projected for November; this is one of several important ICAP commitments. LANL management is increasing attention to this area.

Chemistry and Metallurgy Research Building (CMR): LANL is evaluating the mission needs and safety implications of extending CMR lifetime, notionally to 2016 (site rep weeklies 1/19/07, 12/1/06). Specifically, LANL expects within a few weeks to finish a study on mission needs and durations to support wing closure planning and, by October, to assess associated hazards and potential control strategies, leading to a safety basis upgrade in FY-08.

In parallel, CMR is now vacating offices and removing material-at-risk from the two northern wings (2 & 4), considered to be the most seismically vulnerable. Wing 9 has been quiescent but is about to begin a characterization activity on activated structural components (i.e. Co-60 hazard); planning continues for other Wing 9 missions, including installing a large vessel clean-out capability (a DOE commitment under Recommendations 94-1/00-1) and addressing remote-handled transuranic waste.

Transportation: This week, NNSA approved LANL's annual update for the on-site transportation safety basis, the first approved update in several years. For moves involving Hazard Category 2 inventories, the update specifies a material-at-risk limit and requires using transportainers; it also retains a road closure requirement for publicly accessible roads and removes the requirement for restricted roads (i.e., the Parajito corridor). NNSA and LANL assert that the controls assure equivalent, though not identical, safety to that provided by Department of Transportation requirements.

Management: On Thursday, the LANL Director summarized management's multi-year goals and near-term commitments, including those involving safety, and distinguished these from the performance based incentives negotiated with NNSA. Also this week, LASO re-initiated an integrated operations team focused on the national security mission (i.e., TA-55, CMR, WETF).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 30, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 30, 2007

Goff was on site this week to observe a criticality assembly control system design review.

Operational Assessments: This week, LANL completed its first Institutional Evaluation Board (IEB) review of a nuclear facility (WETF); a report is expected in a few weeks. LANL intends to conduct periodic IEB reviews of its nuclear and high-hazard facilities and has patterned the IEBs after the Facility Evaluation Boards used at other sites to increase senior management's awareness of issues.

Transuranic Waste Operations: LANL has proposed a new safety basis for the WCRR facility to support repackaging high-activity drums; NNSA expects to issue a safety evaluation report (SER) by Apr 13th, eliminating the need for an exemption from the Nuclear Safety Management rule (10 CFR 830). LANL is adding two weeks to the schedule to reflect this change, as well as to provide the facility more time to improve the roughly 80 procedures involved and to train and qualify operators.

LANL management asserts that they will not declare readiness until they are ready; they are adding an extra week for the management self-assessment and resolution of pre-start findings and another week for the NNSA operational readiness review (ORR), for a total slip of about a month. The schedule still assumes that NNSA and LANL forgo a contractor ORR, and it still requires an exemption to the DOE startup order (DOE O 425.1C). The earliest startup would be the week of May 29th.

Except for a non-schedule-controlling ventilation modification, WCRR physical upgrades should be completed within a few days; these upgrades eliminate or reduce some hazards (natural gas, wildfire) and improve seismic capacity, fire suppression, ventilation reliability, lightning protection, and robust outside storage. Predicted unmitigated accident consequences are at least an order of magnitude below those at other LANL Hazard Category 2 facilities (e.g. TA-55, Area G). The primary controls are inventory limits, the waste containers, vehicle barriers, and vehicle access and fueling restrictions.

Plutonium 238 Operations: LANL has committed to disposing of the remaining Pu-238 residues by June 30th from the TA-55 storeroom that was contaminated in Aug 2003. Last November, LANL informed the Board that these residues pose about a quarter of the risk due to TA-55 packaged materials; while improved, their storage conditions (e.g., non-robust containers, some combustibles) mimic those assumed in some of TA-55's highest consequence accident scenarios. Currently, TA-55 has prepared about 100 of the 250 estimated waste drums required, working to a 56 Ci drum limit.

To ensure they meet the commitment and to reduce the significant handling risk and worker dose, TA-55 intends to begin loading higher-activity containers of non-hydrogenous residues into pipe over-pack containers (POCs). While this seems to be a WIPP-compliant configuration, WIPP and LANL are not able to certify such packages now above 100 Ci. Within a few months, they hope to have certified sealed sources available to extend their non-destructive assay calibration range to 200 Ci; by inserting, in some cases, a single can into a POC, this should allow LANL to de-inventory the TA-55 storeroom and ship these high-activity drums to WIPP in a timely manner. LANL appears to need POC certification and shipping capability, possibly to even higher activity levels, in order to address the current large residue backlog and avoid recreating such a backlog in the future.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 6, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 6, 2007

Keilers was offsite this week. T. Davis was onsite to augment site rep coverage.

Los Alamos Throughput Improvement Plan (LATIP): The acting NNSA site office manager introduced the LATIP this week. This plan represents a prioritized list of focus areas for site office management across the breadth of organizational responsibilities (i.e. safety, security, business systems, etc.). Items identified as warranting the most urgent attention include improving the training and qualification status of the existing workforce and addressing site office staffing deficiencies; developing an integrated site office assessment plan; ensuring the laboratory contractor assurance system is open and responsive to site office issues; and, supporting required actions to achieve timely sitewide risk reduction through the disposition of legacy transuranic waste.

Pajarito Laboratory (TA-18): This week, TA-18 was formally downgraded from a Hazard Category 2 nuclear facility to a low hazard radiological facility. Approval to downgrade followed the successful completion of a laboratory management self assessment that verified the reduced facility inventory and confirmed that adequate controls were in place to safely operate and maintain TA-18 as a radiological facility. This downgrade culminates several years of intense effort to de-inventory significant quantities of special nuclear material (see site rep weeklies 6/2/06, 5/20/05, 10/1/04). The new radiological categorization was based on a segmentation strategy where remaining material (mostly large chunks of natural and depleted uranium packaged for shipment to the Nevada Test Site) was split amongst 3 physically separated transportainers to preclude interaction. The balance of TA-18 was identified as a fourth facility segment. Material inventories in the 3 transportainers constitute 83%, 82%, and 50% of the Hazard Category 3 threshold defined in DOE Standard 1027.

Plutonium Facility: TA-55 is currently operating under a safety analysis report that is more than a decade old and a set of interim technical safety requirements (TSR) that were originally slated to expire in July 06. LANL submitted an updated documented safety analysis (DSA) and TSR document last November. The site office recently formally responded to this submittal noting that the documents were deemed noncompliant with the Nuclear Safety Management rule (10 CFR 830) and were not approvable. Identified areas of noncompliance included the use of non-conservative analytical assumptions, inadequate flowdown of credited DSA controls into the TSR, generation of safety-affecting data using computer programs that lacked appropriate software quality assurance, and inconsistencies between fundamental input documents (e.g. the Fire Hazard Analysis) and the DSA. Prior to resubmitting the documents, LANL has communicated an intent to comprehensively review the detailed comments generated by the NNSA review, convene a workshop with NNSA to discuss lessons learned and develop a common understanding of expectations, and subject final revisions to an independent internal review followed by an external review using LANS corporate parent resources.

Developing a rule-compliant safety basis that accurately reflects current facility conditions and operations and identifies effective, well defined controls that are clearly traceable to rigorous hazard and accident analyses is critically important for the operation of TA-55. However, this is a necessary but not sufficient step; material condition and infrastructure issues must also be understood and addressed to ensure the facility can reliably and sustainably support its ambitious future mission.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 13, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 13, 2007

Radioactive Liquid Waste Treatment Facility: Due to unexpected costs only recently recognized, LANL is starting to demobilize the Waste Management Risk Mitigation project, which involved constructing a new Hazard Category 2 pump house and tank facility, now 75 % complete; NNSA has asked for an explanation. This project was intended to increase low-activity liquid waste storage and address concerns that arose during the Cerro Grande fire (site rep weeklies 4/7/06, 1/27/06, 8/30/02).

Contaminated Injury Investigation: Last week, LANL management released the investigation report for the CMR and TA-55 contaminated wound incidents that occurred in January (site rep weekly 3/9/07). The exposures to affected personnel are still being determined. NNSA appears to have accepted the lab's investigation. LANL is developing a corrective action plan.

Plutonium Facility (TA-55): Weaknesses in first-line supervision contributed to the above incidents (site rep weekly 3/9/07). TA-55 is improving first-line management and span of control, including posting about 50 to 60 new management positions that will replace current non-managerial team leader positions. Also, as part of the response to the above incidents, TA-55 management is conducting a glovebox-by-glovebox inspection; the LANL criticality safety group recently joined the inspection team and is simultaneously conducting the annual review of fissile material operations.

On Monday, this joint team discovered two staging gloveboxes in an aqueous processing room that had liquid lines that were valved-out but not disconnected or locked-out, as required by the criticality safety posting; the lines were subsequently locked-out. This was a good catch and illustrates the value of such periodic reviews for continuously improving facility safety.

Transuranic Waste Operations: LANL continues to make progress toward startup of the high-activity waste drum campaign in the WCRR repackaging facility, but the schedule appears increasingly at risk (site rep weekly 3/30/07). Specifically, NNSA has approved the exception to the DOE startup order (DOE O 425.1C) and has informally provided final comments on the WCRR safety basis but has slipped issuance of a safety evaluation report (SER) by 10 days, to Apr 23rd.

While LANL believes that they will be ready for an operational readiness review (ORR) by mid-May, the SER slippage could delay finalizing procedures, training and qualifying operators, and conducting the initial periodic inspections and surveillances of safety systems – thereby impacting readiness for a mid-May ORR. That said, further delay in WCRR startup could eventually impact disposition of both low and high activity drums, which has safety implications for Area G (site rep weekly 1/5/07).

Contractor Assurance System (CAS): LANL is implementing the CAS, but CAS maturity still appears several years away, considering that: • the late discovery of problems with the Waste Management Risk Mitigation Project are possibly linked to the maturity level of CAS; • LANL managers are still having difficulties using the issue management software (LIMTS), which is evolving; • many scheduled assessments are being delayed; • numerous long-standing corrective actions from occurrence reports are now being rapidly but not necessarily effectively closed (site rep weekly 12/1/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 20, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 20, 2007

Plaue was here this week augmenting site rep coverage.

Plutonium Facility (TA-55): TA-55's proactive glove-box inspections, reported last week, are continuing to find discrepancies between operations and their criticality safety postings, such as: • lean solutions in bottles in a glove-box with posting indicating solutions should be in the columns (i.e., tanks) except when filling or emptying, which was done ~2 weeks ago; • a practice of staging small transuranic waste containers (e.g., Hagan cans) on the floor while the posting indicates only 15, 30, or 55 gal drums are permitted on the floor. The latter has led management to curtail transuranic waste packaging until procedures are implemented consistent with the posting, expected next week.

Criticality Safety: These events are similar to the case reported last week and will probably not be the last found by TA-55's ongoing glove-box inspections, which is commendable. Upon review, LANL is also finding that many of these discrepancies (including last week's) were already recognized and documented during last year's criticality safety walk-downs; corrective actions for these typically were assigned a low priority in LANL's extensive multi-year criticality safety improvement plan (site rep weekly 12/22/06). However, operating contrary to criticality safety postings may de-sensitize operators to the postings – an important element of criticality safety and conduct of operations; TA-55 is working on an interim solution. In some cases, such as the TA-55 waste packaging operation, the LANL criticality safety group is reassessing the priority assigned to addressing the issues.

Transuranic Waste Operations: Modifications to the WCRR waste repackaging facility, necessary for the high-activity waste drum campaign, are 98 % complete; ventilation control testing is planned this weekend. LANL expects to submit the final rule-compliant safety basis to NNSA today; NNSA expects to issue a safety evaluation report on it by next Tuesday. The final stage of operator training and qualification begin next week; the management self-assessment is expected the following week.

The highest activity drums and degraded drums are over-packed; inner drum integrity is not readily ascertainable until removed. These drums have been found to be generally robust structurally, with occasional corrosion holes; however, it is conceivable that the inner drum could fail while being lifted, spilling its contents. The current safety basis hazard analysis considers a degraded drum failing during handling outside but not inside the building; NNSA and LANL are now considering this scenario.

LANL still awaits NNSA action on an exemption request to fire protection requirements in the DOE facility safety order (DOE O 420.1B). The most significant proposed exemption involves lack of automatic engineered fire suppression within the WCRR glovebox. Near-term, LANL will stage fire control agents within the glovebox, and train operators in their use, as well as assign a fire watch during high-activity glovebox operations. By December 1st, LANL has committed to evaluate the upgrades required for compliance and has committed to implement those upgrades before processing drums with activity exceeding the current safety basis limit (i.e., 300 Ci combustible waste).

Given the expected NNSA safety evaluation report and the implementation of a rule-compliant safety basis, LANL believes that WCRR can be used not only for the high-activity drums aboveground but also those belowground with activity below the current safety basis limit.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 27, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 27, 2007

Criticality Safety: In response to the issues reported last week, the Plutonium Facility (TA-55) intends to work with the LANL criticality safety group and reconcile known discrepancies between operations and their criticality safety postings before the criticality safety evaluations are updated, which is scheduled during the next three years; this is positive (site rep weekly 12/22/06).

Radioactive and Nondestructive Testing (RANT) Facility: Current material inventory restrictions limit the capacity and packing efficiency of TRUPACT container loading operations at RANT (see site rep weeklies 7/21/06 and 3/18/05). To ease these restrictions and expedite the high activity transuranic waste disposition campaign, the laboratory has proposed a strategy to increase inventory limits inside the building almost 8 fold, up to 1840 Pu-239 equivalent curies. Short term, the strategy calls for development and NNSA approval of page changes to the existing safety basis that re-analyze accidents using new assumptions and credit new administrative controls, including combustible loading limits and vehicle restrictions. Longer term (i.e. by end FY07), the lab plans to use the new analysis to develop a safety basis that is fully compliant with the Nuclear Safety Management Rule. No major modifications or upgrades to existing engineered controls are proposed by this strategy.

Seismic Criteria: The updated LANL Probabilistic Seismic Hazards Analysis (PSHA) is due out in May and is expected to conclude that seismic hazards at the site are higher than previously believed; e.g. roughly 50% increase in PC-3 seismic criteria (see site rep weekly 12/22/06). Prior to PSHA issuance, LANL plans to submit a site-wide justification for continued operations (JCO) to keep running until prioritized facility-specific structural analyses can be prepared to identify vulnerabilities and aid development of JCOs for individual facilities, as needed. Impacts to new design and construction projects in various phases of development have yet to be determined.

Chemistry and Metallurgical Research Building Replacement Project (CMRR): The CMRR safety basis subcontractor has submitted to LANL an initial draft of the CMRR preliminary documented safety analysis (PDSA) that is largely reflective of the current design. The draft PDSA analyzes 11 design basis accidents and provides the preliminary basis for functional classifications and requirements for credited safety controls. The project asserts that it is committed to maintaining close integration between the design and safety analysis efforts. This will be key to ensuring controls are designed with appropriate functional attributes and pedigree, thus preventing costly retrofits.

Nuclear Material Stabilization: Last Friday, LANL management approved a comprehensive nuclear material packaging and storage plan for TA-55 that is intended to address a series of related corrective actions dating from the December 2005 vault contamination and the August 2003 Pu-238 uptakes. The objective is to repackage all non-standard items by the end of 2010, eliminating associated risks. The plan describes the progress made, such as: • the number of non-standard containers has been reduced by a third over 5 years; • the risk to workers due to non-standard containers was reduced by a third between May 2004 and Sep 2006; • 951 items have entered the WIPP-disposal pipeline since FY03. The plan retains a high dependence on Area G receiving about 7.5 kCi/yr during the next four years. It addresses most but not all of LANL's nuclear material (e.g., CMR has ~1,000 containers that are out of scope). LANL expects to establish a site-wide standard in conjunction with DOE actions in response to Board Recommendation 05-1 (site rep weekly 12/29/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 4, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 4, 2007

Anderson, Davis, Bamdad, Laake, Roscetti, Plaue, & Shackelford were here this week reviewing TA-55.

Plutonium Facility (TA-55): The basis for safe nuclear operations in TA-55 remains the interim technical safety requirements (iTSRs) that NNSA approved in July 2005 and that LANL verified to be implemented, with a few issues, in August 2006. The iTSRs constitute a judgement-based consolidated set of controls from unreviewed safety questions against the last approved safety basis (1996), a proposed 2002 safety basis, and the approved 2005 compensatory measures to address building passive-confinement concerns. They are essentially a stop-gap measure taken until LANL develops and justifies and NNSA approves a fully compliant safety basis (site rep weekly 4/6/07).

TA-55 continues to better understand and define their infrastructure needs, but those needs appear increasingly challenging. In particular, the scope of the line-item TA-55 reinvestment project was established 3 years ago and doesn't entirely reflect the currently understood facility needs; it does include some elements that are crucial to nuclear safety, such as seismically upgrading furnace glove-box supports. The facility would benefit from a responsive and stable sub-line-item mechanism to prioritize, plan, and fund upgrades.

Recommendation 04-2: Resolution of TA-55's passive-confinement issue remains elusive. TA-55's last proposed safety basis (Nov 2006) highly relied on personnel taking certain actions during an emergency that minimize building passive leakage (1.6 %). In March, NNSA questioned whether these assumptions were reasonably conservative. Separately, in December 2006, LANL completed a confinement evaluation that identified potentially beneficial active confinement improvements; LANL still awaits federal comments on the study (site rep weeklies 4/6/07, 12/15/06, 9/22/06, 6/16/06).

Delaying the long awaited TA-55 safety basis update in order to resolve the confinement issue would defer important efforts to address a broad range of other issues arising from TA-55's current decade-old, non-compliant safety basis. An alternative might be for the site to commit in the new safety basis to improving TA-55 active confinement, consistent with DOE Secretarial commitments to the Board, and then to plan and execute those improvements during the next few years while updating the safety basis annually to reflect the current confinement capabilities and expected end-state.

Transuranic Waste Operations: NNSA issued a safety evaluation report on April 25th approving the Waste Characterization Reduction and Repackaging Facility safety basis. However, overall readiness preparations for the facility are behind schedule and the operational readiness review to support high activity waste disposition work is likely to slip (see site rep weeklies 4/13/07, 3/30/07, 2/2/07).

Additionally, this week LANL reported the results of a four month inventory reconciliation effort at Area G in which 38 containers with a total of 169 Pu-239 equivalent curies could not be accounted for. For perspective, the current above-ground inventory at Area G includes roughly 20,000 containers that hold approximately 130,000 Pu-239 equivalent curies of material.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 11, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 11, 2007

Federal Oversight: NNSA has directed LANL to implement a set of compensatory measures to address apparent inconsistencies in the application of federal and laboratory readiness review requirements. These measures include requiring NNSA approval of all startup notification reports for nuclear facilities and activities before LANL starts each readiness review and the activity. NNSA expects that implementation of new LANL readiness review procedures that actively include federal personnel in the process for determining level-of-review should resolve these issues.

Transuranic Waste Operations: NNSA has informally directed LANL to conduct a contractor operational readiness review (ORR) for the WCRR repackaging facility's high-activity waste drum campaign; formal direction, including revoking the DOE O 425.1C exemption, is expected shortly. The site reps believe this pushes the federal ORR into July and the campaign's start into early August.

This week, the RANT shipping facility found radioactivity (120 dpm) on an in-line filter while drawing a vacuum on a TRUPACT shipping container; radioactivity (50 dpm) was also found on a second attempt. LANL has sent samples to Carlsbad to establish isotopics, which will determine whether the radioactivity is naturally occurring or contamination from a waste drum.

The Radioactive Liquid Waste Treatment Facility (RLWTF) resumed caustic waste receipt this week after the Plutonium Facility (TA-55) repaired hardware that had interrupted such transfers in March. RLWTF is no longer pursuing a waste processing campaign prior to entering an extended outage to address material condition issues, expected to be finished in September. Without near-term processing capability, waste discharges from TA-55 will be limited by RLWTF storage capacities.

Plutonium Facility (TA-55): TA-55's processes that generate caustic liquid waste, such as those that supply feed to pit manufacturing, have been idle but are now ramping up; LANL currently estimates that the RLWTF caustic waste receipt tank will reach capacity in November. TA-55 is pursuing strategies to temporarily ease reliance on caustic generating processes since operations like pit manufacturing could be impacted due to lack of feed if the RLWTF outage discussed above does not finish as scheduled; such contingency planning appears warranted to reduce schedule pressure on the RLWTF outage, which is long overdue and needs to be deliberately executed.

Chemistry and Metallurgy Research Building (CMR): CMR has completed fire door installation and, on Thursday, closed out the Justification for Continued Operation (JCO) for potential wing-to-wing flash-over across the spinal corridor during a fire (site rep weeklies 3/2/07, 11/17/06).

Weapons Engineering Tritium Facility (WETF): WETF is engaged in a multi-year effort to reduce its legacy inventory, which reduces risk to both workers and the public. For example, the current tritium inventory is significantly less than assumed in the 2002 safety basis and is expected to be an order-of-magnitude less within a few years. Also, legacy items that caused an unanticipated room and stack release in January 2001 have been properly disposed as waste (site rep weekly 3/14/03).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 18, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: Chuck Keilers and Brett Broderick, LANL Site Representative
SUBJECT: Activity Report for Week Ending May 18, 2007

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 25, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending May 25, 2007

Federal Oversight: On Thursday, NNSA transmitted to LANL a conduct of operations assessment of nuclear facility control room activities, and shift routine and operating practices. NNSA facility reps assessed their respective facilities, and collectively reported 9 observations, 3 strengths, 0 findings; the assessment generally concluded that the facility gap analyses in these areas were accurate.

Quality Assurance (QA): Last week, LANL provided NNSA a two-year plan for implementing the recently approved QA Program (site rep weekly 3/16/07). Key steps include: responsible associate directorates (RADs) perform gap analyses in July; RADs submit objective evidence packages in Dec 2007; RADs have programs in place in Mar 2008; LANL perform effectiveness reviews by Mar 2009.

Authorization Basis: This week, NNSA approved a justification for continued operation (JCO) allowing the Chemistry and Metallurgy Research Building (CMR) to operate while removing 6 toxic gas cylinders whose presence violates the safety basis; the non-compliant condition has existed for nearly 3 months (site rep weekly 3/2/07).

Similarly, at Area G, 34 unvented drums have been staged in violation of the approved safety basis, without a JCO, since being discovered in October 2006. Utilization and timeliness of the JCO process continues to warrant improvement (site rep weeklies 2/23/07, 10/27/06).

Transuranic Waste Operations: On May 9th, the RANT shipping facility found Pu-238 and Pu-239 on an in-line filter while drawing a vacuum on a TRUPACT shipping vessel. The TRUPACT trailer is parked at RANT pending development of a path-forward to unload the drums and decontaminate the vessel. Shipment of single-barrier high-wattage drums is suspended, but other shipments continue.

The management self-assessment (MSA) for repackaging high-activity drums starts next Tuesday and should complete June 7th. LANL has determined that at least 72 of the 235 affected drums (30%) meet WIPP requirements; the remainder (at least 156) require removal of prohibited items and repackaging in the WCRR facility; this is scheduled to start in August and to finish by end of Jan 2008.

While the progress on high-activity drums is encouraging, the site reps observe that lower activity drums (i.e., those less than 56 Ci) also drive many Area G accident scenarios and represent an enduring hazard at the current shipping rate. The rate has not improved over that reported in January (i.e., ~220 drums per month, site rep weekly 1/5/07). The 8 kCi shipped during the first eight months of this fiscal year is also comparable to the transuranic waste that TA-55 expects to generate during each of the next 4 years as it addresses its residue backlog; an option to accelerate decoupling TA-55 waste disposition from Area G is apparently not being pursued (site rep weeklies 4/27/07, 3/2/07).

Many legacy waste drums (potentially 70 % or more) will require remediation in WCRR – this is probably the rate-limiting step; however, prior plans to fund a second shift in WCRR this fiscal year have been discontinued. Extrapolation indicates that, at current rate, it could be another 8 to 11 years before the Area G above-ground transuranic waste inventory is eliminated as a hazard. Under the same assumptions, retrieval and shipment of the comparable below-ground inventory doubles the period.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 1, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 1, 2007

Broderick was off-site this week.

Contaminated Injury Investigation: This week, LANL released the corrective action plan for the CMR and TA-55 contaminated wound incidents that occurred in January; exposures to personnel are still being determined (site rep weeklies 4/13/07, 3/9/07, 1/19/07, 1/12/07). Key elements include:

- June - institutional plan for improving human performance
- July - facility-specific models for nuclear facility oversight coverage; institutional process to ensure consistency of management roles and responsibilities; management training plan, including human performance, integrated work management, performance-based leadership
- August – institutional glove-box safety program, capturing best practices, trending breaches
- September – activity-level oversight in nuclear facilities, distinct from work supervision
- October – new first-line leadership positions with technical and operational responsibilities
- January 2008 – human performance training completed by all current managers.

Plutonium-238 Operations: LANL has removed all Pu-238 residues from the TA-55 storeroom contaminated in Aug 2003; the room has been down-posted from an airborne radioactivity area to normal access. The safe recovery of this storeroom and disposition of these residues are significant and commendable accomplishments that eliminated hazards to the public and the workers.

Four years ago, this room had 238 residue packages, containing 800 grams of Pu-238 residues, radiologically equivalent to about a quarter metric ton of weapons-grade plutonium. Some residues were a decade old; some were intermixed with combustibles in poor containers within degrading plastic bags; conditions paralleled those assumed going into TA-55's worst case accident scenarios.

Last November, LANL informed the Board that these residues also posed about a quarter of the worker-related risk due to TA-55 packaged materials. In August 2003, two workers received Pu-238 uptakes in this room when an internally corroded package failed; the simple act of handling the package was sufficient to dislodge corrosion and release contamination into the room.

In 2004, little progress was made decontaminating the room due to safety basis issues and the LANL stand-down. By mid-2005, the room was largely decontaminated; emphasis shifted to the residues. By late 2005, LANL had disposed of the lean residues and 40 % of the packages. High-activity containers were problematic because of the handling risk during contents-splitting and the large projected waste volume, comparable to a decades' worth of TA-55's transuranic waste. By late 2006, LANL and WIPP had agreed on a way to decrease waste volume by an order of magnitude. In 2007, LANL loaded the highest-activity containers into pipe over-pack containers, minimizing handling risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 8, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 8, 2007

Davis, Elliott, Goff, Plaue, and Moury were here this week reviewing criticality safety and TA-55 vault operations. Rizzo and Andersen attended a contractor review on the updated seismic hazard analysis and walked down portions of the CMRR construction site related to seismic investigations. Andersen also attended the in-brief for the month-long CMRR nuclear facility Phase Y design review.

Pit Manufacturing: This week, NNSA certified (i.e., diamond stamped) a W-88 pit made by LANL. The last certified pit was made by Rocky Flats and was delivered in 1989.

Plutonium Facility (TA-55): On Monday (6/4), LANL began a three-week institutional assessment of TA-55 operations, patterned after the Facility Evaluation Board (FEB) model used at other sites. This is the third such assessment at LANL and the second at a nuclear facility (site rep weekly 3/30/07).

On Thursday (6/5), two TA-55 workers were hospitalized briefly due to heat stress. The workers were part of a team removing pencil tanks and were wearing respirators and 3 layers of protective clothing due to chemical (acid) and radiological hazards. The team had previously removed several tanks while wearing 2 layers; the third layer and a thicker acid suit were recent changes. TA-55 is curtailing some work and reevaluating work controls, such as stay-times, for these types of jobs.

Criticality Safety: LANL has near term plans to reestablish the Nuclear Criticality Safety Committee (NCSC) and to augment the cadre of full-time criticality safety officers (CSO). These are positive steps in that the NCSC provides independent institutional oversight to help ensure the criticality safety program is robust and adding well trained CSOs helps ensure the program is implemented effectively.

Other opportunities for improving the effectiveness of the criticality safety program may be gained by strengthening the interfaces with other institutional programs. For example, until planned enhancements to the configuration management system are enacted, changes to processes, procedures, and equipment that could affect assumptions or controls important for criticality safety may not receive appropriate review; compensatory measures may be warranted in the interim. Also, the antiquated security-related MASS software program plays a role in maintaining criticality safety, although it was not designed for this function. MASS modernization and functionality improvements are being planned, but funding for much needed upgrades to this critical system is uncertain.

Transuranic Waste Operations: On Wednesday (6/6), LANL completed a thorough management self-assessment (MSA) for repackaging high-activity waste drums in the WCRR facility. A major focus was proficiency of the operators, who have endured several training iterations and an order of magnitude increase in the number of procedures required to run the facility (now roughly 120).

There were numerous findings and observations, including concerns about whether the facility can meet the NNSA-approved combustible loading limits; some operating, surveillance, and in-service inspection procedures were not finalized; some baseline surveillances were not complete. The two-week contractor operational readiness review is expected to start Monday (site rep weekly 5/25/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 15, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 15, 2007

Burnfield, DeLoach, and Slater-Chandler were on site this week participating in DOE workshops on the line oversight contractor assurance system, federal oversight awareness, and the QA roadmap.

Dual Axis Radiographic Hydrodynamic Test (DARHT) Facility: The DARHT Facility recently performed its first fully-contained hydrotest using an engineered vessel. This new containment philosophy prevents the release of hazardous materials during hydrotests and could facilitate increasing the test rate by eliminating the need for post-shot cleanup at the firing site. Also, the second axis has demonstrated multi-pulse capability and will soon begin commissioning.

Formality of Operations: LANL has proposed to NNSA new milestone dates for implementing conduct of operations, engineering, and maintenance; however, integration with conduct of training is not apparent. Making comparable improvements to institutional training are integral to overall success.

Transuranic Waste Operations: The contractor operational readiness review (ORR) started Tuesday for repackaging high-activity waste drums in the WCRR facility, based on management's judgement that the 13 open pre-start findings from the management self-assessment (MSA) are tractable. The contractor ORR team is proceeding deliberately and should finish next week.

The facility has had difficulty demonstrating proficiency during drills and evolutions, largely because of issues such as (a) the level of maturity of procedures and completeness of records, and (b) the degree of simulation. While the former could have been avoided by a longer shakedown period after the MSA (i.e., at least a week), the latter would likely not have been recognized until operations were reviewed by an experienced ORR team – validating the decision to perform a contractor ORR.

Contractor Assessments: The institutional assessment of TA-55 that began last week had a slow start (e.g., CRADs finalized last Friday); field work is extending into next week. This is a new assessment process for LANL that needs to evolve; it is showing potential to improve management's operational awareness and its ability to identify and correct adverse conditions early.

Plutonium Facility (TA-55): NNSA has approved a safety basis revision to support nuclear material radiography in the tunnel (site rep weekly 3/23/07). The revision includes a new limiting condition for operation (LCO) action statement that allows 8 hours to restore building confinement integrity if lost or if disabled intentionally when no alternatives exist, such as during upcoming tunnel modifications. NNSA approved the revision subject to – prior to such intentional disablement – LANL notifies the NNSA facility rep, confirms safety basis assumptions are not significantly affected (e.g., differential pressures are maintained), and has material staged for quickly restoring confinement in an emergency.

TA-55 operations continue to be impacted by equipment failures, highlighting infrastructure needs. This week, the aqueous processing area wet vacuum system went down when the one operating pump failed while the other pump is undergoing extensive repair; this restricts solution transfers. Last Wednesday, PF-4 went into standby twice due to a facility power loss and to Facility Control System issues. The trolley systems, key to material moves between glove-box lines, are experiencing failures.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 22, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 22, 2007

Plutonium Facility (TA-55): This week, LANL completed the Director's Assessment of the TA-55 Plutonium Facility; the report is in preparation. The assessment included more than 200 interviews, 100 document reviews, and 50 observed evolutions. Some of the team's preliminary observations included: • PF-4 is LANL's signature nuclear facility and should be held to the highest level of asset management, commensurate with its value to LANL's continuing role; • work at TA-55 is performed safely overall, primarily because of the experienced personnel (many approaching retirement); • implementing institutional improvements (e.g. in operations, engineering, maintenance, and configuration management) warrants priority; • slow progress on work control corrective actions is a continuing risk; • there are vulnerabilities in relying on LANL's existing waste facilities (i.e., RLWTF, Area G) but no implementation plan for addressing newly generated transuranic or liquid waste for the next two decades.

As briefed this week, the site reps believe that this assessment establishes a comprehensive and timely baseline of the facility's needs and conditions; the facility should also be commended for thoroughly communicating its recognized issues and plans to the assessment team.

Transuranic Waste Operations: Completion of the contractor operational readiness review (ORR) for the WCRR waste repackaging facility has slipped until next Wednesday to allow additional assessment of the safety basis functional area. Open lines of inquiry are focused on the facility's ability to successfully perform surveillances and inspections that verify effective implementation of credited controls. LANL will present a schedule for issue closure and for the conduct of a federal ORR after the contractor review and report are finalized next week.

NNSA has approved an amendment to the basis for interim operations (BIO) for the RANT waste shipping facility that will increase the inventory limit inside the building to allow shipping high-activity waste drums (site rep weekly 4/27/07). The amended BIO features reduced predicted accident consequences based on data from the new DOE Standard 5506, re-categorization of some engineered controls from safety-class to safety-significant, and new administrative controls. LANL plans to submit a BIO compliant with the Nuclear Safety Management rule (10 CFR 830) by the end of FY07.

Los Alamos Neutron Science Center (LANSCE): In response to the DOE General Counsel decision that LANSCE is an accelerator facility exempt from 10 CFR 830, LANL is working on a safety assessment document (SAD) per DOE Order 420.2B; it's targeted for September and will ultimately serve as the facility's safety basis (site rep weekly 10/20/06). This week, NNSA approved an extension to the existing set of 5 safety basis documents to provide a basis for continued LANSCE operation until the SAD can be approved and implemented.

NNSA has also approved a request to perform dynamic experiments using up to 8 grams of plutonium metal and 4 grams of high explosives (HE) in the proton radiography dome at LANSCE. Experiments will be conducted in a robust vessel designed to contain detonations of up to 10 lbs. of HE; experiments that would cause bulk melting of plutonium samples are prohibited.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 29, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 29, 2007

Broderick was off-site this week.

Federal Management and Oversight: NNSA announced this week the assignment of a new Los Alamos Site Office (LASO) Manager, effective July 8th. The NNSA Chief of Defense Nuclear Safety also had a team on site this week, preparing for the biennial review scheduled Jul 30th - Aug 9th; LASO is the last of the first round of such reviews of site office operations (site rep weekly 1/12/07).

Transuranic Waste Operations: This week, LANL completed their operational readiness review (ORR) of the WCRR repackaging facility high-activity drum campaign and briefed the federal ORR team on the status. LANL expects to declare readiness for the federal ORR on or before July 11th, to support the federal review occurring July 16th - 27th.

LANL has identified 14 pre-start findings that need to be resolved or shown to be manageable before declaring readiness. One involves the presence of about 275 gallons of mineral oil in an external transformer about 5 feet from the facility; LANL plans to construct a fire wall between the facility and the transformer and to propose a safety basis revision that reflects this new design feature. Another involves NNSA action on a proposed exemption to DOE requirements for automatic engineered fire suppression in the glovebox; LANL has staged fire control agents within the glovebox for operator use and is assigning a fire watch during high-activity glovebox operations (site rep weekly 4/20/07).

In other areas, LANL has unloaded and decontaminated the TRUPACT shipping container that was contaminated last month. LANL has also unplugged a blocked line and mobilized residual sludge in a degraded treatment tank in the Radioactive Liquid Waste Treatment Facility; this tank has been a challenge for some time. Both of these operations were well-planned and deliberately conducted.

Plutonium Operations: Operating tempo is high. Both the Plutonium Facility (TA-55) and Chemistry and Metallurgy Research Building (CMR) are conducting extended-hour operations; 24 hour/day - 7 day/week operations are being discussed at TA-55 through next weekend. Facilities are monitoring personnel overtime against LANL safety restrictions involving excessive overtime.

Chemistry and Metallurgy Research Building: LANL has determined the baseline program needs for CMR capabilities beyond 2010 and the risk reduction options; key elements include reducing operational footprint, underway in Wings 2 and 4, and moving Pu-238 analytical chemistry to TA-55. LANL expects to submit detailed planning and a safety basis strategy in September; a new safety basis would notionally be submitted in FY 08 and implemented in FY-09 (site rep weekly 3/23/07).

Tritium Operations: NNSA has closed pre-start findings from the 2004 WETF ORR and intends to declare Bldg 450 operational in cold-standby; ventilation exhaust should be connected within a few weeks. This opens the way for LANL to move radiological-scale tritium operations from other buildings into WETF, which has more robust engineered features and controls (site rep weekly 8/4/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 8, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending June 8, 2007

Davis, Elliott, Goff, Plaue, and Moury were here this week reviewing criticality safety and TA-55 vault operations. Rizzo and Andersen attended a contractor review on the updated seismic hazard analysis and walked down portions of the CMRR construction site related to seismic investigations. Andersen also attended the in-brief for the month-long CMRR nuclear facility Phase Y design review.

Pit Manufacturing: This week, NNSA certified (i.e., diamond stamped) a W-88 pit made by LANL. The last certified pit was made by Rocky Flats and was delivered in 1989.

Plutonium Facility (TA-55): On Monday (6/4), LANL began a three-week institutional assessment of TA-55 operations, patterned after the Facility Evaluation Board (FEB) model used at other sites. This is the third such assessment at LANL and the second at a nuclear facility (site rep weekly 3/30/07).

On Thursday (6/5), two TA-55 workers were hospitalized briefly due to heat stress. The workers were part of a team removing pencil tanks and were wearing respirators and 3 layers of protective clothing due to chemical (acid) and radiological hazards. The team had previously removed several tanks while wearing 2 layers; the third layer and a thicker acid suit were recent changes. TA-55 is curtailing some work and reevaluating work controls, such as stay-times, for these types of jobs.

Criticality Safety: LANL has near term plans to reestablish the Nuclear Criticality Safety Committee (NCSC) and to augment the cadre of full-time criticality safety officers (CSO). These are positive steps in that the NCSC provides independent institutional oversight to help ensure the criticality safety program is robust and adding well trained CSOs helps ensure the program is implemented effectively.

Other opportunities for improving the effectiveness of the criticality safety program may be gained by strengthening the interfaces with other institutional programs. For example, until planned enhancements to the configuration management system are enacted, changes to processes, procedures, and equipment that could affect assumptions or controls important for criticality safety may not receive appropriate review; compensatory measures may be warranted in the interim. Also, the antiquated security-related MASS software program plays a role in maintaining criticality safety, although it was not designed for this function. MASS modernization and functionality improvements are being planned, but funding for much needed upgrades to this critical system is uncertain.

Transuranic Waste Operations: On Wednesday (6/6), LANL completed a thorough management self-assessment (MSA) for repackaging high-activity waste drums in the WCRR facility. A major focus was proficiency of the operators, who have endured several training iterations and an order of magnitude increase in the number of procedures required to run the facility (now roughly 120).

There were numerous findings and observations, including concerns about whether the facility can meet the NNSA-approved combustible loading limits; some operating, surveillance, and in-service inspection procedures were not finalized; some baseline surveillances were not complete. The two-week contractor operational readiness review is expected to start Monday (site rep weekly 5/25/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 13, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 13, 2007

Federal Management and Oversight: The new NNSA Site Office Manager started this week. Also, the DOE Office of Independent Oversight (HS-64) will be here in early August to scope their next on-site health and safety assessment, which is scheduled for October (site rep weeklies 6/29/07, 1/27/06).

Transuranic Waste Operations: LANL has declared readiness for the NNSA operational readiness review (ORR) of the WCRR facility's high-activity drum campaign; this ORR is now scheduled to start July 23rd. NNSA has granted the fire protection exemption for glovebox operations without automatic fire suppression and is poised to approve a WCRR safety basis change that reflects a new fire barrier, which is to be installed between the building and a nearby transformer (site rep weekly 6/29/07).

The Radioactive Liquid Waste Treatment Facility (RLWTF) can currently receive and store but not process liquid transuranic waste discharges from the Plutonium Facility (TA-55) until modifications are completed. While caustic waste receipts are within expectations, the acid waste receipt rate is nearly double planning estimates made earlier this year. The acid tank is now half-full; this may impact TA-55 aqueous operations sooner than previously expected (site rep weekly 5/11/07).

Plutonium Facility (TA-55): LANL has submitted a new safety basis strategy document that establishes a target resubmittal date of September 28th for a compliant TA-55 Documented Safety Analysis (DSA) and describes the approach for meeting commitments stemming from the recent round of safety basis workshops with NNSA (site rep weekly 4/6/07).

Some workshop commitments require LANL to submit prototype revisions for certain topical areas to ensure the modifications meet NNSA expectations before effort is expended to implement these changes globally throughout the document. One such prototype revision, recently submitted by LANL for review and approval, provides additional explanatory discussion of leak path factor (LPF) derivation for fires in Pu-238 lab rooms. The proposed revision identifies engineered and administrative controls and physical properties of fire phenomenology that can be credited to lower the LPF and applies them successively to demonstrate their respective contribution to reductions in calculated LPFs. Application of the full suite of identified controls yields mitigated doses ranging from 14 to 27 rem CEDE for the bounding fire depending on assumptions related to external door closure times. These values do not reflect mitigation provided by the ventilation system.

Although the supplementary LPF analysis is predicated on the existing passive confinement approach, LANL has committed to incorporate any additional controls that may result from on-going activities to address Board Recommendation 2004-2, *Active Confinement Systems*, in the next annual update to the DSA. Onsite efforts to define, fund, and implement additional cost-effective controls to improve the robustness of the Plutonium Facility's confinement posture are currently on hold awaiting feedback from the NNSA Independent Review Panel on an evaluation and options study made by the site in a November 2006 report (site rep weeklies 5/4/07 and 12/15/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 20, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 20, 2007

This week, NNSA, LANL, and the staff held a video-teleconference on accident investigations and corrective actions and held a teleconference on the MASS code, used for material accountability.

Welding Issues: LANL quality assurance division recently audited the institutional welding program. Findings include: lack of control of weld filler material; welding performed to unqualified processes and procedures; welding performed by personnel who have not been adequately trained; welding not inspected in accordance with codes and standards; lack of a NDE examiner to certify inspectors; a structural steel welding procedure used on some projects (e.g., WCRR seismic upgrades) not meeting code requirements; and welding program management assessments not being performed.

These issues are similar to those found in 2003 that were the subject of substantial corrective actions through 2005; momentum and many of these gains appear to have been lost during contract transition due to lack of ownership, a condition that LANL is now correcting (site rep weeklies 9/16/05, 8/19/05, 4/16/04, 3/26/04, 1/2/04).

Nuclear Facility Infrastructure: Recent events illustrate continuing challenges, particularly for staffing and for safety system configuration management and maintenance. The Plutonium Facility (TA-55) has been in extended-hour operations for several months. This week, a wing (Zone2) ventilation system fan failed impacting operations; the shaft and bearing were replaced that night. Personnel working the switchgear upgrade project plugged an electric lift unknowingly into the uninterruptible power supply (UPS) system, impacting the facility control system, which impacted ventilation. An instrument air leak caused ventilation cycling, also impacting operations. Breaker inspections found a degraded (partially welded) chilled water system breaker, which was repaired. Acidic solution leaked from a pipe onto a glovebox and the floor, forcing a lab room evacuation; the facility appropriately responded. Acidic waste transfers to the Radioactive Liquid Waste Treatment Facility are suspended while that facility investigates anomalous tank-level increases.

Additionally, LANL has completed a staffing analysis evaluating cognizant system engineer (CSE) support for vital safety systems (VSS) at 6 operating nuclear facilities. The analysis showed that CSEs are performing numerous ancillary functions including maintenance, design, and plant engineering tasks, leaving the average VSS with only about one-third of the institutionally recommended minimum level of effort for system engineering.

Based on criteria such as expertise, level of effort, and system condition, the evaluation concluded that 9 of the 43 active systems studied had inadequate system engineering coverage and 27 were receiving marginally adequate coverage. Staffing recommendations included adding 26 engineers at TA-55 (29 existing), 5 at CMR (9 existing), 4 at WETF (8 existing), 3 at WCRR (3 existing), and 3 at RANT and Area G (3 existing) for a total recommended increase of 41 engineers to the existing pool of 52. This analysis focused primarily on CSE coverage for active systems; the staffing recommendations will not necessarily be sufficient to ensure system engineering expectations are adequately met for passive safety systems. LANL intends to begin addressing the identified needs by hiring 9 new engineers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 27, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending July 27, 2007

Davis was on site this week observing the WCRR ORR; Plau, Roscetti, and Shackelford were here reviewing safety systems; Broderick was off-site two days reviewing Pantex lightning protection.

Engineered Controls: LANL nuclear facilities have 46 active and 47 passive safety systems. A January 27th, 2004 Board letter identified weaknesses in LANL engineering practices for determining that such systems will adequately perform their intended safety functions; a contributing factor is that the safety functions are often not clearly defined in the safety bases, which generally have not been updated. More recently, a November 2005 DOE-OA assessment reported similar issues and concerns.

Based on the staff's detailed review of 6 active systems, these issues persist: LANL still does not have the configuration management, maintenance, and engineering elements in place to demonstrably assure these systems will adequately perform their credited safety functions. For several years, LANL has been developing a conduct of engineering program to address such issues, but this effort is insufficiently supported, it's understaffed, it's under-assessed, and it has yet to increase confidence in these systems.

Transuranic Waste Operations: The two-week NNSA operational readiness review (ORR) started Monday for the WCRR facility high-activity drum campaign. Last Friday, NNSA approved the safety basis change reflecting a new fire barrier and drainage between the building and a nearby transformer.

On Tuesday, radiography determined that a low-activity drum (less than 0.5 Ci) contained a 2L bottle, half-full of liquid believed to be propane; the drum is two-decades old. LANL has isolated the drum, and pending safety review, intends to move the drum to an Area G permacon and to remove the bottle, possibly next week. LANL recently completed a management self-assessment of this permacon for dewatering and repackaging low-activity solidified drums, which started this week.

Plutonium Facility (TA-55): On Monday, TA-55 workers found a component cleaning glovebox had spent cleaning solution in excess of posted criticality safety limits (i.e., moderator/reflector); the safety margin was not impacted. Workers had intended to sample and remove the spent solution last week, which requires suspending room operations, but did not do so because of production schedule pressure.

Chemistry and Metallurgy Research Building Replacement Project (CMRR): NNSA and LANL have determined that CMRR's preliminary design and preliminary documented safety analysis (PDSA) have diverged from the 2006 nuclear safety strategy; furthermore, the current draft PDSA is based on an earlier version of the design, and its justification for proposed controls is incomplete. LANL subcontractors have begun to revise the design and PDSA to be consistent with the safety strategy, but achievement of this objective is not assured (site rep weeklies 4/27/07, 4/28/06, 3/17/06).

Management: LANL senior management is increasingly focused on the future and sustainability of the laboratory, which affects their level of attention to nuclear operations. At the next tier, management responsible for nuclear and high hazard operations has focused on the WCRR upgrades to meet current standards; this has been essential to driving progress. The operations management tier is largely consumed with solving daily problems, such as those reported last week for TA-55, and frequently struggles with issues involving the authorization bases, material condition, and institutional support.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 3, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 3, 2007

Federal Oversight: This week a team from the office of the Chief of Defense Nuclear Safety began their biennial review of the NNSA site office. The office of Health, Safety, and Security was also on-site this week performing scoping activities for a review tentatively scheduled for later this year.

Transuranic (TRU) Waste Operations: The federal operational readiness review (ORR) for the WCRR repackaging facility concluded this week. The review resulted in 10 pre-start and roughly 20 post-start findings. Of the pre-starts, 3 were newly identified issues and the balance stemmed from inadequately closed findings from previous reviews and contractor-identified open issues.

The review team noted the importance of facility-implemented compensatory measures, particularly the provision of a senior supervisory watch, in ensuring safe and sustainable high activity waste operations. These compensatory measures were put in place to address institutional deficiencies in key areas such as conduct of operations and engineering and in recognition that facility personnel and operators had to come to grips with a new safety basis, significant facility upgrades, approximately 100 new procedures and wholesale retraining and requalification all in the compressed time span of 7 months (site rep weeklies 6/8/07, 4/20/07, 3/16/07, 2/2/07). The ORR team lead will recommend that NNSA and LANL formalize the existing compensatory measures. This would include the development of formal criteria to be met prior to compensatory measure removal and the explicit identification of who is authorized to approve such removal.

Chemistry and Metallurgy Research Building (CMR): Pit manufacturing depends on CMR providing analytical chemistry; however, CMR is five-decades-old, is over-sized for the mission, has not been adequately maintained, and is operating to a nearly decade old safety basis. CMR's credited safety systems suffer from material condition issues, poorly understood and controlled system boundaries, and a weak technical baseline. Until about one year ago, CMR was managed jointly with the Plutonium Facility (TA-55) and was able to share TA-55 practices and procedures. CMR is now managed separately and, among its many challenges, is now having to create and maintain separate practices and procedures. Resource and staffing shortfalls, particularly in the area of engineering support, appear to be exacerbating these problems and impeding progress.

Seismic Criteria: NNSA approved the sitewide justification for continued operations resulting from the ten year update to the LANL seismic hazards assessment that concluded the site's seismic hazard is higher than previously believed (site rep weeklies 7/6/07, 4/27/07). The NNSA approval requires the laboratory to submit, by September 21st, a funded and resource-loaded project plan for completing detailed seismic analyses for nuclear and high hazard facilities by June 2009. NNSA also directed LANL to formalize and implement compensatory measures identified in the JCO for the Weapons Engineering Tritium Facility (inventory limit reductions) and the Radioactive Liquid Waste Treatment Facility (operator training for emergency response to a seismic event).

Criticality Safety: After a significant hiatus, the Nuclear Criticality Safety Committee has been formally re-chartered and held their first meeting this week. This is a positive development that could help strengthen lab-wide criticality safety by providing independent institutional oversight.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 10, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 10, 2007

Keilers was offsite at DNFSB headquarters in Washington, DC, this week.

Federal Oversight: Field activities for the Chief of Defense Nuclear Safety biennial review of the NNSA site office were largely completed this week. Oversight objectives were deemed to be met in 4 functional areas (quality assurance, criticality safety, radiation protection, and packaging and transportation). The balance of roughly 10 functional areas did not meet objectives. The review team noted significant issues associated with site office oversight of contractor training and qualification, maintenance, and safety system engineering. Other concerns identified during the review were weaknesses in site office training and qualification and inconsistent oversight of compensatory measures and corrective actions stemming from contractor gap analyses against DOE requirements.

Plutonium Facility (TA-55): A recent contractor gap analysis concluded that TA-55 fissionable material handlers and their immediate supervisors were not being certified in accordance with DOE Order 5480.20A. The LANL program lacks written examinations, oral examinations, and qualified on-the-job training instructors, all of which are required per the Order. NNSA has approved an action plan that will allow LANL to provisionally certify handlers and supervisors who are demonstrably qualified and proficient. A list of provisionally certified personnel must be submitted for site office approval by August 15th. Personnel who cannot be provisionally certified by this date must be placed on restricted duty. Provisional certifications will expire on November 15th, at which time NNSA expects an Order-compliant certification process to be developed and implemented.

This week, TA-55 also discovered several issues related to the surveillance and effectiveness of credited engineered controls. First, several monthly surveillance requirements for two safety-class confinement doors in the TA-55 basement were found to be absent from the implementing procedure. As a result, these monthly surveillances had not been performed since January 2006. This discovery resulted in a TSR violation. Additionally, during the development of a system design description, TA-55 personnel identified the existence of a pressure relief valve on the isotopic fuels impact test (IFIT) launcher whose design and installed configuration could not perform the credited safety function. The design of the existing valve and its installed set-point could not limit the launcher breach pressure to less than 550 psig, as required. These events share commonalities with issues raised during the 2005 DOE-OA review, TA-55 Director's Assessment, and recent DNFSB staff review conducted July 24-26 (see site rep weeklies 7/27/07, 6/22/07, 1/27/06, 12/9/05).

Institutional Support: LANL has recognized areas of fundamental non-compliance with DOE requirements and has begun to implement important corrective action initiatives including the Formality of Operations effort and the Safety Basis Improvement Plan. The persistence of issues such as those discussed above underscore the need for continued management attention and resource prioritization for these critical improvement initiatives. The certified fissionable material handler issue also serves to highlight that some deficiencies are significant enough to warrant near-term compensatory measures to ensure adequate protection and cannot be allowed to linger until multi-year compliance initiatives have matured enough to correct the underlying problems.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 17, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 17, 2007

Plutonium Facility (TA-55): TA-55 paused fissile material handling operations Thursday and resumed such operations Friday following NNSA approval of the provisional certification of TA-55's fissile material handlers. LANL has also recognized that TA-55 was non-compliant with its approved safety basis, which explicitly invokes the DOE Order 5480.20a certification requirements for fissile material handlers under an administrative control program. While TA-55 fissile material handlers undergo a qualification process with many of the elements appropriate for certification, that process lacked the full rigor of a formal certification process (site rep weekly 8/10/07).

Criticality Safety: While walking down TA-55 pit casting operations on Wednesday, an NNSA facility rep and a criticality safety subject matter expert discovered a discrepancy in criticality safety posting, which led to discovery of staged plutonium metal in excess of the workstation limit. Personnel evacuated the room; the LANL criticality safety group evaluated the situation; the over-mass condition was appropriately corrected; TA-55 pit operations are curtailed pending further review. This single failure appears to have had little effect on the margin of safety of this operation.

The over-mass condition arose as follows. For several years, the casting group has used a glovebox for staging that was divided into two workstations. In May, the casting group began to bring an inactive furnace in this glovebox on-line. Working with the criticality safety group, they reassigned it as a single workstation, consistent with other casting boxes, and assigned new limits. Operators were trained on the change; however, only one of the two glovebox postings was changed, and the MASS database was not updated. Recently, operators began casting in this glove-box. Per procedure, they checked MASS, the postings, the other indicators, all of which incorrectly reflected two workstations; they staged items in the glovebox consistent with those indicators and with the glovebox's prior use.

Updating workstation postings and MASS is expert-based; the site reps believe that informal change control and startup review, coupled with distraction due to production pressure, led to this workstation being incompletely updated. When checking extent of condition, TA-55 identified about two-dozen transfer (i.e., drop) boxes that are properly posted but may be susceptible to similar problems; these boxes as a class were reassigned last year as single locations but MASS still reflects two locations (site rep weekly 3/10/06). TA-55 is working toward correcting these conditions and establishing more formal protocols for declaring operability of gloveboxes and for updating criticality safety postings.

Packaging and Transportation: In two separate incidents this week, LANL discovered unexpected contamination associated with material shipments to Area G. On Tuesday, approximately 20 gallons of rainwater mixed with low activity borehole cuttings from TA-21 was released during transport. Onsite and offsite leakage areas were identified, and appropriate response action was taken to characterize the potential releases, which showed no detectable radioactivity. On Wednesday, external contamination, possibly the result of a degraded gasket, was discovered on a shipping cask containing waste from TA-48. Preparation and execution of these material moves were not conducted by the dedicated LANL packaging and transportation (P&T) group. It appears that moves not conducted or supervised by this group do not benefit from this group's level of rigor and formality in important areas, including inspection of equipment and verification of packaging certification and pedigree.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 24, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 24, 2007

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF has shrinking storage capacity and no operating treatment capability for transuranic liquid waste transferred from TA-55 (site rep weekly 7/13/07). Acidic waste transfers have resumed and, as of Aug 22th, the acid receipt tank was 61 % full. RLWTF is reluctant to exceed 85 % full (100 % indicated) due to potential for overflow into the underground vault (WM-66); an overflow would be contained but would be difficult to clean up.

RLWTF's efforts to reduce transuranic sludge inventory and to restore treatment capability have been hampered by decreased operational supervision and engineering support. Basically, RLWTF draws upon the same limited pool of people and resources as Area G, the RANT shipping facility, and the WCRR repackaging facility; WCRR restart has drawn resources from the other facilities. Operations management has found configuration management and conduct of operations issues that are impacting progress; this includes an instance when operators continued a procedure that could not be completed as written. These issues were perhaps avoidable if the engineering and supervisory functions were fully staffed. This impacts RLWTF directly and could impact TA-55 indirectly within a few months.

Plutonium Facility (TA-55): In a step toward updating the decade-old TA-55 safety basis, NNSA has approved the laboratory's overarching TA-55 safety basis strategy and a white paper describing the proposed methodology for deriving facility leak path factors (site rep weekly 7/13/07). The LANL strategy establishes a Sept 28th target date for submitting a new safety basis. In its approval, NNSA called for control selection to be based on ICRP-30 dose conversion factors. NNSA also expressed concern with the effectiveness of parallel rather than series internal and external quality reviews, which LANL has proposed to support the aggressive schedule. Overall, the prospect of submitting a safety basis that satisfies all existing commitments by Sept 28th appears increasingly challenging.

In approving the leak path factor approach, NNSA acknowledged that the upcoming safety basis submittal will continue to rely on passive confinement. However, NNSA did reinforce the expectation that LANL conduct further investigation of additional safety class controls that could provide significant, cost effective risk reduction. NNSA directed the laboratory to identify potential upgrades to the confinement ventilation system and other systems and programs that could enhance the confinement posture of the facility as planned improvements in the forthcoming safety basis submittal.

Operationally, TA-55 resumed pit manufacturing activities last Friday. On Tuesday, an operator moved an item into a transfer (i.e., drop) box that was posted out-of-service. The posting had a handwritten annotation that it was a MASS location that was not in-service. The facility constructively critiqued the event and identified possible improvements, including: more formal processes for posting equipment out-of-service; better lab-room door posting; clearly defined room controller instructions; and, increased emphasis on pre-job walk-downs and addressing abnormal conditions.

Chemistry and Metallurgy Research Building (CMR): CMR declared a TSR violation this week upon discovering that 31 of about 600 rooms had been omitted from a surveillance procedure to inspect fire sprinkler heads. The surveillance was then performed in the 31 rooms and sprinkler heads were found to be operable. This surveillance went through CMR's procedure review and validation process and passed an independent verification review without the deficiencies being identified.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 31, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending August 31, 2007

Goff, Minnema, Plaue, and Von Holle were here reviewing corrective actions from accident reviews.

Management: LANL nuclear facility staffing requirements, including staff training and qualification, appear to need more visibility to senior management; it is unclear how these needs are being factored into NNSA and LANL priorities and into performance-based-incentives being negotiated for FY-08. In general, LANL does not appear to have leading indicators of staff populations that may be overtaxed by the extended operations that many facilities are experiencing; such metrics would not only provide advance notice of looming safety problems but also flag future staffing needs. It can easily take a year, and often much longer, to train and qualify staff to work safely in a nuclear facility.

Also, the default solution for many problems is to task the facility operations staff; however, this rarely comes with additional resources. An example may be the corrective actions from the TA-55 and CMR contaminated puncture wounds investigation; these would increase the involvement of operations staff in reviewing, approving, and monitoring work – an appropriate action but one that will be demanding to be done adequately if not sufficiently staffed. Another example may be health and safety staff who face increasing demands to review work planning documents, which decreases their operational awareness and time on the floor monitoring activities that can change frequently.

In the engineering area, staffing is critical to LANL addressing longstanding concerns about operability of safety systems and viability of safety bases controls. LANL has identified that 36 of 43 active vital safety systems have inadequate or marginal engineering coverage and that LANL needs about 41 more engineers in addition to the 52 they now have. Also, at the institution level, LANL would be well-served to track and audit progress on reconstituting the technical baseline for vital safety systems in nuclear facilities, previously estimated to be a \$7.4M effort requiring 3 to 5 years to complete (site rep weeklies 7/27/07, 7/20/07, 6/1/07, 8/4/06).

Criticality Safety: The roughly 20 existing criticality safety evaluations (CSEs) for the TA-55 vault are convoluted, occasionally contradictory, and heavily reliant on expert judgement; these are among about 300 CSEs that LANL has identified as missing, technically deficient, or having some other problem that LANL has committed to address during the next few years (site rep weekly 12/22/06).

The vault CSEs require that two vault rooms have 5% borated-polyethylene in the shelving unit doors, but LANL cannot conclusively assure that the installed material has this level of boration – an ANSI/ANS 8.21 requirement. The poly was intended only as radiation shielding. A 2002 CSE credits the boron, as well as fissile mass, spacing, shape, and reflection; a related 2001 CSE states that boron is required to keep the array sub-critical provided each storage location is loaded to the upper limits; current expert judgement is that boron is not required, but that judgement is not backed by analysis.

Based on photographs, procurement requests, and catalog data, TA-55 has no reason to believe that the configuration is other than the one analyzed; however, there is no material certification, and there are other instances where LANL procurement processes have allowed incorrect materials to be installed. LANL should consider (1) if a criticality infraction exists, in accordance with LANL ISD 130-1; (2) if a sensitivity analyses on boron's effect on safety margin is warranted, including double-batching not covered in the 2002 CSE; and (3) if compensatory measures are needed, as indicated by analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 7, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending September 7, 2007

Management: LANL is starting to plan for a possible reduction-in-force; this is driven by the large uncertainty in the FY-08 budget, ranging from a best-case flat-budget to a worse-case \$350M decrement. LANL management believes delaying action will only exacerbate the size of the action ultimately required.

Corrective Actions for Contaminated Puncture Wounds: LANL has issued institutional requirements for glovebox safety (ISD 101-28), in accordance with the corrective action plan for the TA-55 and CMR puncture wounds that occurred in January (site rep weekly 6/1/07). The ISD covers areas such as maintenance, glove integrity, ergonomics, sharps, and housekeeping.

In July, LANL revised this corrective action plan. Specifically, LANL strengthened its dependence on the upcoming revision to the integrated work management (IWM) process but weakened the action to establish a first line management (FLM) position by no longer requiring consistency. Instead, each associate director is expected to define how this position will be implemented in their organization. Weaknesses in first line management played a key role in these accidents. It appears worthwhile for LANL to consider, at least, establishing a consistent FLM implementation in LANL nuclear facilities.

Plutonium Facility (TA-55): TA-55 is planning an outage from Nov 5th through the end of the year, focused on formality of operations, configuration management, condition assessments, procedure standardization, system improvements, etc.; some limited operations would continue (Pu-238, MOX).

Criticality Safety: TA-55 is declaring a potential inadequacy of the safety analysis (PISA) and is suspending fissile material moves into two vault rooms unless the moves are reviewed by the LANL criticality safety group; material moves out of the rooms are unrestricted. While related, this is a different problem and affects different rooms than those reported last week. In this week's case, BISCO neutron shielding with 2 % boron carbide was installed in 1986; material certification was provided but has been lost; it's unclear whether or not the 1986 criticality safety evaluations credited boron. Given the uncertainty, the facility chose to enter the PISA process for these two rooms. LANL expects to have an analysis in about a week on whether the boron is required.

Transuranic Waste Operations: LANL expects to soon complete physical modifications to the RANT shipping facility to support shipping high-activity waste drums; they involve fire suppression, lightning protection, vehicle barriers, and combustible reduction. LANL has also proposed startup of the WCRR repackaging facility with compensatory measures (site rep weekly 8/3/07).

Nuclear Environmental Sites: LANL has suspended low-level waste shipments from TA-21 to Area G after discovering dripping packages were shipped on Thursday. This is similar to the event reported Aug 17th. LANL has launched but has not yet completed a formal investigation of the prior event.

Last Tuesday (8/28), a LANL subcontractor found an area with 1M dpm beta/gamma and 12k dpm alpha fixed contamination in Bayo Canyon, formerly known as TA-10. The area is being posted and controlled. TA-10 was transferred to Los Alamos County in 1967. Last month, NNSA approved downgrading TA-10 from a nuclear facility (HC-3) to radiological status based on updated analyses.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 14, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 14, 2007

Transuranic Waste Operations: This week, LANL received authorization to begin operations involving greater than 56 plutonium-equivalent curies at the WCRR repackaging facility. This is a significant step in the effort to disposition 235 drums at Area G that represent about 2% of the above ground inventory, by number, but approximately one-fourth of the above-ground inventory, by radioactivity. These drums help to drive some of the highest consequence postulated accidents at the laboratory (site rep weeklies 8/3/07, 2/2/07, and 12/8/06). The first high activity drum was processed on Thursday. Initial operations will involve lower hazard drums to allow personnel to build proficiency with new processes prior to remediating the most hazardous drums.

Physical modifications and operator training continue at the RANT shipping facility to support implementation of a safety basis change designed to facilitate timely waste disposition and improve the efficiency of shipping operations (site rep weekly 6/22/07). An independent verification review for implementation of the new safety basis controls is scheduled to begin September 24th.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL can currently transfer and store, but not process, acidic and caustic radioactive liquid waste. On Thursday, the acidic waste tank was 81% full and storage space capacity will become operationally limiting soon (site rep weekly 7/13/07).

Transportation: On Monday, a tritium-contaminated polisher was delivered from the Target Fabrication Facility (TA-35) to the Sigma Complex (TA-3-66). Upon arrival at Sigma, the worker did not stage the polisher in a radiological control area, as required. The worker also left the facility without having the polisher surveyed by an RCT. This violated an institutional requirement developed in response to the 2005 Type B investigation involving the spread of Am-241 contamination from Sigma. This is also the latest in a series of events that indicates requirements and controls associated with material movements are not always well understood and implemented when moves are conducted by personnel outside of LANL's packaging and transportation group (site rep weekly 8/17/07).

Integrated Work Management: A revision to LANL's governing process for integrated work management is targeted to be issued by the end of this month. Among other things, this revision will require Facility Operations Directors (FOD) to review and approve integrated work documents for moderate and high hazard activities. This is positive, although staffing levels for FOD organizations will make performing this new function challenging (site rep weekly 8/31/07). IWM assessments for all functional areas are scheduled for FY08 using a tailored set of criteria developed by NNSA.

Chemical Management: An emergency management review by the DOE Office of Independent Oversight (HS-63) in 2006 concluded that LANL was not adequately managing its chemical inventory. Despite efforts to address identified deficiencies, recent walkdowns by LANL personnel found that problems related to chemical accounting and tracking persist. As a result, direction has been issued for chemical owners and responsible line managers to perform a physical inventory of chemical containers to update and validate the inventory tracking system by the end of the month. Additionally, FODs are being required to develop processes to prevent unauthorized hazardous chemicals from entering their facilities and begin implementing these processes by November 30th.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 21, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 21, 2007

Plutonium Facility (TA-55): LANL has removed the safeguarded trailers from the pad at TA-55 and is evaluating the pad's future use, possibly in support of waste operations (site rep weekly 10/28/05).

Criticality Safety: On Thursday, TA-55 paused all fissile material movements except those involving waste, shipping and receiving, and Pu-238; workers are placing operations in a safe condition for an extended period. This was a prudent response after LANL determined on Wednesday that the margin of safety for four vault rooms with extensive neutron shielding is less than previously believed under normal conditions and is incompletely understood under credible upsets, independent of the presence of neutron poison (boron). New criticality safety evaluations are being prepared for the vault. LANL will resume each unit operation after screening and confirming adequate margin exists (site rep weeklies 9/7/07, 8/31/07).

Safety Basis: At present, LANL anticipates insufficient funding in FY-08 to fully implement updated safety bases, to assess facility-specific impacts of the updated seismic spectrum, and to develop a new CMR safety basis supporting post-2010 operations. LANL nuclear facilities are now operating under a set of safety bases ranging up to 12 years old. LANL has proposed interim technical safety requirements as a stop-gap measure for CMR and intends to propose several safety bases to NNSA within the next two weeks, including TA-55, Area G, and WETF (site rep weeklies 8/3/07, 6/29/07).

Plutonium-238 Operations: TA-55 has resumed Pu-238 pyrolysis of combustible residues, which generates a safer, more chemically inert ash; however, the ash is classified as homogenous waste and lacks an approved WIPP disposal pathway; this is a long-standing problem. TA-55 also continues to successfully run bench-scale aqueous scrap recovery, in the absence of the full-scale line; this is a high-dose operation, resulting in some operators being work-restricted (site rep weekly 6/23/06).

Transuranic Waste Operations: LANL has declared a potential inadequacy in safety analysis related to Area G's lack of drum venting capability. Last Thursday, workers opened an unvented low-activity drum, counter to procedure, after removing the drum from a vented over-pack. The event was discovered on Friday when the same crew encountered another unvented drum but properly responded by stopping work. Area G has 43 unvented drums that were found and segregated last October because LANL has no approved means to vent these drums (site rep weekly 5/25/07).

LANL has made about 110 shipments to WIPP to date in FY-07, shipping about 2,600 drums and nearly 14 kCi. However, the Area G aboveground inventory (about 130 kCi now) has remained relatively static due to receipts, primarily from TA-55 and the Off-Site Source Recovery Program. Disposal of newly generated waste could be expedited by establishing waste certification capability within TA-55; this has been discussed often, but there has been little progress (site rep weekly 3/2/07).

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF acid and caustic transuranic waste receipt tanks are 85% and 31% full, respectively; processing is expected to resume in February 2008. To support the schedule, LANL has elected to delay removing sludge from a sludge treatment tank that constitutes the facility's largest source-term until after a new drum tumbling unit is installed; this increases this effort's complexity and risk.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 28, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending September 28, 2007

Broderick was at DNFSB-headquarters in Washington D.C. this week.

Plutonium Facility (TA-55): LANL has met its milestone of fabricating 10 QA-accepted pits in FY-07.

Criticality Safety: LANL has analyzed the "as-is" condition and credible upsets in the four TA-55 vault rooms in question and has concluded that adequate margin-of-safety exists; LANL has also determined that mass or density limits need to be reduced, in at least two rooms, or an engineered solution needs to be implemented to assure can spacing. Vault fissile material moves remain secured.

This week, after reviewing criticality safety implications, TA-55 resumed a limited number of fissile material operations that improve the facility's safety posture going into the 7-week planned outage, scheduled to begin Nov 5th; examples include processing solutions, terminating furnace runs, emptying furnaces, and removing small analytical specimens. LANL is piloting a screening and resumption review/approval process for the remaining operations. Both NNSA criticality safety personnel and the recently re-established LANL criticality safety committee are conducting oversight.

Site-wide Emergency Exercise: LANL ran its annual exercise on Wednesday; it involved a simulated Pu-238 lab-room explosion in TA-55, facility evacuation, and fire department response. Some artificiality was necessary: before this exercise, lab-room personnel placed work in a safe condition, monitored, and exited to the corridors; fire-fighters and their 2 vehicles were pre-screened by security.

Some emergency capabilities were well-demonstrated (e.g., evacuation). However, two key elements were not well-demonstrated and may need attention. Specifically, these are LANL and the fire department's capabilities to (1) manage resources and address a radiological accident of this scale at TA-55, and (2) provide timely and proper response to contaminated, severely injured personnel. For example, in this exercise, the TA-55 facility incident command (FIC) was overly-crowded but needed more resources; as-is, the FIC appeared challenged. Also, the fire department response was overly-simulated, and the responders present were underutilized. The response for 2 postulated severely injured and contaminated workers was initially simulated and appeared inadequate when it did occur.

Transuranic Waste Operations: This week, LANL completed a review on implementation of new safety basis controls at the RANT shipping facility that support shipping about two-hundred high-activity waste drums to WIPP. Comment resolution is underway (site rep weeklies 9/14/07, 6/22/07).

The concern at RANT has been the building's seismic capacity, which LANL now believes to be adequate for an 800 to 1,000 year return-period earthquake (i.e., PC-2, safety-significant). While the new controls permit a factor of 8 increase in radioactive inventory inside the building, the predicted unmitigated accident consequences have dropped an order of magnitude compared to prior analyses (i.e., to 63 rem for seismic-induced fire); this is due to use of the new TRU standard (DOE STD-5506). The safety-class engineered control is the containers; the specific administrative controls at the safety-class level include radioactive and combustible inventory limits, hot-work restrictions, fueled vehicle restrictions, and separation distance to exterior drum staging. Safety-significant controls include the structure, the fire suppression system, and nearby ground-slope (site rep weekly 7/28/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 5, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 5, 2007

Plutonium Facility (TA-55): The following are noteworthy: • LANL has proposed a new TA-55 safety basis to replace the 1996 facility safety analysis report and the 2005 interim technical safety requirements; if approved, LANL estimates it will take a year to implement within the current budget. • LANL has issued a report on the June Director's Assessment; the report has about 100 findings and basically concludes that TA-55 is not supported in a manner commensurate with its national importance; that operations are not being performed to modern nuclear standards; and that work is done safely primarily due to the collaboration and experience of personnel. • The TA-55 confinement boundary was systematically extended this week to include the tunnel, which is being modified to support nuclear material radiography. • TA-55 is considering splitting the upcoming outage, with the first phase starting on Oct 14th; this takes advantage of the current pause in fissile material operations and would permit some operations in November (site rep weeklies 9/7/07, 8/24/07, 6/22/07, 6/15/07).

Criticality Safety: TA-55 has piloted the screening process on select aqueous operations and finalized the screening procedure; the pilot included two dozen operations, of which half were found to require some future action, ranging from a minor change to full evaluation. These results are consistent with the 2006 screens; the difference now is increased emphasis on identifying unprotected assumptions, on considering credible upsets more deliberately, and on documenting technical rationale more thoroughly.

TA-55 plans to screen about 500 unit operations before they resume. Near-term priorities are assay equipment, and material management & transfer systems – basically, key capabilities for inventorying and moving material around the facility. Vault operations also are a key capability to be screened early; however, the vault analyses are convoluted, and vault operations are likely to be challenging to demonstrably show to have adequate margin-of-safety with existing analyses (site rep weekly 8/31/07).

Transuranic (TRU) Waste Operations: Unrecognized unvented drums are increasingly problematic here (site rep weekly 9/21/07). On Wednesday, the WCRR repackaging facility suspended operations due to the deflagration hazard from unvented internal containers, which can have volumes up to 30 gallons; the safety basis prohibits unvented internal drums, but a purpose of the facility is to remove such drums and containers. For the interim, LANL has proposed using radiography to confirm that drums coming to WCRR have low hydrogen retention potential and can be safely remediated.

The risks associated with the aboveground TRU inventory at Area G are being reassessed under a new safety basis, expected now in November; the 2003 safety basis identified about three-dozen scenarios with unmitigated consequence between 1 and 1,800 Rem CEDE. In spite of making more than 110 shipments to WIPP in FY-07, this inventory has remained largely unchanged because of receipts of newly generated waste, principally from TA-55 (site rep weeklies 9/21/07, 1/5/07).

Due to funding issues, LANL is beginning to close down the project for a new storage and shipping facility for newly generated TRU waste. It may be appropriate for NNSA and LANL to examine certifying and shipping such waste directly from TA-55 (e.g., using the safeguarded trailer pad); this could reduce the drum handling and opening requirements for drums after they leave TA-55 and thereby reduce the load on the Area G legacy waste project (site rep weeklies 3/2/07, 2/17/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 12, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 12, 2007

Broderick was off-site this week.

Federal Oversight: A team from the DOE Office of Independent Oversight (HS-64) will be here next week, preparing for their biennial review, scheduled for Oct 29th - Nov 9th (site rep weekly 7/13/07).

Seismic Criteria: LANL has submitted a two-year \$11M project execution plan for analyzing the effects of the increased seismic spectrum on nuclear facilities; the non-nuclear scope requires 5 years and \$9M. LANL is revising the plan based on only \$0.8M available in FY-08 (site rep weekly 8/3/07).

Transuranic Waste Operations: Waste characterization operations were suspended Wednesday after a WGI employee sustained a foot injury Monday; WGI and LANL have launched a Type-B like investigation. The line of responsibility is convoluted since WGI employees work at LANL under a contract administered by the DOE-EM Carlsbad Field Office; NNSA locally provides oversight.

Resumption of the WCRR repackaging facility is imminent but will be restricted to a small number of drums that have low potential for hydrogen retention. LANL will submit a justification for continued operation with controls intended to prevent processing drums with prohibited (e.g., sealed) containers.

Plutonium Facility (TA-55): TA-55 (PF-4) starts a two-week outage Monday, Oct 15th; a second outage is planned for December. Initial focus is on walk-downs, condition assessments, and drawing updates for some safety-related systems (e.g., ventilation, instrument air, chlorine, steam, wet-vacuum, and acidic waste). Other priorities include certifying fissile material handlers, implementing an integrated plan-of-the-day, and continuing criticality safety reviews. While these initial outages may be uneven, the outage approach should lay a framework for continuously improving TA-55 infrastructure.

Chemistry and Metallurgy Research Building Replacement Project: NNSA has provided LANL comments on the rev 0 draft preliminary documented safety analysis (PDSA); NNSA and LANL expect the rev 1 draft PDSA to be ready in November and to be a substantial improvement. Separately, NNSA has directed LANL to perform a ventilation system evaluation, per the Recommendation 04-2 implementation plan, using the rev 1 draft PDSA and DOE's Jan 2006 evaluation guidance.

Radioactive Liquid Waste Treatment Facility (RLWTF): As of this week, the acidic transuranic waste receipt tank is essentially full; the caustic waste receipt tank is at 36 %. Modifications to the treatment room continue. LANL is considering starting acidic waste treatment before caustic-related modifications are finished; concurrent modification and treatment would introduce new risks.

Chemistry and Metallurgy Research Building (CMR): On Aug 31st, LANL proposed interim technical safety requirements as a stop-gap for CMR operating to an out-dated safety basis (i.e., a 1998 basis for interim operation). Among the proposed changes are a new limiting condition for operation (LCO) for hot-cell safety features (e.g., interlocks, boot-seals), a new LCO for fire doors, an improved LCO for hot-cell wing ventilation, and improved administrative controls for toxic gas control and for operations center staffing (site rep weeklies 9/21/07, 8/3/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 19, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 19, 2007

NNSA and the staff held a video-teleconference this week on projects for new TRU waste facilities.

Criticality Safety: For TA-55 vault rooms, LANL is preparing new, compliant evaluations to address deficiencies. For all the other TA-55 fissile material operations, the screening process developed two weeks ago has proven difficult to implement in a timely and effective manner and is being re-evaluated. Once operations start to resume on a larger scale, operators may become confused on which specific work stations are still paused; TA-55 has a solution for this, but it is not yet implemented.

Transuranic (TRU) Waste Operations: On Tuesday, the WCRR repackaging facility resumed work, focused on drums with low hydrogen retention potential; WCRR has remediated 24 high-activity drums since that campaign began in September. Most Area G characterization activities remain suspended; the investigation of the Oct 8th foot injury continues. The RANT facility is making thrice-weekly shipments to WIPP from the certified backlog; high-activity drums are now being shipped, increasing the total curie-contents for some payloads by a factor of four compared to prior shipments.

Radioactive Liquid Waste Treatment Facility (RLWTF) Replacement Project: The 44-year-old RLWTF is in degraded material condition and is a potential single-point-failure for nearly all LANL nuclear operations. In the last year, due to budgetary issues, the replacement project has slipped expected operational startup from mid-FY-10 to early FY-12 (site rep weeklies 2/9/07, 9/8/06).

While the replacement facility is designated Hazard Category 2 (HC-2), chemicals are the dominant hazard. A radioactive inventory about 40 % above the HC-2 threshold is postulated following a TA-55 upset; more could be done to retain that inventory in TA-55, the more robust facility. Given this inventory and the postulated accidents, LANL believes that the new facility warrants PC-2 for the seismic and wind hazards, and requires a few safety-significant systems, including the structure, fire suppression, vehicle barriers, chemical spill containment, TRU and bulk chemical tanks and piping, and TRU drums; neither active nor passive building confinement is proposed as safety-significant.

Weapons Engineering Tritium Facility: On Monday, during multiple concurrent operations to prepare a vessel to ship tritium offsite, an operator inadvertently transferred gas to the vessel before it had been fully prepared to receive the material. Portions of the vessel preparation activity are robustly proceduralized, but ancillary gas transfers rely heavily on operator experience and training. The mis-transferred material was fully contained by the vessel, and the pressure was well below the rated capacity; however, the conditions did exceed the vessel's normal service specifications. In response, the facility has taken action to increase the rigor of gas transfers by requiring an independent review of the proposed flow path and valve lineup by a second qualified operator prior to executing a transfer.

Los Alamos Neutron Science Center (LANSCE): LANSCE is nearing completion of the readiness process for dynamic experiments with plutonium, which may begin next week (site rep weekly 6/22/07).

Sigma Complex (TA-3-66): On Tuesday, a researcher in Sigma, a radiological facility, received a small burn when a chemical powder he was working with ignited. A second researcher put out the fire with an extinguisher. The fire department responded an hour later, due to communication delays mainly at the facility, and confirmed that the fire was extinguished.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 26, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending October 26, 2007

The staff held a video-teleconference with NNSA and LANL on fire protection this week.

Criticality Safety: This week, LANL submitted the required evaluation of the safety of the situation (EOSS) related to the criticality safety issues in four TA-55 vault rooms and a basement storage location. The EOSS concluded that, given their current inventories, the locations of concern had adequate safety margin under current and credible upset conditions. Material movements in these locations remain secured, and new bounding criticality safety evaluations are being prepared. In the interim, the lab may pursue a justification for continued operations (JCO) to begin removing material from these locations (site rep weeklies 10/19/07, 10/5/07, 9/28/07, 9/21/07).

The following were important developments this week in the effort to evaluate and resume other fissile material unit operations at TA-55: • LANL reaffirmed its commitment to executing the screening process essentially as originally envisioned, rather than pursuing changes that could have expedited resumption but potentially decreased the breadth and rigor of the screening process. • An individual has been assigned to perform a crucial project management role and is spearheading the development of a project plan and prioritized schedule. • Increased attention was observed on the part of NNSA and LANL management and LANL's institutional Nuclear Criticality Safety Committee.

Plutonium Facility (TA-55): Since few operations have completed the criticality screening and resumption process, the facility will extend the first phase of its planned outage through at least next week to maximize beneficial use of the programmatic downtime (site rep weekly 10/12/07).

Transuranic Waste Operations: NNSA has approved closure of 2 longstanding potential inadequacies of safety analysis (PISAs) related to Area G dome fabric and waste drum banding; NNSA withheld approval of a related Area G seismic analysis, pending near-term submittal and review of an updated Area G safety basis. The 2003 safety basis credits drum banding and waste storage domes, including structural members and fabric, as safety-class controls. LANL used guidance in the new DOE standard on safety analysis for transuranic waste facilities to justify reclassifying these two engineered controls as defense-in-depth. The new standard, DOE STD-5506, specifies damage ratios that are approved for use under various postulated accident scenarios, including those for which storage domes and drum banding were previously credited. Using the new damage ratios, the level of consequence mitigation provided by these controls was much lower than previously considered (site rep weekly 7/21/06).

Last week, LANL also submitted a JCO to address the handling and staging of the 53 existing unvented drums at Area G, as well as any that may be discovered in the future. The JCO identifies new safety-significant controls for addressing unvented drums including engineered restraints for drum lids, administrative requirements for drum isolation and segregation, and associated controls for forklift operations. Per NNSA direction, this JCO also prescribes controls to prevent prohibited container types from being shipped to the WCRR repackaging facility (site rep weekly 10/12/07).

Packaging and Transportation (P&T): This week, Department of Transportation conducted an unannounced compliance audit of LANL radioactive material P&T operations, including transuranic waste shipments to WIPP, and low specific activity and Type A shipments at LANL. No violations against LANL P&T were issued, but concerns related to subcontractor P&T operations were identified.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 2, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 2, 2007

Burnfield, Minnema, and Volgeneau were on site this week observing the DOE-HS biennial review (site rep weekly 10/12/07). Elliott was on site for a NNSA headquarters review of criticality safety.

Transuranic Waste Operations: Most Area G dome operations were suspended last Friday (10/25) due to emergent criticality safety questions; some activities not involving drum movement are resuming today. RANT waste shipments slowed in the last week due to the Area G issue and to WIPP slowing down receipts. WCRR repackaging activities were suspended Tuesday when workers found a 55 gal drum with an internal unvented 15 gal container, counter to recently imposed controls; the technicians stopped work and, following management review, placed WCRR in a safe condition.

Criticality Safety: On Oct 24th, NNSA facility reps in Area G questioned a waste drum with a non-conformance tag indicating that the contents exceeded the fissile-gram-equivalent limit (200 g); LANL management conservatively suspended operations and declared a criticality safety infraction. Out of about 20,000 above-ground drums, six exceed the limit, based on original waste generator data, and 58 exceed the limit, based on more-recent shipment certification data. LANL identified controls for high-fissile content drums in 2002, but those controls were not implemented. While mostly a legacy-drum issue, TA-55 has recently been loading drums to close to the limit, exacerbating the issue. Operations management is not always notified when such drums are found or received. Next week, Area G plans to start segregating and spacing high-fissile-content drums in accordance with criticality safety requirements.

Plutonium Facility (TA-55): TA-55 now plans to continue the outage until Jan 3rd. The criticality safety reviews continue; LANL still needs to apply more attention to planning, scheduling, and resourcing these reviews like a project to ensure that they are both timely and thorough.

On Oct 18th, NNSA directed LANL to provide an integrated priority list for TA-55 safety system upgrades identified in the recently proposed safety basis update, the Dec 2006 confinement ventilation evaluation, and the TA-55 reinvestment project. NNSA expects LANL to identify near-term funding for those upgrades necessary to protect assumptions in the safety basis accident analyses. NNSA also expects to complete its review of the safety basis by Feb 1st (site rep weeklies 10/5/07, 5/4/07).

Nuclear Infrastructure: TA-55 is probably LANL's best maintained nuclear facility, but at current funding levels, sub-standard practices persist. For example, TA-55 does not have a proactive maintenance and surveillance program for radioactive liquid systems; they rely on radiological control indicators to identify leaks after they occur. Facility personnel have spent the last week tracking down the source of one such leak for one glovebox line and discovered another leak in the process.

TA-55 lacks sufficient staffing and resources to implement such programs. The LANL Director's Assessment recognized the base issues: TA-55 operations are not being performed to modern nuclear standards, and TA-55 is not supported in a manner commensurate with its national importance. Other issues – such as the recent concerns on criticality safety, fissile material handler certification, and safety system operability – will likely recur until resolving the base issues becomes an institutional priority (site rep weeklies 10/5/07, 9/21/07, 8/31/07, 8/17/07, 7/27/07, 7/20/07, 6/22/07, 3/2/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 9, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 9, 2007

Minnema was on site this week observing the DOE-HS biennial review, which concluded this week.

Operations: LANL has consolidated several Facility Operations Director (FOD) organizations for radiological facilities and has placed explosive operations under the FOD responsible for WETF.

Transuranic (TRU) Waste Operations: Waste operations are struggling to address work control, safety basis, and formality of operations issues. Recent events include: • Last Friday, Area G's radiological-scale drum repackaging operation slightly exceeded its procedural limit (0.56 Ci); LANL has concluded that this limit is not controlled by the safety basis; however, by extrapolating this logic, Area G could repackage high-activity drums, even though Area G lacks safety-related controls for such operations; LANL intends to include a material-at-risk limit for this activity in the upcoming Area G safety basis update. • Based on guidance from the criticality safety group, Area G issued a standing order and procedure for segregating the high-fissile content drums that were reported last week. • Area G also lifted restrictions that had been imposed in response to the criticality safety infraction and resumed limited drum movements to support TRU waste shipments from RANT.

Given the rate of safety and compliance issues experienced in recent weeks, LANL management effected a safety pause of the environmental programs directorate, including TRU operations, on Wednesday. LANL management also committed to perform an external review of environmental programs operations within the next few weeks using senior-level expertise via corporate reach-back.

LANL has recognized for some time the nature of most of these issues and the need for TRU waste facilities to evolve to an efficient, disciplined, and organizationally integrated state. In 2005, LANL provided NNSA an improvement plan designed to achieve such a state. In early 2006, NNSA added this improvement plan to appropriate authorization agreements. Then, in mid-2006, LANL curtailed the plan for budgetary reasons (site rep weekly 8/18/06).

Weapons Engineering Tritium Facility (WETF): Facility management declared two Potential Inadequacies of the Safety Analysis (PISA) this week based on issues raised during the DOE-HS biennial review. One PISA related to whether glovebox pressure relief devices (known as bubblers) could perform their credited safety functions in their current configuration. The other PISA involved a surveillance requirement for the fire suppression system whose acceptance criterion may not be adequate to ensure credited system operability. WETF management issued several standing orders as an interim response to the PISAs until longer-term solutions can be investigated and developed. One standing order restricted the processing of pressurized hydrogen isotopes in gloveboxes. The other imposes a more conservative threshold value for surveillance results that would prompt appropriate actions to verify system operability.

Plutonium Facility (TA-55): TA-55 continues to struggle with infrastructure challenges. This week, TA-55 experienced issues with its paging system and chlorine detection system. Both of these safety significant systems are antiquated and require upgrades or replacement (site rep weekly 7/20/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 16, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 16, 2007

Davis, Plaue, and Tontodonato were on site this week reviewing the status of federal oversight, the contractor assurance system, plutonium and waste operations, safety bases, and formality of operations.

Engineering: LANL is struggling to put in place the configuration management, maintenance, and engineering elements to demonstrably assure that vital safety systems will adequately perform their credited safety functions. A recent LANL staffing analysis indicated that laboratory engineering staffing levels are at about half the assessed need (i.e., about 90 total are needed while 50 are in place). Present budget uncertainties impede adding engineering staff, and LANL management has made only a small number of limited-term offers. This will complicate efforts to address issues related to vital safety systems on a timely basis (ref: Board letter 10/16/07, site rep weeklies 7/27/07, 7/20/07).

Transuranic (TRU) Waste Operations: LANL has slipped proposing an updated safety basis for Area G TRU waste storage to 2nd quarter FY-08. Under the current safety basis (2003), Area G is postulated to have some of the highest-consequence accident scenarios of any LANL nuclear facility, but Area G has few engineered controls other than drums themselves. The slip delays a much-needed improvement in defining the risks and ensuring the adequacy of controls (site rep weekly 10/5/07).

Area G waste characterization operations remain largely curtailed, pending followup actions in response to the Oct 8th worker injury. Drum movements in Area G have been largely restricted to those necessary to segregate the roughly 60 suspected high-fissile content drums to address a criticality safety concern. Segregation is almost complete (site rep weeklies 11/2/07, 10/12/07).

WCRR drum repackaging operations resumed this week following implementation of tighter controls to ensure WCRR does not receive drums with a high potential for hydrogen retention. Under current restrictions, WCRR will only be able to repackage about a dozen drums. LANL intends to propose a safety basis change shortly that would expand this set. WCRR has remediated 39 high-activity drums since that campaign began in September (site rep weeklies 11/2/07, 10/26/07, 10/12/07).

Plutonium Facility (TA-55): The outage and the criticality safety reviews of unit operations at TA-55 continue; the focus of the latter has shifted to resuming plutonium machining operations; reviews related to vault storage, assay, and material transfer systems are still underway.

LANL has completed formal certification of fissile material handlers, which supercedes the provisional certifications put in place in August. LANL also intends to complete in January the integrated priority list, requested by NNSA, for safety system upgrades, including confinement ventilation and other systems identified in the recently proposed safety basis. LANL intends to use this time to improve the pedigree of data supporting the prioritization of much-needed facility investment (site rep weeklies 11/2/07, 10/26/07, 10/12/07, 8/17/07).

Chemistry and Metallurgy Research Building (CMR): CMR has entered an outage in parallel with TA-55. LANL also has proposed a safety basis strategy for post-2010 operation and expects to propose a compliant safety basis in FY-09. LANL continues to develop a risk-mitigation plan focused on reducing operational foot-print and material-at-risk (Board letter 10/23/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 23, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending November 23, 2007

Management: LANL has proposed to NNSA a plan to reduce the LANS workforce by 500 to 750 people (i.e., 6 to 9 %), first by a voluntary process and later, if needed, by involuntary selection.

Chemistry and Metallurgy Research Building Replacement Project: The site reps understand that the multi-contractor design team for the Hazard Category 2 (HC-2) nuclear facility may need to begin to phase down in January, given the continuing resolution and current budget projections; design and construction of the radiological facility (RLUOB) would likely continue. Such a phase-down would further delay the replacement facility and extend the period during which NNSA will likely depend on CMR, particularly if the design team dissolves and has to be reconstituted later (Board ltr 10/23/07).

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL has chosen to accept potential mission impacts on TA-55 and concurrently resume acid and caustic waste treatment following major RLWTF upgrades, instead of pursuing quicker, less-conservative options (site rep weekly 10/12/07). Such treatment could resume in March 2008, provided NNSA accepts LANL's proposal to confirm readiness via a LANL readiness assessment (RA) instead of operational readiness reviews (ORRs).

By the DOE startup order (O 425.1C), the readiness review decision hinges on the facility's hazard categorization: ORRs are needed for HC-2; an RA may be appropriate for HC-3. RLWTF operates under a 1995 safety basis that is based on a HC-3 designation. In 2002, NNSA questioned the HC-3 designation; subsequent authorization agreements cite that correspondence as elevating the facility to HC-2. Unlike WCRR, which was recently elevated to HC-2, RLWTF never received the upgrades to the physical plant, safety basis, procedures, and training, or the ORRs commensurate with HC-2.

The nuclear safety significance of this depends on RLWTF's radioactive inventory, which is typically half or less of the HC-2 threshold but has been postulated to exceed that threshold following certain unlikely TA-55 upsets. LANL is basing the upcoming safety basis upgrade for RLWTF on HC-3 and, last week, submitted justification for HC-3; this hazard categorization decision may also apply to the RLWTF replacement facility, which is now in preliminary design, has been designated HC-2, but does not meet some HC-2 expectations (site rep weeklies 10/19/07, 8/3/07, 10/11/02).

Plutonium Facility (TA-55): TA-55 is in the middle of a major switchgear upgrade project. Last Tuesday (11/13), to save two days of production, project personnel deviated from their design change package and unsuccessfully attempted to switch from the primary feed to the alternate feed before work was completed on the latter; they safely stopped work when the Ops Center could not confirm both feeds were operational. LANL is addressing the communication and configuration control issues.

Earlier this year, TA-55 began to process high-amerium residues under the Recommendation 94-1 stabilization program; processing accelerated in September in order to place operations in a safe state while criticality safety is being assessed. Although appropriate measures were taken to prevent large increases in whole-body dose during this campaign, extremity dose (i.e., to the hands) was not addressed. LANL determined this week that the extremity doses to some affected workers in the last two months are much higher than expected and, in one case, are at the highest level seen in a decade. LANL is reviewing the adequacy of radiological controls for this type and intensity of operation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 30, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending November 30, 2007

Plutonium Facility (TA-55): LANL has proposed a justification for continued operations (JCO) to allow limited material movements in 4 vault rooms and one basement storage location (site rep weekly 10/26/07). The JCO is based on analysis from recently prepared criticality safety evaluations (CSE) that reflect the actual (i.e. "as-found") material present in these locations. The JCO would allow retrieval, but not addition, of items from all locations in vault rooms A and G and from shelves and floor locations in vault rooms B and I. Retrieving items from BISCO-lined drawers in rooms B and I and the basement location are not covered in this JCO because the safety margins for some potential upsets (e.g. dropping a container onto another container during retrieval) are not evaluated in the "as-found" CSEs. However, to support an upcoming required material inventory, the JCO does allow single containers in BISCO-lined drawers to be lifted vertically, inspected, and returned to their original locations.

Activities outside these vault rooms and basement storage location continue to be dispositioned through the lab's internal review and operational release process. A LANS corporate partner is providing two much-needed additional criticality safety engineers beginning Monday. Relatedly, a second dedicated team of criticality safety engineers will begin reviewing unit operations next week. This should alleviate a process choke point and help expedite safe resumption. LANL also intends to identify a single individual to manage and coordinate all aspects of the resumption process.

Transuranic Waste Operations: The Environmental Programs directorate is developing a set of corrective actions and organizational changes to be captured in a forthcoming Deliberate Operations Project Execution Plan (PEP). This is in response to a number of recent safety and operational compliance issues and formal direction from the NNSA site office (site rep weekly 11/9/07).

An external team, consisting of senior-level managers from LANS corporate partners, completed a review this week of the formality of waste operations, and the adequacy and completeness of the draft Deliberate Operations PEP being prepared by the Environmental Programs directorate. Preliminary observations included: • funding has not been allocated to implement a new, compliant Area G safety basis, whose submittal is pending, • there is no dedicated operations funding devoted to implementing important institutional safety programs, • an organizational tolerance of substandard conditions has become normalized within the directorate. A final report is expected by December 13th.

Additionally, the WCRR repackaging facility has faced challenges in effectively implementing controls to prohibit the receipt of drums with unvented inner containers that could retain significant amounts of hydrogen. Receipt of prohibited drums has resulted in two recent Technical Safety Requirement (TSR) violations at WCRR. Last week, LANL submitted a safety basis addendum and TSR changes that address this issue by allowing unvented inner waste packages of up to 30 gallons to be breached and remediated in the WCRR glovebox. Five new TSR-level specific administrative controls have been identified to support this new activity. New controls include the use of a lid restraining device during container breaching, 30 minute cessation of glovebox operations after breaching to allow hydrogen diffusion, and ignition-source controls related to electrical grounding of unvented containers, de-energizing glovebox receptacles, and use of non-sparking tools (site rep weeklies 11/2/07, 10/5/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 7, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 7, 2007

The Board and a staff team were here this week reviewing LANL activities. On Wednesday evening, the Board conducted a public hearing and meeting to assess LANL's safety posture, including the response to suggested actions in a Board letter to the NNSA Administrator, dated Feb 1st, 2007.

Contaminated Puncture Wound Followup: LANL has completed the final dose assessment for the individual who sustained the contaminated puncture wound in January in the Chemistry and Metallurgy Research Building (site rep weekly 1/12/07). The whole-body committed effective dose has a central tendency of about 7.4 rem, which exceeds the federal annual limit for occupational exposure (5 rem, 10 CFR 835). The bone-surface committed effective dose is about 128 rem, which also exceeds the applicable federal annual limit (50 rem, 10 CFR 835). The final dose assessment was delayed because the individual elected to receive periodic chelation therapy for an extended period; the site reps understand that periodic chelation was very effective in reducing retention of plutonium and dose.

LANL's corrective actions from this event and the similar event at TA-55 have been reported (site rep weeklies 9/7/07, 8/31/07, 6/1/07). Contaminated puncture wounds are fortunately rare in the DOE complex. Further systematic review may be valuable to capture lessons learned and to guide the early decision-making process when responding to any future such events at DOE sites.

Nuclear Material Packaging: The Plutonium Facility (TA-55) reported this week that about a quarter of a 5-year-old lot of empty Hagan containers in storage had deteriorated filter gaskets. The Hagan – also referred to as the TA-55 standard container – is a robust screw-top design that is widely used for storing plutonium outside glove-box lines; it is the container-of-choice for current repackaging efforts. The gaskets in question provide the seal between the lids and the lid-filters and were expected to have a 10 to 20 year shelf-life. The deterioration seems localized to the outer edge and to not affect the sealing surfaces, indicating, so far, no loss of sealing function.

TA-54 (Area G) transuranic waste drums use the same gasket and filter design in their lids, and they have been alerted. TA-55 is evaluating quality assurance and safety basis implications using the nonconformance reporting (NCR) system and the unreviewed safety question (USQ) process.

Transuranic Waste Operations: NNSA has approved changes to the WCRR facility safety basis to allow remediation of unvented waste containers up to 30 gallons (site rep weekly 11/30/07).

Infrastructure: Last Friday, high wind and rain caused power loss and water in-leakage in several nuclear facilities, including TA-55, which appears to have significant roof bubbling and degradation.

Federal Oversight: A team from the DOE Office of Independent Oversight (HS-64) was here this week to discuss with NNSA and LANL their draft report from their biennial review. The DOE Inspector General (DOE-IG) also had a team here this week conducting a review of the DOE Material Recycle and Recovery Program, which at LANL is closely linked to nuclear material stabilization and packaging (site rep weeklies 11/9/07, 10/12/07, 4/27/07, 10/29/06).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 14, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 14, 2007

Eyler, Plaue, Shuffler, and Stokes were here this week reviewing the RLWTF replacement project.

Accident Investigation Criteria: Last week's report discussed the final dose, recently assigned, from a contaminated puncture wound that occurred in January. While the whole-body dose was less than the applicable DOE criteria for a federal investigation, the bone-surface dose exceeded the organ dose criteria (ref: DOE O 225.1A). The time lapse between the event and the dose assignment (11 months) illustrates a challenge for effectively applying the criteria and launching a timely federal investigation.

Plutonium Facility (TA-55): On Monday, two electricians working on the switchgear upgrade project shorted two wires that, unbeknownst to them, were energized. This led to a partial power loss in half the building, including partial loss of continuous air monitoring. Because of the upgrade project, the facility is not in a normal lineup; while attempting to restore power, operators took actions that led to a near-complete power loss in that half of the building, including loss of lab-room ventilation (Zone 2). Next, because of changing air pressure, ventilation in the other half of the building was secured. Throughout the event, the facility ensured primary confinement by maintaining glove-box exhaust ventilation (Zone 1); personnel also took appropriate actions, including orderly exit from the facility.

LANL review identified several problems. The integrated work documents were not at the work-site. These work documents had also not been updated to reflect that two fuses were in place, energizing these leads. The facility had learned a week earlier, during weather-related power disruptions, that these fuses were required for the operations center to have an accurate indication of the status of the electrical lineup. The intent was to pull the fuses when hazardous work was being conducted, but the hazard was not recognized for the cabinet being worked. TA-55 has suspended electrical work for this project pending improvements to supervision, configuration management, and work control.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL now expects to restore most of the transuranic (TRU) waste treatment capability in Spring 2008 and install a new drum tumbler next summer. The safety of this operation depends, in part, on the amount and concentration of TRU waste coming from TA-55. NNSA has identified a need to confirm the adequacy of the controls at TA-55 that limit this inventory to less than the hazard category 2 (HC-2) threshold (i.e., 55 Ci, Am-241).

RLWTF Replacement Project: The replacement facility is in an "enhanced" preliminary design phase. While it has a HC-2 designation, the current design does not meet expectations for a HC-2 nuclear facility (site rep weekly 10/19/07). The HC-2 designation is driven by an assumption that the TRU treatment tanks are full of liquid that is at the waste acceptance criteria (WAC) concentrations, thereby maximizing the facility's ability to tolerate an extended shutdown of treatment operations.

However, the mission-need does not appear to require this much capacity: the operating strategy assumes TRU treatment only about 20 hours per month (i.e., 13 % utility, assuming a 40-hour week). It would also take 6 and 30 months for the facility to accumulate radioactivity to the HC-2 threshold, assuming WAC and normal concentrations, respectively. A better strategy might be to ensure the facility can minimize down-time, maximize utility, and minimize in-process inventory. This would require ensuring the adequacy of inventory-limiting controls in the generator facilities (e.g., TA-55).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 21, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 21, 2007

Transuranic Waste Operations: LANL is poised to approve resumption of characterization activities involving one real-time radiography (RTR) unit at Area G. Operations at both RTR units have been suspended since October when a subcontractor employee sustained a serious foot injury. To address judgements of need from the accident investigation, the waste characterization subcontractor revised procedures and integrated work documents to ensure adequate hazard identification and activity-level controls, strengthened conduct of operations through additional training and mentoring, and validated the adequacy of engineered safety features (site rep weekly 10/12/07).

Criticality Safety: NNSA has approved a justification for continued operations (JCO) that allows limited material movements in 4 vault rooms and a basement storage location in the Plutonium Facility (site rep weeklies 11/30/07, 9/21/07). Items may be retrieved from shelf and floor locations in the 4 rooms and drawers in the basement storage cabinet. No items may be added; retrievals and inventory activities must be conducted under a suite of temporary TSR-level controls. Retrieval of material from drawers in 2 vault rooms is not allowed since the safety margin for credible overmass upsets (i.e. material drops) for these activities has yet to be analyzed. New criticality safety evaluations (CSE) for vault rooms are in development, and most rooms are scheduled to be operating under approved, compliant CSEs by February.

Chemistry and Metallurgy Research Building (CMR): Last Friday, 3 KSL workers had nasal smears positive for uranium (192 dpm max. activity) following a CAM alarm in a Wing 4 lab room. The workers were performing D&D activities that involved removing and downsizing potentially internally-contaminated copper piping. Due to communication issues, the workers believed an RCT had lifted respirator requirements for pipe cutting. In actuality, the removed piping had not been surveyed by an RCT and was later found to have internal alpha contamination of 490k dpm.

The radiological work permit for this job requires continuous RCT coverage. However, RCTs are staffed at the 50% level at CMR on Fridays, and the RCT assigned to this job was distracted responding to other potential radiological events and trying to support other on-going work activities. This event highlights the need to augment critical support resources or to scale back operations to a level that can be adequately supported by existing resources.

Management: Approximately 430 employees will be leaving the laboratory by January 10th as part of the voluntary self-selection portion of LANL's workforce restructuring plan. Personnel in some critical functional areas (e.g. cognizant system engineers, criticality safety engineers) were barred from self-selection. However, voluntary staffing reductions were accepted in a number of categories involving key deployed personnel who support nuclear operations such as training coordinators, maintenance technicians, and nuclear work planners.

Staffing reductions in these already overtaxed areas may affect nuclear operations and the timely implementation of important on-going improvement initiatives, such as Formality of Operations. The full impacts of reduced staffing levels are still coming into focus since nuclear facility managers, who use these deployed resources, were not appraised of potential losses during the self-selection process and are only now becoming fully aware of the magnitude of the shortfalls they will be facing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 28, 2007

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending December 28, 2007

This week, the laboratory was closed. Broderick was off-site.

Integrated Work Management (IWM): On Nov 30th, LANL issued a revised institutional IWM Procedure, IMP 300.5, which is the first substantive revision in nearly 3 years. While work control expectations are basically unchanged, IMP 300.5 now separates activities into four categories – maintenance, operations, research and development, and subcontracted work – and references separate tailored procedures/processes for each. This may lead to departures from the integrated work document (IWD) format used for the last 4 years for moderate and high hazard work, as long as the intent is met by other means, particularly for routine operations where LANL favors strengthening operating procedures per the DOE conduct of operations order (DOE O 5480.19, Chapter 16). IMP 300.5 also now suggests, rather than requires, use of the automated job hazard analysis tool.

Implementation of sound, consistent work control practices here has long been problematic; it remains to be seen if IMP 300.5 will address prior issues and bring improvement (site rep weeklies 10/31/03, 1/16/04, 5/7/04, 9/24/04, 6/3/05, 7/8/05, 11/4/05, 3/31/06, 8/18/06, 10/20/06, 3/23/07, 9/7/07, 9/14/07).

Readiness Reviews: NNSA and LANL have increased the rigor of the process for assigning the level of readiness review before startup or restart of nuclear activities. Specifically, facilities now prepare an activity description worksheet (ADW) that supplements the startup notification report (SNR) and that describes in detail each proposed new activity. The facility then formally presents the new activity to the new joint LANL-NNSA evaluation team – the JET, which meets periodically, reviews the ADWs, and formally recommends the level of review to NNSA management. The JET process, implemented in November, has begun well and has the potential to increase readiness review quality and consistency, which have been challenging here in the past (site rep weeklies 5/11/07, 12/29/06).

Nuclear Environmental Sites: In one of its first actions, the JET has proposed that NNSA and LANL conduct operational readiness reviews (ORRs) before remediation begins at TA-21 Material Disposal Area B (MDA-B). MDA-B occupies about 5.5 acres and is located on the south side of DP Road, opposite several commercial businesses. Between 1944 and 1948, LANL disposed of chemical and radioactive wastes at MDA-B in ten 40 ft wide by 12 ft deep trenches. The entire area's radioactive inventory is estimated to be about 12 Ci (i.e., about 200 g Pu-239 equivalent). LANL intends to remove the trench contents and clean up the site to meet residential requirements. Remediation is complicated by proximity of the public and the presence of small amounts of shock-sensitive chemicals. LANL expects to submit a safety basis for the remediation in January and to have an experienced subcontractor remediate MDA-B after the ORRs are conducted, expected in FY-09.

Criticality Safety: In September, due to emergent concerns with vault limits, LANL committed to reviewing criticality safety limits for 520 unit operations in the Plutonium Facility (TA-55) before the operations resumed. As of last week, per the LANL database, 218 operations have entered the review process (42 %); 188 have been accepted or have had actions approved (36 %); 64 have been recommended for release (12 %); and 32 have been released, based on criticality safety evaluations done since April 2006 (6 %). While the fraction released is low, the scope is sufficient to allow significant operations to proceed, including: sampling, staging, pyro-chemistry, casting, machining, roasting, blending, drop-box transfers, and container welding; many of these will resume next month.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 4, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 4, 2008

LANL resumed operations Wednesday, Jan 2nd.

Plutonium Facility (TA-55): TA-55 has secured from the outage, is continuing criticality safety reviews of fissile material operations, and is systematically resuming programmatic operations.

Radiological Protection: On Thursday evening, radiography of a TA-55 component began and then was immediately secured when it was discovered that one person had not exited the room. Electronic dosimetry indicates little exposure; thermoluminescent dosimeter (TLD) results are pending. TA-55 has suspended radiography until the event can be critiqued and corrective actions put in place.

Chemistry and Metallurgy Research Building (CMR): CMR is working to resolve problems with the compressed air system, which is a balance-of-plant system affecting safety-significant ventilation and safety-class fire suppression (i.e., freeze protection). Testing raised concerns that backup air compressors might not automatically start upon loss of control air. CMR is providing capability to promptly detect and manually recover from such loss by continuously manning the operations center.

Radioactive Liquid Waste Treatment Facility: Upgrades to the transuranic (TRU) waste treatment systems continue on a tight schedule; craft are working 12-hour shifts this weekend to prepare for hydro-tests. Also, the Joint Evaluation Team (JET) is proposing that TRU operations resume following a lab readiness assessment, with NNSA as the authorization authority; this is subject to NNSA accepting the facility as a hazard category 3 nuclear facility (site rep weeklies 12/14/07, 11/23/07).

Environmental and Waste Operations: On Dec 20th, LANL submitted an outline of a project execution plan (PEP) for disciplined operations in the Environmental Protection Directorate (EP); this was developed in response to NNSA direction and was motivated by 31 safety and compliance issues that arose in Area G and elsewhere last September and October (site rep weeklies 11/30/07, 11/9/07).

LANL causal analysis found that integrated safety management is not effectively implemented for EP: clear roles and responsibilities are not always defined and understood; line management responsibility for safety is not always evident; competence commensurate with responsibility has not always been established; hazard identification and control implementation are not comprehensive, including for safety bases; priorities are not balanced; safety standards and requirements are not always identified.

In November, LANL began to address these issues, including pausing operations to communicate lessons learned and management expectations. Per the outline, LANL intends to: • evaluate the 2005 improvement plan, develop detailed cost estimates, and issue the initial PEP by Jan 14th; • implement formality of operations, as funding permits, by Jan 31st; • implement integrated work planning and authorization, establish and staff a core Area G operations organization, and propose an updated Area G safety basis by Feb 29th; • identify gaps between current procedures and the safety basis by Mar 28th; • identify critical EP staff positions, establish a formal procedure review process, develop qualification standards, and train personnel on conduct of operations by Apr 7th; • implement the new Area G safety basis, at risk, in advance of NNSA approval, projected for Jun 29th; • verify safety basis implementation by Jul 31st; • walk down all EP facilities and correct safety concerns, by Sep 30th.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 11, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending January 11, 2008

Contaminated Puncture Wound Followup: Pursuant to 10 CFR 820.8(b), *Special Report Orders*, NNSA has directed LANL to submit a report within 90 days on the causes and the corrective actions for the CMR and TA-55 contaminated puncture wounds of January 2007. NNSA and the DOE Office of Enforcement will then evaluate the effectiveness of the actions taken (site rep weekly 12/7/07).

Federal Oversight: On December 20th, the NNSA Site Office issued the Performance Evaluation Plan (PEP) for FY08. The PEP includes performance based incentives (PBI) and for the first time defines award term measures that would allow LANS to earn a one year extension to the prime contract. Incentivized objectives for FY08 include: • manufacturing 10 diamond stamped pits; • strengthening and exercising integrated nuclear planning capabilities; • formalizing plans for CMR facility consolidation and life extension; • continuing, and in some cases accelerating, implementation of Formality of Operations; • developing system design descriptions for safety-significant systems; • performing system assessments and developing system health reports for safety-class systems; • achieving timely implementation of new safety bases, including TA-55; • improving the effectiveness of integrated work management; • completing high priority corrective actions on time.

Transuranic (TRU) Waste Operations: LANL has requested NNSA input this week on a proposed safety basis strategy for Area G; LANL intends to submit a new safety basis by the end of February and to implement the new safety basis, in parallel with NNSA review, by the end of June. Operations to be considered include not only drum characterization, storage, and movement, but also TRUPACT mobile loading, underground waste retrieval, drum repackaging, and large-item (e.g., glove-box) size reduction. LANL intends to submit a basis for interim operation (BIO), continue reliance on containers as the principal engineered control, and increase reliance on specific administrative controls (SACs), such as restrictions on vehicle access, combustibles, and drum storage array arrangement.

The expedited timing is driven by several factors. The current Area G safety basis (2003) is not fully implemented; LANL views efforts would be better spent accelerating implementation of a new safety basis. Under the current safety basis, Area G is postulated to have some of the highest-consequence accident scenarios of any LANL nuclear facility, but Area G has few engineered controls. LANL believes that a reevaluation of the accident scenario suite using the new DOE standard (DOE STD-5506) would reduce predicted unmitigated off-site consequences by an order of magnitude (i.e., to about 120 rem); while this still exceeds the DOE evaluation guideline (25 rem), it changes the perspective on the risks and the level of mitigation needed from controls. Area G needs a safety basis closely tailored to expedited TRU waste de-inventory and shipment, to support completing TRU operations by 2012 and closing Area G in 2015, as required by the New Mexico Consent Order.

Some of the more significant safety concerns in Area G involve the high-activity drums (325), the unvented drums (~53), and the unvented, high-activity drums (~10), common to both sets. LANL continues to make progress in remediating and shipping the set of 235 high-activity drums discussed in the Deputy Secretary's letter of Apr 9th, 2007. On Nov 30th, NNSA approved a justification for continued operation for movement, segregation, and storage of unvented drums. On Dec 13th, LANL proposed an Area G safety basis addendum for remotely-controlled venting of unvented drums, necessary to support the high-activity drum campaign (site rep weeklies 11/16/07, 10/26/07, 10/5/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 15, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 15, 2008

The staff had a video-teleconference with LANL and NNSA this week on the use of the MASS code.

Plutonium Facility (TA-55): On Wednesday, a deflagration occurred in two electrical cabinets in a pump house (PF-10) when an operator pressed a button to start an electrical fire pump. The cause was a natural gas leak elsewhere at TA-55; natural gas migrated down an electrical conduit to the cabinets and ignited when the button was pressed. In response, TA-55 isolated natural gas until the leak was found and patched Wednesday night. There were no injuries and no impact on nuclear operations. Visible damage is limited to bowing of the cabinet doors. TA-55 will conduct full diagnostics before returning affected equipment to service and is investigating the cause of the leak.

Criticality Safety: TA-55 has updated its criticality safety procedure to reduce operator dependency on the MASS code. TA-55 also began a pilot last week on having fissile material handlers use status boards and material transfer worksheets, in place of the traditional pegboards, to track fissile material quantities. The emphasis is on the operator confirming before material transfer that an over-mass condition will not occur at the destination or along the transfer route, which seems appropriate.

DOE Independent Oversight: On Jan 30th, The DOE Office of Independent Oversight (DOE-HS) transmitted to NNSA and LANL its final report from the biennial review conducted last November. DOE-HS was complimentary of the facility operations director (FOD) model, the formality of operations and safety basis improvement initiatives, the site chief engineer and design authority functions, the management review boards, the dashboard metrics management system, and the new Director's institutional assessment program, which is roughly analogous to the facility evaluation boards conducted at other sites. DOE-HS also pointed out continuing weaknesses in LANL implementing an effective integrated work management (IWM) process, integrating IWM with formality of operations, and ensuring that safety systems in nuclear facilities can demonstrably perform their safety functions. On the federal side, DOE-HS asserted that NNSA headquarters and site office oversight is still ineffective. DOE-HS recommendations include accelerating current improvement initiatives; addressing skill-mix issues and staffing shortfalls in engineering, safety basis, and health & safety; and expediting operability determinations and reliability improvements for nuclear facility safety systems. NNSA and LANL corrective action plans are expected in late March.

Transuranic Waste Operations: Approximately 53 unvented drums with the potential to retain flammable gas mixtures have been identified and segregated under a justification for continued operations at Area G. Last week, NNSA approved a DSA Addendum that analyzes drum deflagration scenarios associated with handling and remotely venting these types of drums. A suite of new safety-significant specific administrative controls were identified for these operations that involve: segregation and over-packs or lid restraints for unvented drums, venting only in an enclosure using non-sparking tools and drum grounding, and using only forklifts with enclosed cabs and spotters for movements. A contractor readiness assessment (RA) followed by an NNSA RA will be conducted to verify readiness to perform remote drum venting activities (site rep weeklies 1/11/08, 10/26/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 18, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: Chuck Keilers and Brett Broderick, LANL Site Representative
SUBJECT: Activity Report for Week Ending January 18, 2008

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 25, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending January 25, 2008

Environmental and Waste Operations: LANL continues to develop the project execution plan (PEP) for disciplined operations in the Environmental Protection Directorate. In a letter dated Dec. 20th, 2007, LANL projected submitting the PEP, detailed cost estimates, and an evaluation of the similar-purpose 2005 improvement plan by Jan 14th. The PEP and its effective execution are key elements in LANL resolving issues in environmental and waste operations (e.g., Area G, RLWTF) such as ineffective implementation of integrated safety management and incomplete implementation of nuclear facility safety bases (site rep weeklies 1/11/08, 1/4/08, 11/30/07, 11/9/07).

Transuranic Waste Operations: LANL has declared a technical safety requirement violation in Area G, based on having a number of unvented legacy waste boxes that date from the 1980s. The Area G safety basis requires transuranic waste containers to be vented to prevent flammable gas buildup.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL is still targeting completing upgrades and resuming RLWTF transuranic waste treatment in March. Before resumption, LANL plans to improve conduct of operations, maintenance, and engineering for the transuranic waste treatment systems, including reconstituting the technical baseline, and to verify implementation during the LANL readiness assessment. The model for these activities is the process LANL used for RANT and WCRR last year before those facilities began the high-activity drum campaign. Separately, LANL is strengthening its case for a hazard category 3 designation, including considering controls for upstream waste generators. These are positive steps (site rep weeklies 1/4/08, 12/14/07, 11/23/07).

Waste Characterization, Reduction, and Repackaging Facility (WCRR): The WCRR glovebox does not have automatic fire suppression as required by DOE directives (DOE Order 420.1B, DOE Standard 1066). An equivalency based on compensatory measures is currently in place to support the on-going processing campaign, but is limited to operations involving waste up to 300 PE-Ci combustible equivalent. In November, LANL submitted an engineering study of potential upgrades to provide compliant automatic fire suppression to allow future processing in excess of the current limit.

The study evaluated options including gaseous systems, water-based systems, and glovebox inertion. Water-based systems were identified as the most desirable. A system using standard sprinklers was evaluated, but not selected due to concerns about discharged water breaching glovebox confinement and the resulting contamination in the event of failure. The study recommended a water mist system due to considerations involving suppression capability, effluent management and cost effectiveness. This week, the NNSA site office returned the study to the contractor without action because it had not been reviewed and approved by the appropriate Authority Having Jurisdiction prior to submission.

Chemistry and Metallurgy Research Building (CMR): CMR continues to work to resolve air compressor problems that affect the safety-significant ventilation and safety-class fire suppression systems (site rep weekly 1/4/08). During the week of Jan 11th, the facility secured from continuously manning the operations center, based on having personnel on-call via pager who can respond quickly.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 1, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 1, 2008

Gerlach was on site attending Safety Basis Academy training.

Chemistry and Metallurgy Research Building (CMR): Next week, an NNSA team will perform a detailed review of CMR processes and special nuclear material storage locations to better understand the quantity of material at risk (MAR) required to perform CMR's mission. Results of this review will inform decisions related to the acceptability of the current MAR limit for the facility.

This week, NNSA also approved a safety basis strategy for a life extension DSA that would support CMR operations beyond 2010. This DSA, scheduled for submission in FY09, is intended to be compliant with the nuclear safety management rule (10 CFR 830) and will cover enduring CMR mission activities and reflect efforts to consolidate the facility's operational and hazard footprint via wing closures, process changes, and MAR reductions. To achieve compliance, DSA development will involve a new hazard identification process and include new hazard and accident analyses. The strategy document also recognizes that most engineered controls available to be credited have known vulnerabilities and do not meet current standards. NNSA expects that all vulnerabilities will be clearly identified and analyzed and exemption requests prepared, as appropriate. The strategy document postulates a worst case unmitigated dose of less than 150 rem for the bounding accident.

In parallel with CMR life extension planning, NNSA headquarters has tasked LANL to lead an evaluation of alternatives to using CMR to support programmatic activities past 2010. Facility support options required to be evaluated include Lawrence Livermore National Laboratory's Superblock, the Nevada Test Site's Device Assembly Facility, and some combination of LANL's Plutonium Facility and the CMR Replacement Radiological Laboratory Utility Office Building.

Radiochemistry Facility (TA-48-1): On Jan. 23rd, three continuous air monitors alarmed during routine operations being performed in TA-48-1 hot cells in support of medical isotope production. Personnel evacuated appropriately, and nasals smears of affected individuals were negative.

An air compressor failure caused inlet air dampers on two exhaust fans to close, securing ventilation air flow to the hot cells. With hot cell ventilation isolated, exhaust flow from an adjacent fume hood caused the required differential pressure between the hot cells and occupied gallery area to be lost. The change in differential pressure created conditions for an air-flow reversal where contaminated air was drawn from the hot cells into the area where personnel were performing work. No alarms are installed to alert personnel of ventilation failure. Hot cell operations are suspended pending equipment repair and installation of personnel warning devices.

Radioactive Liquid Waste Treatment Facility (RLWTF): In a January 17th letter, the New Mexico Environmental Department challenged the RLWTF's exemption from the Resource Conservation and Recovery Act (RCRA) and directed NNSA and the laboratory to submit a RCRA permit application by April 30, 2008. The implications for radioactive liquid waste treatment operations are unclear.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 8, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending February 8, 2008

Bamdad, Plaue, March, McFarland, and Spatz were here reviewing the proposed TA-55 safety basis.

Environmental and Waste Operations: This week, LANL briefed the NNSA Site Office on the Project Execution Plan (PEP) for disciplined operations in the Environmental Protection Directorate; LANL expects to submit the PEP next week. Key elements include standing up an integrated project team (IPT) management structure, hiring and embedding experienced senior operations managers, reviewing procedures, evaluating behavior-based safety programs, walking down facilities and fixing unsafe conditions, submitting a new safety basis for Area G this month, and implementing that safety basis in parallel with NNSA review, which LANL projects will be completed by June.

While many of these elements are useful, the linkage between the actions and the problems to be addressed is fading; it is not clear that the elements constitute the necessary and sufficient solution set to address the issues in a timely manner, nor is it clear that adequate compensatory measures are in place to support current operations. The sense-of-urgency expressed in December has waned, and several milestones that were to be completed in January have been missed, including evaluating the curtailed 2005 improvement plan, developing detailed cost estimates, implementing formality of operations, as funding permits, and submitting the PEP. This is unfortunate, given the significance of the issues previously reported (site rep weeklies 1/11/08, 1/4/08, 11/30/07, 11/16/07, 11/9/07).

Plutonium Facility (TA-55): LANL has developed an integrated project list (IPL) that captures and prioritizes upgrades and modifications required to meet safety, infrastructure, and programmatic needs. The IPL will be continually updated, through formal change control, as new projects are identified and circumstances change. Separately, LANL has a parent-company assist team evaluating options to improve building confinement (i.e., Recommendation 04-2); results are expected in April and will be folded into the IPL (site rep weeklies 11/16/07, 11/2/07).

Weapons Engineering Tritium Facility (WETF): Last Fall, WETF placed gloveboxes in standby pending actions to ensure that pressure relief devices (i.e., bubblers) would prevent gloveboxes from exceeding their maximum allowed working pressure. On Jan 30th, NNSA approved a justification for continued operation that, coupled with hardware modifications, addresses this condition. This week, WETF verified the new controls and resumed normal glovebox operations (site rep weekly 11/9/07).

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL has an extensive double-lined low-level liquid waste collection system that includes 65 low-point vaults that would capture any leakage from the primary piping. About one-third to one-half of the vaults have detectors in alarm, indicating water intrusion. In September 2007, LANL began sampling vault water and has completed sampling from all but two of these vaults. This week, LANL reported that one vault near WCRR has water with detectable activity (i.e., 71 pCi/L); the other vaults sampled have been less-than-detectable. LANL suspects the cause is legacy contamination from WCRR and is investigating the cause.

Transuranic Waste Operations: Based on verification of controls, LANL and the Carlsbad contractor have resumed operations of the second real-time radiography unit; operations were suspended following the foot injury last October (site rep weekly 12/21/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 22, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending February 22, 2008

The site reps were on-travel and at DNFSB headquarters in Washington DC for most of this week. The staff also had a video-teleconference on the safety of waste and environmental programs.

Radiological Facilities: LANL has corrected conditions that caused an air-flow reversal in the Radiochemistry Laboratory (TA-48-1) hot cells and has resumed hot cell operation (site rep weekly 2/1/08). While investigating the event, LANL found safety-related weaknesses involving ventilation maintenance and testing, temporary modification control, equipment potential single-point-failures, and operator responsiveness to alarms.

These safety problems are not unique to TA-48; LANL recently found another facility with similar configuration control issues. Radiological facilities have less oversight and lower management awareness of such issues than hazard category 2 and 3 nuclear facilities. Under the formality of operations initiative, LANL is becoming increasingly aware of these problems in radiological facilities and is beginning to set consistent expectations. However, determining extent-of-condition and implementing consistent practices that ensure safe operations with high confidence will be challenging.

Criticality Safety: TA-55 has resumed operations for one vault room after completing the augmented limit review process for it; two other vault rooms are close to resumption. Vault operations were suspended last September due to margin-of-safety concerns (site rep weeklies 9/28/07, 9/21/07).

Transuranic (TRU) Waste Operations: LANL has resumed the new TRU waste facility project. The New Mexico Environmental Department has concerns on the supporting Resource Conservation and Recovery Act permit modification. Because of these concerns and funding issues, NNSA and LANL appear at-risk of a multi-year hiatus in the repackaging, storage, and shipping functions for newly generated TRU waste after the legacy waste project closes (site rep weekly 10/5/07).

Integrated Nuclear Planning: Last week, representatives from LANL, NNSA Headquarters, and the NNSA Site Office held an Integrated Nuclear Planning (INP) workshop. LANL presented their recently established Office of Integrated Nuclear Planning organization, which has secured dedicated funding and time-and-effort commitments for key individuals. Agenda items included a general discussion on how onsite INP efforts would interface with the headquarters-level Integrated Plutonium Activities Committee. Other topics included CMR life extension; impacts to TA-55 aqueous processing, specifically the Advanced Recovery and Integrated Extraction System, due to budgetary issues and headquarters sponsorship changes; and the outlook for future LANL Pu-238 operations.

Chemistry and Metallurgy Research Building (CMR): Floor storage wells in Wing 9 are equipped with a cooling water system. The cooling water system is not authorized for use and was thought to be isolated, however, water was recently discovered in the system. In response, facility personnel removed the residual water and installed robust isolation to preclude inadvertent water intrusion in the future. Water extracted from the system was sampled and found to have no detectable activity.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 29, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and C. H. Keilers, Jr.

SUBJECT: Los Alamos Report for Week Ending February 29, 2008

The staff held a teleconference on the Radioactive Liquid Waste Treatment Facility Replacement.

Environmental and Waste Operations: On Tuesday (2/26), LANL announced organizational changes to strengthen operations under the Environmental Programs Directorate. LANL also paused non-essential waste operations, to allow management and the workforce to refocus on improving disciplined operations. Essential operations are continuing, particularly at the Radioactive Liquid Waste Treatment Facility (RLWTF). Some operations have been reviewed and may resume today, such as Area G waste characterization and the WCRR waste repackaging facility. Remaining operations, particularly at Area G, are scheduled to resume next week (site rep weekly 2/8/08).

This week's activities included setting expectations, evaluating material condition and operations (e.g., rounds, operations center), reviewing closure of readiness review and accident investigation findings, and conducting training on safety basis and conduct of operations. On-going actions for Area G include: • assigning a senior supervisory watch, • communicating roles and responsibilities, • achieving interim operator qualifications, • cross-walking activities and work control documentation (IWDs), • implementing select elements of formality of operations, • reviewing occurrence reports, • selecting technical safety requirements (TSRs) common to the current and proposed safety bases for accelerated implementation, and • drafting an updated disciplined operations project execution plan.

Weapons Engineering Tritium Facility (WETF): On Monday (2/25), during multiple concurrent operations, an operator inadvertently transferred approximately 3 grams of tritium to the tritium waste treatment system (TWTS). The mis-transferred material was fully contained by the TWTS.

These types of gas transfers at WETF are not proceduralized and rely heavily on operator training and experience. In response to a similar inadvertent transfer event in October, the facility developed a standing order that required an independent review of the proposed flow path and valve lineup by a second qualified operator prior to executing a gas transfer. Despite the standing order, in practice, operators were identifying and independently verifying the intended flow path, but not explicitly specifying and verifying the proper valve alignment prior to transfers. Failure to confirm the necessary valve lineup created the conditions for this event, since independent activities involving another portion of the tritium gas handling system caused the actual system configuration to be different than the operator expected. Gas transfers have been suspended until the verification process can be strengthened and confirmed to be effectively implemented (site rep weekly 10/19/07).

Chemistry and Metallurgy Research Building Replacement (CMRR): NNSA has received funding to continue design activities for the CMRR Nuclear Facility and its special equipment (e.g. gloveboxes). Recent program direction calls for the existing project scope to be validated against NNSA Complex Transformation planning in parallel with continued design. However, any future scope changes resulting from the validation effort could perturb the design and delay the project, prolonging reliance on the existing CMR facility (site rep weekly 11/23/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 7, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 7, 2008

Andersen, Bamdad, Kasdorf, Kimball, and Plaue were on site reviewing CMRR. The staff separately discussed notional TA-55 facility improvements, RLWTF influent projections, and nuclear material management and packaging. Broderick was off-site one day for a Pantex lightning protection review.

Environmental and Waste Operations: Waste operations, including Area G, resumed this week after thorough review by its strengthened operations management team. Overall, the two-week pause accomplished the objective of jump-starting improvements in disciplined operations. In the process, operational awareness increased, but also the post-resumption scope grew and schedule lengthened.

For example, LANL now anticipates that the new Area G safety basis, submitted last Friday, will be implemented by December instead of June, the prior estimate; consequently, LANL intends to verify the current safety basis is fully implemented this month, reducing the dependence on the new safety basis prior to its federal acceptance. Overall, LANL expects to issue an updated disciplined operations improvement plan next week. Risk reduction depends on timely execution of the plan while continuing operations that reduce transuranic waste inventory (site rep weeklies 2/29/08, 2/8/08).

Chemistry and Metallurgy Research Building Replacement Project (CMRR): The radiological lab construction remains on track for late FY09 beneficial occupancy. The nuclear facility preliminary design is in review; final design is expected to start in late 2008 following the records of decision for the site-wide and the programmatic environmental impact statements. Technical challenges include: structural design to accommodate higher vertical accelerations from the new seismic spectrum; glove-box automatic fire suppression; trolley penetrations through fire barriers; and the tunnel interface with PF-4. NNSA and LANL continue to evolve the path-forward on the building confinement strategy.

Plutonium Facility (TA-55): TA-55 operational tempo is increasing, as expected, following the outage. The criticality safety augmented limit reviews continue; vault operations are limited, but major manufacturing and aqueous operations are released. Separately, LANL has a notional, phased, path-forward that could substantially improve PF-4's engineered safety systems, including confinement ventilation, within a few years at reasonable cost; this is being considered for the integrated priority list.

Chemistry and Metallurgy Research Building (CMR): LANL is preparing a safety basis addendum to support the large vessel cleanout project in Wing 9 of CMR. The current project scope would remove and dispose of actinide materials in 9 legacy vessels currently staged at TA-55 (a commitment under Rec. 94-1/00-1). This would leave 5 additional vessels staged at TA-55 whose bulk materials have been largely removed but require additional remediation before they can be dispositioned. The ability to process these additional vessels in the future at the CMRR facility is unclear since the Large Vessel Handling mission is being considered for removal from the CMRR project scope.

Weapons Engineering Tritium Facility (WETF): NNSA's intent is to deinventory and downgrade WETF; deinventory without updating the safety basis had been suggested. LANL observed this week that it will take several years to deinventory. Assuming NNSA approval of the proposed safety basis this month, LANL intends to implement the new safety basis by September, thereby ensuring that on-going operations, including deinventory, occur under an up-to-date, compliant, safety basis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 14, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 14, 2008

The staff held a teleconference with LANL and NNSA to discuss Integrated Work Management.

Federal Oversight: The NNSA site office has issued a Revitalization Plan that analyzes issues and obstacles hindering performance and identifies actions designed to address these issues. The plan includes actions to augment staffing, address training deficiencies, and ensure more reasonable management span of control by creating a new assistant manager position that would oversee facility representatives (FR) and safety system oversight (SSO) engineers. Additionally, the site office recently hired two experienced individuals to serve as an FR and SSO engineer, respectively, and full qualifications have been achieved or are imminent for the site office criticality safety engineer, emergency management program manager, and two current FRs (site rep weekly 8/10/07).

Integrated Nuclear Planning (INP): This week, LANL, the NNSA site office, and NNSA headquarters held an INP workshop focused on projects for new waste facilities including the Radioactive Liquid Waste Treatment Facility Replacement (RLWTF-R), the new solid transuranic waste facility (New TRU), and the Waste Management Risk Mitigation project (Tank Farm). The workshop was productive, but highlighted a number of significant challenges facing these projects.

The TA-50 Tank Farm project was halted in April 2007 at about 75% construction due to project management and quality assurance issues. Additional evaluation of the severity and cost to disposition roughly 50 open non-conformance reports is required before a decision can be made to complete the partially constructed facility or pursue a new facility. The decision on how to proceed with this project will affect the RLWTF-R, which currently relies on the Tank Farm for low-level liquid waste influent storage. If this capability cannot be performed by the Tank Farm, then additional influent tankage must be added to the scope of the RLWTF-R project, requiring redesign work and likely prolonging reliance on the problematic existing facility. Finally, the baseline capabilities to be provided by the New TRU facility are being re-evaluated. Marginal existing facilities such as WCRR and RANT could be called upon to perform a longer-term mission than originally envisioned if certain capabilities such as repackaging or shipping are dropped from the New TRU project scope. Also, due to schedule delays in this project, a gap exists between when Area G must cease receipt of newly generated waste and when the New TRU facility will become operational. The strategy for dealing with newly generated waste during this gap is not yet clear (site rep weeklies 2/22/08, 4/13/07).

Plutonium Facility: The programmatic mission to use TA-55 aqueous processing capabilities to produce 330 kg of polished plutonium oxide by 2012 for use in the Mixed Oxide Fuel Fabrication Facility has been terminated. This provides an opportunity to use this newly available aqueous processing capacity to expedite other ongoing efforts, such as chemical stabilization of legacy materials (Rec 94-1/00-1). Current plans call for legacy residues to be repackaged into more robust storage containers by late-2010, but subsequent handling of these materials would still be required for ultimate processing and stabilization. Although it requires more up-front funding, accelerating legacy material stabilization would reduce worker exposure and risk by eliminating the need to handle these items multiple times. This approach could also increase operational flexibility by freeing up highly constrained vault space currently being consumed by these items.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 21, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 21, 2008

Criticality Safety: NNSA has approved a revised TA-55 justification for continued operation that releases Vault Room A, which is one of the four rooms identified last September as having reduced criticality safety margin. NNSA asserts that the Room A updated criticality safety evaluation bounds both normal and credible abnormal conditions. NNSA expects LANL to incorporate assumptions into the TA-55 technical safety requirements during the next safety basis update (site rep weekly 2/22/08).

Environmental and Waste Operations: LANL has issued an updated disciplined operations project execution plan that runs through December, as expected; it also includes a crosswalk of findings to corrective actions. Management operational awareness, worker sensitivity to stop-work conditions, and overall emphasis on operating to the approved safety bases have increased. Appropriate senior management attention is currently being applied (site rep weekly 3/7/08).

Transuranic Waste Operations: As of last Friday, the current high-activity drum campaign has shipped about one-third of the drums and one-fifth of the inventory (i.e., 84 of the 235 original drums, 6 kCi of 30 kCi). Also, the WCRR repackaging facility has remediated more than 150 high-activity drums and appears close to completing its part of this campaign. There are about 12 unvented, high-activity drums that will need to undergo remote venting when that operation starts up, which is expected after upcoming LANL and NNSA readiness assessments (site rep weekly 2/15/08).

Recent problems include two instances of cracked glove-box windows and one instance of a failed glove during heavy item handling at WCRR; Area G had a non-waste drum with a calibration source tip-over on a conveyor due to a software problem. LANL is appropriately addressing these events.

Chemistry and Metallurgy Research Building (CMR): As part of facility life extension, NNSA has directed LANL to take actions following up on a federal review of CMR material-at-risk last month. That review noted accomplishments but also several weaknesses, including sub-standard packaging (e.g., bagged slip-lid cans, a few bagged plastic bottles) and inappropriate crediting of ANSI and other containers that may be susceptible to failure during a fire (ref: site rep weeklies 1/6/06, 2/3/06). Key directed actions included: ensuring ownership and timely decisions on disposition of legacy materials; expediting disposal of waste and non-required legacy material; establishing a single material tracking system; moving retained legacy materials to a more robust storage location (i.e., from floor safes to the vault); revisiting the technical basis for excluding certain packaged materials from material-at-risk.

Also, last week, CMR had a contamination-release in the Wing 3 sample management room, resulting in 3 of 4 people in the room with bootie contaminations and 100k dpm maximum on the floor; airborne indicators and nasal smears were negative. CMR is reviewing waste bag-out and sample transfer practices for lessons learned.

Los Alamos Neutron Science Center (LANSCE): LANL has changed plans and is now preparing to propose that LANSCE continue to operate under the current basis for interim operation (BIO) during this year's run cycle, which runs from May through December (site rep weeklies 10/19/07, 6/22/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 28, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending March 28, 2008

The staff held a teleconference on the Radioactive Liquid Waste Treatment Facility Replacement.

Plutonium Facility (TA-55): On Thursday, TA-55 had a valid glove-box over-temperature alarm during a furnace operation that resulted in a fire department response. The facility appears to have responded appropriately and is critiquing the event and the response next week.

Weapons Engineering Tritium Facility (WETF): NNSA site office personnel toured WETF this week to evaluate the effectiveness of corrective actions taken in response to the February 25th tritium mis-transfer event. NNSA determined that the revised process for controlling tritium gas transfers still lacks sufficient rigor. As a result, WETF management has restricted the facility to one operation at a time involving the gas handling system; both recent inadvertent transfers occurred during multiple concurrent operations. Management also mandated Operations Manager involvement and concurrence prior to gas transfers (site rep weeklies 2/29/08, 10/19/07).

Radioactive Liquid Waste Treatment Facility (RLWTF): RLWTF is currently operating as a hazard category 2 nuclear facility. LANL has proposed downgrading RLWTF to hazard category 3 based on administrative limits for the aggregate material-at-risk allowed in the facility, and on controls in place upstream at the Plutonium Facility that preclude an inadvertent criticality.

The RLWTF hazard categorization decision will affect the level of readiness review required to restart transuranic liquid processing when ongoing modifications are completed. Also, both the RLWTF Replacement Project and the Waste Management Risk Mitigation (i.e., tank farm) Project currently assume hazard category 2 designations but are evaluating whether a similar categorization downgrade would be justified for their efforts (site rep weekly 11/23/07).

Formality of Operations: LANL needs to execute on a number of proposed institutional initiatives to improve worker safety and the site's overall nuclear safety posture. These principally involve four areas: safety bases, integrated work management, quality assurance, and formality of operations. The last focuses on operations, engineering, maintenance, and training.

Implementation of formality of operations appears to be slipping. Last week, LANL submitted to NNSA a revised schedule and draft criteria-for-success for a two-phased implementation of formality of operations. "Core" implementation would constitute a minimum state of compliance with applicable requirements and may include interim compensatory measures that are no longer required once "mature" implementation is achieved.

While progress is being made, the detailed scope definition needed to reliably estimate costs and establish a schedule appears to still be evolving. Developing a consensus, appropriately detailed definition of scope is complicated by the facts that the scope is large; the scope covers the broad range of LANL operations and delivered services; and the resources and staffing to achieve timely implementation clearly exceed those currently available.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 4, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 4, 2008

Keilers was off-site this week.

Plutonium Facility (TA-55): Last week, operators were conducting normal plutonium operations in two furnaces and post-modification function-testing on a third furnace that was in an abnormal configuration that heated the glove-box more than normal. In this condition, rising ambient glove-box temperature exceeded the thermal detector setpoint of 190° F, prompting an alarm. Personnel exited to the corridor and upon assessment of the situation made a conscious decision to re-enter the room to de-energize the 3 operating furnaces in the alarmed box. There was no damage or material release. The Fire Department responded.

Follow-up investigation identified issues with the configuration management of over-temperature controls for furnace operations: some interlocked over-temperature alarms were found to be disabled; over-temperature set-points were higher than necessary; and the abnormally-configured furnace was operating without one of its normally-installed temperature sensors. In response to this event, facility management has suspended all furnace operations. Identified corrective actions include evaluating, baselining, and formalizing configuration control for alarm status and set-points for all furnace controllers; and establishing formal pre-operational checks to ensure proper equipment configuration and system line-ups. Operating groups must present corrective actions to a board that will evaluate their adequacy and approve resumption (site rep weekly 3/28/08).

This week, NNSA also formally sent comments on the proposed TA-55 DSA; these require resolution before the document can be approved. NNSA noted that the current control strategy is overly-focused on minimizing the building leak path factor and raised the prospect of a condition of approval that mandates the identification of safety system upgrades and a commitment to their implementation.

Chemistry and Metallurgy Research Building (CMR): NNSA has approved a revision to the CMR interim Technical Safety Requirements (iTSR) that addresses discrepancies between the 1998 Basis for Interim Operations (BIO) and the previous set of iTSRs. The revised iTSRs credit new limiting conditions of operation and surveillance requirements for Wing 9 ventilation and a suite of hot cell controls that includes manipulator boot seals, interlocks, door enclosures, shielding, and confinement features. With the exception of one control that is not currently applicable, NNSA expects the new iTSRs to be implemented within eight months (site rep weekly 10/12/07).

Transuranic Waste Operations: Waste remediation in a Permacon at Area G is currently limited to very low activity (about 0.5 PE-Ci) operations involving solidified waste forms. LANL is proposing future activities in this Permacon that would entail prohibited item disposition for debris waste. Currently, this kind of activity would have to be performed in a glovebox at the WCRR repackaging facility. NNSA initially questioned the adequacy of proposed controls for worker protection. LANL is developing engineered confinement features that will reduce reliance on operator personnel protective equipment, such as respirators and anti-contamination clothing.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 11, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 11, 2008

Von Holle was on site this week attending an Enhanced Surveillance Campaign meeting.

Federal Oversight: This week, LASO submitted to NNSA headquarters (NA-10) the LASO-LANL interim corrective action plan developed in response to last year's DOE Office of Independent Oversight (DOE-HSS) review. LASO noted that LANL took immediate actions in response to safety system deficiencies and that this plan builds on those immediate actions. The plan will be finalized and submitted for approval after final headquarters' review (site rep weekly 2/15/08).

Also this week, in response to a Special Report Order (10 CFR 820.8(b)), LANL submitted a report to NNSA headquarters (NA-1) on the causes and the corrective actions for the CMR and TA-55 contaminated puncture wounds of January 2007. LANL observed that a formal corrective action plan is in place, many of the actions are completed, and an effectiveness evaluation has been scheduled for July and August (site rep weeklies 1/11/08, 12/14/07, 12/7/07).

Emergency Management: The postulated highest consequence nuclear accidents at LANL are fire-related. TA-55 responded appropriately to the overheated glove-box during furnace operations on Mar 27th; however, there is a clear need to improve the TA-55 fire pre-plan. Based on site rep observations of drills and exercises last year, this need may not be limited to TA-55. In addition to resources, better definition of possible responses during a fire and of criteria and timing for reentry need consideration.

LANL and the fire department's joint capability to respond to radiological events – such as multiple contaminated, injured people or a fire coupled to radioactive material – has not been well demonstrated recently. Relatedly, the 2004 baseline needs assessment is overdue for update, required every 3 years by DOE O420.1B, *Facility Safety*; also, NNSA and Los Alamos County continue to negotiate on the fire department contract (ref: Board letters 2/1/07, 5/21/05; site rep weeklies 9/28/07, 11/24/06).

Electrical Safety: An electrical disconnect box at the Radioactive Liquid Waste Treatment Facility was recently found to contain a length of metal conduit deliberately installed in place of an electrical fuse. The circuit did have over-current protection upstream, but laboratory management is appropriately treating this discovery as a serious event. The institutional electrical safety committee has been consulted and a plan is being developed to perform sampling inspections to characterize the extent of condition. In addition, this event appears to be spurring action to catalogue, prioritize and systematically address other legacy electrical code compliance issues and known deficiencies.

Los Alamos Neutron Science Center (LANSCE): LANL has proposed a set of experiments be conducted at LANSCE that involve parking a small truck with up to 200 g plutonium-equivalent within a four-sided detector bank. LANL did not propose any additional controls other than an inventory limit, although additional controls (e.g., high-quality containerization) appear warranted.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 18, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and C. H. Keilers, Jr.
SUBJECT: Los Alamos Report for Week Ending April 18, 2008

This is Keilers's last site-rep report. It's been an education and a pleasure to serve in this capacity.

Management: LANL operations management has a fairly complete picture of LANL's nuclear safety challenges and has initiated actions to address or compensate for many challenges. This picture strongly indicates further needs for investing in infrastructure and critical staffing, reducing legacy inventories, and accelerating improvements in formality of operations, quality assurance, and integrated work management. Also, about one-fifth of the LANL workforce has received some training in human performance improvement, an area essential to LANL evolving into a high-reliability organization with attributes such as those described in DNFSB/TECH-35, December 2004.

Safety Basis: The lack of updated safety bases impedes progress. LANL now has 18 nuclear facilities, including on-site transportation and ten environmental sites, covered by nine safety bases. The median and maximum ages for the safety bases are 5 and 12 years. Technical safety requirements have had more recent changes, and safety bases configuration control has improved; the average age of the safety basis document lists is 40 days. However, it's challenging to prioritize improvements, such as confirming adequacy of engineered safety systems, without first having updated control sets, functional classifications, and safety system requirements that are derived from updated safety bases.

Transuranic Waste Operations: Area G aboveground transuranic waste inventory has decreased about 12 % since January 1st and stands at 114 kCi aboveground, including 16 kCi in OSRP sources, as of April 14th. Most of the reduction has occurred since mid-March. The rate of drum shipments has been fairly constant since the June 2006 contract transition: about 250 drums per month, averaging 6 Ci per drum. At this rate, it will take 6 to 7 years to de-inventory the aboveground waste, assuming no further waste receipts. Newly generated waste exacerbates this situation, in more ways than just adding to the inventory. For example, the TA-55 vault has about 14 kCi in Pu-238 residues that ought to be disposed, that could be compliantly packaged for disposal, but that can not meet current waste certification requirements, and therefore has no open disposition path. Improving waste disposition efficiency from the generators to WIPP would improve LANL's nuclear safety posture.

Plutonium Operations: By LANL's metric, the risk associated with non-standard packaging of plutonium in the TA-55 vault has decreased by 40 % since September 2003, primarily due to use of more robust containers. LANL now has about 1,700 non-standard containers, mostly in the TA-55 vault. LANL continues to defer chemical stabilization of some of this material because of aging infrastructure issues with the Radioactive Liquid Waste Treatment Facility and emergent mission priorities (e.g., LLNL mission transfer). Considering criticality safety, LANL has reviewed the limits for three-quarters of TA-55's fissile material operations and expects to complete these reviews within a couple of months; two-thirds of the operations examined have required improvements before resumption. LANL is also updating its criticality safety program improvement plan to reflect actions still required to achieve a program that is fully compliant with national consensus standards.

Tritium Operations: The Weapons Engineering Tritium Facility is decreasing its tritium inventory, which now stands at less than a quarter of that assumed in its 2002 safety basis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 25, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick

SUBJECT: Los Alamos Report for Week Ending April 25, 2008

The staff held a teleconference on the Radioactive Liquid Waste Treatment Facility Replacement.

Plutonium Facility: On Thursday, an inadequately controlled furnace operation caused a glove-box window to crack during post-maintenance testing on two clamshell-type furnaces. After testing the first furnace, an operator opened the clamshell to allow the unit to cool. Then, intending to test the second furnace, the operator inadvertently re-energized the first furnace that remained in an open configuration. This furnace, which is not interlocked to preclude operation when the clamshell is open, ran unattended for a period of time causing the glove-box window to crack due to thermal insult. Personnel de-energized the furnace when they returned to the area and observed the damage. No nuclear material was present and ambient glove-box temperature did not exceed the alarm threshold.

The facility recently underwent a deliberate review and resumption process for furnace operations in response to another inadequately controlled furnace event. Operating procedures were reviewed to ensure that robust pre-operational checks are executed prior to conducting furnace operations. Maintenance personnel typically use these operating procedures to perform post-maintenance tests, however, the maintenance group involved in Thursday's event use dedicated procedures that had not been reviewed and validated during resumption. Facility management suspended furnace operations by this maintenance group until their procedures are revised to include appropriate pre-operational checks and verifications. This event also illustrated opportunities to improve furnace interlocks and to make relationships between controller units and furnaces clearer to operators (site rep weekly 4/4/08).

Safety Basis: LANL has submitted a strategy document defining a path forward for revising the proposed Plutonium Facility DSA and TSRs based on NNSA comments. The goal is to resubmit, before July 2008, a package that includes a clear and consistently applied control selection methodology; validation of inputs and assumptions from key supporting documents (e.g. the leak path factor analysis); and incorporation of planned improvements, including any compensatory measures required until these improvements and upgrades can be implemented (site rep weekly 4/4/08).

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL has proposed downgrading the RLWTF to a hazard category 3 nuclear facility based on limiting aggregate material at risk to less than the hazard category 2 threshold specified by DOE Standard 1027. LANL intended to scale this threshold value for cemented waste drums that can be staged at the facility based on their low release fraction. The standard allows this scaling approach provided that the release fraction used is bounding. NNSA recently challenged the conservatism of the value used by LANL. As a result, the laboratory has decided to forego any scaling for the cemented waste. Revised interim TSRs that reflect this change have been resubmitted for NNSA review and approval (site rep weekly 3/28/07).

Emergency Response: Laboratory personnel held a workshop with members of the Los Alamos Fire Department (LAFD) this week to update and expand pre-response plans for a fire at the Plutonium Facility. This workshop is the latest in a series of positive steps taken by Plutonium Facility management and the LAFD to improve facility familiarization for first responders and to strengthen overall coordination between the facility and the fire department (site rep weekly 4/11/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 2, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick
SUBJECT: Los Alamos Report for Week Ending May 2, 2008

Plutonium Facility: During furnace operations this week, the facility experienced another glove-box thermal alarm. After assessing the situation, personnel re-entered the room and de-energized the 2 operating furnaces. The Fire Department responded and swept the area. No material was released and no equipment was damaged during this event (site rep weeklies 4/25/08, 4/4/08, 3/28/08).

The alarm occurred in the same glove-box line as the over-temperature event on March 27th. At the time of the alarm, only two of three in-line furnaces were running and they appeared to be properly configured and operating as expected. There was no obvious cause for the glove-box temperature to rise above the 190° F alarm set point. The facility has not yet determined if the alarm was valid.

In response to this event, furnace operations in this glove-box line have been suspended. New thermal detectors will be installed in this line and the removed detectors will be function tested to determine whether malfunction or drift could have caused a spurious alarm. Prior to reintroducing material, the glove-box line will be instrumented with temperature sensors and controlled diagnostic runs will be performed to better characterize the temperature profile inside the line during furnace operations.

Federal Oversight: The NNSA site office has developed and continues to refine a set of metrics to gauge and trend performance. At a high-level, these measures score performance in field oversight activities, internal issues management, contractual incentive evaluation, personnel training and qualification, and staffing. Overall, the availability of quantified performance data, which is also visible to NNSA HQ, appears to be further focusing management attention into the most critical areas.

The latest data indicates that meeting staffing goals continues to be a challenge, in part due to high turnover. Currently only 50% of required personnel are trained and qualified, although over 90% of unqualified personnel are meeting or exceeding their qualification schedule which should drive steady improvement. Assessment performance appears to represent the area most in need of improvement. Through March, the site office had completed only 8 of the 20 independent assessments that had been scheduled. Additionally, the site office has completed and documented only 36% of its commitments to observe and shadow priority contractor assessments. These shadowing activities are vital for judging the effectiveness and maturity of LANL's Contractor Assurance System and for maintaining an appropriate level of operational awareness. In response to this persistent negative trend, site office management has noticeably increased emphasis on timely completion of assessment activities.

Chemistry and Metallurgy Research Building (CMR): A CMR criticality safety officer (CSO) identified a potential infraction this week involving neptunium stored in a Wing 9 floor hole location. The criticality safety posting for this location did not identify neptunium-specific mass limits and the quantity of neptunium in the floor hole exceeded the posted limits for other isotopes. Eventually, an approved memorandum from the Nuclear Criticality Safety Group was located that provided a neptunium mass limit for this location. The material in the floor hole complied with this limit and a determination was made in consultation with the NCSG that there was no infraction. The CSO has updated the posting to include the neptunium limit and CMR management is conducting an extent of condition review to identify any other areas where postings do not explicitly cover exotic isotopes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 9, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick
SUBJECT: Los Alamos Report for Week Ending May 9, 2008

Transuranic Waste Operations: TSR implementation at Area G is being validated as part of the ongoing Deliberate Operations Project Execution Plan. This effort has identified issues with the safety-significant lightning protection systems (LPS) that service waste storage domes. Issues include poorly defined inspection requirements to verify system function, failure to take necessary action when required measurements could not be taken or did not meet acceptance criteria, and use of inspection procedures that had not been properly evaluated against the facility safety basis.

Subsequent evaluation of the LPS also identified a condition that could compromise the system's ability to perform its safety function. Metal bodies within a certain distance of the LPS are required to be electrically bonded to the system to prevent uncontrolled arcing. Unbonded metallic waste drums are staged in proximity to LPS components in some domes. A follow-up critique will be held next week to determine whether proximate metal drums impact LPS function, how to respond if they do, and whether discovery of this situation constitutes a Potential Inadequacy of the Safety Analysis.

Radioactive Liquid Waste Treatment Facility (RLWTF): NNSA has approved downgrading the RLWTF to hazard category 3. This downgrade is based on controlling the material-at-risk such that aggregate facility inventory remains less than 55 americium-equivalent curies.

Work continues to complete the campaign to upgrade process equipment to restore the transuranic liquid waste processing capability that has been down since 2006. Physical modifications are largely complete. Limited startup testing using clean water will likely begin next week, although a leaking tank connection must be addressed before full system testing can be performed. Given the downgrade to hazard category 3, the proposed level of review to authorize restart of transuranic liquid waste processing will be a laboratory readiness assessment (site rep weeklies 4/25/08, 3/28/08, 1/25/08).

Chemistry and Metallurgy Research Building (CMR): A criticality safety infraction was declared this week when about 40g of uranium in solution was identified in a Wing 4 location that did not have explicit limits for solutions. This infraction was discovered as part of the extent of condition review prompted by the neptunium posting concern reported last week. The infraction was graded as the lowest severity level (i.e. Level 5) meaning that although criticality safety controls were not implemented as intended, there was no actual impact to the safety margin (site rep weekly 5/2/08).

Emergency Management: The NNSA site office recently issued a letter communicating concerns with the laboratory's progress in improving its Emergency Management Program. Noted concerns include an inadequate number of trained and qualified Emergency Managers and a lack of up-to-date Emergency Preparedness Hazards Assessments for hazardous material facilities. The letter directs LANL to provide a formal response with details on how these issues will be addressed within 15 days.

Weapons Engineering Tritium Facility (WETF): LANL has proposed conducting a series of experiments using gram-quantity samples of plutonium at WETF. The current WETF DSA does not allow weapons-grade plutonium in the facility. LANL has submitted a set of DSA page changes that analyze the new hazards and credit additional controls for the proposed activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 16, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: Brett Broderick, LANL Site Representative
SUBJECT: Activity Report for Week Ending May 16, 2008

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 23, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 23, 2008

Davis reported for duty this week as a site representative.

Contractor Assurance: So far this year, Director's Assessments for the Chemistry and Metallurgy Research Building, Transuranic Waste Operations, and the WCRR repackaging facility have been canceled and the outlook for future Director's Assessments is uncertain. These assessments provide independent, broad-based review of compliance with DOE requirements and appear to represent an important component of the laboratory's overall assessment program that supports the Contractor Assurance System. Discontinuing Director's Assessments would eliminate a valuable tool to help facility management identify deficient or non-compliant areas that require action and to help senior management maintain awareness of conditions and issues associated with operating nuclear facilities.

Chemistry and Metallurgy Research Building (CMR): Representatives from NNSA Headquarters, the NNSA site office, and LANL participated in an integrated nuclear planning workshop this week on the strategy for authorizing and operating CMR beyond 2010 when its current safety basis expires.

Analytical chemistry and material characterization (ACMC) activities and the Bolas Grande project to remediate legacy containment vessels were endorsed as the primary CMR mission activities to receive support for post-2010 operations. Future ACMC would be conducted inside a smaller facility footprint and MAR-intensive operations like sample preparation and Pu-238 activities would be moved into the Plutonium Facility to reduce hazards at CMR. Very preliminary results from the evolving DSA conservatively calculate a worst case unmitigated offsite dose consequence from a seismically-induced fire to be approximately 53 rem. The unmitigated consequence from this bounding accident may be reduced as the analysis matures; however, existing and currently anticipated controls provide little mitigation due to the seismic fragility of CMR. Potential upgrades are being reevaluated and reprioritized based on the extent to which they support anticipated DSA controls and facilitate eventual DSA implementation. Major seismic upgrades are not envisioned.

Transuranic Waste Operations: This week, LANL completed shipment of the last vented drums associated with the ongoing high-activity drum campaign. This is an important step in the direction of overall hazard reduction at the site. Of the approximately 235 original high-activity drums in the current campaign, only 11 unvented drums remain. These drums require remote venting of potentially flammable headspace gas prior to ultimate disposition. A remote drum venting capability has been established at Area G and is undergoing startup activities. A laboratory readiness assessment (RA) began this week to be followed by an NNSA RA prior to authorization to begin hot operations.

Plutonium Facility: This week, an NNSA RA team completed their field activities for startup of the interim radiography project at TA-55. This project provides a 6 MeV radiography capability in a tunnel connected to the TA-55 basement. The RA team has identified numerous potential pre-start findings. Some preliminary issues involve the facility control system, procedures, job hazard analyses and the potential impact of construction modifications on the safety class confinement structure. The RA team plans to complete their review and provide an outbrief to LASO and LANS management next week (site rep weeklies 6/15/07, 3/23/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 30, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director

FROM: B. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending May 30, 2008

The staff held a teleconference on the Radioactive Liquid Waste Treatment Facility Replacement.

Formality of Operations: NNSA has accepted formal implementation criteria for each of the four elements of Formality of Operations (operations, engineering, maintenance, and training). Implementation is divided into two phases, 'core' and 'mature', and separate criteria are provided for each phase. Core implementation represents minimum compliance with DOE requirements and mature implementation correlates to the establishment of robust programs that incorporate best practices. Once a nuclear facility declares it has implemented any of the four elements of Formality of Operations, an independent review will be performed using the accepted implementation criteria.

Facility Operations Directors have revised their Formality of Operations implementation schedules based on the new criteria. The most significant schedule impacts were for conduct of engineering, where core implementation criteria now include additional requirements for technical baseline reconstitution and control, and the performance of operability determinations for credited controls. The last facility scheduled to achieve core implementation of conduct of engineering is the Plutonium Facility in mid-2011. This date is driven by the time needed to develop or revise technical baseline documentation such as piping and instrumentation diagrams; however, the Plutonium Facility expects to meet all other conduct of engineering requirements by late-2009 (site rep weekly 3/28/08).

Chemistry and Metallurgy Research Building (CMR): Last week, LANL declared a Potential Inadequacy in the Safety Analysis (PISA) at CMR based on inconsistencies between the Interim Technical Safety Requirements (ITSRs) and National Fire Protection Association (NFPA) 72, *National Fire Alarm Code*. These inconsistencies involve ITSR surveillances to ensure adequate backup power and audibility for the CMR Fire Alarm System and were identified by an NNSA site office Safety System Oversight assessment. CMR facility management promulgated a standing order to address these issues pending evaluation via the unreviewed safety question (USQ) process.

Transuranic Waste Operations: As previously reported, Area G personnel were evaluating a number of issues related to the safety-significant lightning protection system (LPS). One concern related to whether LPSs protecting all Area G waste storage domes complied with NFPA 780 *Standard for Implementation of Lightning Protection Systems*, as required, due to unbonded metallic waste drums staged in proximity to LPS components in some domes. Additionally, the required in-service inspection for this system is vague, referencing NFPA 780 rather than providing more detailed and explicit inspection criteria to verify system function. Ultimately, LANL declared a PISA. As part of the evaluation triggered by the PISA process, LANL recognized a need to evaluate potential impacts to the WCRR repackaging and RANT shipping facilities that have similarly vague in-service inspections for their credited LPSs (site rep weekly 5/9/08).

Safety Basis: For the case discussed above, NNSA site office interaction with LANL was required prior to PISA declaration. In addition, the PISA was declared several weeks after issues were initially identified. Timely and conservative PISA evaluations are an important part of the overall USQ process for managing and maintaining the safety envelope for operating nuclear facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 6, 2008

MEMORANDUM FOR: J. Kent Fortenberry, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 6, 2008

Worker Safety: Recently, personnel have sustained a series of hand and finger injuries while performing work in nuclear and radiological facilities. In one case, a KSL worker severed the tip of his finger while performing circuit breaker maintenance at the Sigma complex (TA-3-66). In two other cases, one at the WCRR repackaging facility and the other at a TA-48 radiochemistry laboratory (RC-1), hand wounds were sustained inside radiological areas. While subsequent wound counts were negative, these near-miss events had the potential to cause radiological uptakes and share some similarities to the January 2007 contaminated puncture wounds sustained at TA-55 and CMR.

Contractor Assurance: Preliminary activities supporting an institutional review of integrated work, safety, and security management systems began this week. Part of the scope of this review will be to evaluate the first line manager program that was established as a corrective action from the Type B-like investigation of the 2007 contaminated puncture wound events mentioned above.

The contaminated puncture wound accident investigation produced a judgment of need to provide supervision that exerts positive control and surveillance over all workers, work activities, and work space. First line manager (FLM) positions were created to satisfy this judgment of need. Although each laboratory directorate established FLMs, actual implementation of this program diverged sharply across the site in terms of the rigor of the selection and vetting process, training and indoctrination received by FLMs, and ultimate FLM span of control. Given the drastic differences in FLM implementation, insights into the effectiveness of first line supervision at all nuclear and radiological facilities appear particularly relevant and timely in light of recent operational and potential precursor events, including the worker injuries described above (site rep weeklies 1/11/08, 9/7/07, and 1/19/07).

Plutonium Facility: This week, the NNSA Readiness Assessment (RA) team provided an outbrief to site office and lab management on their review of the interim radiography project at TA-55. The RA team did not recommend that the authorization authority (NA-10) approve startup of this activity based on the number of findings (18 pre-start and 22 post-start findings were presented at the outbrief), questions about the adequacy of the preceding laboratory RA, and the potential for additional issues to be identified. The site office plans to review the final report and provide a recommendation to NA-10 on how to proceed (site rep weeklies 6/6/08, 6/15/07, and 3/23/07).

Federal Oversight: The NNSA site office updated its Facility Representative (FR) staffing plan. The new plan does not change the overall FR staffing requirement of 14, but does adjust individual facility allocations and identifies the need to provide a level of FR coverage for a number of radiological and high hazard facilities that did not previously have the benefit of a dedicated NNSA field presence. Additional facilities receiving FR coverage under the updated plan include the DARHT hydrodynamic test facility, the LANSCE accelerator facility, TA-48 radiochemistry facilities, the Sigma Complex, the Beryllium Technology Facility, the High Magnetic Field Laboratory, and the Health Research Laboratory. The updated plan also provides more focused FR coverage for the Chemistry and Metallurgy Research Building and the Weapons Engineering Tritium Facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 13, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 13, 2008

Board members Bader and Winokur and staff members Minnema, Plaue, and Tontodonato were onsite this week.

High Explosive Operations: On Wednesday, programmatic activities at TA-39 caused a wildland fire that required partial activation of the Emergency Operations Center to coordinate a fire fighting response. The fire was controlled and response activities concluded Thursday evening. Approximately 12 acres were burned. No nuclear or radiological facilities were directly threatened.

The fire resulted from performance testing of a powder gun that will ultimately be fielded at the Nevada Test Site to support the dynamic plutonium experiments program. Forensic investigation of the exact cause of the failure that initiated the fire is ongoing. However, preliminary information suggests that an explosively-driven valve was breached during the test. The resultant loss of system containment allowed hot reaction-product gases to vent from the gun assembly, which ignited nearby vegetation. Firing site personnel alerted the Fire Department and attempted to suppress the incipient fire until wind conditions caused the fire to grow beyond their capacity to safely respond.

During the pre-shot review, this gun test was deemed to be 'contained' and was therefore allowed to be performed under conditions that would not have been allowed for an uncontained shot (i.e. high winds, proximate vegetative fuel loading, and lack of pre-staged fire response apparatus). Development of more conservative criteria for what constitute contained shots appears warranted.

Transuranic Waste Operations: LANL management has decided to re-staff and re-perform the recently executed laboratory readiness assessment for remote drum venting operations at Area G. This decision was based on concerns about the adequacy of the initial review and lessons learned from the Plutonium Facility interim radiography readiness review process (site rep weekly 6/6/08).

Weapons Engineering Tritium Facility (WETF): NNSA has approved hazard analysis and TSR changes to support a series of experiments that will expose gram-quantity plutonium coupons to tritium gas at WETF. The plutonium samples will be enclosed in a leak-tight test cell designed to interface with the WETF tritium gas handling system through a filtered manifold. Rupture disks are provided to ensure the test cell does not experience pressures exceeding its capacity. In addition, a protective fixture is provided for the test cell assembly to prevent mechanical failures resulting from drops during transit. New TSR controls to support these experiments include a facility MAR limit of 24 g of weapons-grade plutonium where 8 g are allowed in the process line with the balance staged in robust containers. The test cell assembly and its protective fixture are also credited as design features.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 20, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 20, 2008

Davis was offsite this week.

Weapons Facilities: A follow-up critique was held on emergency response actions associated with last week's wildland fire caused by powder gun operations at TA-39. Firing site personnel became aware of a problem almost immediately subsequent to the test shot and when the brush fire was observed, personnel took action to fight it. After 5 to 10 minutes of unsuccessful attempts to control the spreading brush fire, a series of calls was initiated through 2 separate firing site access control centers that ultimately resulted in Fire Department notification and response (site rep weekly 6/13/08).

In response to this event, the laboratory has implemented compensatory measures for high explosive operations at firing sites and initiated a review of shot authorization and control prescription processes. Under the compensatory measures, senior management authorization is required to conduct any shot under particularly hazardous fire conditions (i.e. 'Red Flags') and expectations have been strengthened for having pre-staged Fire Department coverage for shots.

Last week a fire also occurred in the Weapons Material Laboratory (TA-16-304) during an electric oven operation to destroy a plastic classified part. When checking the status of the evolution, a technician observed a small fire inside the oven. Upon discovery, the technician called the oven operator who reported back to TA-16-304 from another facility. By this time, the oven fire had grown too large to be safely suppressed by facility personnel. The individuals exited the facility and notified the Fire Department, which responded and extinguished the fire.

Emergency Response: The events above appear to highlight an opportunity for improvement in communicating and implementing the expectation to call 911 upon discovery of a fire and prior to personnel initiating any actions to fight or control fires themselves.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, the RLWTF declared an iTSR violation. The iTSR requires that a monthly combustible loading surveillance be performed using approved criteria. These criteria are provided via memo by the Fire Protection Engineering group. In November 2007, a new memo with more restrictive combustible loading surveillance criteria was issued; however, this iTSR-affecting criteria change was not formally controlled. The engineer who regularly performs this surveillance was not aware that the criteria had changed and since the implementing procedure did not explicitly specify the combustible loading criteria, the surveillance continued to be performed using the less restrictive criteria from the superseded memo. Upon discovery, the facility revised the implementing procedure and re-performed the surveillance. A limiting condition of operation was entered and excess combustibles were removed from RLWTF.

Training: The NNSA site office conditionally approved a Training Implementation Matrix (TIM) for the RLWTF. Development of compliant and approvable TIMs has been a persistent challenge for LANL, so approval of the RLWTF TIM is a significant step toward establishing compliance with DOE training requirements and can be used as a model for generating other nuclear facility TIMs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 27, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 27, 2008

Davis was off site this week. The staff held a video-teleconference on software quality assurance.

Plutonium Facility: Last week, facility personnel discovered that safety-class seismic bracing had been improperly removed from a glove box. The bracing is credited to prevent glove box toppling and release of Pu-238-doped material in a seismic event. Given this discovery, LANL declared a TSR-violation based on a significant breakdown of the configuration management program.

The credited bracing was removed for a glove box modification project that began over a year ago under a design change package (DCP), but was never completed. When the project was abandoned, the bracing was not reinstalled and the DCP remained open. The glove box was being used to stage weapons-grade Pu when the discrepant condition was found. An annual in-service inspection (ISI) of the glove box and its bracing was performed in May 2008; however, a scientist who did not use a required system drawing when performing the ISI, inappropriately noted the bracing as satisfactory.

In response to this event, the facility operations director (FOD) suspended Pu-238 and Pu-238-doped material operations until appropriate portions of the ISI could be re-performed to verify credited bracing was intact and operable on other glove boxes. Personnel performing ISIs must now be approved by the FOD. An action plan to remove the weapons-grade Pu from the affected glove box is in development. Finally, facility personnel are working on a process to screen and triage the hundreds of legacy DCPs that remain open to identify and address other latent vulnerabilities.

Site-wide Seismic Hazards: LANL recently submitted for NNSA concurrence a revised Project Execution Plan (PEP) for the SAFER project designed to evaluate the impacts of increased site-specific seismic hazards on operating facilities. In the new PEP, LANL commits to evaluate all structures, systems, and components (SSC) credited to perform seismic safety functions in nuclear facilities before the existing site-wide justification for continued operations expires in June 2009. However, the detailed list of SSCs to be evaluated under SAFER does not clearly capture all SSCs credited to perform seismic safety functions (e.g. WCRR drum lift fixture). NNSA review is ongoing.

In terms of progress, modeling activities are underway for the Plutonium Facility and an important kickoff meeting was held this week to discuss the proposed evaluation methodology and acceptance criteria with the expert panel that will provide peer review for SAFER analyses and conclusions.

Transuranic Waste Operations: Last week, the NNSA site office formally disapproved the Area G BIO and TSR package submitted in February 2008. Issues with the control selection strategy and control definitions contributed to the NNSA review team judgment that the proposed TSR set was not adequate or effective.

A key facet of the ongoing Deliberate Operations Project Execution Plan to improve the safety of Area G operations is accelerated implementation of new or enhanced controls from a modern and complaint safety basis. LANL and NNSA personnel met subsequent to the disapproval decision to discuss which controls were still suitable for continuing accelerated implementation efforts.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 4, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 4, 2008

Plutonium Facility: While attempting to open a taped slip-lid container using a screwdriver, an operator inadvertently punctured the glove-box glove and an interior glove. The screwdriver did not lacerate the operator's hand but resulted in 15,000 dpm alpha contamination on his innermost cotton glove liner. Subsequent discussions with the operator indicated that the taped container did not have tabs (as expected) to facilitate removing the tape nor was the screwdriver the appropriate tool for tape removal. The operator was also not aware of previous similar incidents (e.g., the January 2007 contaminated puncture wounds) or the associated corrective actions. Based on this information, facility management met with first line managers to discuss methods of ensuring that lessons learned and corrective actions are adequately disseminated down to the worker level. In addition, the facility is using this event to re-emphasize the use of appropriate tools and the need to pause work when unexpected conditions are identified (site rep weeklies 1/19/07, 1/12/07).

Last week, LANL submitted to NNSA an updated path forward on Board Recommendation 2004-2. The proposed approach is supported by an external independent review performed by URS. The submitted plan identifies a series of analyses and upgrades intended to be executed over the next 5 years to achieve safety class active confinement ventilation, safety class fire suppression (credited for operational vice seismically-induced fires), and inerted environments for high-risk glove-boxes. LANL asserts that these collective upgrades should effectively reduce mitigated off-site doses to well below the DOE evaluation guideline. This would represent a significant improvement in the safety posture of the Plutonium Facility; however, the funding sources for many key upgrades are currently identified as 'to be determined.' The ultimate recommended end state in the external URS report is the addition of robust safety class sand filters. The current submittal defers a decision on sand filters and does not specify the time frame for a decision on whether they will be pursued.

Chemistry and Metallurgy Research Building (CMR): Last Friday, CMR management declared a Potential Inadequacy in the Safety Analysis based on a newly identified failure mode for the facility vault during a seismic event. The current safety basis credits the vault structure to prevent the release of nuclear material during bounding accidents, including a seismic event. Hence, material in the vault is excluded from counting against the facility material-at-risk (MAR) limit. During development of the new Documented Safety Analysis, safety basis analysts identified that failure of one of the CMR wings could potentially collapse the vault roof structure. In response, CMR management issued a standing order requiring the vault inventory be included as part of the overall facility MAR limit. This week, CMR management declared this issue an Unreviewed Safety Question and is developing a Justification for Continued Operations (JCO) for NNSA approval. The JCO will likely formalize vault inventory inclusion in facility MAR calculations.

Federal Oversight: As a part of the corrective actions from the Chief of Defense Nuclear Safety review in 2007, site office personnel held the first series of Operational Awareness briefings this week. These briefings, which will be held quarterly, provide management with a status of key on-going initiatives (e.g. Formality of Operations) and nuclear facility conditions. They also provide field personnel with an additional forum to surface issues that warrant management attention.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 11, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 11, 2008

Bamdad and Kimball were onsite this week attending a workshop on safety-class controls for the Chemistry and Metallurgy Research Building Replacement. Laake, Martin and Von Holle were also onsite to discuss LANL activities related to unresolved electrostatic discharge issues at Pantex.

Chemistry and Metallurgy Research Building Replacement (CMRR): This week, the Integrated Safety Committee held a workshop to discuss the preliminary safety basis accident scenarios and selection of safety-class controls. For the facility fire scenarios, the preliminary safety-class controls include fire barriers, fire suppression and aspects of the material container. The facility structure is also credited as safety-class for several accident scenarios including seismic events. The facility active ventilation system is identified as safety-significant (performance category-3) and will provide additional mitigation for most of the postulated accident scenarios. The CMRR project team plans to submit an updated Preliminary Documented Safety Analysis to the site office in November.

Plutonium Facility: As noted on June 6th, the NNSA Readiness Assessment (RA) team did not recommend approval to startup interim radiography operations (IRO). Upon reviewing the RA team final report, the site office provided recommendations to the authorization authority (NA-10), including: LANL will perform an independent review of IRO design changes (focused on extent-of-condition for engineering issues); and LANL will demonstrate the IRO procedure to an experienced NNSA team. Upon successful completion, the site office will recommend startup to NA-10.

Transuranic Waste Operations: LANL has formally responded to NNSA's disapproval of the Area G safety basis. The LANL response does not challenge the disapproval, but does highlight areas of technical disagreement that need to be addressed prior to re-submittal. One significant area of disagreement is whether the control selection strategy and control definitions comply with relevant directives, such as DOE-STD-3009 and DOE-STD-5506. LANL also expressed confusion over NNSA issues related to controls for remote drum venting operations since proposed controls are nearly identical to recently approved controls that serve as the basis for the ongoing startup activities discussed below. To promote better communication on these types of issues during future safety basis development cycles, LANL proposes establishing "phase-gate" meetings with NNSA at strategic intervals during the preparation of all future safety bases (site rep weekly 6/27/08).

In June, LANL management decided to re-perform the laboratory RA for remote drum venting operations at Area G based on lessons learned from the IRO startup and concerns about the adequacy of the review. Last week, the subsequent laboratory RA team concluded their review. The team identified several pre-start and post-start findings but concluded that the remote drum venting operations could be safely performed following causal analysis and closure of pre-start findings. Notably, the team identified a post-start finding that the Integrated Safety Management System did not appear effective based on a number of issues identified during the review.

Readiness: In response to issues related to the IRO and remote drum venting readiness activities, the site office formally directed LANL to report on the adequacy of staffing for readiness preparation and review functions, as well as, lessons learned and corrective actions stemming from these activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 18, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 18, 2008

Plutonium Facility: Over the last few weeks, there have been a number of equipment and performance problems associated with the Facility Control System (FCS). Based on the persistence and severity of these problems, facility management placed the Plutonium Facility in standby (Mode 2). The FCS is a safety-significant system that provides facility monitoring and control capabilities, and serves as a support system for the facility's active confinement ventilation. Recent FCS problems are related to the communication infrastructure for the system and were resulting in numerous failures each day. When the FCS is declared inoperable, the facility enters a limiting condition of operation requiring verification of differential pressure provided by facility ventilation every 15 minutes and restoration of the FCS within 24 hours. In response, facility personnel performed troubleshooting and maintenance that involved removing some FCS hardware from service to reduce the load on the communication network. These actions restored system operability and allowed the facility to resume normal operations late this week. Limited system upgrades to replace servers and software are in progress; however, persistent failures and system age seem to indicate problems with FCS reliability.

While the FCS was inoperable, facility management identified two mission-critical material shipments that could not be performed while the facility was in standby mode. A temporary safety basis modification was submitted to the site office to allow these activities to be performed with compensatory measures (mainly ventilation monitoring). The site office approved the safety basis change but did not issue a safety evaluation report or formal memo documenting the approval basis.

Glovebox Safety: Recently, LANL began an effectiveness evaluation of the corrective actions associated with the puncture wounds that resulted in internal contamination in early-2007. The review plan includes evaluation of institutional actions but will maintain a specific focus on the safety of glovebox operations. The evaluation team is developing guidance cards with specific lines of inquiry for line managers who will perform parts of the evaluation. In addition, the institutional evaluation team will perform an independent verification for a subset of the line management evaluations. Field activities are expected to be complete in August. Several other reviews of glove box safety issues are also on-going, including a management evaluation of glove breaches over the last two years and an assessment of the Plutonium Facility glove integrity program.

Site-wide Fire Protection: Recently, a rupture in the system that supplies fire water to TA-21 caused a release of nearly 4 million gallons of water. Although this failure impacted fire protection and response capabilities for facilities in TA-21, the laboratory did not receive timely notification of the problem. In response, LANL is formalizing protocols with Los Alamos County for timely notification when abnormalities are detected that could affect LANL systems. TA-21-specific compensatory measures have also been developed that include performing more frequent system surveillances and establishing a limited remote monitoring and alarm capability. LANL management indicated that the need for additional site-wide action will be evaluated. Understanding and addressing the site-wide extent of condition appears warranted to increase confidence that a failure elsewhere in the site-wide water supply system that could impact credited fire suppression systems in nuclear facilities would be identified quickly to allow the affected facilities to take appropriate response actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 25, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 25, 2008

Staff members March and Galaska were on site this week for a fire protection review.

Federal Oversight: Based in part on a perceived inconsistency in the condition of facility equipment and LANS metrics related to equipment maintenance, the NNSA site office performed a “for cause” review of deferred maintenance. The review team recently completed their review and concluded that LANL does not maintain equipment to prevent damage, loss or deterioration. Key preliminary findings included: LANL’s deferred maintenance definition is not consistent with DOE’s definition and is not managed, adequately funded and worked off; equipment condition assessments are not performed as required; preventive, corrective and predictive maintenance are not used to ensure equipment availability; and LANL is not adequately informing NNSA of significant risks related to equipment condition. A final report is expected by the end of July.

Criticality Safety: This week, the site office performed an assessment of the LANL Nuclear Criticality Safety Program focused on aspects of field implementation at the Plutonium Facility, Chemistry and Metallurgy Research Building and Area G. The assessment was conducted using some of the same personnel from the 2005 review that prompted development of the Program Improvement Plan to establish a compliant, standards-based criticality safety program. During the outbrief, the team observed that significant progress has been made since 2005 on priority issues. They also observed a need for increased criticality safety group presence on the operating floor in facilities and better-defined roles, responsibilities, and interface expectations for criticality safety officers.

Plutonium Facility: The site office has approved changes to a justification for continued operations (JCO) to reconfigure material in two Plutonium Facility vault rooms to bring them into compliance with new interim criticality safety evaluations (CSE). The new CSEs specify a lower limit for material staged in floor locations and a new limit for storage drawers in which no more than one location per drawer may contain metal items. Some floor locations and many drawers in the affected vault rooms are not currently in compliance with the new limits. These locations will be remediated using controls identified in the revised JCO. Once this material reconfiguration is effected, the four vault rooms that prompted concerns about reduced criticality safety margins last September will all be in compliance with new, standards-based CSEs (site rep weeklies 3/21/08, 12/21/07, 9/21/07, 9/7/07).

Hoisting and Rigging: Recent crane incidents prompted an institutional task team review of cranes, hoists and rigging equipment. Based on a sampling review, the task team concluded that despite prior corrective actions, laboratory processes remain inadequate to ensure that all in-service cranes, hoists and rigging have been inspected and maintained in accordance with applicable requirements. In response, LANL management issued a set of aggressive compensatory measures including direction to equipment-owning organizations to immediately check inspection and maintenance records and lock and tag any deficient equipment out of service. Facility Operations Directors (FOD) were also instructed, within two weeks, to perform independent verification walkdowns to ensure deficient equipment has been locked and tagged out of service. FOD verification walkdowns are ongoing and this process has already resulted in dozens of cranes being removed from service.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 1, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 1, 2008

Weapon Response: LANL recently issued a weapon response related to an electrostatic discharge issue that has caused W76 operations at the Pantex Plant to be suspended since May. Based on the high-priority nature of this issue, LANL dedicated all available subject matter experts to the weapon response development effort. As a result, no truly independent electrostatic discharge experts were available to participate in the peer review of the technical results, as required by LANL's approved procedure. Due to the highly aggressive schedule imposed on this activity, LANL did not engage LLNL to provide independent technical reviewers. NNSA has reviewed LANL's weapon response process to ensure that it satisfies applicable requirements from DOE-NA-STD-3016-2006; however, the NNSA site office does not currently perform oversight of weapon response execution to ensure that LANL is appropriately implementing its approved process.

Plutonium Facility: LANL recently completed switchgear upgrades at the Plutonium Facility to provide automatic diesel generator startup and supply to key facility loads (e.g., ventilation). Although the facility receives power from multiple feeds, electrical transients were causing numerous loss of power events that impacted facility safety systems and facility operation. Facility management is also pursuing additional improvements including better transfer capabilities between available power feeds and improving the facility power factor (site rep weekly 12/15/06).

In accordance with the recommended site office path forward for interim radiography operations (IRO), facility personnel attempted to demonstrate the operating procedure in early-July. Numerous issues were identified during the evolution prompting the site office to request another demonstration be performed. On Friday, facility personnel successfully demonstrated execution of the revised procedure. As required by the path forward, LANL also completed an independent review of IRO design changes and provided a report to the site office (site rep weekly 7/22/08, 6/6/08).

Transuranic Waste Operations: NNSA is poised to begin a readiness assessment on Monday for remote drum venting operations at Area G. The remote drum venting capability is required to remediate the remaining 11 of roughly 235 original drums in the high activity drum campaign.

LANL is also nearing completion of readiness preparation activities for restarting the transuranic waste processing capability at the Radioactive Liquid Waste Treatment Facility. Physical upgrades and modifications are complete and have undergone startup testing, a strengthened operations center has been established, and operators are being trained to an updated set of procedures.

Site-wide Fire Protection: In response to a recent event and questions raised concerning the fire water supply for defense nuclear facilities, LANL has initiated a comprehensive review of the site-wide water distribution system. The review is evaluating the supply tanks and distribution system for single point failures, alarm capabilities (e.g., tank low-level), system maintenance/surveillance and requirements for notifying nuclear facilities of degraded system conditions. Based on the preliminary review to-date, LANL has taken action to ensure receipt of low-level alarms for an Area G water tank that was previously not monitored by the laboratory (site rep weekly 7/18/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 8, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 8, 2008

Broderick was at the Sandia National Laboratory Tuesday and Wednesday attending the nuclear weapons complex lightning protection committee meetings.

Chemistry and Metallurgy Research Building (CMR): Earlier this year, NNSA approved a revision to the CMR interim Technical Safety Requirements (iTSRs) to address discrepancies between the 1998 Basis for Interim Operations and the previous set of iTSRs. This week, LANL completed an Implementation Verification Review to confirm these controls are incorporated into appropriate facility procedures and that facility personnel are knowledgeable of the controls and requirements. The review team observed field performance of all of the revised or new surveillance requirements. Several pre-implementation findings were identified associated with procedural issues. The team concluded that upon resolution of the pre-implementation findings, CMR will be able to safely implement the revised iTSRs. LANL also continues to develop a Documented Safety Analysis to support post-2010 operations at CMR (site rep weeklies 5/23/08, 4/4/08).

Transuranic Waste Operations: On Friday, the NNSA Readiness Assessment (RA) team completed their review of remote drum venting operations at Area G and provided an outbrief to site office and contractor management. The following five pre-start issues were identified:

- hazards and controls have not been completely identified in some cases
- implementation of controls was inadequate in a few cases
- performance of dose estimates and As Low As Reasonably Achievable review have not been completed
- the startup plan is inconsistent concerning plans for drum processing
- procedures can't be performed as written in some cases

Three post-start issues were identified associated with hoisting and rigging, conduct of operations and training. The RA team recommends that the startup authority approve remote drum venting operations following closure of the pre-starts findings and development of corrective actions for the post-start findings (site rep weekly 8/1/08)

Plutonium Facility: Last week, LANL submitted a draft of the Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs) to the site office for review. This draft is noted to be 99% complete and was provided to the site office for verification that the technical content of these documents meets NNSA expectations.

Federal Oversight: This week, LANL responded to a site office request to assure resources are adequate such that nuclear facilities can be operated in a safe, secure and environmentally-compliant manner. LANL has established an Infrastructure Validation Team to meet this objective. The team will evaluate and improve the LANL process for prioritization, planning, budgeting and execution. Deliverables from this team will include a definition of facility safe operating requirements, facility planning/execution guidance and a maintenance program improvement action plan. The validation team plans to complete their deliverables and reviews by mid-September.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 15, 2008

MEMORANDUM FOR: T. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 15, 2008

Broderick was off-site this week.

Plutonium Facility: On Wednesday, an operator punctured his hand while performing a stainless steel cutting operation in a glovebox. Operators and radiological control personnel took appropriate action to respond to the injury and transport the injured operator to the on-site Occupational Medical Facility. Initial wound counts were positive; however, subsequent medical efforts were able to remove a small metal sliver and significantly reduce the wound contamination.

Based on initial investigation, the Integrated Work Document (IWD) included the puncture hazard and controls were identified. In particular, the IWD required use of puncture resistant gloves for this activity. The pre-job brief included a discussion of this hazard and controls. In addition to the first line manager and other operators in the area, two members from the effectiveness evaluation team for the January 2007 contaminated puncture wound corrective actions were in the area and observing the activity. Personnel observing the activity noted that the procedure and controls (including puncture resistant gloves) were followed by the operator. This particular cutting operation with stainless steel creates a rough edge that appears to have breached the operator's glove. Based on the injury sustained by the operator, it appears that the controls identified may not be adequate.

All machining activities at the Plutonium Facility have been suspended pending causal analysis of this event. In addition, the Director has requested that a formal investigation be performed.

Radioactive Liquid Waste: The Waste Management Risk Mitigation Project (TA-50 Tank Farm), which involved construction of a new Hazard Category 2 pump house and tank facility, was intended to increase the low-activity liquid waste storage and address concerns that arose during the Cerro Grande fire. This project was halted in April 2007 at about 75% construction completion due to project management and quality assurance issues. This week, the site office approved a LANL recommendation to complete this project as a radiological facility to provide low-activity liquid storage during emergency conditions. This decision may impact plans to use the TA-50 Tank Farm for influent storage for the Radioactive Liquid Waste Treatment Facility Replacement Project.

Federal Oversight: LANL recently responded to a site office request to report on the status of staffing for readiness preparation and lessons learned from issues associated with the Interim Radiography and Remote Drum Venting readiness activities. The LANL report notes that current readiness staffing is not adequate to perform their mission and additional resources have been requested for Fiscal Year-2009. LANL is also establishing formal qualification training for Laboratory Readiness Assessment team leaders, core review team members and readiness review coordinators. The report also identifies numerous lessons learned from the Interim Radiography and Remote Drum Venting readiness activities for planning, scoping, performance and other areas (site rep weekly 7/11/08).

Plutonium Facility: On Friday, the startup authority (NA-10) approved startup of Interim Radiography at the Plutonium Facility (site rep weeklies 8/1/08, 7/11/08, 6/6/08, 5/23/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 22, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 22, 2008

Contaminated Puncture Wound: The Deputy Laboratory Director has formally chartered a team to investigate the glovebox glove puncture event that occurred last Wednesday and resulted in a contaminated wound. The scope of the investigation, which began this week, is to collect relevant facts and determine the causes of the glove puncture. The charter also specifically tasks the team to evaluate the following: • adequacy of activity hazard analysis and control identification for glovebox operations, • work controls and procedures relevant to the associated activity, and • training and qualification of the involved workers on relevant work controls and procedures. A causal analysis and accompanying report are due to the Deputy Director by September 25th and corrective actions to address the causal factors are due by October 24th (site rep weekly 8/15/08).

Plutonium Facility: In response to the puncture event, Plutonium Facility management suspended all metal cutting and machining operations. The facility has developed a review and release process to ensure controlled resumption of suspended operations. For a given operation, the process evaluates the types of metals involved, the potential for sharp pieces or turnings to be produced, and the extent to which cut pieces or turnings need to be handled. Operations that pose a puncture risk based on these factors are subjected to more rigorous review requirements, including a process walkdown involving appropriate safety subject matter experts. Multiple levels of management approval are required to release an operation once it has been reviewed and controls have been verified as adequate. Few of the roughly 80 suspended metal cutting and machining operations have been released to date.

Formality of Operations: This week, the NNSA site office approved revised Formality of Operations implementation schedules based on previously approved criteria that define 'core' and 'mature' levels of implementation. The approval memo emphasizes that the objective for FY09 is to substantially achieve core implementation for conduct of operations, engineering, and maintenance in LANL nuclear facilities. Most of the newly approved implementation dates support this objective. For those that do not, (e.g. conduct of engineering at the Plutonium Facility and the Weapons Engineering Tritium Facility) the site office directed LANL to provide, for separate concurrence, further definition of what specific elements will not be implemented by the end of FY09.

Implementation dates for conduct of training generally lag those for other functional areas and in many cases stretch into FY10. For FY09, the site office identifies an expectation for LANL to establish qualification cards for key positions, cross-walk personnel training and experience against the qualification cards, and identify and implement compensatory measures, as needed.

In the approval memo, NNSA acknowledges that there is residual risk associated with the current state of incomplete Formality of Operations implementation, but contends that substantial progress has occurred and risk has decreased over time. The site office asserts that further efforts to analyze gaps and characterize residual risk would only detract from on-going implementation efforts. Based on the above, NNSA formally accepts the residual risk and states its belief that attention should remain focused on implementation (site rep weeklies 5/30/08, 8/10/07, 6/15/07, 3/28/07, 2/2/07).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 29, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 29, 2008

Contaminated Puncture Wound: The laboratory accident investigation continued this week, with the team focused on personnel and management interviews and timeline development. In addition to the on-going investigation, a number of other efforts to evaluate glovebox safety and glovebox glove integrity are progressing. These include the LANL effectiveness evaluation for corrective actions associated with the January 2007 puncture wounds; an evaluation of glovebox glove breaches at the Plutonium Facility; and an assessment of Glovebox Glove Integrity Program implementation. These parallel efforts are being performed under the auspices of several different laboratory organizations, but appear to be analyzing different facets of the same problem. As such, upon completion of these activities, there may be value in having a single entity collect and review the results, consolidate identified issues, and coordinate an integrated response (site rep weeklies 8/22/08, 8/15/08, 7/18/08).

Chemistry and Metallurgy Research Building (CMR): This week, LANL submitted a revised program execution plan (PEP) to support operations in CMR beyond 2010. The revised PEP incorporates decisions and actions stemming from the May integrated nuclear planning workshop devoted to CMR. The programmatic baseline has been revised and de-scoped to reflect only Confinement Vessel Disposition Project work in Wing 9 through 2013 and analytical chemistry and material characterization work continuing in Wings 5 and 7 until the CMR Replacement facility is operational. Relatively few changes were made to the list of priority safety system upgrades, however, deferred breaker maintenance and enhancements related to the fire alarm and fire suppression systems have been added. The revised PEP also explicitly identifies risk mitigation through relocation of non-essential personnel to more robust facilities (site rep weekly 5/23/08).

NNSA Headquarters (NA-10) recently issued a letter directing the site office to prepare an exit plan, due in mid-December, to transition activities out of CMR 'as soon as practicable.' It is not yet clear the extent to which this direction will alter the baseline path forward codified in the revised PEP.

Transuranic Waste Operations: On Wednesday, the site office authorized startup of remote drum venting operations at Area G. The authorization memo requires LANL to demonstrate operational maturity by venting five low-activity drums without needing process or procedural changes prior to addressing any of the 11 high-activity drums that require venting to complete the current campaign.

Plutonium Facility: Interim Radiography Operations (IRO) were also authorized to begin this week. The IRO capability eliminates hazards associated with shipping pits round-trip to LLNL for high-energy radiography and significantly improves the efficiency of LANL pit manufacturing.

Readiness: Startup authorization for the new capabilities discussed above is positive in that both help to reduce or eliminate hazards. However, the NNSA site office perceives that LANL prematurely declared implementation in both cases, based on readiness assessment findings that some procedures could not be performed as written and some controls were not fully implemented. The site office has set an expectation for LANL to systematically review these experiences, identify lessons learned, and track corrective actions to closure. LANL has identified and begun executing steps to prevent recurrence (site rep weeklies 8/15/08, 8/8/08, 8/1/08, 7/11/08, 6/13/08, 6/6/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 5, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 5, 2008

Radioactive Liquid Waste Treatment Facility (RLWTF): On Saturday (8/30), an equipment malfunction following a maintenance evolution at the Chemistry and Metallurgy Research Building (CMR) caused an inadvertent discharge from the chilled water system at a rate of approximately 60 gallons per minute. This water soon began draining into a line leading to the low-level waste influent collection tanks at RLWTF. The 75,000 gal primary collection tank level began rising at a rate of 5% an hour. The computerized monitoring and control system initiated an automated alarm call-out, an operator reported to RLWTF, assessed the situation and contacted plant management. There was initial confusion about the source of the influent water and early efforts to isolate the upstream source focused on the TA-48 radiochemistry facility rather than CMR. By the time the upstream source was isolated and the plant was put into operation to begin processing liquid, around 300 gallons overflowed from the primary tank and was pumped into a 100,000 gal secondary tank, already approximately 75% full of legacy material. About 50,000 gal of total influent was received.

This event appears to be prompting a comprehensive evaluation of instrumentation both at RLWTF and at generator facilities to ensure that equipment needed for timely and accurate identification of abnormal conditions is appropriately maintained and calibrated. There also appears to be heightened attention and urgency for remediating legacy material held in the secondary tank to increase margin. This remediation requires offsite vendor support and has been delayed due to funding issues.

Transuranic Waste Operations: Waste storage domes in Area G are equipped with lightning protection systems (LPS) credited with reducing the frequency of lightning-induced fires that can impact transuranic waste. Performance and in-service inspection criteria for the safety-significant LPSs are vague and simply reference NFPA 780. A potential inadequacy of the safety analysis (PISA) was declared in May based on metal waste drums staged within the code-mandated arc-flash exclusion area around LPS components. Three months later, this condition was determined to be a positive unreviewed safety question (USQ). Affected domes are in the process of being remediated and operational restrictions are in place for domes where drums remain inside the exclusion area.

This week, the results of an NNSA site office safety system oversight review of the LPS were briefed to Area G management. The review highlighted a number of other code compliance issues, including lack of surge suppression for domes and ground resistance readings for some LPSs that were outside the acceptable range. Many, if not all, of these issues had been previously identified by LANL. After reassessing the known information and deficiencies, Area G management declared a TSR violation. The initial PISA declaration, identification of the positive USQ, and the recent declaration of a TSR violation were all prompted by NNSA engagement (site rep weeklies 5/30/08, 5/9/08).

Weapons Engineering Tritium Facility (WETF): This week, WETF declared a PISA related to the safety-significant fire suppression system. A TSR for this system requires sprinkler heads to have a maximum temperature rating of 100° C. Two sprinkler heads that are collocated with heated equipment have a rating of 141° C. The higher rating of these sprinklers is necessary to comply with NFPA code requirements, but is not consistent with the language in the TSR.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 12, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 12, 2008

Plaue, Shackelford, and Roscetti were onsite this week to review safety system design, functionality and maintenance. Plaue also reviewed nuclear materials management topics.

Transuranic Waste Operations: Subsequent to the TSR violation declared last week related to the Area G lightning protection system (LPS), management suspended all operations not directly involved with establishing the required arc flash exclusion area around LPS components. This week, LANL submitted and NNSA approved a formal recovery plan that defines the conditions and compensatory measures needed to allow the resumption of unrestricted transuranic waste operations in Area G. Prior to the suspension of operations last Friday, LANL had identified a situation that constituted a positive unreviewed safety question but had continued performing some limited operations without any formal approval by NNSA. The recovery plan provided a mechanism to gain this formal approval. The recovery plan also identifies longer-term actions to revise the current safety basis to permanently address LPS issues by December 1, 2008. Authorization to operate under the recovery plan expires on December 31, 2008 (site rep weeklies 9/5/08, 5/30/08, 5/9/08).

Site-Wide Seismic Hazards: The site office recently approved a revised Project Execution Plan (PEP) for the SAFER project, which will evaluate the impacts of increased site-specific seismic hazards. The approval letter requested LANL to revise the PEP to include evaluation of the Weapons Engineering Tritium Facility and ensure that all structures, systems and components (SSCs) credited to perform a seismic safety function are included. The site office's approval of the site-wide Justification for Continued Operations (JCO) that addresses the increased seismic hazard for LANL facilities requires LANL to complete the SAFER project for nuclear and high-hazard non-nuclear facilities by June 2009. The site office also requested quarterly updates on the SAFER project.

Last week, the SAFER project team presented the initial results of their evaluation of the Plutonium Facility to the peer review team. These results indicate that the vertical acceleration of the facility floor may be much larger than expected and would have a significant impact on SSCs that perform a seismic safety function. Based on these results, LANL plans to pursue a probabilistic analysis for the Plutonium Facility and revisit conservatisms in the Probabilistic Seismic Hazard Analysis.

As noted on July 4th, LANL also recently declared an unreviewed safety question and prepared a JCO based on a seismic vulnerability identified for the Chemical and Metallurgy Research (CMR) Facility main vault. While the site office concurs with the compensatory measure (including the vault material-at-risk against the overall facility safety basis limits), the JCO was not approved because a limited duration was not identified for the JCO (site rep weekly 6/27/08).

Integrated Nuclear Planning: This week, LANL, the NNSA site office and NNSA Headquarters held a workshop to discuss plutonium infrastructure and waste management at LANL including capabilities, vulnerabilities, programs and projects. The workshop highlighted the significant challenges at LANL to adequately support safe operations at existing aging facilities while also achieving progress on several projects to replace or upgrade these facilities (e.g., CMR Replacement, Radioactive Liquid Waste Treatment Facility Replacement and new Transuranic Waste Facility).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 19, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 19, 2008

Plutonium Facility: This week facility personnel recognized a condition where 3 uncredited containers bearing Pu-238 were incompletely submerged in the vault water bath. Compensatory measures stemming from a 2006 potential inadequacy of the safety analysis (PISA) and positive unviewed safety question (USQ) require uncredited containers to be fully submerged. The control derived to ensure this condition is satisfied relates to maintaining the water in the vault water bath above a certain level. However, the water level control was based on assumptions associated with container dimensions and storage configurations. These assumptions were not protected and operators were not aware that certain container sizes and storage configurations could defeat the intent of the control. As a result, the water level was maintained at the prescribed level, but this did not prevent uncredited containers from being stored in an incompletely submerged state. Upon recognition of this situation, facility management remediated the condition, reengaged the PISA process and revised the ineffective compensatory measures associated with the legacy PISA.

TRU Waste Operations: Waste storage dome door restraints are credited for preventing doors from becoming wind-borne missiles that can impact transuranic waste drums. The approved Area G DSA states that door restraints will survive wind speeds up to 96 mph. A calculation performed in 2007 determined that the door restraints will fail at lower wind speeds than identified in the DSA. The new information provided by this calculation does not appear to have been formally captured and acted on at the time. A cognizant system engineer rediscovered this information while conducting a vital safety system assessment (VSSA) of the door restraints. As a result, management declared a PISA.

The SER approving the current Area G DSA mandates that vehicle barriers be credited as safety-significant and comply with NRC NUREG 6190 to prevent errant vehicles from impacting waste storage domes. A 2005 NNSA site office assessment identified that the vehicle barriers could not meet NUREG 6190. This prompted a TSR violation and the institution of compensatory measures that have evolved and been strengthened several times since 2005. However, the vehicle barriers have never been modified to comply with NUREG 6190 and still cannot perform their credited safety function. This information was reviewed as part of a VSSA, prompting another PISA.

Conduct of Engineering: Performance of VSSAs played a direct or indirect role in the declaration of each PISA discussed above. These assessments appear to be providing an effective mechanism for identifying latent vulnerabilities in credited safety systems caused by outdated, non-compliant safety bases and lack of robust Formality of Operations. VSSAs for most safety-class and safety-significant systems in LANL nuclear facilities are scheduled to be completed by the end of FY09.

Safety Basis: Once an applicable issue is identified, the PISA process provides a formal, systematic, and transparent mechanism to determine appropriate compensatory measures and helps inform NNSA's understanding of risks. In each of the three cases above, once issues were identified through VSSAs or other means, facility management promptly declared PISAs. This type of timely and conservative utilization of the PISA process is an important tool for effectively managing emergent issues and vulnerabilities as they are identified through efforts to reach 'core' compliance with Formality of Operations and to implement modern, compliant DSAs once they are approved.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 26, 2008

MEMORANDUM FOR: Timothy Dwyer, Technical Director
FROM: Brett Broderick/Todd Davis, LANL Site Representative
SUBJECT: Activity Report for Week Ending September 26, 2008

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 3, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 3, 2008

Contaminated Puncture Wound: This week, the LANL accident investigation team issued their final report on the recent Plutonium Facility contaminated puncture wound. The team concluded that an undetected metal spur left on a part during a machining operation penetrated the worker's personal protective equipment and punctured the worker's hand. The following three judgments of need (JONs) were identified: LANL should require specific procedures for machining and cutting hard metals (e.g., stainless steel) that identify appropriate hazards and controls; LANL should require part inspection and mitigation of sharps hazards after each cutting or machining operation; and LANL should develop remote and automatic metal handling, cutting, and machining techniques to reduce worker exposure to potential puncture hazards. A separate team is scheduled to develop a corrective action plan based on these JONs by the end of October (site rep weeklies 8/29/08, 8/22/08, 8/15/08).

Site-Wide Fire Protection: This week, after years of negotiation, the National Nuclear Security Administration (NNSA) and Los Alamos County signed a contractual Cooperative Agreement for providing enhanced fire department services to LANL. The new Cooperative Agreement formalizes expectations for minimum overall fire department staffing per shift, minimum shift staffing at key fire stations, response times for nuclear facility emergencies, and compliance with National Fire Protection Association (NFPA) standards. The agreement also establishes a 'major nuclear facilities reserve force' of 7 fire fighters that cannot be deployed to respond to non-LANL events without notifying NNSA. Finally, the Cooperative Agreement creates a requirement for fire department personnel training plans to be jointly reviewed and approved annually by both the county and NNSA.

LANL also recently completed an assessment that verified the site-wide water supply system has adequate tank capacity and appropriate alarm set-points to support the functional requirements of credited fire suppression systems in LANL nuclear facilities. The report did identify several opportunities for improvement including the need to formalize reporting to nuclear facilities when supply system upsets or degradation may impact fire suppression system operability and a need to assess maintenance instructions against the NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*. These improvements are planned for FY09. Because a number of LANL fire suppression systems are credited in nuclear facility DSAs, timely completion of these improvements seems warranted (site rep weeklies 8/1/08, 7/18/08).

Radioactive Liquid Waste Treatment Facility Replacement Project (RLWTF-R): The RLWTF-R project is currently planning to combine Critical Decisions (CD) 2 and 3 and to perform substantive final design activities prior to gaining combined CD 2/3 approval. Because of this deviation from the traditional CD process described in DOE Order 413, the NNSA site office issued a direction letter this week to clarify expectations for what deliverables are required prior to proceeding into final design. NNSA-mandated deliverables included the following: • Safety Design Strategy document, • Rec. 2004-2 confinement ventilation evaluation, • final materials selection recommendations for process tanks and piping, • Preliminary Documented Safety Analysis, • recommendations for hold points during final design to ensure adequate integration of safety and the design, and • identification of adequate influent storage capacity via Waste Management Risk Mitigation tankage or a viable alternative.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 10, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 10, 2008

Transuranic Waste Operations: The RANT shipping facility credits several 1-hour rated fire walls with preventing the propagation of fires that could impact transuranic waste. A sealant material with an unknown fire rating was used to treat two credited fire walls. With this sealant present, the fire rating of the walls is indeterminate and may not provide the required 1-hour rating. Facility management declared a potential inadequacy of the safety analysis (PISA) and suspended operations.

The sealant fire rating issue had been previously identified. The Facility Operations Director (FOD) issued a standing order that established additional combustible loading controls as compensatory measures to disposition the concern. However, this standing order did not adequately address all relevant fire propagation scenarios and had been allowed to expire. In addition to declaring the PISA, facility management also stated that FOD-issued standing orders were no longer considered an appropriate way to disposition issues where a TSR-level design feature cannot perform its credited safety function. Like other recent PISAs at transuranic waste facilities, these deficiencies were identified as a result of a vital safety system assessment (site rep weekly 9/19/08).

Formality of Operations: In August, the NNSA site office directed LANL to provide additional detail and justification for any required elements of Formality of Operations that wouldn't be implemented by the end of FY09. Last week, the site office acted on LANL's response, approving post-FY09 implementation for specific conduct of engineering deliverables at the Plutonium Facility including completion of priority drawings for vital safety systems. The site office disapproved proposed post-FY09 implementation dates for conduct of maintenance and conduct of engineering at the Weapons Engineering Tritium Facility (WETF) and directed LANL to either resubmit acceptable implementation milestones or provide justification for why FY09 implementation is not feasible along with compensatory measures that can be instituted in the interim (site rep weekly 8/22/08).

With the exceptions noted above for the Plutonium Facility and WETF, all approved milestones for Formality of Operations implementation at LANL nuclear facilities are in FY09. The site office has heavily incentivized meeting these aggressive implementation milestones with an award term performance-based incentive (PBI). The award term PBI appears to have helped garner senior management support for adding substantial resources to accelerate implementation efforts.

Chemistry and Metallurgy Research (CMR) Building: LANL is in the process of developing a 10 CFR 830 compliant Documented Safety Analysis (DSA) that supports operation of CMR beyond 2010. As a part of the safety basis development strategy, LANL committed to submitting portions of the analysis to the site office at key points (phase gates). Last week, LANL submitted draft portions of the DSA to the site office for comment including the hazard and accident analysis. Notably, the unmitigated off-site consequences for a seismically induced facility fire scenario were estimated to be approximately 43 rem. Engineered safety controls identified to mitigate or prevent accident scenarios include the fire suppression system, ventilation system and material containerization (floor wells, safes). Administrative controls include facility material inventory (i.e., material-at-risk) and transient combustible controls. Following site office review of the submittal, LANL will schedule a phase gate review session to resolve issues and obtain site office concurrence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 17, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 17, 2008

Contractor Assurance: Last week, the Institutional Management Review Board approved the laboratory's baseline integrated assessment schedule (IAS) for FY09. The approved IAS shows roughly 350 assessments planned for FY09, down from about 500 in FY08. LANL management noted that the decrease reflects a more mature institutional process for identifying and eliminating duplicative reviews across the lab. The FY09 IAS includes three Director's Institutional Assessments focused on functional areas including subcontractor safety, waste management and the maintenance program. However, the IAS does not include any 'facility-centered' Director's Assessments that would provide independent, broad-based review of compliance with DOE requirements for LANL's nuclear facilities. These types of facility-centered reviews have not been performed at the lab since FY07 (site rep weekly 5/23/08).

Weapons Engineering Tritium Facility (WETF): The TSR-level Pressure Safety Program at WETF requires the maximum allowable working pressure for tritium-bearing systems to be identified and protected. Based on concerns raised by the Board's staff, WETF personnel concluded this week that a portion of the safety-significant Tritium Gas Handling System was not adequately protected from potential overpressurization. This issue led to broader questions about the implementation of Pressure Safety Program requirements across WETF. As a result, facility management declared a TSR violation based on a breakdown of the Pressure Safety Program and suspended operations. LANL management is chartering an independent review of the implementation of all TSR-level controls at WETF to identify any other latent deficiencies that may exist.

Chemistry and Metallurgy Research Building Replacement (CMRR): The CMRR Nuclear Facility will be connected to the Plutonium Facility by an underground tunnel to support safe and secure nuclear material transfers. The original intent was to tap into an existing section of tunnel that currently houses interim radiography operations, based on the assumption that by the time CMRR Nuclear Facility construction began, radiography operations would have moved into a new Long Term Radiography facility. However, Long Term Radiography project activities have been suspended and the existing tunnel will be occupied by interim radiography operations longer than originally assumed. This will likely require the CMRR project to design a new tunnel to connect the two facilities. This could present a number of new design and construction challenges including locating a suitable site to create a large new penetration in the Plutonium Facility structure. The design and equipment sizing for key safety systems including fire suppression and confinement ventilation could also be affected.

Plutonium Facility: In Board correspondence dated May 30, 2008, the staff noted that hazards associated with hydrogen generation for weapons-grade plutonium aqueous processing operations may have been inappropriately screened during development of the new Documented Safety Analysis. The current facility safety analysis also does not identify this potential hazard. In response to this concern, facility personnel recently completed preliminary calculations for hydrogen concentrations in the aqueous process vessels. On Friday, LANL declared a potential inadequacy of the safety analysis based on these calculations. Currently, only one process vessel contains significant plutonium solution. Facility management identified an initial compensatory measure to provide a vacuum purge for this vessel. In addition, plutonium dissolutions are on hold pending resolution of

this issue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 24, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending October 24, 2008

Bamdad and Plaue were onsite this week reviewing Plutonium Facility safety basis and safety system upgrade efforts. Andersen, Hadjian, Kimball, and Rizzo were also onsite reviewing sitewide seismic issues and the structural design of the Chemistry and Metallurgy Research Building Replacement.

Contractor Assurance: The LANL Deputy Director has approved a change to the laboratory's Integrated Assessment Schedule for FY09 to include a 'facility-centered' Director's Assessment of the Chemistry and Metallurgy Research Building and select waste facilities. The resumption of facility-centered Director's Assessments, which haven't been performed since FY07, is positive and should help strengthen the overall effectiveness of LANL's Contractor Assurance (site rep weekly 10/17/08).

Plutonium Facility: The TA-55 Reinvestment Project (TRP) is a 3 phased effort to improve and upgrade safety systems and overall facility infrastructure. Phase 2, which is nearing critical decision-2, includes several important safety improvements (e.g., glovebox stand upgrades, uninterruptible power supply replacement, confinement door replacement and vault water bath storage tank replacement). Completion of these projects, along with implementation of a safety class active confinement ventilation system, is crucial to the overall LANL effort to significantly improve the confinement strategy and overall safety posture of the Plutonium Facility over the next 3 to 5 years. Recently, facility management requested a significant acceleration of Phase 2 of the TRP. This request is based on the high priority nature of the replacement and upgrade projects in Phase 2 and recognition that recent program decisions have reduced the anticipated operational tempo of the facility near-term, opening a window of opportunity to accelerate work on critical infrastructure.

Transuranic Waste Operations: LANL recently exercised the new remote venting capability at Area G to address the last 11 unvented drums associated with the High Activity Drum campaign. Once vented, the flammable gas concentration inside of a drum must fall below a specified limit before it can be handled as a normal vented drum at Area G or be shipped to the WCRR repackaging facility for any additional processing that may be required prior to final disposition. Five of the newly-vented high activity drums retained steady-state hydrogen concentrations above the existing administrative limit of 1%.

This week, LANL requested and received NNSA approval to increase the allowable hydrogen concentration limit to 4%, based on analysis and guidance contained in DOE Standard 5506, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*. In its approval memo, NNSA stipulated that this TSR change is only applicable to the five remaining high activity drums and the limit will revert to 1% after these drums are dispositioned. All remaining drums associated with the High Activity Drum campaign have now been transferred to WCRR for final processing.

Training: Development of compliant and approvable Training Implementation Matrices (TIM) for LANL nuclear facilities has been a persistent challenge. However, LANL recently submitted TIMs for all nuclear facilities. These TIMs describe selection, qualification, certification and training requirements, per DOE orders. This is an important step in the overall implementation of conduct of training, which continues to lag behind other elements of the Formality of Operations initiative.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 31, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 31, 2008

Radioactive Liquid Waste Treatment Facility (RLWTF): On Wednesday, LANL identified an active leak site in a legacy sludge tank (TK-7) associated with liquid transuranic waste processing operations. This tank contains approximately 17 Am-equivalent curies of settled sludge and water. A plastic containment measure, which was recently applied at this location due to visual indications of corrosion, contained the leakage. No external surface or airborne contamination was identified. Initial response actions included providing a more robust plastic containment around the leak site and a larger containment feature beneath the tank to mitigate a more catastrophic failure.

As a part of the restart efforts for transuranic liquid waste operations (Room 60), a newer sludge tank (TK-7A) was installed to replace TK-7. LANL had previously attempted to deinventory TK-7 but failed due to clogging of the transfer piping. Most of the clogged transfer piping was replaced and TK-7 deinventory was planned to be performed as an initial evolution following Room 60 restart. To resolve the TK-7 leak and place the facility in a safe/stable configuration, LANL requested site office approval on Wednesday to perform this deinventory in advance of the contractor readiness assessment (currently scheduled to begin next week) and NNSA authorization to restart Room 60 operations. LANL noted that the necessary procedures and qualified operators were available for this operation. Also, the transfer path (except a small portion associated with TK-7) has been recently tested in anticipation of restart. Following site office approval of LANL's plans for this evolution, facility personnel attempted to deinventory the tank on Friday; however, efforts to transfer sludge from TK-7 to TK-7A were unsuccessful. LANL is currently considering additional options to resolve this issue.

Formality of Operations: Available site resources, in particular facility and system engineering, have constrained LANL's plans and progress on implementing Formality of Operations to increase confidence in facility safety systems and safety programs. Recently, LANL designated approximately \$20 M in FY09 funding to provide additional external resources to augment facility resources for implementation of Formality of Operations. Each of the LANL nuclear facilities has identified their functional area needs (e.g., system engineers, procedure writers, and training instructors) and these are being matched with specific resources available from corporate partners.

Weapons Engineering Tritium Facility (WETF): On October 20th, the circuit that provides power to the WETF ventilation system was de-energized during the latest evolution in support of a vaguely-defined, on-going troubleshoot-and-repair maintenance activity. This secured the dedicated ventilation feature that had been provided to exhaust offgas from tritium-contaminated components that were staged in plastic bags in a WETF room. Without this ventilation, offgassing from the staged components caused the tritium-level in the room to rise, prompting a tritium monitor to alarm when the concentration reached 20 $\mu\text{Ci}/\text{m}^3$. While this event did not result in appreciable worker uptake or room contamination, it did highlight or reemphasize a number of important opportunities for improvement that facility management now appears to be pursuing. These include: •increased formality in identifying and reviewing changes to previously authorized work scope to ensure new hazards or facility impacts are recognized and appropriately addressed; •more specificity in the scope definition of maintenance activities; •validation of the bases for current alarm set points and moving to a more robustly proceduralized alarm response protocol that is less reliant on expert judgment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 7, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending November 7, 2008

This week, Board members Bader, Brown and Mansfield were onsite to conduct facility walkdowns and discuss topics including the Radioactive Liquid Waste Treatment Facility Replacement and Formality of Operations. Staff members Eyler, Kasdorf, Pasko, Plaue and Sautman were also onsite.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Monday, facility personnel successfully transferred sufficient material from TK-7 such that the tank level is below the active leak site that had been identified. Additional actions, which have yet to be developed, will be required to remove the remaining residual sludge from this degraded tank; however, these actions will not be performed prior to formal restart of transuranic liquid waste operations (site rep weekly 10/31/08).

This week, LANL began their Readiness Assessment (RA) for the restart of transuranic liquid waste processing at RLWTF after extensive upgrades were completed to restore the capability to process transuranic liquid waste from the Plutonium Facility. This capability has been unavailable since 2006. On Wednesday, the RA team concluded that the facility had not met the approved readiness prerequisites and LANL management agreed to terminate the review. A number of evolutions could not be performed because facility personnel identified errors in the approved procedures at the pre-evolution brief. Reviews of the remaining procedures by the RA team identified several additional errors that point to inadequate procedure verification and validation. LANL is developing a path forward to resolve these issues and restart this readiness activity. Similar issues with regards to procedure adequacy were identified during other recent readiness assessments related to interim radiography and remote drum venting (site rep weeklies 8/8/08, 6/6/08).

Plutonium Facility: Last week, LANL formally submitted a proposed Plutonium Facility documented safety analysis (DSA) to the NNSA site office for review. New features of the proposed DSA include elevating the functional classification of the fire suppression system from safety significant to safety class for non-seismically induced fires and specifying material-at-risk limits for weapons-grade Pu. While the proposed DSA continues to rely on safety class passive confinement, the planned improvements section commits to implementing a safety class active confinement ventilation system and other important upgrades to improve the Plutonium Facility's safety posture over the next three to five years. If approved, the proposed DSA would replace the existing 1996 Final Safety Analysis Report and a compilation of several dozen other documents that currently constitute the Plutonium Facility safety basis. The scope of the NNSA site office review is limited to ensuring comments from previous review cycles have been adequately resolved. NNSA intends to complete its review and formally act on the proposed DSA by the end of the calendar year.

Formality of Operations: The NNSA site office has reviewed about three-quarters of FY08 Conduct of Engineering deliverables (e.g. Vital Safety System Assessments, System Health Reports, Operability Determinations and System Design Descriptions) and estimates that greater than one-third have quality or consistency issues. The site office plans to provide feedback to LANL on the issues identified during these reviews. Timely communication of NNSA issues and observations appears warranted to ensure that new deliverables, which continue to be produced at an aggressive pace, do not continue to suffer from known process deficiencies.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 14, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 14, 2008

Transuranic Waste Operations: This week, LANL completed shipment of the last of the approximately 235 drums identified in the initial high-activity drum campaign, completing an important step in reducing hazards at Area G (Board letter 1/18/07). Approximately 90 additional above-ground high-activity drums remain in Area G that either exceed the WCRR repackaging facility material-at-risk limit or are cemented sludge drums that require an appropriate method of sampling prior to shipment. LANL plans to perform facility upgrades at WCRR in 2009, in particular, installation of fire suppression in the waste processing glovebox, and associated safety basis upgrades to support processing the waste drums that contain higher material-at-risk. In addition, LANL is working to develop a sampling plan and technique for the cemented drums.

Plutonium Facility: This week, a criticality safety infraction was declared when an item containing roughly 2900g of material was discovered in a vault location with a criticality safety limit of 2500g. This item was shelved in January 2007 and the direct cause of the infraction could not be determined. However, this event did highlight an opportunity to improve the robustness of vault operating procedures. Currently, an operator is required to perform a hand calculation to ensure that an item will comply with the criticality safety limits of its intended vault location prior to shelving. To reduce the probability of human error causing criticality safety infractions, the relevant vault procedure will be revised to require independent verification of the calculation and criticality safety limit compliance.

Next week, the Plutonium Facility will begin a nominal outage period that will continue through December. Unlike last year's outage, on-going programmatic work in the Plutonium Facility will not be suspended. Although the demand to perform programmatic operations during the outage period is expected to be low, a full stand-down was deemed not to be required based on the assertion that concurrent programmatic work would not impact the ability to accomplish outage objectives. These objectives include: • implementing upgrades to the facility control system, • replacing credited HEPA filters, • labeling equipment associated with the ventilation and instrument air systems, • performing system walkdowns to support technical baseline reconstitution, and • establishing a warehouse in the basement for controlled staging of safety class and safety significant equipment and components.

A key lesson learned from last year's facility outage was to complete detailed planning, scheduling and resource-loading well in advance of the outage itself. While high-level outage objectives have been defined, detailed planning and scheduling is still under development with the outage set to begin next Monday. In an effort to ensure timely and effective outage preparation in the future, the Facility Operations Director intends to create a permanent position for a dedicated outage manager.

Chemistry and Metallurgy Research Building Replacement (CMRR): Two recent events at the CMRR Radiological Laboratory, Utility, and Office Building (RLUOB) construction site have prompted LANL management to pause RLUOB construction. One event involved the tipping of a manned boom lift and the other involved a collision between heavy equipment and a forklift. In response, the CMRR project is pairing LANL supervisors with subcontractor supervisors in the field to improve oversight. Management also intends to communicate these lessons learned across the lab.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 21, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 21, 2008

Anderson, Pasko and Plaue were onsite this week to review the Transuranic Waste Facility Project.

Weapons Engineering Tritium Facility (WETF): A number of 1980s-vintage tritium-bearing components are stored for surveillance at WETF in credited containment vessels known as Standard Tubs. As a credited containment vessel, the maximum allowable working pressure (MAWP) of Standard Tubs is required to be defined and protected. This summer, WETF personnel rediscovered a previously-identified discrepancy between the actual bolts installed on the Standard Tubs and those assumed in MAWP derivations. Given this discrepancy, calculations indicated that under worst-case conditions, failure and venting of the legacy components could exceed the MAWP of some tubs.

In July, based on these discoveries, facility management concluded that the situation did not constitute a PISA and could instead be handled through the non-conformance reporting (NCR) process. While LANL's approved PISA process currently provides wide latitude to use NCRs rather than declaring PISAs, there is an expectation to perform an unreviewed safety question determination (USQD) if conformance cannot be restored within hours. The Standard Tub NCR remained open for roughly four months and no USQD was performed. The final NCR closure package determined that the actual MAWP of the Standard Tubs would not be challenged by failure of the legacy components. However, WETF management decided to declare a TSR violation based on the length of time the operability of the credited Standard Tubs was indeterminate and the failure to perform a timely USQD, as required.

Transuranic Waste Facility Project: Solid transuranic waste operations are currently conducted in the 'limited-life' WCRR repackaging and RANT shipping facilities, and at Area G which is required to close by 2015 under a March 2005 Consent Order with the State of New Mexico. The Transuranic Waste Facility Project is intended to design and construct a facility that can provide all necessary solid transuranic waste handling capabilities (i.e. staging, characterization, repackaging, size reduction, and shipping) required to support LANL's future programmatic missions. This week, the Critical Decision-1 (CD-1), *Approve Alternative Selection and Cost Range*, package including the conceptual design report, project execution plan and preliminary hazard analysis report was completed and endorsed by the site office. A decision on CD-1 approval is expected in mid-December. However, if CD-1 is approved, LANL plans to conduct a series of value engineering studies to evaluate, among other things, the feasibility of extending the life of existing facilities (e.g. WCRR and RANT) in order to decrease the scope and cost of this project. If these studies result in significant changes to the project's scope, design, and/or safety strategy following CD-1 approval, then commensurate independent evaluation of the adequacy of these changes appears warranted.

Confinement Vessel Disposition: The Bolas Grande project is currently scoped to remediate 14 six-foot diameter legacy confinement vessels in Wing 9 of CMR. This scope does not include remediating four additional six-foot vessels containing transuranic waste that are staged at Area G and have no defined disposition path. An additional 23 three-foot diameter legacy confinement vessels are also staged at Area G with no defined disposition path. Some of the options that are currently under consideration for dispositioning the three-foot vessels would involve new or prolonged use of the Chemistry and Metallurgy Research Building.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 28, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 28, 2008

Transuranic Waste Operations: Last Sunday, a deflagration occurred during remote drum venting operations at Area G. The affected drum contained roughly two Pu-239-equivalent curies of material that was cemented into 35 one gallon containers and packed in a 55 gallon drum in the 1980's. The deflagration did not cause energetic ejection of drum contents and the venting enclosure was not breached so all resultant contamination was contained in the enclosure. Five operators involved in the evolution were taken to the hospital after reporting respiratory distress thought to be caused by chemical vapors emanating from the newly vented drum or combustion products from the deflagration. All operators have reported back to work, although one remains on medical restriction.

The cause of the deflagration remains unclear and investigation continues. Eight operators were maintaining the TSR-controlled 90 foot separation distance from the HEPA-filtered enclosure when the event occurred. Personnel reported hearing an abnormally loud noise when the spark-resistant venting tool punctured the 55 gallon drum and almost immediately thereafter smelled an unusual sulfurous odor. Three operators outfitted in personnel protective equipment and respirators (the balance of operators were in street clothes) made a re-entry into the enclosure, observed evidence of a deflagration, and exited the area. Soon after, the five operators developed respiratory symptoms.

The LANL Emergency Management and Emergency Response groups and the Los Alamos Fire Department were notified and responded to the event. Laboratory HAZMAT personnel characterized the drum using thermography to detect any residual combustion. When none was observed, they re-entered the enclosure and plugged vent holes with sample ports, thereby resealing the 55 gallon drum. While the Fire Department did transport the five affected operators to the hospital, they never entered Area G to survey the scene of the deflagration. The affected drum has since been decontaminated, re-secured in a filtered 85 gallon overpack and restored to a segregated and tightly controlled unvented drum storage array pending further investigation and the development of a path forward.

Weapons Engineering Tritium Facility (WETF): Last week WETF management declared a TSR violation related to credited containment vessels known as Standard Tubs. The maximum allowable working pressure (MAWP) of Standard Tubs is required to be identified and protected. Some tubs contain legacy tritium-bearing components that are known to be over-pressurized, and the TSR violation was based on a long period of indeterminacy as to whether a worst case failure of the legacy components would exceed the MAWP of the tubs. Despite the TSR violation, the ultimate conclusion was that the MAWP of the Standard Tubs would not be exceeded under worst case conditions.

This week, new information surfaced that a critical parameter used in calculating worst-case pressures inside the tubs was in error. Recalculated maximum internal pressures show that the MAWP for two tubs is approached, but not exceeded under normal ambient temperature (i.e. 20°C); but is exceeded under credited fire conditions (i.e. 120°C). In response, WETF management has declared a potential inadequacy of the safety analysis. The two affected tubs are stored in an access-restricted room with stringent combustible loading limits. An initial justification for continued operations (JCO) is being prepared for interim storage and a follow-on JCO is planned to remove the legacy components from tubs and reclaim their tritium to eliminate the pressure hazard (site rep weekly 11/21/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 5, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 5, 2008

Davis was offsite this week.

Plutonium Facility: A corrective action plan has been issued to address judgments of need developed during the LANL accident investigation of the August 2008 contaminated puncture wound. The puncture wound was sustained by a Plutonium Facility operator who was using a mechanical cutting device called a nibbler to prepare a stainless steel sample. In addition to the judgments of need, development of the six individual 'Action Plans' also considered information resulting from on-going efforts to analyze all unplanned glove openings at the Plutonium Facility.

The approved Action Plans involve: • revising the Plutonium Facility Design Change Package process to require more participation from glovebox workers in equipment planning and design, and requiring consideration of remote and automated approaches, • piloting and evaluating use-every-time procedures that incorporate Human Performance Improvement principles for a process that involves latent sharps hazards, • restructuring the Plutonium Facility Glovebox Glove Integrity Program to effectively monitor and analyze glove opening data to define better controls and glove properties, • review existing procedures for working with hard materials to ensure adequate controls are provided, • revising Plutonium Facility procedure writing guidance to reflect inspection and latent sharp mitigation expectations for operations involving hard materials, and • reviewing these Action Plans for applicability at the WCCR repackaging facility which was asserted to be the only other LANL facility faced with similar hazards (site rep weeklies 10/3/08, 8/29/08, 8/15/08).

Conduct of Engineering: The pace of progress for a number of important elements of Conduct of Engineering and the broader Formality of Operations initiative has been limited by the availability of cognizant system engineers (CSE). This week, LANL management announced a significant incentive program designed to attract qualified engineers to voluntarily become CSEs. The incentive program seeks to quickly fill the current nuclear facility staffing shortfall of approximately 20 CSEs. The program involves a bonus for becoming a CSE, a bonus for timely completion of CSE qualifications, and a large bonus for remaining a qualified CSE for three years. To help reduce attrition, the large retention bonus will also be available for some existing CSEs.

Chemistry and Metallurgy Research Building (CMR): Wing 9 hot cell work in support of the Advanced Nuclear Fuel Cycle Initiative (AFCI) is not currently reflected in the programmatic baseline for post-2010 operations at CMR. The Department of Energy's Office of Nuclear Energy (NE-51) recently sent a letter to the NNSA site office attesting that CMR was uniquely suited for performing mission-critical AFCI work related to fuel research, development, and qualification. In response, the site office has proposed a path forward in which the AFCI program will fund the development of an addendum to the CMR Documented Safety Analysis being prepared for post-2010 operations. This addendum is intended to allow decision-makers to clearly understand the scope and material-at-risk associated with proposed AFCI activities and the incremental hazards and risk posed to workers and the public should the AFCI scope be incorporated into the programmatic baseline (site rep weekly 5/23/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 12, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 12, 2008

Pasko was onsite this week to attend the Integrated Nuclear Planning workshop.

Formality of Operations: Recently, the site office met with LANL to provide comments on the Fiscal Year (FY) 2008 Conduct of Engineering products including Vital Safety System Assessments (VSSAs), System Health Reports, Operability Determinations and System Design Descriptions. For the VSSAs, the site office noted that the depth of assessments were inadequate in many cases (inadequate document review, interviews and walkdowns, failure to evaluate surveillance test procedures). In addition, the site office noted that the assessment team members were intimately involved with the system being assessed in many cases (e.g., the system engineer or maintenance manager), which may have adversely impacted the assessment outcome. For example, several assessment issues were identified as 'opportunities for improvement' instead of deficiencies in cases where the issue could impact system operability. This feedback was provided informally to LANL with the expectation of improving the Conduct of Engineering products during FY 2009.

This week, LANL personnel noted that a revised VSSA procedure that addresses these issues is planned in the near future. However, the bulk of the VSSAs and other engineering products completed during the later part of FY 2008 were done on safety class systems at LANL facilities (i.e., the most important safety systems). Because of the issues identified by the site office, LANL may need to revisit the Conduct of Engineering products for these important facility safety systems.

Radioactive Liquid Waste Treatment Facility Replacement Project (RLWTF-R): Last week, LANL submitted the Recommendation 2004-2 confinement ventilation evaluation and the material selection recommendations to the site office. For the confinement ventilation evaluation, LANL concluded that the system classification of "important to safety" (defense in depth) is appropriate based on a conservative analysis of the worst case accident scenario (full facility fire). Dose consequences for this accident scenario are estimated to be 0.76 rem offsite and 45 rem to the collocated worker. LANL evaluation of the confinement ventilation system against the Ventilation System Evaluation Guidance document did not identify any gaps. For the material selection recommendation, LANL concluded that lined stainless steel was appropriate for the majority of the facility safety significant tanks and pumps. Although fiberglass-reinforced plastic was identified as a preferred material because of compatibility with the process streams and cost, use of this material would significantly increase the facility fire loading and was therefore not considered a viable option. The site office is reviewing these products, which represent two of the documents identified by the site office in late-October that are required prior to proceeding into final design (site rep weekly 10/3/08).

Integrated Nuclear Planning: This week, LANL, the NNSA site office and NNSA Headquarters held a workshop to discuss the waste management programs and projects. For the Transuranic Waste Facility Project, NNSA decided to postpone the Energy Systems Acquisition Advisory Board meeting that was scheduled for later this month to support a critical decision-1 (approve alternative selection and cost range) for the project. NNSA and LANL plan to revisit the overall solid transuranic waste program to identify the best option (within current constraints) that supports the enduring waste mission at LANL.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 19, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 19, 2008

Davis was offsite this week. The staff held teleconferences on the Chemistry and Metallurgy Research Building and Radioactive Liquid Waste Treatment Facility Replacement projects.

Weapons Engineering Tritium Facility (WETF): Hot operations in WETF have remained suspended since October when a TSR violation was declared based on a programmatic breakdown of the Pressure Safety Program. In response to these issues, facility management initiated a comprehensive review of the implementation of pressure safety requirements for all pressurized tritium systems credited at WETF (e.g. tritium gas handling system and tritium containment vessels). A separate, but related effort is evaluating the implementation of other important credited safety management programs such as the Containerization Program and the Hazardous Material Protection Program. When these evaluations are complete, WETF management intends to use established criteria to bin resulting issues and non-compliances into those that must be addressed prior to resuming hot operations and those that can be dealt with post-resumption.

Resumption of hot operations is needed to allow the processing of over-pressurized legacy tritium-bearing components that are currently stored in credited containment vessels whose maximum allowable working pressures could be exceeded under worst-case accident conditions. These containers were the subject of a potential inadequacy of the safety analysis that resulted in a positive unreviewed safety question. A justification for continued operations (JCO) was submitted to the NNSA site office on December 2nd to define and authorize the conditions under which the affected containers could continue to be safely stored since their current configuration is outside the approved WETF safety envelope. The site office has yet to act on this JCO. WETF personnel are developing a second JCO intended to scope, analyze, and define controls for ultimate processing of the pressurized legacy components to eliminate the existing hazard (site rep weeklies 11/28/08, 11/21/08, 10/17/08).

Chemistry and Metallurgy Research Building (CMR): Last week, CMR management declared that the facility had achieved 'core' implementation of Conduct of Operations. CMR is the first nuclear facility to declare implementation of Conduct of Operations since LANL established formal criteria defining requirements for 'core' and 'mature' implementation of the conduct of operations, maintenance, engineering and training elements of the Formality of Operations initiative. For the operations element, core implementation requires a facility to achieve compliance with all 18 chapters of the LANL Conduct of Operations manual that is modeled on DOE Order 5480.19, *Conduct of Operations*. The review to independently verify adequate implementation is scheduled for January.

Transuranic Waste Operations: Investigation continues into the November remote drum venting deflagration event at Area G. The investigation team is evaluating a number of potential causes of the event including a hydrogen deflagration (possibly initiated by electrostatic discharge between the venting tool and electrically isolated metallic objects inside the drum) and the in-drum formation of shock sensitive energetic materials that could have been impacted during venting. In an effort to gather additional data to help determine the cause of the event, preparations are being made to analyze combustion residue collected from the scene and to allow the lid of the 55-gallon 'event drum' to be removed to perform visual and forensic examination (site rep weekly 11/28/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 26, 2008

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending December 26, 2008

Broderick and Davis were offsite this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 2, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 2, 2009

Mr. Broderick was offsite this week.

Plutonium Facility: Last week, the site office issued their Safety Evaluation Report (SER) for the Documented Safety Analysis (DSA) and Technical Safety Requirements. Implementation of these documents includes upgrading the classification of the fire suppression system for non-seismically induced fires and identification of material-at-risk (MAR) limits for weapons-grade plutonium. The SER identified 13 Conditions of Approval (COAs) including the following:

- submittal of an integrated project management plan in March 2009 for the upgrades proposed in the DSA that provide a safety class active confinement ventilation system within the next 3 to 5 years;
- for the facility fire suppression system, completion of a gap analysis against NFPA 13 and 25, system adequacy analysis and TSR operability requirements – these actions are due in March 2009 with a subsequent projectized plan to address the results in May 2009;
- completion of a comprehensive Fire Hazards Analysis (FHA) that is integrated with the DSA and the identification of effective combustible loading control procedures that eliminate the possibility of a floor-wide fire – the FHA is due in June 2009 with procedures and DSA integration during the next annual update (December 2009);
- LANL shall accelerate the schedule for seismically upgrading gloveboxes – completion by the end of Fiscal Year 2011.

All of the COAs are required to be included in the site issues management tracking system. LANL is also required to submit a resource-loaded implementation schedule with a completion date of no later than the end of calendar year 2009.

Chemistry and Metallurgy Research Building (CMR): Recently, LANL submitted their evaluation of an exit strategy for the CMR Building that does not include use of the CMR Replacement Nuclear Facility (CMRR NF). The report asserts that all options evaluated given this constraint substantially increase the safety, security and programmatic risks at LANL versus the current approved baseline. Alternatives for analytical chemistry/material characterization were identified as having the largest scope, schedule and budget implications. LANL recommends additional evaluation of elevating the Radiological Laboratory, Utility, and Office Building to a category 2 nuclear facility if the CMRR NF is significantly delayed. LANL also recommends pursuing additional actions to improve the Plutonium Facility vault utilization.

To support operations at CMR beyond 2010, LANL is in the process of developing a 10 CFR 830 compliant DSA. During development of the safety basis, LANL committed to providing portions of the analysis in 3 phases. In early October, LANL submitted the second phase of the analysis. This week, the site office provided comments to LANL including better identification of MAR for accident scenarios and identification of safety class controls for assumptions that are identified during scenario development for design basis accidents.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 9, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 9, 2009

Plutonium Facility: This week, a glovebox glove breach occurred while an operator was performing housekeeping activities in a heat source plutonium (i.e. Pu-238) glovebox. To prepare a glass condenser tube to be removed as waste, an operator applied tape to the outside of the tube, broke the glass with a blunt tool, then folded the broken tube over to reduce its size. Post-evolution monitoring found contamination in excess of two million disintegrations per minute on the palm of the operator's inner glove. The inner glove was intact and nasal smears showed no indication of an uptake.

An integrated work document (IWD) provided activity-level work control for the glass breaking and handling portion of this operation. Although one section of the IWD calls for protective leather or Kevlar gloves to be used over the glovebox gloves 'as necessary,' the section identifying required personnel protective equipment (PPE) and the IWD's procedural steps clearly require the use of protective over-gloves and puncture resistant inner gloves. The operator was not wearing either of these two required pieces of PPE during the glass breaking and handling operation, nor was the evolution performed in accordance with the procedural steps in the IWD.

The breached glovebox glove is being removed for examination in an attempt to determine the direct cause of the event. Even if the broken glass is determined not to have breached the glovebox glove, this event still highlights a case where an operation involving latent sharps in a high hazard environment was performed without appropriate controls in spite of the significant attention that has been focused recently on safe handling of sharps inside gloveboxes. In response, facility management has suspended all glass breaking and handling operations by the affected group and has committed to developing a single procedure for use in all glass breaking and handling operations in the facility. This new procedure will be incorporated into the glovebox worker training process.

Transuranic Waste Operations: Area G is operating under a justification for continued operations (JCO) that addresses positive unreviewed safety questions related to deficiencies found in the credited vehicle barriers and dome door restraints. The JCO includes several commitments to improve analyses and implement improvements to the vehicle barriers and dome door restraints by December 31, 2008. When this date passed without all commitments being satisfied and without formal relief from the NNSA site office on the deliverable dates, there was significant confusion as to whether the safety basis had been violated and whether Area G operations continued to be authorized. On Thursday, the site office issued a letter granting relief on the original deliverable dates. This experience has prompted LANL to begin screening all other existing JCOs, to identify other instances where there may be ambiguity in whether a commitment constitutes a formal control or requirement.

Site-Wide Seismic Hazards: Recently, LANL provided the site office with an update on the plans to re-evaluate the Updated Probabilistic Seismic Hazard Analysis (UPSHA). The approach includes near-term actions to complete recommendations in the UPSHA (e.g., use of next generation attenuation ground motion relationships and trenching studies) and a series of longer-term actions. The near-term actions and analyses are expected to result in a 9 to 12 month delay in facility-specific evaluations (i.e., the SAFER project). LANL plans to submit a revised JCO to accommodate this delay. The existing JCO expires in June 2009 (site rep weeklies 9/12/08, 6/27/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 16, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 16, 2009

This week, Board members Bader, Brown and Winokur were onsite to conduct facility walkdowns and discuss topics including Formality of Operations, the Chemistry and Metallurgy Research Building exit plan and transuranic waste activities. Staff members Moury and Plaué were also onsite.

Transuranic Waste Operations: In September 2008, LANL submitted and the site office approved a formal recovery plan to address a Technical Safety Requirement (TSR) violation associated with the Area G lightning protection system. The site office approval letter included a condition of approval (COA) that required specific actions to be performed prior to December 1, 2008. The letter also noted that the approval expires on December 31, 2008. One of the actions required ground resistance measurements on all transuranic waste storage areas and has yet to be completed. LANL submitted a written request for relief from this requirement in early-December; however, the site office did not respond to this request. On Tuesday, the Facility Operations Director was notified of this issue and directed a suspension of transuranic waste operations. On Thursday, the site office approved an extension of the recovery plan and operations were allowed to be resumed. Although Area G did not comply with a COA and approval of the recovery plan had expired, the LASO letter on Thursday concluded that the facility was not in violation of its TSRs. Instead, LASO concluded that Area G was not in compliance with the hazard controls specified in a recovery plan. The site office also requested that LANL improve its performance in tracking and completing COAs in a timely manner.

Chemistry and Metallurgy Research Building Replacement (CMRR): The site office recently requested that the CMRR project team charter an independent review using corporate reachback to determine if the technical requirements in the Preliminary Documented Safety Analysis (PDSA) have been adequately captured in the interim design and to evaluate key project procedures that will be utilized during detailed design. This week, the team completed their review and provided feedback to NNSA Headquarters and the site office. The team identified a number of positives and the following four issues: specific design criteria for safety class fire suppression systems have not been established by DOE; most design documents have not been revised for consistency with the most recent PDSA (although redline documents reviewed by the team for most safety systems did appear consistent); several codes and standards identified in the PDSA and system design descriptions need to be revised; and project specific procedures need to be developed or revised in some cases. Overall, the team concluded that the design for key safety structures, systems and components is well developed and meets the requirements identified in the PDSA. This team will provide their final report as input to the Technical Independent Project Review that is scheduled to start the last week in January.

Weapons Engineering Tritium Facility (WETF): Currently, activities at WETF include gas transfer system research, development, and design authority functions. NNSA Headquarters (NA-10) has announced a decision to consolidate these types of gas transfer system activities at Sandia National Laboratories and has tasked Sandia to develop a transition plan detailing how this consolidation will be effected. The ramifications of this decision on the near and long term future of WETF are not yet clear. However, this new direction may shift focus at WETF to rapidly de-inventorying the roughly 330 grams of tritium remaining in the facility and affect the strategy, priority and schedule for improving the facility's safety basis and implementing Formality of Operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 23, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 23, 2009

Weapons Engineering Tritium Facility (WETF): Tritium stored outside of process equipment or gloveboxes is required to be contained within credited vessels whose maximum allowable working pressure (MAWP) is identified and protected. LANL has submitted and the NNSA site office is reviewing a justification for continued operations (JCO) to store, handle and ultimately process a population of primary containment vessels (PCV) that are known, or have the potential, to have internal pressures exceeding their MAWP. This population of PCVs was identified in the aftermath of a related potential inadequacy of the safety analysis and issues associated with the implementation of WETF's credited Pressure Safety Program. Processing these PCVs is required to eliminate the hazard they currently present. The JCO and its supporting hazard analysis rely primarily on existing controls to perform these processing activities (site rep weeklies 12/19/08, 11/28/08, 10/17/08).

The JCO covers continued storage and processing of 217 PCVs (32% of the total number stored at WETF). Of these, 146 PCVs are currently stored inside some other credited feature (e.g. a glovebox or secondary vessel) that would contain the released tritium should the PCV fail. The remaining 71 PCVs that contain roughly 9 grams of tritium are currently stored in open drums. Since these 71 PCVs exceed (or potentially exceed) their MAWP, the PCVs themselves cannot be relied upon to provide credited containment. Therefore, although the room housing these items is not routinely occupied and is equipped with tritium monitors, the 9 grams of tritium in these 71 PCVs is not protected by a credited containment barrier. Access to the room where these 71 PCVs are stored is not currently restricted and the primary control to ensure worker protection during continued storage of these items appears to be the tritium monitors that would detect, but not prevent a release.

Transuranic Waste Operations: This week, LANL environmental programs management met with the NNSA site office to discuss preliminary plans to augment Area G capabilities in order to substantially increase transuranic waste shipments beginning this fiscal year. LANL continues to be challenged to complete closure of Area G by 2015. To achieve a planned 114 shipments to WIPP this fiscal year (versus roughly 75 shipments last year), LANL plans to add a second shift at the WCRR repackaging facility and the Dome 231 Permacon, startup a debris waste processing line inside the Decontamination and Volume Reduction System facility and other near-term capability and process improvements. To support these activities and to allow additional repackaging activities to occur in Area G, LANL is considering a series of changes to the existing safety basis in parallel with the planned submittal of a new safety basis document. Longer-term plans include a standard waste box characterization line, size reduction capability and preparations for below ground waste retrieval.

Chemistry and Metallurgy Research Replacement (CMRR) Project: The current design response spectra contained in the LANL Engineering Standards Manual (ESM) is based on the May 2007 Updated Probabilistic Seismic Hazard Analysis (UPSHA) and provides bounding spectra applicable anywhere onsite at LANL. In December, LANL committed to updating the ESM to provide site-specific spectra for TA-55/CMRR that reduces some of the conservatism in the bounding site-wide spectra. At the request of the CMRR Project, LANL recently provided site-specific spectra for use during design in advance of the ESM update. Additional LANL activities to refine the UPSHA are on-going and will be reflected in the CMRR spectra when appropriate (site rep weekly 1/9/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 30, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 30, 2009

Management: This week, LANL management announced an impending organizational change affecting the Radioactive Liquid Waste Treatment Facility (RLWTF). Programmatic ownership of RLWTF will transfer from the Associate Director (AD) for Environmental Programs to the AD for Stockpile Manufacturing and Support. Responsibility for maintaining and protecting the RLWTF safety basis will also transfer from the Facility Operations Director (FOD) for Environmental and Waste Management Operations (who also oversees solid transuranic waste facilities such as Area G, the WCRR repackaging facility, and the RANT shipping facility) to the Plutonium Facility FOD. Formal transfer of responsibility for RLWTF is expected to occur as early as next week.

Weapons Engineering Tritium Facility (WETF): On Thursday, approximately 100 gallons of water was inadvertently released from a pressurized safety significant fire suppression system during a corrective maintenance activity. The work package for this activity incorrectly identified lock-out/tag-out for an isolation valve associated with a different wet pipe fire suppression system. Once maintenance personnel recognized the system was pressurized, the correct isolation valve was closed, which stopped the release of water. WETF personnel then entered the Limiting Condition for Operation (LCO) for the second fire suppression system (that was now isolated) and access to the WETF complex was controlled due to the potential for contamination. Subsequent samples concluded that the water was not contaminated and clean-up efforts were conducted. Actions were taken Thursday afternoon to return both of the fire suppression systems to service and exit the LCOs. On Friday, WETF management declared a stand-down of all maintenance activities to evaluate and address the potential for similar issues. Criteria for release of these packages are being developed and will be applied based on work priority and risk. LANL investigation of the event is on-going.

Transuranic Waste Operations: NNSA site office personnel recently performed a safety system oversight assessment on waste drums that are credited in the safety bases for Area G, RANT, and WCRR. These drums serve as a key engineered barrier for preventing release of material at risk at LANL's solid transuranic waste facilities, especially at Area G where these drums are typically the only form of robust safety class containment. Preliminary findings presented at an assessment outbrief this week identified a number of issues that the site office asserts could challenge the ability of the waste drums to perform their credited safety functions. One such finding concludes that LANL drum closure procedures do not conform to the drum manufacturer's closure instructions, thus invalidating the required DOT Type A certification of the drum. LANL personnel are reviewing the preliminary report for factual accuracy and to determine appropriate responses to identified issues.

Federal Oversight: Assessments performed by site office safety system oversight (SSO) engineers, like the one described above, have been effective in identifying issues and latent deficiencies in credited safety systems at LANL. SSO engineers are also performing valuable reviews and providing useful feedback on important deliverables (e.g. Vital Safety System Assessments and System Design Descriptions) produced to support implementation of LANL's Conduct of Engineering program. However, the number of these types of assessments and reviews is limited by SSO resources. The site office is currently staffed with two SSO engineers versus an identified need of 6.5 full time equivalents. The on-going NNSA hiring freeze is impacting the ability to fill these key vacancies.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 5, 2009

MEMORANDUM FOR: Timothy Dwyer, Technical Director
FROM: Brett Broderick/Todd Davis, LANL Site Representative
SUBJECT: Activity Report for Week Ending February 5, 2009

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 5, 2009

MEMORANDUM FOR: Timothy Dwyer, Technical Director
FROM: Brett Broderick/Todd Davis, LANL Site Representative
SUBJECT: Activity Report for Week Ending February 5, 2009

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 13, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 13, 2009

Board member Bader and staff member Pasko were onsite this week to observe an Integrated Nuclear Planning workshop. Pasko also discussed Board Rec. 2004-2 with LANL and NNSA personnel.

Chemistry and Metallurgy Research (CMR) Building: LANL recently submitted the Documented Safety Analysis (DSA) and associated Technical Safety Requirements (TSR) for post-2010 operations in the CMR Building. The DSA supports continued analytical chemistry and material characterization activities in Wings 5 and 7, confinement vessel disposition activities in Wing 9 and deactivation activities in the other CMR wings. Wing 9 hot cell work in support of the Advanced Fuel Cycle Initiative is not currently analyzed in the DSA. Off-site consequences for a seismically induced facility fire scenario are estimated to be approximately 36 rem (Wing 9 material-at-risk to support confinement vessel disposition contributes approximately 14 rem to this scenario).

Weapons Engineering Tritium Facility (WETF): Hot operations at WETF have been suspended since October due to systemic pressure safety issues. A comprehensive review of potentially affected safety systems is underway to evaluate the full extent of pressure safety issues at WETF. This ongoing review recently identified a situation where the failure of a compressor servicing a glovebox could release a sufficient volume of gas to over-pressurize and breach the glovebox. No tritium was present in the affected glovebox upon discovery; however, this condition did result in facility management declaring a TSR violation. The compressor is now physically isolated and its failure can no longer challenge glovebox integrity. Although it resulted in a TSR violation, this discovery is positive because the identification and correction of this type of issue was the reason facility management chartered the ongoing safety reviews at WETF (site rep weeklies 12/19/08, 10/17/08).

This week, LANL also resubmitted a DSA and associated TSRs for WETF that were revised to address comments from a previous NNSA review. The priority for review, approval and implementation of the resubmitted WETF safety basis documents is likely to be highly dependent on the outcome of ongoing transition planning to consolidate all gas transfer system research, development and design activities at Sandia National Laboratories (site rep weekly 1/16/09).

Plutonium Facility: LANL management has submitted an implementation plan for the recently approved Plutonium Facility DSA and associated TSRs. Although the site office Safety Evaluation Report requested implementation by the end of calendar year 2009, the resource loaded schedule currently shows implementation completing in March 2010. LANL plans to implement the TSRs in four phases with an Implementation Verification Review after each phase (site rep weekly 1/2/09).

Safety Basis: LANL currently has ten nuclear facilities (or activities) that require DSAs. Three of these facilities have 10 CFR 830-compliant DSAs that are approved and implemented (WCRR repackaging facility, Nuclear Environmental Sites, and Onsite Packaging and Transportation); two facilities have compliant DSAs that are approved but not yet implemented (Plutonium Facility and Material Disposal Area-B); two facilities have submitted nominally compliant DSAs pending NNSA review (CMR and WETF); and three facilities are still developing compliant DSAs (Area G, Radioactive Liquid Waste Treatment Facility and RANT shipping facility).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 20, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 20, 2009

Plaue was onsite this week to discuss the Chemistry and Metallurgy Research Building and the Chemistry and Metallurgy Research Building Replacement Project.

Fire Protection: This week, laboratory management announced an organizational change that would consolidate all personnel with fire protection-related roles and responsibilities into a single division that would report to the Associate Director for Nuclear and High Hazard Operations. The individual who had been serving as LANL's Fire Marshal has been selected to head this new division. The independent Fire Marshall function will be eliminated and the division leader will be responsible for ensuring the robustness and effectiveness of the program and the quality of program-related deliverables. This new approach and management structure for fire protection is consistent with the way other institutional safety management programs (e.g. safety basis) are implemented at LANL.

Also, lab personnel are designing and will soon begin providing training courses to Los Alamos County (LAC) fire fighters on radiological hazards and fire fighting techniques in radiological environments to improve the preparedness of the LAC Fire Department to effectively respond to a fire in a LANL nuclear facility. Eventually, qualification cards for fire fighters will also be developed.

Plutonium Facility: LANL recently completed a backfit analysis on the Plutonium Facility fire suppression system, which was upgraded from safety significant to safety class in the recently approved Documented Safety Analysis. The backfit analysis concluded that the system could meet its safety function for operational fire events (i.e. fires that are not seismically induced) but recommended actions that could significantly improve reliability. The analysis also identified a vulnerability associated with a lack of redundant risers but concluded the system could perform its safety function based on overall system reliability estimates. A project plan to address gaps identified in the backfit analysis and other system evaluations is being developed.

Chemistry and Metallurgy Research Building (CMR): Last week, a contamination event in Wing 3 of CMR resulted in a worker uptake. An operator was moving bags of contaminated equipment that had been removed from a deactivated glovebox. Following a continuous air monitor alarm, radiological control technicians responded and found alpha contamination on the operator's personal protective equipment and personal clothing. Nasal smears were positive, reading approximately 200 dpm per nostril. The affected operator has been put on a bioassay program and is on restricted duty until bioassay results are available. Follow-up actions determined the event was likely caused by the bag of contaminated equipment being dragged across a rough spot on the lab room floor causing abrasions and eventual breaching of the outermost plastic bag used to control contamination.

Transuranic Waste Operations: Prohibited item disposition and repackaging operations are rate limiting steps to prepare transuranic waste to be shipped offsite. To help meet aggressive waste shipment goals for FY09, LANL management has established a second shift for repackaging low-activity (< 0.47 PE-Ci) solidified waste forms in the Dome 231 Permacon and is preparing to begin a second shift for higher-activity operations at the WCRR repackaging facility.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 27, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 27, 2009

Bamdad, Batherson, Grover, Gwal, Kasdorf, March and Spatz were onsite this week to review the preliminary documented safety analysis and the designs for key safety systems for the Chemistry and Metallurgy Research Building Replacement Project.

Chemistry and Metallurgy Research Building (CMR): Last week, a custodian's personal protective equipment became contaminated while mopping a floor in the basement of Wing 7 of CMR. Follow-up actions identified an area on the floor of the affected basement room with contamination levels greater than one million dpm (removable contamination measured at roughly 150,000 dpm). The source of contamination was traced to a leak in the (uncredited) Industrial Liquid Waste System piping that transfers low-level radioactive liquid waste from CMR laboratory rooms to the collection system that routes it to the Radioactive Liquid Waste Treatment Facility in TA-50. The CMR Industrial Liquid Waste System is known to have significant material condition issues and some effort has been made to wrap and bag pipe flanges to help control leaks. The leak site that caused last week's Wing 7 basement contamination event did not have any form of leak containment.

In response to this event, facility management has directed that all Industrial Liquid Waste System flanges be systematically wrapped and bagged. Management also intends to establish a periodic surveillance of the bagged flanges to identify and respond to active leak sites and areas where containment may have been lost. Although ensuring potential leak sites have catch containment bags is an important compensatory measure for widespread Industrial Liquid Waste System material condition issues, there are currently no funded plans for physical repairs or upgrades for this system. The Industrial Liquid Waste System is required to remain in service to support current and future programmatic analytical chemistry activities in Wings 5 and 7 of CMR. Since radioactive liquid released from the Industrial Liquid Waste System is a routine source of contamination in certain parts of CMR, improvements or upgrades may warrant additional consideration as part of the ongoing campaign to reduce operational risks and extend the service life of CMR.

Plutonium Facility: A criticality safety infraction was declared recently when an overmass condition was discovered in a glovebox. Last week, operators moved a plutonium part from a casting glovebox into a machining glovebox that still contained metal turnings from a previous operation. The machining glovebox had separate criticality safety limits for approved metal shapes and plutonium metal. The casting operators mistakenly believed that the higher mass limit for approved metal shapes applied to this material move; however, since the machining glovebox already contained metal turnings from a different part, the plutonium metal limit should have been applied. Once the part was moved, the aggregate mass of plutonium in the glovebox was roughly 110% of the posted limit for plutonium metal. Machining operators recognized the overmass condition the next day and responded appropriately. Upon consultation with the Nuclear Criticality Safety Group, facility personnel corrected the overmass condition. This infraction was binned in the lowest significance category.

This event appears to highlight opportunities to improve the clarity and operator understanding of which posted limit (if multiple limits exist) is in force for a given material move, and to strengthen communications between operators on the transferring and receiving ends of material moves.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 6, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 6, 2009

Plutonium Facility: This week, LANL declared a potential inadequacy of the safety analysis (PISA) based on the presence of an unvented transuranic waste container in the facility that may pose hazards that are not analyzed in the safety basis. In late 2007, this roughly 2' x 2' x 4' metal waste container, which was long thought empty, was assayed and found to be holding contents that included gram quantities of plutonium. Upon discovery, the container was entered into the facility waste item database and operators partially removed the container lid under a radiological work permit in an attempt to characterize the unknown contents. A bagged metal cylinder was observed and when contamination was detected on the outside of the bag, the container lid was restored. The container remained in this state until an NNSA facility representative noticed the container was not vented and notified facility management of a potential safety basis concern.

The container vintage and its briefly observed contents suggest that the items inside may have come from a legacy glovebox line that handled tritium and was decommissioned in the early 1990's. If the metal cylinder seen inside the container does hold tritium, helium in-growth from over one half-life of tritium decay could pose a pressurization hazard. Additionally, the known plutonium inventory makes the unvented metal container transuranic waste. The current facility safety basis requires transuranic waste to be packaged in containers with filtered vents and does not analyze hazards that could be presented by unvented transuranic waste containers. The container has been posted and cordoned off while additional information is gathered to support safe handling and ultimate disposition.

Plutonium Facility Safety Basis: The site office safety evaluation report for the plutonium facility included a condition of approval (COA) for the storage of heat source plutonium (HS-Pu) in the safety class vault water bath (VWB). This COA required LANL to 1) modify the VWB limiting condition for operation (LCO) to address conditions of uncovered non-safety class (non-SC) containers, 2) provide a basis for how long non-SC containers would survive uncovered, and 3) provide a schedule for repackaging these containers. These activities were required to be complete by the end of March 2009. This week, LANL requested relief from the second part of this COA noting that additional time is required to provide a basis for how long non-SC containers would survive uncovered.

There are approximately 210 non-SC HS-Pu containers stored in the VWB of which 50 are of various types. In order to perform pressure calculations to address the COA or to support a disposition path for these containers, LANL plans to begin radiography in April. The radiography and associated calculations are scheduled to be complete by December 2009 and March 2010, respectively. A calculation for the other approximately 160 containers stored in the VWB is being updated and will be reflected in the revised LCO. LANL has dispositioned (e.g., processed) 7 of these containers since October 2008 and plans to ramp up to one container per week. In parallel, LANL is pursuing qualification of Fuel Storage Outer containers (both existing and new generation) per the Nuclear Material Packaging Manual to allow over-packing of existing non-SC containers.

Chemistry and Metallurgy Building (CMR): Based on the recent completion of an effectiveness assessment for implementation of Conduct of Operations (10 findings identified), LANL has declared conduct of operations implemented at CMR and submitted this information to the site office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 13, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 13, 2009

Elliott and Pasko were onsite this week to review criticality safety.

Transuranic Waste Operations: In late February, LANL submitted a proposed waste disposition project strategy for Technical Safety Requirement (TSR) page changes and specific TSR changes to support clarification of safety basis requirements and to improve the efficiency of transuranic waste operations. The submittal of the Area G documented safety analysis, previously scheduled to occur in February, has been delayed to support these and other proposed TSR changes. Last week, the site office approved the following Area G TSR changes: 1) removal of the restriction to only open one transuranic waste container inside the Area G Dome 231 permacon 2) identification of a specific administrative control for arc flash standoff distance between unbonded metal items and the lightning protection down conductors and 3) a revision to the lightning protection system inspection criteria to provide specific requirements and remove broad reference to NFPA 780. The site office also noted that the LANL proposal to change the WCRR repackaging facility allowable headspace gas concentration limit from less than 25% lower flammability limit (LFL) to less than 100% LFL for hydrogen will be evaluated as part of the WCRR annual safety basis update.

Per direction from the NNSA site office, LANL has also submitted a final report on the November 2008 drum deflagration event that occurred during remote drum venting operations at Area G and a proposed path forward for addressing the remaining population of unvented drums. The report postulates that the most credible cause of the event was an electrostatic discharge igniting a flammable mixture of hydrogen and air that had been trapped inside the drum. The electrostatic discharge was thought to be created when the grounded, conductive venting tool punctured the 55-gallon drum lid and a thin layer of lead shielding and came into contact (or near contact) with the charged surface of an insulative plastic containment bag or the charged conductive surface of one of the one-gallon tin cans that were electrically isolated from the larger drum by the bag. This type of electrostatic discharge would be sufficiently energetic to ignite flammable gas concentrations trapped inside the plastic bag since hydrogen-air mixtures have very low ignition energies. Based on analysis of the structural deformation of the affected drum, the report estimates that an 11-12% hydrogen concentration deflagrated during the event. The 'sulfur smell' reported by operators who experienced respiratory distress after the event is thought to be the result of nitrogen oxides created by a chemical reaction initiated by the high temperatures of the deflagration.

Remote drum venting operations have been suspended since November 2008 when the deflagration event occurred. Thousands of additional drums will require venting prior to ultimate disposition, including the 21 remaining above ground unvented drums that are currently in a controlled and segregated storage array. LANL has recommended continued suspension of remote drum venting operations until the existing venting apparatus can be replaced with a more robust engineered system that includes a blast chamber, blast shields, a glovebox, and a HEPA filter train. Until this robust venting system can be procured and fielded (with a target to be operational in 3QFY10), LANL has proposed affixing drum lid restraints and then overpacking the 21 above ground unvented drums to improve the safety of interim storage (site rep weeklies 12/19/08, 11/28/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 20, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 20, 2009

The staff held a video teleconference with LANL and NNSA representatives this week to discuss Area G closure planning and the strategy to safely maintain solid transuranic waste processing capabilities. Kimball was also onsite to discuss re-evaluation efforts for sitewide seismic hazards.

Plutonium Facility: Based on questions from an NNSA site office facility representative concerning a temporary modification, LANL declared a Technical Safety Requirement (TSR) violation this week associated with the lack of an alarming oxygen monitor for a particular glovebox. A Plutonium Facility Specific Administrative Control (SAC) requires use of an oxygen monitor that is calibrated quarterly to ensure local alarm response occurs at less than or equal to 5%. This requirement only applies for “potentially pyrophoric processes (plutonium machining/hydriding)” and is intended to reduce the likelihood of a glovebox fire. For the glovebox in question, an oxygen monitor was installed as a temporary modification (the primary monitor was out of service); however, the temporary unit did not provide the local alarm feature. The temporary modification was evaluated under the Unreviewed Safety Question process but two qualified analysts failed to recognize the potential safety basis impact of this modification. Although specific operations in the glovebox did not involve potentially pyrophoric processes, facility management conservatively declared a TSR violation based on a lack of any controls to prevent such operations from being performed.

Follow-up by facility management also identified issues with implementation of this control for other gloveboxes. Although operational oxygen monitors were available and used primarily for quality assurance purposes, some monitors were not being calibrated quarterly per the SAC. In addition, implementing procedures for processes that create pyrophoric material do not include requirements to verify compliance with the SAC. The implementation validation review that evaluated this control noted that the gloveboxes where this control applied were out of service pending installation of the monitors but did not discuss procedural requirements that implement the control.

Fire Protection: The Cooperative Agreement between NNSA and Los Alamos County mandates that the Fire Department (LAFD) notify the laboratory whenever any LAFD emergency response capability drops below 50% of its normal strength. LANL has established protocols to take this initial notification and alert Facility Operations Directors (FOD) via pager so they can take appropriate action. For example, all FODs have been directed to terminate confined space entries and cease hot work that is not protected by an operable fire suppression system, upon notification. Individual FODs will also take facility or area-specific actions, such as instituting roving watches to monitor operations using high temperature equipment and curtailing firing site operations (site rep weekly 10/3/08).

Criticality Safety: LANL has submitted, for NNSA approval, a significant revision to the Nuclear Criticality Safety Program Improvement Plan (PIP). The revised PIP differentiates unit operations that are subject to process drift that could erode criticality safety margin over time and those operations that are resistant to this type of drift. About 215 drift-prone operations must have a compliant criticality safety evaluation (CSE) by October 2010 or stop work. The roughly 175 remaining drift-resistant operations do not have a deadline for compliant CSE completion and could continue using limits that were validated as part of the Augmented Limit Review in the interim.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 27, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 27, 2009

Davis was offsite this week.

Plutonium Facility: This week, prompted by concerns raised by the staff, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) and implemented a series of compensatory measures related to the transportation, storage and protection of non-safety class (non-SC) heat source plutonium (HS-Pu) containers. About 200 non-SC containers holding a significant quantity of HS-Pu are stored in the Plutonium Facility's safety class vault water bath (VWB). The VWB is relied on to prevent overpressurization of non-SC HS-Pu containers by keeping them fully covered with water to remove heat generated by intense radioactive decay. This week, facility personnel discovered that the process, hazards and controls associated with transporting non-SC HS-Pu containers from the VWB to laboratory rooms and staging these containers in rooms on the laboratory floor are not adequately described and evaluated in the DSA. As a result, even though non-SC containers being transported or staged are subject to the same stresses from internal heat generation as the non-SC containers in the VWB, they did not benefit from the protection of a safety class control to prevent overpressurization. These discoveries resulted in the declaration of a PISA.

This week, facility management also recognized weaknesses in the content and frequency of surveillances used to ensure the safety class VWB was performing its safety function. Existing surveillances were performed monthly to confirm the water in the VWB was above a minimum level and to visually confirm that all non-SC HS-Pu containers remained fully covered with water. However, due to the length of certain non-SC containers, the existing minimum water level checked by the surveillance was too low to keep all non-SC containers fully covered, as required. Additionally, although VWB surveillances were only required to be performed monthly, LANL calculations indicated that credible system upsets could cause water in the VWB to boil in as little as 18 hours, using conservative assumptions. The loss of water level due to this boiling would quickly begin to uncover non-SC containers. Since an unacceptable condition could be created in a matter of hours, the monthly surveillance frequency was deemed to be inappropriate.

In response to the PISA and recognized weaknesses in VWB surveillance practices, facility management took the following actions. All non-SC HS-Pu containers, except for two particularly large containers, were returned to the VWB. Formal controls have been established to protect the two large non-SC containers in their current location until a path forward can be developed. All operations involving transportation and staging of non-SC containers outside the VWB have been restricted pending further evaluation. The minimum water level has been increased to a height sufficient to submerge all non-SC containers currently in the VWB and this level will be verified daily. Control of container configurations inside the VWB will also be established to ensure non-SC containers are not stacked in an arrangement that is higher than the new minimum water level.

LANL and NNSA site office personnel have begun discussing strategies to accelerate longer-term efforts to better understand and protect non-SC HS-Pu containers. Sustained management attention and urgency appear warranted to reduce risk by dispositioning unneeded or unsuitable HS-Pu material and expeditiously processing or robustly overpacking usable HS-Pu stored in non-SC containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 27, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 27, 2009

Davis was offsite this week.

Plutonium Facility: This week, prompted by concerns raised by the staff, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) and implemented a series of compensatory measures related to the transportation, storage and protection of non-safety class (non-SC) heat source plutonium (HS-Pu) containers. About 200 non-SC containers holding a significant quantity of HS-Pu are stored in the Plutonium Facility's safety class vault water bath (VWB). The VWB is relied on to prevent overpressurization of non-SC HS-Pu containers by keeping them fully covered with water to remove heat generated by intense radioactive decay. This week, facility personnel discovered that the process, hazards and controls associated with transporting non-SC HS-Pu containers from the VWB to laboratory rooms and staging these containers in rooms on the laboratory floor are not adequately described and evaluated in the DSA. As a result, even though non-SC containers being transported or staged are subject to the same stresses from internal heat generation as the non-SC containers in the VWB, they did not benefit from the protection of a safety class control to prevent overpressurization. These discoveries resulted in the declaration of a PISA.

This week, facility management also recognized weaknesses in the content and frequency of surveillances used to ensure the safety class VWB was performing its safety function. Existing surveillances were performed monthly to confirm the water in the VWB was above a minimum level and to visually confirm that all non-SC HS-Pu containers remained fully covered with water. However, due to the length of certain non-SC containers, the existing minimum water level checked by the surveillance was too low to keep all non-SC containers fully covered, as required. Additionally, although VWB surveillances were only required to be performed monthly, LANL calculations indicated that credible system upsets could cause water in the VWB to boil in as little as 18 hours, using conservative assumptions. The loss of water level due to this boiling would quickly begin to uncover non-SC containers. Since an unacceptable condition could be created in a matter of hours, the monthly surveillance frequency was deemed to be inappropriate.

In response to the PISA and recognized weaknesses in VWB surveillance practices, facility management took the following actions. All non-SC HS-Pu containers, except for two particularly large containers, were returned to the VWB. Formal controls have been established to protect the two large non-SC containers in their current location until a path forward can be developed. All operations involving transportation and staging of non-SC containers outside the VWB have been restricted pending further evaluation. The minimum water level has been increased to a height sufficient to submerge all non-SC containers currently in the VWB and this level will be verified daily. Control of container configurations inside the VWB will also be established to ensure non-SC containers are not stacked in an arrangement that is higher than the new minimum water level.

LANL and NNSA site office personnel have begun discussing strategies to accelerate longer-term efforts to better understand and protect non-SC HS-Pu containers. Sustained management attention and urgency appear warranted to reduce risk by dispositioning unneeded or unsuitable HS-Pu material and expeditiously processing or robustly overpacking usable HS-Pu stored in non-SC containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 3, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 3, 2009

Plutonium Facility: The NNSA site office approved a new documented safety analysis (DSA) and technical safety requirements (TSR) document for the Plutonium Facility last December. Upon approval, facility management began using the new DSA as the safety basis of record, superseding the patchwork of several dozen documents that had been serving as the Plutonium Facility safety basis. Although the new DSA represents the most up-to-date and complete description of the NNSA-approved risk envelope for the facility, the TSR controls associated with the new DSA are not scheduled to be fully implemented and verified until the second quarter of FY10. Until the new TSRs are verified to be fully implemented, the facility continues to operate under a set of legacy interim TSRs whose development was, in part, a judgment-based consolidation of available controls versus a control set that cleanly and explicitly derived from the collection of previous safety basis documents.

Once it became the safety basis of record, facility personnel began performing unreviewed safety question (USQ) evaluations (both screens and full determinations) against the new DSA and did not consider the previous set of safety basis documents in these evaluations. This week, the NNSA site office challenged the approach of performing USQ evaluations against only the new DSA, rather than against both the new DSA and the previous set of safety basis documents, since the TSRs associated with the new DSA have not yet been fully implemented.

In response to site office concerns, LANL management placed the facility in stand-by mode until the roughly 125 USQ evaluations that have been performed since January can be re-evaluated against the set of previous safety basis documents. Once this evaluation is complete and operations resume, USQ evaluations will be performed against both the new DSA and the previous set of safety basis documents until the TSRs associated with the new DSA are verified to be fully implemented.

Authorization Basis: This week, LANL submitted for NNSA review and approval a revision to the lab's USQ procedure. This proposed revision addresses situations like the one described above by instructing that, "[t]he USQ process must be performed against the relevant safety basis documents, both the current 'implemented' safety basis, and the newly approved safety basis document as appropriate." The proposed revision also introduces a New Information Process for evaluating whether new information constitutes a potential inadequacy of the safety analysis (PISA).

Material Disposal Area (MDA)-B: The NNSA site office recently approved a LANL request to re-categorize MDA-B from hazard category (HC)-3 to less than HC-3 (i.e. radiological). MDA-B is a six acre legacy waste disposal site in Technical Area 21 that received radioactive and chemical wastes from 1944-1948. The boundary of MDA-B is only meters away from public areas. The justification for re-categorization assumes that the estimated 12.4 PE-Ci (200 g Pu-239 equivalent) total site inventory is homogeneously distributed throughout the buried waste disposal unit volume. A segmentation argument based on DOE-STD-1120 is then used to conclude that only less than HC-3 quantities of material can be exposed or disturbed at any time during controlled excavation activities. As a result of re-categorization, environmental restoration activities at MDA-B will be performed using a LANL-approved facility safety plan vice an NNSA-approved DSA and readiness will be confirmed through a lab management self assessment vice an NNSA operational readiness review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 10, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 10, 2009

Chemistry and Metallurgy Research Building (CMR): LANL recently completed the CMR Actinide Disposition Strategic Plan that details the initiative to disposition excess (i.e., no defined programmatic use) materials currently stored in multiple locations at CMR (including the floor well storage locations in Wing 9). The plan details a disposition strategy, including processing, packaging, shipping and final destination details, for 41 different material types to be completed by October 2010. The more difficult materials that will require some processing and repackaging include neptunium-237, curium-244, americium-241/243 and uranium-233. To support the disposition strategy for most of these materials, restart of alpha box operations in the Wing 9 hot cells will be required. LANL is performing an engineering evaluation to determine the scope of maintenance and design changes (including safety basis requirements) needed for startup of the alpha box (scheduled for December).

Plutonium Facility: The plutonium facility fire suppression system is being upgraded from safety significant to safety class as a part of the on-going safety basis implementation. In accordance with a site office Safety Evaluation Report condition of approval, LANL recently submitted a gap analysis for this system against National Fire Protection Association standards 13, 25 and 72. LANL notes that despite identified non-compliant conditions, the fire suppression system is able to meet its credited safety function. This submittal also provides a proposed path forward on recommendations identified during the backfit analysis that was completed in February. A new hydraulic analysis is being performed to address several of the recommended evaluations and upgrades. LANL is developing a project plan to address the issues identified in the gap analysis and will provide this to the site office by May 31, 2009.

The site office condition of approval also requested that LANL identify Technical Safety Requirement (TSR) action statements should a sprinkler system be declared inoperable consistent with the requirements in the LANL Fire Protection Criterion 733, *Fire Protection System Impairment Control Program*. The LANL submittal recommends development of an impairment control procedure (implemented under the fire protection program) that would be used by operations center personnel to identify compensatory measures. The site office is currently evaluating this recommendation.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, LANL management presented their strategy to resume transuranic liquid waste processing at RLWTF, which has been down since 2006. A previous attempt to startup a portion of this system in November 2008 was not successful due to issues identified during the laboratory readiness assessment. The strategy now includes startup of the drum tumbler along with other transuranic liquid processing equipment. Along with the additional scope, LANL plans to implement conduct of operations (including personnel training and revising procedures) prior to startup. Based on this additional scope, the schedule for completing the management self assessment, readiness assessment and restart is now October 2009. In the interim, LANL has concluded that additional solution storage space is available in the RLWTF influent storage tanks (both acid and caustic tanks) based on ultrasonic testing. This space will allow limited aqueous chloride recovery and aqueous nitrate operations in the plutonium facility to resume.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 17, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 17, 2009

Plutonium Facility: This week, the Plutonium Facility returned to Operations mode after LANL personnel completed a re-evaluation of all unreviewed safety question (USQ) screens and determinations performed for the facility since January. This re-evaluation was prompted by NNSA site office concerns that facility management had prematurely declared that the recently approved documented safety analysis (DSA) was 'implemented' and began performing USQ evaluations against this document rather than the collection of several dozen documents that served as the facility's previous safety basis. In response, each USQ evaluation that had been performed against the new DSA was re-evaluated against the set of previous safety basis documents. The re-evaluations did not change the outcome of any USQs. Facility personnel will begin performing USQ evaluations against both sets of safety basis documents until the TSRs associated with the new DSA are verified to be fully implemented (site rep weekly 4/3/09).

Sitewide Seismic Hazards: This week, the NNSA site office approved a revision to the sitewide Justification for Continued Operations (JCO) that authorizes nuclear and high hazard operations to continue while the impacts of new information contained in the 2007 updated Probabilistic Seismic Hazards Analysis (PSHA) are evaluated. The 2007 PSHA concluded that seismic hazards at LANL are higher than previously believed. The NNSA-approved revision to the JCO deletes the requirement for additional quantitative analysis and the need for JCO coverage for 18 of the original 24 in-scope nuclear and high hazard facilities. Facility-specific rationale for exclusion was provided for each of the 18 de-scoped facilities. The approved revision also extends JCO coverage for the Plutonium Facility for one year (until June 30, 2010) to provide additional time to perform quantitative analysis of the new seismic spectra on Plutonium Facility structures, systems, and components that are credited with post-seismic safety functions. The JCO expires for the balance of facilities (WETF, RLWTF, WCRR, RANT, and CMR) on June 30, 2009, meaning that facility-specific evaluations performed under the SAFER project must be complete by that date (site rep weeklies 1/9/09, 9/12/08, 6/27/08).

Weapons Engineering Tritium Facility (WETF): WETF personnel have completed reviews of facility safety systems affected by the widespread Pressure Safety Program issues that have kept the facility in Warm Standby mode since last October. Corrective actions associated with deficiencies identified by these reviews have been categorized as either prerequisites or follow-on activities for resuming hot operations and have been vetted by LANL's institutional pressure safety committee. Prerequisites include physical system modifications to install pressure relief devices, improved administrative control of valves and system lineups, and additional personnel training.

The current safety basis requires that the maximum allowable working pressure (MAWP) of systems be known and protected. Given the incomplete technical baseline for some credited systems, the MAWP for a number of components and sub-systems cannot be readily determined. Facility management is expected to pursue a safety basis change to allow resumption of hot operations with compensatory measures to protect credited system components with indeterminate MAWPs. Timely resumption of hot operations is being sought to allow the processing of legacy tritium-bearing components known to exceed their MAWP in order to eliminate the hazard these items present.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 24, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 24, 2009

Galaska, Gerlach, Pasko, and Plaue were onsite to review the proposed Documented Safety Analysis for post-2010 operations at the Chemistry and Metallurgy Research Building. Pasko and Plaue also reviewed the safety strategy for seismically-induced fire scenarios at the Plutonium Facility.

Conduct of Engineering: Last week, LANL issued revised procedures governing system health reporting and vital safety system assessments (VSSA). These revisions are intended to incorporate lessons learned from prior experience and comments from LANL, NNSA and DNFSB reviewers.

VSSAs are a critically important tool for identifying issues that could impact the operability of credited safety systems. To assess the quality and effectiveness of the VSSA process, LANL management chartered a team of highly experienced personnel engaged through corporate reach-back to perform an independent review of VSSAs performed in FY08. This review assessed 31 VSSAs (many of which evaluated safety class systems) and determined that the operability of 18 (58%) of the assessed systems was indeterminate based on the information documented in the VSSA. Inadequate VSSAs will be re-performed using the revised procedure and review teams that are augmented with experienced personnel to provide assistance and mentoring. In the interim, lab senior management has directed Facility Operations Directors to review any potential operability issues identified by the independent team to determine if immediate actions or compensatory measures are warranted.

Chemistry and Metallurgy Research (CMR) Building: During a facility walkdown associated with this week's staff review of CMR, fixed and transient combustibles were observed in an area posted "No Combustible Storage Permitted." This area was posted because sprinkler heads associated with the safety class fire suppression system were obstructed by a large duct and had been declared inoperable. A follow-up critique concluded that TSR requirements related to sprinkler inoperability had been satisfied by removing material-at-risk from the affected areas. The critique also concluded the posting was erroneous because combustibles were allowed to be stored in these areas based on an undocumented assessment performed by a fire protection engineer. This event appears to highlight an opportunity to improve the robustness of management and control of 'affected areas' that do not meet TSR-mandated limiting conditions of operation due to inoperable safety systems or components.

Plutonium Facility: This week, LANL presented their plans for restart of the Plutonium Facility's Isotope Fuel Impact Test (IFIT) Facility to the Joint Evaluation Team (JET), which determines the LANL recommendation for level of startup review. The IFIT is used to impact (using an inert gas launcher) heat source plutonium objects to obtain data that support engineering, quality assurance and mission safety analysis. LANL began IFIT operations in 1996 following a DOE operational readiness review, but the last IFIT evolution occurred in 2001. Based on a customer need, LANL plans to restart this activity and conduct impact testing in FY10. Although subject to site office approval, the JET recommends a laboratory readiness assessment for restart of this activity. This decision is predicated on an assertion that gas launcher activities involving similar hazards and controls are currently conducted at the Plutonium Facility. Ongoing gas launcher activities are performed in a separate laboratory room using a different launcher assembly that involves different TSR-level design features.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 1, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 1, 2009

Plutonium Facility: In late-March, LANL completed the TA-55 Facility Improvement Implementation Plan for TA-55 infrastructure investment to support a long-term plutonium capability at Los Alamos. The upgrades required to transition from a passive confinement strategy to an active confinement strategy (e.g., improvements identified in the DSA) have been captured in the Safety System Upgrade Project (SSUP) and are a part of this overall plan. A project management plan for the SSUP was provided to the site office in accordance with a DSA condition of approval. This plan includes the preliminary scope definitions, execution schedules and cost estimates for 30 subprojects including ventilation system modeling and upgrades, glovebox stand seismic upgrades and fire suppression system upgrades. To support these plans, backfit analyses are required for several systems that will be upgraded to safety class. The ventilation system backfit analysis is expected to be complete in the next two months and will include evaluation against PC-3 seismic criteria.

Transuranic Waste Operations: LANL is pursuing several initiatives to increase the throughput and capability to process and ship solid transuranic waste and achieve closure of Area G by 2015. To support these initiatives, an Area G safety basis change package is under review by the NNSA site office that would allow debris waste repackaging activities involving up to 15 PE-Ci (30 times the current limit) and waste storage of up to 56 PE-Ci (120 times the current limit) of material at the Decontamination and Volume Reduction System (DVRS) Facility. No new controls are identified for higher activity repackaging and DVRS Facility storage activities in the safety basis submittal.

LANL management intends to award a contract early this month to install a debris waste repackaging line inside DVRS. LANL also plans to pursue a 2nd repackaging line at DVRS in the near future. This additional capability, along with the addition of a 2nd shift at WCRR, is expected to allow shipment of the remaining above ground debris waste drums by spring 2010. At that point, LANL intends to pursue upgrades at WCRR (e.g., glovebox fire suppression) prior to the below ground campaign. To support Area G closure, LANL is also conducting life extension studies for WCRR and RANT. The results of these studies will be factored into the plans for WCRR upgrades. Other engineering studies to determine the optimum solution for the enduring transuranic waste mission (i.e., after Area G closure) are ongoing and will be presented at the July Integrated Nuclear Planning workshop.

Additionally, there are 16 remote handled canisters stored in Area G that LANL plans to retrieve and configure for offsite shipment. The Joint Evaluation Team, which determines the LANL recommendation for level of startup review, evaluated this activity and determined that a laboratory readiness assessment (LRA) was appropriate. Based on "urgent operational needs" that appear to be driven by the schedule and availability of shipping assets managed by the Department of Energy (DOE-EM), the site office requested that LANL provide actions needed to augment the management self assessment in lieu of the previously planned LRA. In response to this request, LANL proposed several steps to strengthen the MSA including augmenting the review team with experienced off-site personnel to improve the independence of the assessment. On Friday (5/1), the NNSA site office approved the change to verify readiness to perform these activities through an MSA vice an LRA. The augmented MSA is scheduled to begin the week of May 11th.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 8, 2009

MEMORANDUM FOR: Timothy Dwyer, Technical Director
FROM: Brett Broderick/Todd Davis, LANL Site Representative
SUBJECT: Activity Report for Week Ending May 8, 2009

The site representatives were at DNFSB-headquarters in Washington, D.C. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 15, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 15, 2009

The staff held a video-teleconference with NNSA and LANL personnel to discuss the Chemistry and Metallurgy Research Building Replacement project.

Transuranic Waste Operations: This week, the site office requested an exemption to DOE Order 425.1C to allow a Management Self Assessment (MSA) to verify readiness to retrieve 16 remote handled waste canisters at Area G. The exemption request notes an assertion that the planned MSA review is essentially indistinguishable from an appropriately graded Order-compliant readiness review. The exemption request was approved by NNSA-HQ.

Consistent with the exemption request discussed above, the site office also directed that the site office manager be identified as the startup authorization authority (SAA) and that a plan of action for the MSA be submitted for approval. On Wednesday, LANL started the self assessment and completed field activities and interviews on Friday. Although some independent personnel were added to the MSA team, several of the key functional areas were assessed by facility and programmatic personnel responsible for achieving readiness and ultimately performing these activities.

The Waste Disposition Project (WDP) Program Director recently chartered a Senior Readiness Review Board consisting of laboratory senior management to evaluate an activity's readiness posture and approve the declaration of readiness in advance of formal review. For this remote handled retrieval activity, the Board met on Friday to perform this function after completion of the MSA field activities. Following resolution of MSA pre-start findings and startup approval from the SAA, this activity is planned to begin in late-May (site rep weekly 5/1/09).

Chemistry and Metallurgy Research Building (CMR): The credited CMR fire alarm system includes batteries that provide back-up power to allow the system to perform its safety function if primary facility power is lost. These fire alarm system batteries must meet requirements specified in National Fire Protection Association (NFPA) Standard 72, *National Fire Alarm Code*. Recently, CMR facility personnel recognized that the institutional procedure used to inspect and test these batteries did not include formal acceptance criteria that satisfied NFPA 72 requirements. This discovery prompted a broad extent of condition review to identify other credited fire alarm systems with back-up power supplies whose operability may be affected by the deficient institutional procedure.

In the course of evaluating CMR fire alarm system operability, facility management concluded that a table listing fire alarm control panel battery capacities in the interim Technical Safety Requirements document did not have a defensible technical basis. This discovery prompted facility management to declare a potential inadequacy of the safety analysis.

Emergency Management: LANL has established a 24 hour-a-day, 7 day-a-week Emergency Operations Support Center, staffed by trained personnel, to create a single point of contact for reporting and dispositioning non-life threatening abnormal events or conditions at the laboratory.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 22, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 22, 2009

Plutonium Facility: To improve the safety posture of Pu-238 enriched heat source plutonium (HS-Pu) stored at the Plutonium Facility, LANL management intends to demonstrate, by June 2010, that all HS-Pu storage containers can perform a safety class containment function without requiring heat removal from the vault water bath. Achieving this end state will require repackaging a fraction of the HS-Pu material into safety class containers, overpacking some existing non-safety class containers, and analytically demonstrating that others can meet safety class functional requirements. In the interim, actions are being taken to improve the level of protection for non-safety class containers that continue to require cooling from the vault water bath. One such action is the development of an emergency operating procedure to deal with hardware failures that could result in water loss from the system. This procedure is expected to formalize response actions to isolable system leaks, non-isolable but patchable system leaks, and catastrophic breaches where the baths cannot maintain required water levels (site rep weekly 3/27/09).

This week, the site office approved the implementation plan for the Documented Safety Analysis that was approved in December 2008. The plan divides the control set implementation into four groups with the first Implementation Validation Review scheduled to begin this month. Overall control implementation is scheduled to be complete in March 2010.

Transuranic Waste Operations: In April, a panel of subject matter experts reviewed a draft of the new Area G Basis for Interim Operations (BIO) and provided recommendations to improve document quality and DOE Order compliance. The panel recommended modifying the hazard analysis methodology, applying DOE-Standard-5506, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*, and revising dispersion calculations. This week, LANL management delivered to the NNSA site office a resource loaded schedule for implementing these recommendations. The schedule shows the revised BIO being delivered to NNSA for final review on September 30, 2009.

Last week at the WCRR repackaging facility, an operator observed sparks during an evolution that involved opening and repackaging small vials containing poorly characterized radioactive solids and powders. The operator stopped work and after consultation with facility management, deliberate actions were taken to establish a safe and stable condition. While the cause of the sparks is not yet known, markings on some containers involved in the evolution suggest that the vials may contain pyrophoric material. The WCRR BIO does analyze hazards associated with pyrophoric materials and specific administrative controls are identified to furnish the glovebox with a fire blanket and carbon spheroids and to ensure operators are trained in their use to extinguish small fires. However, the WCRR glovebox is not inerted and although future upgrades are planned, it is not currently equipped with automatic fire suppression. WCRR management has suspended the movement and processing of drums with similar contents pending the results of additional investigation.

Fire Protection: This week, the site office approved the recently completed baseline needs assessment that addresses fire department emergency response services. The site office requested an implementation plan to address the 15 recommendations identified in the assessment by August 2009.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 29, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 29, 2009

The staff held a teleconference with NNSA and LANL personnel to discuss decontamination, decommissioning and environmental restoration activities at TA-21.

Management: The laboratory is establishing a new Facility Operations Director position to oversee the TA-21 work scope that has been accelerated via the American Reinvestment and Recovery Act.

Weapons Engineering Tritium Facility (WETF): Hot operations have not been performed at WETF since pervasive pressure safety issues were recognized last October. During this interval, significant effort has been applied to characterizing and correcting pressure safety deficiencies associated with credited safety systems. Despite these efforts, a number of unresolved issues continue to prevent compliance with existing TSR-level Pressure Safety Program requirements.

During this quiescent period, facility personnel also recognized that some legacy tritium-bearing components stored at WETF may have built up sufficient internal pressure to challenge and potentially breach their containment. Processing these legacy units to eliminate this hazard requires the facility to enter Operations mode, which is currently prohibited due to the TSR non-compliances noted above. This week, LANL submitted proposed TSR revisions that would allow the LANL Pressure Safety Committee to approve acceptable compensatory measures where TSR-level pressure safety requirements cannot be met. The proposed revisions would also lower the WETF facility MAR limit from 560 g to 400 g and reduce the MAR allowed in the Tritium Gas Handling System from 150 g to 100 g (site rep weeklies 4/17/09, 2/13/09, 1/23/09, 12/19/08, 11/28/08, 11/21/08, 10/17/08).

Plutonium Facility: This week, a criticality infraction was declared at the plutonium facility when a plutonium metal sample was identified in a glovebox that was only analyzed and posted for plutonium oxide. Following evaluation by criticality safety engineering, the material was removed from the glovebox. The metal sample was originally placed in the glovebox several years ago in compliance with criticality safety requirements at that time. The glovebox limits were subsequently changed to require oxide only; however, presence of the metal sample that did not comply with the revised limit was not identified at that time. Based on this issue, facility management plans to revise their criticality procedure to require verification of field compliance whenever new or revised limits are established.

Transuranic Waste Operations: On Wednesday, the site office manager authorized the startup of retrieval and loading operations for 16 remote handled transuranic waste containers following review of closure packages associated with the Management Self Assessment pre-start findings. The startup approval included the following 4 conditions of approval: 1) evaluation of programmatic deficiencies and root causes for pre-start findings, 2) treatment of several observations as post-start findings, 3) review of issues associated with implementation of the unreviewed safety question process and 4) evaluation of training records for Area G supervisory personnel (expired or incomplete training not specific to this activity was identified by the site office for some Area G supervisors). A corrective action plan is required for each of these conditions of approval. On Thursday, LANL successfully retrieved the first canister and loaded it into a cask for shipment to the Waste Isolation Pilot Plant.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 5, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 5, 2009

This week, the staff held a conference call with LANL and site office personnel to discuss safety basis changes and resumption of tritium processing operations at the Weapons Engineering Tritium Facility.

Federal Oversight: The NNSA Chief of Defense Nuclear Safety began their two week biennial review of LANL safety programs this week. In addition to evaluating corrective actions for issues that were identified in 2007, the team is focusing on safety system and startup/restart oversight.

Transuranic Waste Operations: This week, LANL began their implementation assessment for conduct of operations and maintenance following facility declaration of implementation at the WCRR repackaging facility and the RANT shipping facility. The LANL team expects to complete their review and provide a recommendation in the next two weeks.

Weapons Engineering Tritium Facility (WETF): Resumption of processing operations at WETF is needed to support disposition of legacy tritium-bearing components that have built up sufficient pressure to challenge their containment. To support a return to operations, LANL had planned to perform a Management Self Assessment (MSA) that would address hardware, procedure and personnel changes, implementation verification review for safety basis changes and independent management observation verifications for conduct of operations chapters that have been implemented. This week, these plans were reviewed by the Joint Evaluation Team (JET), which determines the LANL recommendation for level of startup review. The JET concluded that the planned approach for performing a MSA was appropriate.

Plutonium Facility: In October 2008, LANL declared a Potential Inadequacy of the Safety Analysis (PISA) based on hazards associated with hydrogen generation for weapons-grade plutonium aqueous processing operations. LANL subsequently concluded that an unreviewed safety question existed based on this issue and submitted an evaluation of the safety of the situation (ESS) in February. An active purge for appropriate process vessels was established as a compensatory measure. This week, the site office directed LANL to incorporate appropriate description and analysis for this hazard in the next annual update of the documented safety analysis, which is due in December 2009.

In March, LANL declared a PISA based on the presence of an unvented transuranic waste container that could pose hazards not analyzed in the safety analysis. This issue was subsequently declared an unreviewed safety question and an ESS was submitted to the site office; however, a justification for continued operation or safety basis revision has not been requested. This week, the site office directed LANL to determine a method to resolve this issue and submit appropriate safety basis revisions for approval within the next four weeks.

Formality of Operations: This week, the site office approved a revision to the implementation criteria for Conduct of Engineering. Notably, the revised criteria do not require completion of assessments for all vital safety systems prior to declaring implementation. Instead, the lines of inquiry focus on adequate implementation of the processes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 12, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 12, 2009

Andersen, Bamdad, Batherson, Hadjian, Kasdorf, Kimball, Pasko, and Spatz were onsite this week to review aspects of the Chemistry and Metallurgy Research Building Replacement Project.

Federal Oversight: This week, the Chief of Defense Nuclear Safety (CDNS) completed a review of LANL nuclear safety performance and NNSA site office management/oversight of nuclear safety. Initial feedback from the team was that overall performance had significantly improved since the 2007 CDNS review. However, two Management Concerns (i.e., “a significant issue, or collection of similar issues, that indicates a systemic problem”) were identified. The team noted that site performance in the functional area of readiness did not meet expectations and that the site office has not executed its delegated startup authority in a manner that ensures compliant performance. The team recommends that NNSA Headquarters take immediate action to address this issue. For the maintenance functional area, the team concluded that a compliant maintenance safety management program has not been fully implemented for LANL nuclear facilities and that LASO oversight in this area is not adequately planned and executed.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Monday, a filter system associated with the low-level waste processing system failed resulting in the release of approximately 500 gallons of contaminated liquid waste at RLWTF. The low-level liquid waste spill was limited to one room of the facility and collected in a sump. Low-level waste processing was suspended to address the spill and perform corrective maintenance. The failure mode appears to be cracking of a plastic connection assembly (there are over 300 of these connectors associated with this filter). This same failure mode caused a similar event in October 2008. During inspections this week, 9 additional cracked connectors were identified and replaced. LANL is pursuing corrective actions including information from the vendor and identification of appropriate preventive maintenance.

To address low-level waste processing outages (such as the one described above) and ensure adequate influent storage, LANL recently developed a graded protocol for low-level liquid waste generators that helps reduce influents when storage capacity is low. The least restrictive level of the new protocol was effected this week, requiring generators to take certain actions (e.g., limit safety shower testing and facility mopping) which aided the facility in maintaining sufficient influent storage capacity.

Plutonium Facility: This week, LANL submitted for NNSA review and approval a justification for continued operations (JCO) that would remove existing operational restrictions that prohibit removal of non-safety class heat source plutonium containers from the vault water bath. The JCO proposes a specific administrative control that limits the total time a non-safety class container may be removed from the vault water bath and placed in temporary baths to eight hours and limits the time a non-safety class container may be removed from all water cooling to one hour. An approved JCO is required to radiograph and evaluate a set of poorly characterized non-safety class containers in the near-term, and to support plans for the ultimate remediation of the entire population of non-safety class heat source plutonium containers by June 30, 2010 (site rep weeklies 5/22/09, 3/27/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 19, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 19, 2009

The staff held a teleconference this week with NNSA and LANL personnel to discuss the Chemistry and Metallurgy Research Building Replacement Project.

Engineering: LANL recently achieved a significant milestone in strengthening its engineering program and coming into compliance with DOE expectations. Every vital safety system at LANL now has an assigned cognizant system engineer (CSE) and each system's CSE has completed at least an interim level of qualification. Significant work remains to improve the overall maturity and effectiveness of the CSE program. However, the sustained management attention and resource allocation being devoted to recruiting, training and qualifying CSEs is establishing the foundation necessary to achieve the critically important goal of improving and maintaining confidence in the efficacy of LANL's vital safety systems (site rep weekly 12/5/08).

Contractor Assurance: Last week, a 'facility-centered' Director's Independent Assessment began at the Chemistry and Metallurgy Research Building. Eighteen functional areas (including engineering, operations, maintenance and safety basis) will be evaluated using formal criteria, review and approach documents. This is the first 'facility-centered' Director's Assessment performed by the laboratory since FY07. These assessments are intended to provide independent, broad-based evaluation of a facility's compliance with DOE requirements (site rep weeklies 10/24/08, 10/17/08, 5/23/08).

Sitewide Seismic Hazards: LANL continues to evaluate the impacts of the 2007 updated Probabilistic Seismic Hazards Analysis (PSHA) on structures, systems and components (SSCs) in nuclear facilities. As approved by the site office in April, the Justification for Continued Operations (JCO) that covers this multi-facility issue expires on June 30, 2009 for WETF, RLWTF, WCRR, RANT and CMR and on June 30, 2010 for the Plutonium Facility.

Last week, LANL requested a 5 month JCO extension for the facilities scheduled to expire in June 2009 (i.e., to November 2009) to accommodate an increased need for site subject matter experts in seismic and structural areas to support the CMR Building Replacement Project. For each of the facilities identified above, LANL plans to 1) perform quantitative seismic analysis of SSCs, 2) develop a facility-specific JCO, if required based on the analysis, 3) revise the safety basis, if required, and 4) identify modifications/upgrades to address deficiencies (site rep weeklies 4/17/09, 1/9/09, 9/12/08, 6/27/08).

Transuranic Waste Operations: The NNSA site office recently approved the annual updates of the WCRR repackaging facility Basis for Interim Operation and Technical Safety Requirements. In addition to including previously approved safety basis revisions, the update includes the following notable changes: use of ICRP 72 dose conversion factors; changes to the TSR minimum staffing level and; revision to the WCRR acceptance criteria to allow transuranic waste containers with headspace hydrogen concentrations up to 4%. The site office approval letter reiterates that operations in the waste characterization glovebox that exceed 300 PE-Ci will require a safety basis change and installation of an NFPA Standard 801-compliant automatic fire extinguishing system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 26, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 26, 2009

Davis was offsite this week.

Readiness: This week, NNSA Headquarters issued a letter directing the site office to take a number of corrective actions to address readiness issues identified during the recent Chief of Defense Nuclear Safety Biennial Review. One corrective action requires NNSA Headquarters (NA-17) review and comment prior to approval of key readiness-related documents and decisions, including Startup Notification Reports and authorization to startup or restart hazard category 2 nuclear facilities or activities. The site office must also provide documents describing all activities under consideration for possible startup and restart action to NA-17. The need to maintain these corrective actions will be evaluated by NNSA Headquarters personnel in six months (site rep weekly 6/12/09).

Transuranic Waste Operations: A TSR violation was declared this week at the WCRR repackaging facility for failure to perform required actions when a limiting condition of operation for the fire suppression system (FSS) could not be met. The safety significant WCRR FSS relies on water supplied by the laboratory's sitewide water distribution system that feeds domestic water and fire protection systems in nuclear and non-nuclear facilities across the site. Last week, the Los Alamos County Fire Department (LACFD) performed a fire hydrant flow test in the vicinity of the WCRR facility. This test caused water pressure in the system to drop below the level required for the WCRR FSS to be operable. Although LACFD contacted LANL representatives (including the WCRR Operations Center) prior to testing, WCRR facility personnel did not recognize the TSR implications of the hydrant flow evolution and did not perform required actions to mitigate risks resulting from the safety system impairment.

Since a number of LANL nuclear facilities rely on the sitewide water distribution system to support their credited fire suppression systems, weaknesses in test coordination and facility response protocols could cause similar issues elsewhere. LANL management appears to understand the institutional scope of this issue and has initiated steps intended to improve awareness at nuclear facilities of upcoming LACFD tests and the appropriate response actions required when these tests occur.

Plutonium Facility: Three drum-sized containers staged in the Plutonium Facility basement were recently recognized to be unvented. These legacy containers hold plutonium that is in contact with hydrogenous material. This configuration could result in hydrogen gas being produced via radiolysis, which over time could create a flammable environment inside in the unvented container. Facility management declared a potential inadequacy of the safety analysis (PISA) because it is not clear that this type of hydrogen deflagration hazard is analyzed in the facility safety basis. The affected containers have been cordoned off and an isolation area has been established around them.

This situation has parallels to a PISA declared in March involving the discovery of an unvented legacy transuranic waste container that had also been staged in the Plutonium Facility basement for many years. Both situations were identified by the same NNSA Facility Representative. Facility personnel intend to conduct an extent of condition review to find and address any other unvented containers that may reside in the Plutonium Facility basement (site rep weekly 3/6/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 3, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 3, 2009

Transuranic Waste Operations: This week, LANL successfully completed the campaign to retrieve sixteen remote handled transuranic waste canisters from underground storage at Area G and ship them to the Waste Isolation Pilot Plant (site rep weeklies 5/29/09, 5/15/09 and 5/1/09).

Also at Area G, operators in the Dome 231 Permacon recently began processing low-activity drums containing debris waste forms. Until several weeks ago, the Permacon had been used to remove free liquids from very low-activity (less than hazard category 3) drums containing non-dispersible solidified waste forms. The new campaign involves transferring bagged debris waste from degraded or suspect drums into new, compliant drums for disposal at WIPP. These activities do not involve any sorting or segregating of the debris waste and inventory limits remain below the hazard category 3 level. Personnel protective equipment, including a respirator, is relied on to protect workers from hazards associated with the contaminated debris waste. This new activity is the first step in the lab's plans for increased use of the Permacon to perform open-drum processing activities that will eventually include sorting operations with higher-activity debris waste to increase LANL's legacy waste disposition rate (site rep weekly 5/1/09).

Plutonium Facility: The site office approved a justification for continued operation (JCO) this week that provides the safety basis to allow movement, handling and radiography of non-safety class heat source plutonium containers. The JCO includes compensatory measures that will be implemented as specific administrative controls to limit the time non-safety class containers will be removed from the vault water bath and subject to increased temperatures due to self heating. The JCO also includes implementation of a daily surveillance of the vault water bath to ensure non-safety class containers are covered by at least one inch of water. This control was previously required by a standing order and is also included in the new Documented Safety Analysis that has yet to be implemented. The JCO now formalizes this control and ensures earlier implementation (site rep weeklies 6/12/09, 3/27/09).

There are two particularly large non-safety class containers that have been stored under water in a sink outside of the vault. The JCO retains the previously identified compensatory measure to perform a daily surveillance to ensure these containers remain covered with water. The JCO allows seven days after implementation to either open the containers in a glovebox or reconfigure the vault water bath to support storage of these containers. LANL has also successfully completed qualification activities, including drop testing, of a new robust container called the Fuel Storage Outer (FSO). The JCO approves the use of FSOs as safety class containers for overpacking and storing heat source Pu.

Chemistry and Metallurgy Research Building (CMR): This week, LANL presented the preliminary results from the recent Director's Independent Assessment of CMR facility operations. Overall, the team concluded that CMR was operated in a safe and secure manner due to the commitment and performance of CMR's facility and programmatic personnel. The review team did note staffing shortages in several areas (e.g. engineering, fire protection, emergency preparedness) that may impact the sustainability of compliant operations. The team also noted system and equipment inadequacies, with the fire protection systems in particular, and a lack of clarity and

formality for a facility SAC and some safety management programs (site rep weeklies 6/19/09, 10/24/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 10, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 10, 2009

Technical Area-35 (TA-35): On Wednesday, an Operational Emergency was declared following an energetic chemical reaction at a radiological facility in TA-35. A student had been cleaning small sample vials with acetone. Although unsure of the proper disposal method for the acetone (approximately 30 mL), the student poured it into an acid waste storage container because the sample vials had originally contained trace amounts of nitric acid. The student had not been briefed on the work control document governing this activity and the student's assigned mentor was not present when the acetone was discarded. Later, after the student had left the laboratory, an energetic exothermic reaction took place breaching the primary and secondary acid waste storage containers as well as a bottle containing approximately 2 L of nitric acid in an adjacent acid storage cabinet that had been jarred open by the event. Two workers were in the lab room at the time and exited the area after hearing a loud noise and seeing spilled liquid. These workers re-entered the room to apply a spill kit to the chemicals on the lab room floor and exited again after observing the open acid storage cabinet and realizing the extent of the damage. The event did not impact any radiological material at the facility.

LANL Emergency Management, the LANL Emergency Response Hazardous Materials response team, and the Los Alamos County Fire Department were all notified and responded. As responders were planning and staging equipment to enter the room, they observed brown fumes evolving from the spilled chemicals and being swept through an operating fume hood that exhausted out the facility stack. Recognition of this stack release prompted the declaration of an Operational Emergency. After some complications caused by uncertainty over exactly what chemicals were stored in the breached acid cabinet, responders re-entered the room in appropriate personnel protective equipment and stabilized the scene.

The two workers who initially re-entered the room were taken to Los Alamos Medical Center for evaluation and released without restriction. Their potential level of chemical exposure is being assessed. An investigation into this event will determine root causes and corrective actions.

Weapons Engineering Tritium Facility (WETF): This week, LANL submitted safety basis changes for site office approval to support a return to Operations mode to allow limited tritium de-inventory and MAR reduction activities. These changes supersede Technical Safety Requirement (TSR) changes previously submitted in late-May. LANL now plans to approach the WETF return to Operations mode in two phases. The first phase, which is supported by the safety basis changes submitted this week, only involves the overpacking and shipping of tritium containers outside of tritium pressure systems (i.e., no operations involving the tritium gas handling system or introduction of greater than residual amounts [1.6 g] of tritium into gloveboxes). This initial safety basis change also resolves inconsistencies between the TSRs and the WETF safety analysis report. Following site office approval and facility implementation, LANL plans to perform an Implementation Verification Review prior to performing these limited de-inventory activities. The second phase includes operation of the tritium pressure systems that were subject to the pressure safety issues recognized in October 2008. The safety basis changes and level of readiness determinations needed to support phase 2 operations that involve gas transfers are under development. (site rep weekly 5/29/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 17, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 17, 2009

Board member Bader and staff members Anderson and Moury were onsite this week to observe an Integrated Nuclear Planning workshop. Key topics discussed during this workshop included the projects and plans to support current and long-term solid and liquid transuranic waste missions.

Plutonium Facility: This week, LANL successfully completed the implementation verification review for the controls identified in the Justification for Continued Operations (JCO) that support the movement, handling and radiography of non-safety class heat source plutonium containers. Following implementation and consistent with the requirements in the JCO, LANL relocated the two particularly large non-safety class containers that have been stored in a laboratory room sink to a facility glovebox. These containers were then opened, eliminating any over-pressurization hazard they could have posed. LANL also began overpacking other non-safety class containers into the DOE Nuclear Material Packaging Manual (DOE M 441.1-1)-compliant Fuel Storage Outer containers that were approved as safety class by the recent JCO. The approved JCO also allows other miscellaneous non-safety class container types to be radiographed to provide information needed to determine their ability to survive internal pressurization challenges when not afforded water cooling (site rep weeklies 7/3/09, 6/12/09).

Radioactive Liquid Waste Treatment Facility Replacement (RLWTF-R) Project: LANL is approximately 60% complete with the design effort for this project and has revised the Preliminary Documented Safety Analysis. These products are currently being reviewed by the federal project team with a Technical Independent Project Review planned for October and Critical Decision-2 targeted for May 2010. One important unresolved decision affecting this project is how to provide 100,000 gallons of low-level liquid waste influent storage capacity, which is not included in the current design.

Waste Management Risk Mitigation (WMRM) Project: The WMRM Project was intended to establish a 300,000 gallon low-level liquid waste storage capability in TA-50 that could be used under emergency conditions, like those encountered during the Cerro Grande fire. Work on a Hazard Category 2 tank farm facility proceeded until April 2007, when the WMRM project was halted at the 75% construction completion phase due to significant project management and quality assurance issues. A re-design of the liquid waste receipt tie-in point precluded the introduction of transuranic liquid waste into the tank farm facility. Subsequent approval was granted to complete the WMRM project as a radiological facility that would include only very rudimentary facility systems and could be used only in emergency situations, primarily to receive and store low-level liquid waste. Last month, the project identified enough remaining funds to add scope to install fire suppression, fire alarm, emergency lighting, lightning protection and mechanical ventilation systems. Additionally, in May NNSA approved an equivalency allowing the installed WMRM receipt tanks to be used for liquid storage at the radiological level, although they are constructed of a combustible fiberglass reinforced plastic material. Given these developments, a portion of the installed WMRM tank space is now being strongly considered as a way to provide the low-level influent storage capacity needed by the RLWTF-R, as discussed above. Changing the RLWTF-R project baseline to reflect a reliance on WMRM for low-level influent storage will require formal approval by NNSA, which has not yet

been requested by LANL (site rep weeklies 8/15/08, 3/14/08).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 24, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 24, 2009

Emergency Management: On Thursday, LANL conducted its annual full scale emergency exercise. The exercise simulated an explosion in the Beryllium Technology Facility foundry resulting in several worker casualties and a release of Beryllium from the facility. At one point, the exercise had to be paused for several hours when key participants including Los Alamos County Fire Department, LANL Emergency Response and LANL Emergency Management personnel were called away to deal with an actual hazardous material event, discussed below. Work has begun on an exercise after-action report that will analyze performance and identify opportunities for improvement.

Target Fabrication Facility: The event that led to the pause in the full scale exercise occurred at the Target Fabrication Facility, a radiological facility in Technical Area 35. A worker was transferring a nitric acid solution into a shipping container to prepare it for disposition when an unexpected chemical reaction occurred causing reddish fumes to begin evolving from the container. The worker became concerned that an exothermic reaction occurring inside the shipping container could cause it to fail, so he attempted to transfer the reacting solution into a more robust container. During this attempted transfer liquid began to bubble out of the container. At this point the worker left the room and prompted a facility evacuation. The facility evacuation was complicated by the evacuation alarm being out of service. Also, one individual had not been issued a facility emergency notification pager and remained unaware of the situation and inside the facility for a significant period of time.

Incident command decided to order adjacent facilities in TA-50 to shelter-in-place to protect personnel from exposure to any chemical vapors being exhausted from the Target Fabrication Facility through an unfiltered stack. Notification to shelter-in-place does not appear to have been effectively communicated to all impacted TA-50 facilities, including the WCRR repackaging facility.

Ultimately a hazardous materials team made entry into the facility and stabilized the scene. Fourteen workers, including the individual directly involved in the event were transported to Occupational Medicine where they were examined and released without restriction. The direct cause of the chemical reaction that initiated the event is still under investigation. In part due to similarities with the July 8th exothermic chemical reaction event at another TA-35 facility, the Material Science and Technology division has paused operations involving chemicals, pending reviews of work control documents and walkdowns of laboratory spaces where work with chemicals is performed (site rep weekly 7/10/09).

Formality of Operations: This week, the RANT shipping facility and the WCRR repackaging facility declared 'core' implementation of Conduct of Engineering. RANT and WCRR are the first operating nuclear facilities to complete core implementation of Conduct of Engineering and are also the first nuclear facilities to have declared the set of Conduct of Operations, Maintenance and Engineering as implemented. An independent verification review of Conduct of Engineering at RANT and WCRR is scheduled to begin next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 31, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 31, 2009

Federal Oversight: At the request of NNSA-Headquarters, a review of the implementation of DOE-STD-1189, *Integration of Safety into the Design Process*, for LANL projects was conducted in conjunction with the Chief of Defense Nuclear Safety review in June 2009. The results of this review were recently communicated to the site office. The review concluded that LASO is using contract performance based incentives and other mechanisms to drive implementation of DOE-STD-1189 and improvements in the integration of safety into design; however, additional elements of the LANL contractor assurance system could be better utilized. The review identified the following 3 weaknesses: 1) lack of a schedule/plan for appropriately incorporating DOE-STD-1189 into institutional processes and procedures, 2) inconsistent and ineffective performance of a gap analysis for each nuclear project and 3) incomplete use of all elements of the contractor assurance system to effectively drive implementation of the standard for all nuclear projects.

Chemistry and Metallurgy Research (CMR) Building: In January, LANL submitted a Documented Safety Analysis (DSA) and associated Technical Safety Requirements (TSR) for post-2010 operations in the CMR Building. Following initial site office review, the site office provided the following significant issues (partial list) to LANL: 1) the hazards analysis methodology is incomplete and may not be consistent with DOE-STD-3009, 2) control selection that does not appear consistent with DOE-STD-3009 (identification of safety management programs as controls versus engineered controls and/or specific administrative controls), 3) inadequate TSR derivation from hazard and accident analyses and 4) concerns with the fire accident modeling and consistency between the DSA and Fire Hazards Analysis (FHA). The site office requested LANL to resolve these issues and to submit an updated hazards analysis in August 2009. This week, LANL submitted a request to extend the resubmission of the CMR DSA/TSRs until December 2009. The extension notes that a revised hazard analysis is well underway and is expected to be complete by the end of September. The DSA/TSRs will then be revised based on the updated and improved hazard analysis (site rep weekly 2/13/09).

Plutonium Facility: This week, the site office approved TSR changes submitted by LANL that address non-safety class heat source plutonium (HS-Pu) container storage in the vault water bath. These TSR changes specifically require that water level in the vault water bath be one inch above all non-safety class HS-Pu containers with a daily surveillance and a surveillance following any container movement. In addition, the changes provide actions for conditions when the vault water bath is unable to contain water. LANL also continues actions to repackage HS-Pu into pedigreed safety class containers and to better characterize other miscellaneous containers (site rep weeklies 7/3/09, 6/12/09, 3/27/09).

The site office also approved a delay in the submittal of the TA-55 FHA to August 2009. A condition of approval in the safety evaluation report required a revised FHA to be submitted in June with subsequent DSA integration during the annual update. LANL still intends to incorporate the results of the revised FHA into the DSA during the next annual update.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 7, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 7, 2009

Transuranic Waste Operations: Last week, LANL declared a Potential Inadequacy of the Safety Analysis at the RANT shipping facility based on the discovery of smoke and heat detectors that do not comply with National Fire Protection Association (NFPA) Standard 72 requirements. The issue was identified during a site office safety system oversight review of the RANT safety significant fire suppression system. The current location of smoke and heat detectors on the bottom of facility beams and detector coverage reduction based on ceiling height are not in compliance with NFPA 72. This standard is specifically cited in the RANT safety basis for the fire detection system. This week, LANL submitted a Justification for Continued Operation (JCO) that includes a compensatory measure for a fire observer, specifically trained to perform a periodic walk-through (once every 30 minutes), to be present whenever MAR is inside RANT (excluding MAR inside a Type B container).

LANL also recently submitted safety basis changes for Area G that support Sort, Segregate, Size Reduction and Repackaging (SSSR) activities involving transuranic waste at Area G. The change allows up to five structures (e.g., the TA-54-412 building and dome structures) to be used with individual MAR limits of 2.5 PE-Ci equivalent combustible waste (previously limited to 0.47 PE-Ci) and an overall Area G MAR limit of 12.5 PE-Ci. LANL estimates that approximately 90% of the roughly 14,000 remaining above ground containers contain less than 2.5 PE-Ci. Existing radiation protection program requirements specify methods for minimizing contamination spread during SSSR activities (e.g., use of a Perma-Con or other containment control enclosure). LANL plans to submit an implementation plan that includes details for MAR tracking within 30 days of site office approval.

Radiological Work Control: Several weeks ago, an irradiated target from the Los Alamos Neutron Science Center (LANSCE) was transferred to the Radiochemistry Facility (RC-1) and chemically processed in an RC-1 hot cell to create a sample of radioactive arsenic (As-73 and As-74) needed for an activity back at LANSCE. The radiation work permit (RWP) used for handling the As sample assumed hazards would be dominated by gamma radiation, so dose rate limits and controls were gamma-based. When the As sample was removed from the RC-1 hot cell, an RCT took several dose rate measurements. Gamma measurements were below the RWP limit of 5 rad/hr at 30 cm, but a measurement that accounted for both gamma and beta radiation indicated a combined dose rate of about 30 rad/hr at 30 cm. Since the gamma-based RWP limit was not exceeded, work continued to handle and package the sample for shipment to LANSCE. Some attempt was made to communicate the radiation levels between RC-1 and LANSCE. However, when the sample was received at LANSCE, the researcher who unpackaged the sample was unaware of the high beta dose rate. As a result, the researcher manually handled the sample, putting his gloved hands in proximity to the highly radioactive As for roughly 30 seconds. The researcher was not wearing a wrist dosimeter because it was not required by the RWP. This week, the facility operations directors for LANSCE and RC-1 became aware of these events and initiated follow-up investigation, including a dose reconstruction for the LANSCE researcher's extremities. Among other things, this event appears to highlight opportunities for improvement in the identification of hazards during the work planning and RWP development processes, as well as, personnel responses upon discovery of new or unexpected hazards.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 14, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 14, 2009

Staff members J. MacSleyne, J. Pasko and R. Verhaagen along with outside expert D. Volgenau were onsite this week to review activity-level work planning and control.

Plutonium Facility: On June 24th, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) based on an NNSA facility representative's discovery of three unvented 55-gallon assay standards staged in the facility basement. These unvented standards contain plutonium in contact with hydrogenous material that could evolve hydrogen gas and create an explosive atmosphere inside the sealed drum, creating a potential deflagration hazard. To address the PISA, facility management established a compensatory measure to cordon off, post, and prohibit handling of the unvented standards, as well as, a compensatory measure to relocate 16 transuranic waste drums that were immediately adjacent to the unvented standards. On July 1st, the three unvented standards resulted in a positive unreviewed safety question (USQ), thereby requiring NNSA approval before compensatory measures could be lifted. Subsequent to the positive USQ determination, facility personnel realized that eight of the sixteen palletized transuranic waste drums collocated with the unvented standards could not be accessed by a forklift without handling the unvented containers. As a result, eight transuranic waste drums remain within about one foot of the unvented standards. On Tuesday, a formal evaluation of the safety of the situation (EOSS) was submitted to the NNSA site office. The EOSS concludes that existing compensatory measures related to cordoning off and proscribing handling of the unvented standards should remain in effect and that the eight collocated transuranic waste drums could remain in place until further options are evaluated.

Compensatory measures established to address PISA conditions are identified by LANL procedures as part of a nuclear facility's safety basis. The current Plutonium Facility Safety Basis Document List (SBDL) does not capture the compensatory measures related to the unvented standards, as required. Effective configuration control of the Plutonium Facility SBDL has been a recurring problem.

Chemistry and Metallurgy Research Building (CMR): Last week, LANL submitted temporary safety basis changes associated with use of an alpha box (a confinement enclosure used for dispersible materials located in the Wing 9 hot cells) to repackage seven legacy items. This activity is part of the effort to de-inventory actinide materials (including Cm, Am, Np, and U) currently stored in Wing 9 floor wells by the end of 2010. The existing safety basis credits alpha box ventilation and HEPA filters during hot cell processing activities that involve dispersible materials. The LANL submittal recommends eliminating the safety basis controls specifically associated with alpha boxes inside of hot cells because of the limited amount of material planned to be processed, the limited time at risk (estimated to be approximately 4 weeks) and the availability of other credited hot cell confinement features. LANL asserts that the hot cells and associated exhaust ventilation HEPA filters provide credited filtration and adequate controls for the planned activity. However, to limit the spread of contamination in the hot cells, LANL does plan to use an alpha box with its existing HEPA filter (that cannot be tested) along with a temporary blower and additional non-credited HEPA that discharge into an adjacent hot cell. The NNSA site office is reviewing the proposed safety basis change.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 21, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 21, 2009

Transuranic Waste Operations: Last week, a transuranic waste drum was mistakenly transferred from Area G to WCRR. The identification number on the mis-transferred drum was one digit different than the drum that was intended to be sent to WCRR. Six separate proceduralized verification checks on the drum identification number, performed by three different organizations, all failed to discover the discrepancy. The mis-transferred drum violated Transportation Safety Document TSRs during onsite shipment and WCRR TSRs when it was introduced into the facility.

Also last week, personnel performed preventive maintenance inside WCRR using two lubricants while the facility was in Warm Standby mode. Both lubricants are categorized as flammable liquids. The work planning and approval process did not recognize that using these flammable liquids inside the facility while inventory was present would violate a limiting condition of operation (LCO) associated with the combustible loading TSR control. As a result, the applicable LCO was never entered, as required. Action statements associated with the combustible loading LCO require inventory to be placed in a safe configuration immediately and require a fire patrol to be established within two hours. Facility management asserted that inventory remained in a safe configuration (i.e. inside sealed Type A waste drums) throughout the evolution and that the flammable liquids remained in the facility for less than two hours. Because no action statement completion times were exceeded (albeit fortuitously), facility management concluded that this event did not constitute a TSR violation.

Finally, during transuranic waste operations on Wednesday, an airborne contamination release occurred in the WCRR processing area causing multiple continuous air monitor (CAM) alarms (the highest CAM measurement exceeded 3300 DAC-hrs). All eight personnel in the area were wearing anti-contamination personnel protective equipment (PPE), including respirators. Personnel responded per procedures to place work in a safe configuration and exit the area. Although PPE contamination was identified on 5 of the 8 workers, surveys indicated no skin contamination and subsequent nasal smears were negative. Based on PPE contamination identified on operators and subsequent facility surveys, it appears that the release occurred as operators were overpacking an empty 55 gallon drum whose contents had been removed, sorted and placed in a daughter drum. It appears likely that the plastic sleeve and tape used on the 55 gallon drum for contamination control failed during the overpacking activity. Given the extent of contamination spread, facility decontamination efforts are expected to continue into next week.

Weapons Engineering Tritium Facility (WETF): Implementation of safety basis changes and other readiness activities to allow limited operations that do not involve the tritium gas handling system are in progress. Resumption of these limited operations will support inventory reduction and will allow overpacking (in credited secondary containers or gloveboxes) of approximately 70 containers that may exceed their maximum allowable working pressure and do not currently have any secondary confinement. These limited operations are scheduled to begin in September. The NNSA site office is also reviewing safety basis changes that would support tritium gas handling system activities. A Laboratory Readiness Assessment is planned to support resumption of this activity in October.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 28, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 28, 2009

Transuranic Waste Operations: Last week, a transuranic waste drum with a small hole in the bottom was transferred from Area G to the WCRR repackaging facility. A required drum integrity inspection at Area G failed to identify the hole, which was ultimately discovered during a more thorough receipt inspection at WCRR. Onsite shipment of a degraded waste drum resulted in a Transportation Safety Document (TSD) TSR violation. Upon discovery of the hole, separate TSD and WCRR TSR controls prohibited the drum from either being shipped back to Area G or being introduced into WCRR (which was still undergoing decontamination from a prior event). As a result, a LANL HAZMAT team was called in to overpack the degraded drum in the WCRR parking lot.

This week at Area G, an NNSA facility representative identified a pallet of transuranic waste drums that did not have any required banding to stabilize and restrain drums stacked on the third tier of a waste array. A key element of a TSR-level safety management program requires each four-drum pallet to be stabilized with two circumferential metal bands. Steps to install and verify drum banding are formalized in multiple Area G procedures.

These two events are the latest in a series of recent TSR violations and other problematic occurrences involving transuranic waste operations. LANL management has recognized this negative trending and is taking action to reinforce the importance of procedural compliance and attention to detail, as well as, initiating efforts to identify and address other common root causes shared by the recent events. Ensuring effective corrective action seems imperative given that the recent string of events is concurrent with a significant ramp-up in the transuranic waste operational tempo driven by aggressive inventory reduction milestones associated with LANL's Consent Order agreement with the state of New Mexico. LANL has recently begun making five waste shipments to WIPP in a typical week, up from 3 shipments in a typical week last year. Establishing and maintaining disciplined operations, including deliberate compliance with effective procedures will be critical to ensuring safety as the pace continues to increase and then must be sustained for years to come (site rep weekly 8/21/09).

Plutonium Facility: As part of the Documented Safety Analysis approved in December 2008, LANL committed to a series of engineered and administrative control upgrades to improve the safety posture of the facility. A near-term cornerstone of site plans to reduce the consequences of challenging accident scenarios, such as a post-seismic fire, is to seismically upgrade glovebox stands, as part of the line item TA-55 Reinvestment Project. The site office SER included a Condition of Approval to accelerate seismic upgrades for select, high-priority gloveboxes to be completed by the end of FY11. However, during this week's Integrated Nuclear Planning workshop, it was reported that these priority upgrades would be delayed rather than accelerated due to line item funding issues. With regard to implementing a safety class confinement ventilation system, a recent site office position paper concluded that a decision on pursuing PC-3 seismic upgrades to the system would not be made until mid-FY11. The site office asserted that completion of several key activities is required prior to making this decision, including: 1) completion of ventilation and ventilation support system backfit analyses 2) evaluation of systems and components against the updated Probabilistic Safety Hazard Analysis via the SAFER project and 3) comparison of system capacity versus seismic demand.

However, during this week's Integrated Nuclear Planning workshop, it was reported that these priority upgrades would be delayed rather than accelerated due to line item funding issues. With regard to implementing a safety class confinement ventilation system, a recent site office position paper concluded that a decision on pursuing PC-3 seismic upgrades to the system would not be made until mid-FY11. The site office asserted that completion of several key activities is required prior to making this decision, including: 1) completion of ventilation and ventilation support system backfit analyses 2) evaluation of systems and components against the updated Probabilistic Safety Hazard Analysis via the SAFER project and 3) comparison of system capacity versus seismic demand.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 4, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 4, 2009

Radioactive Liquid Waste Treatment Facility: Radioactive Liquid Waste Treatment Facility personnel began a management self assessment (MSA), this week, to support resumption of transuranic liquid waste processing activities in Room 60/60A. After several years of work to replace or refurbish Room 60/60A piping and equipment; implement conduct of operations, maintenance, and engineering; and retrain operators, MSA commencement is a key step in reestablishing this critically important waste processing capability. The MSA will be followed by a laboratory readiness assessment prior to restart.

Transuranic liquid waste processing operations were last conducted in 2006. Inability to process this waste has caused a number of Plutonium Facility operations that generate transuranic liquid waste streams to be curtailed. Affected Plutonium Facility activities include the effort to chemically stabilize and recycle legacy plutonium-bearing residues to improve worker safety and to increase the availability of highly constrained vault storage space (site rep weeklies 4/10/09, 11/7/08).

Plutonium Facility: This week, a Technical Safety Requirement (TSR) violation was declared when an NNSA facility representative discovered a loose round sheet in the facility basement that indicated required TSR-level surveillances of HEPA filter differential pressures had not been completed. Plutonium Facility operations center personnel were aware of the missing record for these rounds, but incorrectly believed that their existing review and verification process would have contemporaneously identified and corrected any required rounds that had not been completed. Corrective actions have been identified to strengthen control, accountability, and review of multi-page round sheets.

Transuranic Waste Operations: In early-August, an NNSA site office safety system oversight review of the RANT shipping facility fire suppression system (FSS) identified National Fire Protection Association standard 72 (NFPA 72) code compliance issues that led to a positive Unreviewed Safety Question and associated Justification for Continued Operation (JCO). During transmittal of the assessment results, the site office requested LANL to provide a path forward and schedule to 1) address all findings, 2) increase confidence in the FSS 3) evaluate compliance with TSRs and 4) review extent of condition for issues identified. The LANL response this week noted that a prompt operability determination was completed that concluded the FSS is operable with the compensatory controls identified in the JCO (no additional TSR compliance issues were identified). To improve near-term confidence in the system, LANL is developing a design change to actuate the pre-action valve upon sprinkler head activation (this valve is currently actuated by heat and smoke detectors that are not located in compliance with NFPA 72). To address the extent of condition issues, LANL is evaluating maintenance practices for Environmental and Waste Management Operations, in particular, how deficient conditions identified during maintenance activities are documented and tracked. LANL is also developing a formal return to service process for safety related equipment and will require shift operations manager and system engineer review of completed work packages.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 11, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 11, 2009

Weapons Engineering Tritium Facility (WETF): Physical modifications and other prerequisite activities continue in anticipation of resuming hot operations at WETF. During a recent work package closeout review for a maintenance activity to replace a valve, facility personnel discovered that a required approval signature was missing from work control documentation. In the course of critiquing this work control issue, a significant conduct of operations concern was identified. During the performance of the maintenance evolution, personnel recognized that executing the work instruction as written would have the unwanted effect of rendering the credited tritium waste treatment system inoperable. To avoid impacting the tritium waste treatment system, personnel made a series of field changes to the work instruction that altered valve alignments and changed which components would be locked and tagged out of service to provide hazardous energy control. These field changes to the work instruction did not receive required reviews prior to being executed.

A number of LANL nuclear facilities, including WETF, have recently declared 'core' implementation of conduct of operations. This declaration is meant to correspond to being demonstrably compliant with the basic requirements of DOE Order 5480.19, *Conduct of Operations Requirements for DOE Facilities*. Despite the significant efforts to achieve basic compliance with the conduct of operations manual, this event underscores the challenges that remain in effectively implementing the critically important expectation to pause work if a procedure cannot be performed as written, or if unexpected conditions are encountered.

Radioactive Liquid Waste Treatment Facility Replacement (RLWTF-R) Project: This week, the site office approved the Preliminary Documented Safety Analysis based on the project 60% design without conditions of approval. The safety basis review team concluded that the maturity and technical content of the safety basis associated with the 60% design package were sufficient to support Critical Decision-2 (CD-2), Approval of Performance Baseline. A Technical Independent Project Review is currently scheduled for October with CD-2 approval targeted for May 2010.

Transuranic Waste Operations: Based on the previously anticipated plans for use of the RANT shipping facility, LANL intended to submit an updated Basis for Interim Operation (BIO) in accordance with DOE-STD-3011 for limited life facilities in March 2010. Recent planning discussions for maintaining an enduring transuranic waste capability at LANL have included the potential for extended use of RANT; however, a final decision has not been made. This week, LANL recommended continuing on the current path for a BIO submittal in March regardless of this decision. LANL would then submit a DOE-STD-3009 compliant Documented Safety Analysis at the next annual update should a decision be made to utilize RANT as part of the enduring waste mission.

Fire Protection: The laboratory has made impressive progress on a program of training courses and facility tours designed to improve the knowledge and familiarity of Los Alamos County Fire Department personnel with LANL facilities, their unique hazards, and the fire fighting techniques and tactics most effective in a nuclear environment.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 18, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 18, 2009

This week the staff held a teleconference with NNSA Headquarters, NNSA site office and LANL personnel concerning the restart plans, safety basis and readiness evaluation for the Weapons Engineering Tritium Facility.

Chemistry and Metallurgy Research (CMR) Building: On Monday, a CMR worker self-identified skin and personal clothing contamination in a non-radiologically controlled office area after handling a legacy material item with no radiological markings. Radiological Control Technicians responded and identified approximately 40,000 dpm alpha on his hand and clothing. In addition, floor surveys indicated contamination in the uncontrolled area. Subsequent worker nasal smears were positive. CMR personnel took appropriate actions to decontaminate the worker and cordon off and control the office area that was contaminated. This worker and another worker that had potentially come into contact with the item were placed on a special bioassay program.

During a chemical inventory walk down, this legacy item was identified in a cardboard box that was labeled precious metal and stored in cold laboratory. To properly secure the precious metal that was not believed to be contaminated, the item was transferred to the appropriate custodian (i.e., the worker that was contaminated). During inspection of the item by this custodian, degradation of the plastic around the item was noted which caused suspicion about the potential for contamination. The custodian appropriately paused his inspection and proceeded to the nearest contamination monitor and self-identified the contamination. CMR management initiated an extent of condition review to walk down other cold laboratory and office areas to identify potentially contaminated legacy items.

Plutonium Facility: This week, Plutonium Facility management declared a TSR violation when an unvented transuranic waste drum was discovered by an NNSA facility representative in the Plutonium Facility basement. This is the third discovery of an unvented container in the facility basement over the past seven months that has resulted in either a TSR violation or declaration of a potential inadequacy of the safety analysis. All three situations were identified by NNSA facility representatives.

In this case, the legacy unvented drum had been re-categorized from low level waste to transuranic waste in January based on new assay data, but the drum had not been labeled or re-barcode to indicate this change. In response to this event, facility procedures and processes are being revised to ensure safety basis and compliance implications are evaluated when the status of a waste container changes from low level to transuranic. Also, facility management has directed the conduct of a thorough and rigorously documented extent of condition review that will assess all containers in all applicable areas of the Plutonium Facility. This review is intended to differ in scope and formality from ineffective previously conducted extent of condition reviews that focused only on drums that were known to be, or were readily identifiable as, transuranic waste containers (site rep weeklies 6/26/09, 3/6/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 25, 2009

MEMORANDUM FOR: Timothy Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis, DNFSB Site Representatives
SUBJECT: Los Alamos Activity Report for Week Ending September 25, 2009

The site representatives were at DNFSB Headquarters in Washington, DC. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 2, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 2, 2009

Plutonium Facility: On Wednesday, facility management declared the fire suppression system inoperable based on recent hydraulic calculations that conclude the system does not achieve the water density coverage required in the safety basis (0.19 gpm/ft^2). Facility activities were placed in a safe and stable condition to support a transition to standby mode, which was accomplished Wednesday afternoon, consistent with the Technical Safety Requirements (TSRs). To support upgrading the classification of the fire suppression system from safety significant to safety class, LANL performed a system adequacy analysis (backfit analysis) in 2008. This analysis noted that limited portions of the fire suppression system may not achieve the density coverage required by NFPA 13 for Ordinary Hazard Group II (the group designation for the Plutonium Facility) and recommended that an evaluation be performed. The hydraulic calculation recently completed for the system identifies that 13 of approximately 100 hydraulic areas do not meet the density requirement. LANL has identified this deficiency as a Potential Inadequacy in the Safety Analysis and plans to pursue safety basis changes including compensatory measures (e.g. additional combustible control/fire watches in affected areas) until the system can be upgraded.

Also this week, personnel found a surface-contaminated legacy item in an unposted area outside of the Plutonium Facility proper (i.e. PF-4) during an extent of condition walkdown performed in response to a recent contamination event and worker uptake at CMR (site rep weekly 9/18/09). Plutonium Facility management established a systematic and thorough inspection plan for uncontrolled auxiliary areas that could contain contaminated legacy items that are not appropriately marked or labeled. This inspection process included opening locked drawers that have not been accessed for many years. In one locked drawer, personnel found legacy radiation sources in an unmarked container. One of these radiation sources was found to have removable americium contamination. Upon discovery of the contamination, appropriate actions were taken to exit the room, post the area and develop a recovery plan with support from radiation protection personnel. The management decision to undertake a broad extent of condition review to identify problematic legacy items in unexpected locations led to the isolation and elimination of this previously unknown and uncontrolled hazard.

Weapons Engineering Tritium Facility (WETF): Last month, as a part of the ongoing extent of condition reviews for pressure safety issues at WETF, LANL declared a TSR violation for the Containerization Program because many containment vessels do not meet the TSRs (drop test, temperature rating, leak rate testing and maximum allowable working pressure). This week, LANL submitted safety basis changes to address this issue. The submittal recommends the following compensatory measures for legacy containers that do not meet the TSRs: labels to indicate specific vulnerabilities; storage in a restricted access area; and storage of containers that do not meet drop test requirements within 1 foot of the floor. WETF continues implementation of previous safety basis changes and other readiness activities in preparation for facility restart.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 9, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 9, 2009

Plutonium Facility – Fire Suppression System: As discussed last week, the Plutonium Facility remains in standby mode pending resolution of operability issues associated with the fire suppression system. This week, LANL submitted a Justification for Continued Operations (JCO) to the NNSA site office that would allow a return to normal operations for most of the facility with specific compensatory measures for the affected areas (i.e. the areas that do not meet the safety basis requirement for flow density). Most of the affected facility areas (11 of 13) meet the NFPA 13 flow density requirement for Ordinary Hazard Group 1 (OH1) of 0.15 gal/ft² but not the safety basis requirement of 0.19 gal/ft². One area is only slightly below the OH1 flow density requirement and another area is significantly below this density requirement. LANL notes that NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, requires an OH1 fire suppression system for Class C laboratory units and that the recently updated Fire Hazards Analysis identified the facility as containing Class C chemistry laboratory units.

To allow normal operations to resume, the JCO recommends the following compensatory measures: 1) for the 11 areas that meet the OH1 flow density and the one area slightly below this density, these areas will be inspected prior to resuming operations and daily to ensure combustibles and flammable chemicals meet the requirements for OH1 Class C laboratory units and 2) for the one area with significant deficiencies, operations will remain suspended. As part of the Documented Safety Analysis (DSA) implementation, an improved combustible control program was in the process of being rolled out. This program and associated procedures will now be used to implement the first compensatory measure including an Implementation Validation Review prior to mode change. LANL is also pursuing design changes to improve system performance such that the safety basis flow density requirement will be met. The site office is currently reviewing the JCO.

Plutonium Facility – Legacy Material Disposition: LANL recently completed a study of nuclear materials stored at the Plutonium Facility to identify a path forward for eliminating nuclear material congestion and legacy container issues. The study concluded that a significant portion of the nuclear materials (approximately 1/3 of the containers) should be dispositioned off-site and that significant improvements in floor and vault storage could be achieved through disposition, processing and consolidation of materials. The study also notes that approximately 40% of the roughly 10,000 existing material containers need to be either dispositioned or replaced with more robust containers that meet the nuclear material packaging manual. For this fiscal year, the NNSA site office identified performance based incentives that are focused on removal of legacy nuclear materials and repackaging of nuclear materials into robust containers.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL recently submitted a revised DSA and associated TSR document for NNSA site office review and approval. Unlike the existing 1990s-vintage authorization basis that relies solely on administrative controls, the new submittal credits a number of transuranic liquid waste tanks to provide confinement. Also, a Specific Administrative Control limiting material inventory is identified to protect the facility's Hazard Category 3 status.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 16, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 16, 2009

Staff member B. Rosen was onsite to attend a working group meeting on Nuclear Material Packaging.

Plutonium Facility: On Tuesday, a general evacuation alarm caused by a Criticality Alarm System (CAS) signal, a loss of all facility ventilation and failure of the Facility Control System (FCS) occurred at the Plutonium Facility. The CAS alarm was subsequently identified to be erroneous and troubleshooting efforts were able to restore ventilation and FCS after approximately 3 hours. The facility was in standby mode during this event due to previously identified issues with the fire suppression system and, therefore, limited personnel were in the facility. During the event, personnel responded appropriately to alarms/announcements and evacuated the facility. Subsequent activities this week have focused on investigation into the cause of the event and reentry and evaluation of the facility condition. One laboratory room was identified to have some spread of contamination based on a continuous air monitor alarm.

All of the systems that alarmed or failed (i.e., CAS, FCS and ventilation) have an interface with the facility Uninterruptible Power Supply (UPS). Just prior to the event, control room operators heard a noise that appears to have been caused by a failure of a power supply that is also supplied by the UPS. While investigation continues including discussions with the UPS vendor, initial indications are that a transient on the UPS bus likely caused the event.

Nuclear Material Packaging: The Nuclear Packaging Manual (DOE M 441.1-1) working group met to review the container design, test plans and overall status of the Standard Nuclear Material Container (SNMC) being developed at LANL. The SNMC is a new generation packaging system designed and tested to meet the more stringent requirements of the manual. Other NNSA sites that handle and store plutonium appear likely to adopt and use the LANL SNMC package rather than designing and qualifying their own manual-compliant containers.

Safety enhancements over the current generation package (i.e. the Hagan container) include a more corrosion and drop resistant stainless steel body, improvements to the filter and o-ring seal material and design, and an improved positive lid closure mechanism. The principal challenges to meeting containment requirements of the manual include thermal and radiation resistance of the o-ring seal and filter, corrosion resistance of the container, impact resistance of the package, and a surveillance program to validate the design criteria and package life.

Several sizes of prototype SNMCs have been tested and passed the post-drop release rate requirements of the manual. The Los Alamos Site Office has requested that the NNSA Packaging and Certification Division assist LANL in developing technically defensible nuclear material packaging and storage safety documents for review and approval by site office management. This additional independent review should provide greater confidence in the technical basis for the SNMC design, surveillance program, and safety documentation process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 23, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 23, 2009

Transuranic Waste Operations: This week, Area G personnel discovered two unvented containers dispositioned as low level waste that should have been characterized as transuranic waste. One container was retrieved from a disposal pit and secured in a vented overpack and planning continues to retrieve the other affected container from a disposal shaft. Both affected drums originated at TA-18 and both contain actinide sources contained within lead shielding pigs. During the characterization process at TA-18 the weight of the shielding material was inappropriately applied to the calculation that determines whether an item is low level or transuranic waste. In response to this discovery, Area G management has suspended all source shipments to Area G until weaknesses in the characterization process can be addressed. An extent of condition review is also being conducted to determine if other sources previously disposed of as low level waste were affected by similar characterization errors.

Chemistry and Metallurgy Research (CMR) Building: LANL declared a Potential Inadequacy in the Safety Analysis this week associated with HEPA filters at CMR. During a LASO safety system oversight review of HEPA filters across the site, LANL could not verify performance of three tests at CMR (related to air distribution and mixing in the filter plenums) in accordance with ASTM F1471, *Standard Test Method for Air Cleaning Performance of a High Efficiency Particulate Air-Filter System*. This standard is specifically called out in the CMR Technical Safety Requirements. As a compensatory measure, CMR personnel are verifying fire suppression riser pressure daily (the accident scenarios that credit the HEPA filtration are certain wing fire scenarios).

Plutonium Facility: On Friday, facility personnel completed the corrective actions and operability determinations associated with Uninterruptible Power Supply (UPS) transient that occurred last week and returned the facility to operations mode (with the exception of one area that is impacted by the fire suppression issue discussed below). The LANL investigation into this event to date indicates that a power supply failure (associated with a data server) caused a power transient on the UPS bus sufficient to result in the event (i.e. facility control system loss of communication, criticality alarm system activation and ventilation shutdown). As a part of the corrective actions, LANL is evaluating additional diagnostics and other actions to improve the existing UPS. For the longer term, a seismically qualified safety class UPS will be installed in the facility as a part of ventilation system improvements included in the TA-55 Reinvestment Project Phase 2. Facility management also plans to pursue a procedure to manually start and maintain zone 1 (i.e., glovebox) ventilation for situations when the facility control system is not operable.

Programmatic activities at the Plutonium Facility remain suspended pending implementation of Justification for Continued Operations controls associated with flow density issues for the fire suppression system. This week, LANL began Implementation Verification Reviews, which will be done for each individual laboratory room, to review implementation of the improved combustible loading program. LANL expects to complete reviews (and corrective actions, if any) to support resumption of programmatic operations for some laboratory rooms next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 30, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 30, 2009

Plutonium Facility: Programmatic operations in the Plutonium Facility remain suspended as a result of the recent discovery that portions of the facility's fire suppression system cannot deliver the minimum required flow density of fire water. A Justification for Continued Operations (JCO) has been approved by the NNSA site office that would allow programmatic operations to resume in most areas after compensatory measures to reduce combustible loading have been implemented. The facility is in the process of standing up a new transient combustible loading control program that satisfies both the JCO requirements and a key part of an NNSA condition of approval associated with the 2008 Plutonium Facility documented safety analysis requiring implementation of more robust combustible loading controls (site rep weeklies 10/9/09, 10/2/09).

The new program establishes transient combustible permits for each laboratory room and basement area that specify allowed quantities of various types of combustibles. Areas will be inspected daily to ensure compliance with permit limits. Initially, the transient combustible limits reflected on the permits are based on NFPA code requirements, but facility management intends to gradually tighten permit restrictions with the goal of allowing only the minimum required combustibles needed to support specific operations. The new transient combustible control program goes into effect next week and upon verification of successful implementation of the program and the JCO controls, the facility will pursue resumption of programmatic operations in high-priority laboratory rooms.

Formality of Operations: Achieving 'core' implementation of conduct of operations, maintenance and engineering under the Formality of Operations initiative was a major area of emphasis for LANL and NNSA in FY09. Core implementation generally represents reaching a state of minimum compliance with DOE requirements. By the end of FY09, LANL had declared core implementation of all elements of Formality of Operations except for conduct of maintenance and engineering at WETF and conduct of engineering at the Plutonium Facility, which are scheduled to complete in FY10 and FY11, respectively. This week, the site office concurred with LANL's declarations of implementation with three exceptions (conduct of operations at the Plutonium Facility, conduct of maintenance at the WCRR repackaging facility, and conduct of maintenance at the RANT shipping facility). NNSA directed action to be taken to improve the three areas of non-concurrence. NNSA also noted that without continuous attention, the gains made in these critical areas will be lost. Implementing conduct of training, the final element of Formality of Operations, will be a focus area for FY10 and has been contractually incentivized by NNSA.

Waste Management Risk Mitigation (WMRM) Project: Physical work to create a connection between the WMRM tank farm and the low level waste collection system completed this week. This a major step toward establishing a capability to provide 250,000 gallons of low level liquid waste storage space for use in an emergency. Also, NNSA-Headquarters (NA-10) has concurred with the LANL and LASO recommended path forward to use 100,000 gallons of WMRM tank space to provide continuous-use low level waste influent storage for the Radioactive Liquid Waste Treatment Facility Upgrade project that is currently in design.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 6, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 6, 2009

Staff members C. March, M. Moury, J. Pasko, J. Plaue and R. Tontodonato were onsite this week to discuss Recommendation 2009-2, *LANL Plutonium Facility Seismic Safety*, with NNSA Headquarters, site office and LANL personnel.

Radioactive Liquid Waste Treatment Facility: This week, LANL completed the Laboratory Readiness Assessment (LRA) associated with the restart of transuranic liquid waste processing activities in Room 60/60A. A total of 6 pre-start findings (3 closed during the review), 17 post-start findings (one closed during the review) and 4 noteworthy practices were identified by the LRA team. Pre-start findings that remain open include fire protection issues in an adjacent room (e.g. obstructed sprinkler head), fire department access road and water connection issues, and Potential Inadequacy of the Safety Analysis compensatory measures that are not included in the facility Safety Basis Document List. As a noteworthy practice, the team observed that the reader/worker method of procedural compliance and system status board updates both worked extremely well. Restart of transuranic liquid processing in Room 60/60A will allow resumption of aqueous processing activities in the Plutonium Facility that had been curtailed due to the inability to process radioactive liquid waste effluents.

Plutonium Facility – Ventilation: A backfit analysis on the Plutonium Facility Active Confinement Ventilation System was recently completed to evaluate gaps and recommend actions to upgrade the system from safety significant to safety class. The analysis concluded that with appropriate upgrades and improvements the system can perform a safety class function. Recommendations identified during the analysis to improve the system include 1) installation of a new safety class control system, 2) replacement of the uninterruptible power supply (this is part of the TA-55 Reinvestment Project, Phase II), 3) installation of electro-hydraulic actuators for dampers, 4) provide functional backup for basement exhaust and 5) complete ventilation modeling. LANL plans to complete backfit analyses for support systems (electrical and instrument air) this fiscal year.

This week, LANL personnel noted that seismic evaluations of ventilation, fire suppression and support systems against the updated Probabilistic Seismic Hazards Analysis will be completed using the methodology established during the SAFER Project. These evaluations along with the ventilation system modeling and analysis will provide key information to inform decisions related to the selection and upgrade of safety class systems for challenging seismic accident scenarios.

Plutonium Facility – Safety Basis Strategy: This week, the NNSA site office approved a revised Safety Basis Strategy for the annual update to the Plutonium Facility Documented Safety Analysis scheduled to be submitted in early December. The revised strategy document discusses an approach for refining analysis of the seismically-induced fire accident scenario by disaggregating the material at risk into the various physical forms (e.g. metal, oxide, solutions, etc) actually found in the facility and assigning analytical values that correspond to the dispersibility of these different material forms. The current DSA assumes that all material at risk on the laboratory floor that could be involved in a seismically-induced fire has the extremely high dispersibility of molten plutonium metal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 13, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 13, 2009

Low Level Waste Operations: While performing sorting and segregation operations for mixed and low level waste on Monday, a continuous air monitor (CAM) alarmed indicating airborne contamination. Workers responded appropriately and exited the area. Subsequent surveys found that one worker had contamination on his lab coat and positive nasal smears. Surveys of the area and analysis of the CAM filter paper indicated uranium contamination levels in the range of 250 to 1000 dpm per 100 cm².

This year, LANL began a campaign to disposition approximately 20 legacy metal crates that contain mixed and low level waste. The Integrated Work Document (IWD) and Radiological Work Permit (RWP) used for the legacy campaign had been developed for activities involving a different waste stream. Respiratory protection was required for the initial opening of waste crates; however, if initial surveys indicate no contamination, respirator protection was not required for subsequent sorting and segregation activities. For the legacy campaign, the IWD and RWP were not re-evaluated to ensure work controls were appropriate for the hazards associated with this new activity. Corrective actions identified by LANL management include re-evaluation of the process and work controls specific to the legacy waste campaign and evaluation of triggers that would drive changes in work scope to receive an appropriate level of review to ensure hazards are adequately captured and controlled.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, RLWTF experienced another failure of the low level waste tubular ultrafilter unit when a plastic connection assembly failed, releasing contaminated water to the room. This is the third event in the last 13 months caused by the same failure mode. A plastic curtain, installed after the last failure in June, mitigated water spray and prevented equipment damage. However, three workers were in the vicinity when the failure occurred. Exit surveys of the workers found no personnel contamination and nasal swipes were negative. Recovery efforts to decontaminate the room, inspect the tubular ultrafilter unit and isolate affected portions of the system completed this week (site rep weekly 6/12/09).

Also, work continues to address pre-start findings from the recently completed Laboratory Readiness Assessment for transuranic waste processing operations in RLWTF's Room 60/60A. One pre-start finding requires physical modifications to change the sprinkler head configuration for a section of the facility's fire suppression system. This work may complete in time to support resumption of transuranic liquid processing this calendar year (site rep weekly 11/6/09).

Transuranic Waste Operations: This week, the NNSA site office provided comments to LANL on draft hazard and accident analyses reviewed to support the upcoming submittal of a rule-compliant Area G Basis for Interim Operations. As part of their 64 total comments, the site office noted that safety management programs had been selected over engineered controls or specific administrative controls (SAC) for some accident scenarios without adequate justification. Also, some SACs were found to lack specificity in control limits or did not have well defined technical bases to support explicitly identified limits.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 20, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 20, 2009

Weapons Engineering Tritium Facility (WETF): This week, LANL began an Implementation Verification Review (IVR) for multiple Technical Safety Requirement (TSR) page changes at WETF. The changes include revisions to the containerization and pressure safety programs to address legacy containers that may exceed their maximum allowable working pressure and to modify requirements for pressurized tritium systems. The changes were also required to resolve inconsistencies between the safety analysis and the TSRs. The IVR is expected to conclude early next week. A laboratory readiness assessment is planned in December to support resumption of tritium gas handling activities.

Technical Area (TA)-21: During activities to support American Recovery and Reinvestment Act demolition work at the legacy TA-21 site, three unvented transuranic waste drums were discovered in a decommissioned radiological facility. The drums, which contain a total inventory of less than 0.25 plutonium equivalent-Ci, show no signs of internal pressurization. However, to mitigate the risk of hydrogen deflagration, this week laboratory personnel applied lid restraints to the three unvented drums and restricted operations that can be performed in the vicinity of the staged drums. LANL personnel are preparing a transportation plan for NNSA review and approval to place the three unvented drums in vented over-packs and move them from TA-21 to Area G where they will be placed in a controlled, segregated storage array to await ultimate venting and disposition.

High Explosive Operations: This week, LANL senior management paused all high explosive operations at the laboratory in response to the latest in a series of events where personnel deliberately bypassed safety barriers or disregarded safety postings. During the operational pause, compensatory measures were developed to improve access control and communications at high explosive firing sites. Also, personnel received a refresher briefing focused on safety requirements and management expectations for strict compliance with these requirements. Prior to resuming work, operations at high explosive firing sites had to be reviewed and approved by programmatic line management and released by the Facility Operations Director's organization.

Sitewide Seismic Hazards: The site office previously approved an extension for the Justification for Continued Operation (JCO) associated with the updated probabilistic seismic hazards assessment for six nuclear facilities to November 23, 2009 and to June 30, 2010 for the Plutonium Facility. This week, LANL requested another extension for the six nuclear facilities (i.e. WETF, CMR, RLWTF, WCRR, RANT and interim radiography operations at PF-4) to March 2010. LANL notes that the independent peer review of safety basis calculations is taking longer than expected. The schedule for seismic evaluation and resolution of the JCO for the Plutonium Facility remains unchanged.

Plutonium Facility: A laboratory readiness assessment began this week to support the start-up of surveillance activities related to DOE-STD-3013, *Stabilization, Packaging, and Storage of Plutonium Bearing Materials*. These new activities involve drilling into the outer and inner welded containers of a 3013 packaging configuration to obtain headspace gas samples for analysis and evaluation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 27, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 27, 2009

The laboratory was closed on Thursday and Friday in observance of the Thanksgiving holiday.

Plutonium Facility – Material Relocation: Plutonium Facility personnel have identified a number of large uranium items currently stored in the vault that could exchange places with large plutonium items currently staged on the laboratory floor. This type of material swap would place the more hazardous Pu items in a more robust storage location and lower the aggregate amount of actual material-at-risk that could be involved in severe postulated accident scenarios such as seismically-induced fires. With programmatic operations largely resumed in the Plutonium Facility, the timing and execution of these types of material swaps appear to be limited primarily by priority and funding.

Plutonium Facility – Isotopic Fuels Impact Test (IFIT) Readiness: This week, the NNSA site office approved a plan of action for a laboratory readiness assessment (LRA) related to the restart of IFIT activities in the Plutonium Facility. The IFIT assembly is a seven inch inert gas launcher used to perform high velocity and high temperature impact tests on robust Pu-238 heat sources designed for space applications. These operations were last conducted in 2001. An NNSA readiness assessment will also be conducted prior to restarting IFIT activities involving Pu-238 heat sources.

Weapons Engineering Tritium Facility (WETF): This week, LANL completed an Implementation Verification Review (IVR) of Technical Safety Requirement (TSR) page changes at WETF. The IVR team concluded that, except for the identified pre-implementation findings, WETF personnel adequately demonstrated appropriate implementation of the TSR page changes. The following six pre-implementation findings were identified:

- Inadequate tritium containment vessel cognizant system engineer level of knowledge
- Use of process information with unknown uncertainty for compliance with a TSR
- Safety basis document list did not contain all required documents
- Lack of a pressure safety program documentation package for tritium containment vessels
- A radioactive material inventory per the TSRs was not demonstrated
- A job task analysis was not performed to ensure appropriate personnel are adequately trained on the TSR page changes

The IVR team also identified four post-implementation findings and 17 observations. The function of the Work Scope Review Team that will be used to evaluate potential tritium activities to ensure compliance with the safety basis and pressure safety program requirements was identified as a positive.

WETF personnel have also begun performing sensitive leak testing on pressurized tritium systems. This is one of the final steps in verifying that these credited systems comply with pressure safety program requirements and in confirming their operability. A leak detected in a vacuum pump fitting has been repaired and a retest of this portion of the system is being performed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 4, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 4, 2009

Plutonium Facility – Documented Safety Analysis (DSA): This week, LANL submitted the annual update of the DSA and the Technical Safety Requirements to the site office for review and approval. Notably, this update includes revised analysis of the post-seismic accident scenarios (both with and without fire). As discussed in the safety basis strategy, LANL disaggregated the material-at-risk into the various physical forms (e.g. metal, oxide, solutions) present in the facility and assigned the specific analytical values for dispersibility for each of these material forms. In addition, LANL proposes a specific administrative control for material-at-risk for each of these forms to protect the assumptions made in the DSA. Based on the revised analysis, the dose consequence for the postulated post-seismic fire accident scenario is reduced by more than an order of magnitude versus the DSA approved in December 2008. However, mitigated consequences (the only credited control for this scenario is the building structure with an associated leak path factor) remain above the DOE evaluation guideline.

The DSA was also updated to use the most recent weather data for dispersion modeling which resulted in an increase of approximately 30% for all offsite dose calculations. In addition, LANL addressed several conditions of approval that were identified by the site office Safety Evaluation Report including the following: incorporation of the results of the backfit analysis and industry code evaluation for the safety class fire suppression system; identification of criticality safety controls for inclusion in the DSA (vault racks and shelving criticality safety functions were included in this update); improved safety system, structure and component descriptions in chapter 4; clarification and improved basis for Technical Safety Requirements; and improved process descriptions in chapter 2.

Radioactive Liquid Waste Treatment Facility Replacement (RLWTF-R) Project: This week, NNSA Headquarters began their Technical-Independent Project Review (T-IPR) of the RLWTF-R Project to determine whether the current status of design, scope, cost, schedule, safeguards and security and safety aspects meet mission objectives and project performance requirements. Specifically, the T-IPR team has been asked to focus on the overall design (e.g. material selection, confinement strategy, nuclear safety strategy, seismic design), the system engineering approach used to manage the design requirements, adequacy of the design solution against technical requirements, the quality assurance program and implementation and actions to resolve DNFSB issues. LANL is currently at the 60% design point for this project and plans to pursue Critical Decision-2, Approval of Performance Baseline, in May 2010.

Weapons Engineering Tritium Facility (WETF): This week, LANL continued to resolve pre-implementation findings identified during the safety basis Implementation Verification Review and complete other readiness activities to support a return to operations mode in the near term. This mode change will allow WETF personnel to begin overpacking (in credited secondary containers or gloveboxes) approximately 70 containers that may exceed their maximum allowable working pressure and do not currently have secondary confinement. Consistent with site office direction, LANL will complete a Laboratory Readiness Assessment (LRA) prior to tritium gas handling operations. The LRA is now scheduled for January 2010.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 11, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 11, 2009

Staff member M. Moury and outside expert B. Matthews were onsite this week to meet with site office and LANL personnel to discuss near term actions in response to Recommendation 2009-2.

Plutonium Facility: This week, the NNSA site office transmitted to NNSA Headquarters (NA-10) a document describing the seismic safety posture of the Plutonium Facility. The site office document discusses the following: • planned and completed near-term actions intended to reduce the probability and consequence of a seismically-induced fire scenario, • differences in assumptions and accident consequence results between the December 2008 DSA and the recently submitted 2009 annual DSA update, • accident consequence sensitivity to changes in various analytical assumptions and parameters, and • the attendant tradeoffs and rationale for not performing certain near-term actions.

Radioactive Liquid Waste Treatment Facility Replacement (RLWTF-R) Project: This week, NNSA Headquarters completed the field work for the Technical-Independent Project Review (T-IPR) of the RLWTF-R Project. The final report is expected to be complete in January. During an outbrief with site office and LANL personnel, the team reported that 36 criteria areas out of approximately 200 were graded as red, which require resolution prior to critical decision-2 (CD-2). However, the T-IPR team also noted that many of these issues had clear paths to closure prior to CD-2. Several key unresolved issues were identified including compliance with central technical authority guidance on chemical hazards, LANL configuration management of project documents, and resolution of 60% design review comments that may impact cost and scope baselines (LANL disputes this issue).

Radioactive Liquid Waste Treatment Facility: LANL requested and the site office approved an evaluation of the safety of the situation (ESS) for a 2005 Potential Inadequacy of the Safety Analysis (PISA) that was identified due to degraded transuranic liquid waste processing equipment. Since the PISA was identified in 2005, LANL has repaired or replaced the degraded equipment to support resumption of transuranic liquid waste processing operations, which have been shutdown since 2006. The ESS eliminates a number of compensatory measures that had been identified in response to the PISA. LANL has also completed closure of pre-start findings identified during the laboratory readiness assessment and will resume transuranic liquid waste processing following site office verification of closure packages, which will occur as early as next week.

Transuranic Waste Operations: The RANT shipping facility has begun an outage that will include physical modifications to address operability issues associated with the facility's safety significant fire suppression system (FSS). The RANT FSS is a dry pipe system that requires pre-actuation which had been triggered by heat or smoke detectors. In August, an NNSA site office safety system oversight assessment identified National Fire Protection Association (NFPA) code non-compliances associated with the heat and smoke detector configuration that rendered the system inoperable. TSR-level compensatory measures requiring fire watches at RANT can be lifted upon successful completion of physical modifications and testing, as well as, approval and implementation of a safety basis page change that reflects the new pre-action arrangement (site rep weekly 9/4/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 18, 2009

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 18, 2009

Davis was offsite this week. Also, the Board's staff held a video teleconference with LANL and NNSA site office personnel to discuss ongoing Plutonium Facility seismic analyses.

Radioactive Liquid Waste Treatment Facility (RLWTF): The NNSA site office has authorized LANL to resume transuranic liquid waste treatment operations in RLWTF's Room 60 and 60A. Reconstituting this critical processing capability, which has been unavailable since 2006, is a significant milestone. RLWTF management intends to resume transuranic processing in a highly controlled fashion, in accordance with their approved Startup Plan. Limited operations to decant and sample liquid from a transuranic sludge thickening tank are scheduled to begin next week.

Technical Area (TA)-15: On Wednesday, a containment assembly catastrophically failed during an indoor propellant-driven experiment at TA-15 involving a large bore powder gun. No radioactive material was present in this experiment and no personnel were injured, however, the failure did cause significant structural damage to the building housing the powder gun. The cause of the failure is not yet well understood and LANL is planning an investigation. This is at least the second containment failure of this powder gun, which is ultimately intended to be fielded underground at the Nevada Test Site to perform dynamic experiments involving plutonium (site rep weekly 6/13/08).

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a TSR violation based on a programmatic breakdown of the Quality Assurance Program. This violation was prompted by the discovery that important instrumentation, such as pressure and temperature sensors needed to implement TSR-level controls, had not been calibrated for many years and are not controlled through a formal measurement and test equipment calibration program. This issue was identified during an implementation verification review of multiple TSR page changes that have been submitted and approved recently to address legacy issues that have been discovered as part of WETF management's deliberate and systematic resumption process (site rep weeklies 12/4/09, 11/27/09).

As additional legacy issues have been identified and dispositioned, the schedule to restart WETF programmatic gas transfer operations has continued to slip. This week, the NNSA site office formally notified LANL that due to the length of time (more than 14 months) since gas transfer operations have been performed, a dedicated federal readiness assessment will be required prior to resumption.

Chemistry and Metallurgy Research (CMR) Building: The current CMR interim TSRs credit Mosler safes as safety class design features that protect radiological material from being impacted by facility accident scenarios (i.e. Mosler safes are credited with a damage ratio of 0). Based on this credited safety function, material inside Mosler safes at CMR did not count toward the facility's material-at-risk (MAR) inventory limit. Recent analysis performed as part of the SAFER project has concluded that Mosler safes cannot be credited to survive seismically-induced mechanical insults resulting from falling debris. The facility has instituted a compensatory measure to begin counting inventory inside Mosler safes toward the facility's MAR limit. A TSR page change is pending.

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B. P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending December 25, 2009

The site representatives were offsite this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 1, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B. P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending January 1, 2010

The laboratory was closed this week. This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 8, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 8, 2010

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, LANL resumed transuranic liquid waste operations in Room 60/60A at RLWTF. For legacy transuranic waste in the sludge thickening tank, operators decanted the supernate in preparation for sludge sampling to support drum tumbler operations. RLWTF personnel also performed simulated sampling of the transuranic liquid waste receipt tanks consistent with the startup plan. Actual sampling and transfer of acidic waste, which will free up receipt space and allow transuranic liquid waste transfers from the Plutonium Facility, are expected to commence next week.

Plutonium Facility – Seismic Safety: In December, the site office provided direction to LANL on actions to improve seismic safety at the Plutonium Facility including a request for a plan and schedule to complete the following improvements in FY-2010: 1) seismic electrical power shutoffs 2) installation and use of fire-rated nuclear material storage systems (e.g., robust safes) 3) conceptual designs for ventilation and fire suppression seismic upgrades 4) fire hazard analysis corrective actions (16 of 29 deficiencies) 5) evaluation of glovebox fire protection options 6) fire barrier assessment (including any required repairs for the main facility dividing wall, known as the H-Wall). The site office plans to identify contract incentives for completion of these activities.

Other important safety improvements at the Plutonium Facility (e.g., conceptual design for a safety class ventilation system for non-seismic accident scenarios, backfit analysis for electrical and instrument air systems, and implementation of a safety class fire suppression system for non-seismic fires) have also been incentivized for this fiscal year. For material reduction and repackaging, the site office requested that LANL provide separate goals to complete overpacking of non-safety class heat source plutonium containers (targeted for completion in June 2010) and other material-at-risk reduction activities.

Weapons Engineering Tritium Facility (WETF): In late December, WETF returned to Operations mode after a series of Technical Safety Requirement page changes were approved and verified to be implemented. The facility had been in Warm Standby mode since October 2008. This mode change allows facility personnel to handle vessels containing greater than ‘residual quantities’ of tritium. However, gas transfer and processing activities remain restricted pending successful completion of laboratory and federal readiness assessments. Return to Operations mode should remove an obstacle to overpacking roughly 70 tritium vessels in WETF that are known or suspected to exceed their maximum allowable working pressures and currently reside outside of credited containment (i.e. gloveboxes or secondary containment vessels).

Technical Area (TA)-15: LANL management has chartered a Type B-like investigation of the December 16th event at TA-15 where containment features catastrophically failed during the operation of a large bore powder gun. The failure caused extensive structural damage to the building housing the gun assembly.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 15, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 15, 2010

Technical Area-35 (TA-35): Recently, LANL completed an investigation of two events involving the eruption of nitric acid waste solutions at Materials Science and Technology Division TA-35 facilities (site rep weeklies 7/10/09 and 7/24/09). The first event involved a student discarding acetone waste into a gas-tight acid waste container that resulted in an over-pressurization breaching both primary and secondary containers. The second event occurred when a worker discarded a mixture of nitric acid and sodium hydroxide solution into a shipping container that resulted in a rapid reaction and expulsion of solution. The investigation team concluded that separate causal analysis was warranted for these events because the causes were sufficiently different.

For the first event, the team concluded that the root cause was a lack of hazards assessment as a part of work planning for the waste disposal activity. Contributing causes included a lack of student training and knowledge and inadequate communication between the student and mentor. Five specific Judgments of Need were identified for this event.

For the second event, the root cause was identified as inadequate Integrated Work Management implementation (work planning), including use of subject matter experts during work planning, and appropriate use of stop work authority. Contributing causes included waste management issues, weaknesses in worker knowledge, training and qualification and inadequate communications. Nine Judgments of Need were identified for this event. For both events, the team identified several management concerns related to Integrated Work Management development, implementation and institutional requirements and identified suggested improvements for emergency response.

Technical Area-48 (TA-48): Late last week, a post-doctoral researcher began a chemical synthesis activity in a TA-48 laboratory facility that required the operation of an unattended oven over the weekend. When personnel returned on Monday morning they discovered that an energetic chemical reaction had breached the reaction vessel, damaged the oven and released chemicals into the room. This event exhibits similarities with the TA-35 events discussed above, including inadequacies in the work planning and control associated with this activity.

Chemistry and Metallurgy Research Building: This week, LANL submitted a revised Documented Safety Analysis and Technical Safety Requirements to support post-2010 operations at CMR. This safety analysis updates the previous January 2009 submittal based on comments from the site office and includes updated identification of facility hazards. The analysis supports continued analytical chemistry and material characterization activities in Wings 5 and 7, confinement vessel disposition activities in Wing 9 and deactivation activities in the other CMR wings. The scenario with the highest mitigated offsite dose consequence and only mitigated consequence that exceeds the DOE evaluation guideline is for a seismic collapse and fire, with an offsite dose of approximately 36 rem (Wing 9 material-at-risk to support confinement vessel disposition contributes approximately 12 rem to this scenario). LANL plans to implement safety basis controls by the end of December 2010 (except confinement vessel disposition activity, which will be implemented prior to execution).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 22, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 22, 2010

Plutonium Facility – Seismic Safety: This week, LANL responded to the December site office direction on improving seismic safety at the Plutonium Facility (site rep weekly 1/8/10). LANL proposes completion of several improvements this fiscal year including the following: 1) complete 100% design of seismic electrical interlocks (August) 2) implementation of ignition source control (March) 3) installation of 6 robust safes (August) 4) testing of existing containers to establish a defensible damage ratio during a fire (September) 5) seismic evaluation of fire suppression and ventilation systems (September) and 6) fire-barrier assessment (July). LANL also identified material-at-risk reduction goals for the Plutonium Facility. For weapons grade plutonium, the laboratory plans to repackage into robust containers or ship off-site 200 kg (Pu-239 equivalent) of material. For heat source plutonium, LANL plans to overpack the roughly 100 remaining non-safety class Russian Product Containers by the end of June.

To accomplish these objectives, LANL proposes to modify or defer other activities that were planned for this fiscal year including a delay in fully implementing the 2008 safety basis from March to May, a delay in hiring additional cognizant system engineers to offset attrition and a delay in implementing the criticality safety program improvement plan from September 2010 to April 2011.

Transuranic Solid Waste Operations: This week, the site office approved a short duration (less than 5 months) transuranic solid waste sorting operation in the Dome 231 Permacon. LANL plans to use this processing line to remove WIPP-prohibited items from transuranic waste drums. The operation will be limited to 0.52 PE-Ci. During evaluation of this activity, the site office expressed concerns about the flammability of a strippable wall coating on the Permacon structure. To address this issue, the site office included conditions of approval that require removal of this coating within 3 weeks and additional controls pending removal of the coating. The site office also directed LANL to control ignition source proximity to the Permacon and establish a combustible control program. In addition to startup of this debris line operation, LANL is also pursuing installation of a second processing line at the Decontamination and Volume Reduction System Facility (Building 412).

Work Control: This week, the NNSA site office issued a letter to the laboratory contractor expressing concern over a series of recent events related to research and development and programmatic work that exhibit common weaknesses in work planning and control. The site office notes that similarities between the recent events and prior events (examples are cited dating back to 2002), indicate that previous corrective actions have not been effective or have degraded over time. Based on these observations, the site office asserts that achieving mature, sustainable work control implementation has lagged in the areas of research and development and other programmatic work. The NNSA letter also notes that similar observations related to work control deficiencies were identified in a December 2, 2009, letter from the DNFSB. To address these concerns, the letter directs the contractor to evaluate recent safety incidents and to provide to the site office by February 5th the actions that will be taken to improve institutional safety in programmatic and research environments (site rep weeklies 1/15/10, 12/18/09, 8/7/09, 7/24/09, 7/10/09).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 29, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 29, 2010

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, LANL attempted to perform the first transuranic sludge drum tumbling activity in Room 60A since restart. The initial steps in this activity involve slurry and transfer of sludge from TK-7A, the sludge settling tank, to TK-6 and then gravity drain of the sludge to a waste drum. The transfer to TK-6 went as expected; however, during the gravity feed to the waste drum, a blockage in the system occurred such that only a couple of gallons of sludge were transferred to the drum (22 gallons were expected). To address the blockage, RLWTF personnel developed a temporary modification to allow backflush of TK-6. During installation of the modification, a small amount of sludge was released causing contamination in the area and on the personal protective clothing of one operator. Next week, RLWTF personnel plan to resume installation of the temporary modification to address the system blockage.

RLWTF personnel have made two transuranic liquid transfers from the WM-66 acid waste receipt tank into Room 60 tanks. These transfers provide sufficient tank space for the Plutonium Facility to make a transuranic liquid waste transfer, which is currently scheduled for mid-February.

Plutonium Facility – Isotopic Fuels Impact Test (IFIT): This week, LANL began the Laboratory Readiness Assessment (LRA) for IFIT operations at the Plutonium Facility. These operations involve impact testing heat source plutonium assemblies using an inert gas launcher to obtain data that will support engineering, quality assurance and NASA mission safety analysis. The last heat source plutonium test at IFIT was performed in 2001. Field observations associated with the LRA were completed on Friday and included an inert surrogate shot and drill (simulated loss of assembly and inner containment). The LRA team plans to complete their assessment next week. An NNSA Readiness Assessment is planned for late-February to support IFIT operations beginning in April.

Plutonium Facility - Fire Suppression System: Physical modification work has begun to address deficiencies associated with fire suppression system (FSS) components in one of the primary heat source plutonium processing laboratories. These deficiencies do not allow the FSS to provide the required fire water flow density to all areas of the room. Programmatic work in this laboratory is restricted until the fire suppression system modifications are complete, which could be as early as this weekend. Addressing fire-related vulnerabilities in this room are particularly important since it contains both a large amount of material at risk and a large quantity of combustible material in the form of thick plexiglass slabs used for radiation shielding (site rep weeklies 10/30/09, 10/23/09).

Fire Protection: In the late 1990's, the NNSA site office granted several equivalencies to National Fire Protection Association (NFPA) standards that allowed LANL facilities to perform required inspection, testing and maintenance (ITM) activities for fire suppression and alarm systems less frequently than prescribed by NFPA. Last week, the site office formally cancelled these equivalencies for LANL's nuclear and high hazard facilities and directed LANL to achieve compliance with the NFPA-mandated ITM frequencies within 60 days.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 5, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B.P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending February 5, 2010

The site representatives were at DNFSB Headquarters in Washington, DC. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 12, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 12, 2010

Mr. Broderick was out of the office this week.

Radioactive Liquid Waste Treatment Facility (RLWTF): Last week, RLWTF personnel installed a temporary modification that allowed backflush of waste tank TK-6 and resolved the sludge blockage issue discussed in the January 29th site rep weekly. Since resolving this issue, LANL has completed several drum tumbling evolutions to produce cemented sludge drums for transfer to Area G and ultimately for disposition at the Waste Isolation Pilot Plant. On Thursday, RLWTF also received an acid waste transfer from the Plutonium Facility.

Plutonium Facility – Fire Suppression System: LANL recently completed upgrades and repairs to deficient areas (i.e., insufficient water flow density) of the fire suppression system in Room 201. Last Friday, LANL submitted a revision to the Justification for Continued Operations (JCO) to address restart of programmatic operations in Room 201 (i.e., heat source plutonium operations). The JCO revision also provides clarification for returning other deficient laboratory floor areas to increased operations as fire suppression system flow density issues are resolved.

Transuranic Waste Operations – RANT Shipping Facility: In July 2009, a Potential Inadequacy of the Safety Analysis was identified at the RANT shipping facility because facility smoke and heat detectors were identified as not complying with NFPA 72 requirements. These issues were identified by the site office during a safety system oversight review of the RANT safety significant fire suppression system. A JCO was approved that included compensatory measures (fire observer) when material-at-risk was inside the facility. The RANT fire suppression system uses a pre-action valve that must be actuated (based on a signal from the smoke and heat detectors) for the system to perform its safety function. LANL recently submitted a safety basis change that removes the smoke and heat detectors as credited components. Instead, LANL plans to make a system change that will result in pre-action valve actuation upon loss of nitrogen in the dry pipe system. Loss of nitrogen would occur when a sprinkler head activates due to heat from a fire. The site office is currently reviewing this safety basis change.

Weapons Engineering Tritium Facility (WETF): Last Friday, LANL submitted a safety basis strategy for pursuing safety basis changes and a 10 CFR 830 compliant Documented Safety Analysis (DSA) and associated Technical Safety Requirements (TSR). WETF is currently operating under a 2002 safety basis (with TSR page changes as recent as December 2009). In October 2009, the site office provided comments on most recently submitted DSA. The proposed WETF safety basis strategy includes three phases: 1) the initial near-term safety basis changes required to support risk reduction activities (i.e., tritium gas handling operations to support unloading containers that exceed their maximum allowable working pressure and restart of function testing operations); 2) an annual update that will address approximately half of the site office comments and 3) evaluation of WETF activities as part of the Integrated Nuclear Planning process and submittal of a safety basis that will address the remainder of the site office comments.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 19, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 19, 2010

Weapons Engineering Tritium Facility (WETF): On Thursday, WETF management declared a potential inadequacy in the safety analysis (PISA) based on issues with a facility fire wall. In 2006, LANL identified that the fire wall in question was degraded due to an inadequately sealed penetration. At that time, WETF personnel decided to eliminate credit for the fire wall vice pursuing corrective actions. During a recent NNSA site office safety system oversight review of the fire suppression system, assessors noted that the hydraulic calculations assume this fire wall is present and compliant. LANL fire protection initial evaluation of the situation indicates that the fire suppression system will not meet National Fire Protection Association requirements for water flow density without taking credit for this fire wall.

The NNSA site office currently has three full time engineers evaluating safety systems at LANL nuclear facilities. Over the last year, this group has identified a number of safety system deficiencies that resulted in the declaration of PISAs.

Transuranic Waste Operations: At an integrated nuclear planning workshop this week, LANL described plans for increasing processing capability and throughput to accelerate shipments to WIPP. In addition, LANL discussed Area G closure plans and planning to support an interim waste capability (i.e., how to accommodate waste generated after Area G stops accepting new receipts and before an enduring waste facility is operational). For the long term, LANL is pursuing a Consolidated Waste Capability concept that will address newly generated transuranic, mixed, and low level wastes and hazardous chemicals. The concept for the new transuranic project has been revised to include only capability for transuranic waste storage and characterization (i.e., no open-drum waste processing or size reduction). Transuranic waste generators will be required to have qualified processes to package only WIPP compliant containers. The line item project to establish a long term transuranic waste storage and characterization facility is nearing completion of a Safety Design Strategy and is aggressively pursuing a critical decision-1 in May 2010.

Also this week, operators using a glovebag inside the Dome 231 Permacon at Area G observed a flash of light while processing a transuranic waste drum to remove WIPP prohibited items. The flash occurred while operators were crushing small glass vials in a metal tray inside the glovebag. When the flash occurred, operators suspended operations and notified the Operations Center. No singeing or charring was evident as a result of the flash; however, operators did observe a brown powder released from a recently crushed vial. Information about the event became confused in the notification chain resulting in Operations Center and supervisory personnel authorizing processing operations to resume to address the few remaining contents of the affected drum.

The critique of this event identified a number of areas requiring corrective action. First, the procedure governing Permacon drum remediation activities did not address whether or how to process small glass vials and did not analyze the hazards that could result from crushing vials containing potentially pyrophoric or reactive materials. Also, a similar event occurred at the WCRR processing facility and the lessons learned associated with handling small glass vials were not incorporated into Permacon operations. Glovebag operations in the Dome 231 Permacon have been suspended until the procedure is

revised and operators trained to address proper handling of small glass vials.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 26, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 26, 2010

Staff members Galaska, March, Moury and Pasko held a teleconference with NNSA and LANL personnel to discuss fire protection issues including plans to address recommendations from the 2009 Baseline Needs Assessment and improvements in fire fighter training and facility familiarity.

Plutonium Facility: This week, LANL declared a Potential Inadequacy in the Safety Analysis (PISA) based on a potential issue with the safety class ceiling armor for the Isotope Fuel Impact Test (IFIT) facility. The ceiling armor is designed and implemented to prevent a projectile from breaching the facility (projectiles are gas propelled in the vertical direction). The technical safety requirements note that the armor is designed to withstand a projectile with speeds up to 200 m/s; however, there are no safety class controls that protect this assumption (e.g., a relief valve that would limit the maximum projectile velocity is installed but is not credited as safety class). This issue was identified during the recently completed laboratory readiness assessment. The NNSA readiness assessment is scheduled to begin the week of March 8th.

Weapons Engineering Tritium Facility (WETF): During LANL's continuing evaluation of issues identified by NNSA site office safety system oversight engineers (see last week's report), WETF management declared a PISA for the Building TA-16-450 (the building adjacent to WETF's primary tritium processing facility) safety significant fire suppression system. In the basement of this building, lighting fixtures physically block fire suppression system sprinkler heads. LANL has been aware of this vulnerability for several years (the issue was noted in a September 2007 Fire Hazards Analysis) and there is an upgrade planned to resolve the issue; however, this vulnerability is not identified in the safety basis and the PISA process was not pursued until this week. This issue was also not identified in a vital safety system assessment that was performed for the system. A walkdown by site office and LANL fire protection engineering concluded that with the current combustibles in the basement, the sprinkler system could perform its safety function. WETF management has established access control to help ensure additional combustibles are not added while a system upgrade is completed to resolve this issue.

Fire Protection: Last October, a LANL memorandum to the site office suggested that the standing Cooperative Agreement between NNSA and Los Alamos County be revised to address several recommendations in the Baseline Needs Assessment. Last week, the NNSA site office issued a response to the LANL memorandum asserting that gains in fire and emergency response effectiveness and timeliness can be achieved without modifying the existing Cooperative Agreement. The NNSA response directs the laboratory to take a series of actions that contribute to satisfying BNA recommendations and improve response services. Directed actions include coordinating with the Los Alamos County Fire Department to develop Fire Chief's Directives that describe and document laboratory-specific fire and emergency response issues and to develop response time metrics that can be tracked and trended to identify opportunities for improvement.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 5, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 5, 2010

This week, Board members J. Bader, L. Brown, J. Mansfield and P. Winokur along with staff members T. Dwyer, M. Moury and J. Pasko were onsite to meet with NNSA site office and LANL personnel to discuss Recommendation 2009-2 and activities at LANL defense nuclear facilities.

Plutonium Facility – Seismic Safety: LANL described the plans and progress on risk reduction activities at the Plutonium Facility that will be captured in a seismic safety strategy, which is expected to be issued this month. Near-term actions to be completed by the end of calendar year 2010 are expected to further reduce the potential offsite dose consequence for the bounding seismically-induced fire scenario. The plan will also include longer term actions to evaluate and potentially upgrade key safety systems (fire suppression and ventilation systems).

Transuranic Waste Facility Project: This week, LANL submitted the Safety Design Strategy, developed in accordance with DOE-STD-1189, for the Transuranic Waste Facility (TRUWF) to the site office for review. The scope of the TRUWF includes waste storage and characterization functions only (i.e., no open-drum waste processing or size reduction). The safety strategy currently does not anticipate the need for safety class structures, systems or components. Safety significant control functions identified are the facility structure, fire suppression system (in storage buildings), transuranic waste containers, and controlled separation distance between storage buildings to prevent fire propagation. The safety strategy asserts that because of the confinement provided by containers, no safety related building confinement or exhaust ventilation will be necessary. The seismic design criteria (SDC) for the storage buildings and associated fire suppression systems are expected to be SDC-2. A LANL safety design integration team, as recommended by DOE-STD-1189, has been chartered for this project.

Work Control: In February, the LANL Principal Associate Directors for Science, Technology and Engineering; Weapons Programs; and Global Security issued a joint response to a January NNSA site office letter that highlighted recent safety incidents involving research and programmatic operations and requested corrective action. The LANL response identified areas, including hazard definition and evaluation, where the implementation of institutional work control processes were inconsistently applied across the laboratory.

In their response letter, LANL senior management outlines a plan to address the areas of inconsistency and improve the safety of research and development (R&D) activities. Steps in the improvement plan include developing common approaches for defining the safety envelope for moderate hazard R&D work, improving the training and supervision of students and post-docs, and identifying communities of expertise in elevated risk areas that can be drawn upon to peer review proposed experiments to strengthen subject matter expert review. The LANL Principal Associate Directors also commit in the letter to meet with site office personnel quarterly to provide progress reports (site rep weekly 1/22/10).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 12, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 12, 2010

Plutonium Facility – Isotopic Fuel Impact Test (IFIT) Facility: This week, NNSA completed the Readiness Assessment (RA) for operation of the IFIT Facility to support testing required by NASA. The RA team recommends that operations commence following site office approval of closure for pre-start findings and corrective action plans for post-start findings. The team identified five pre-start findings including issues with the design and procurement of safety significant components, procedure inconsistencies/errors, operator qualifications/work authorization status and unanalyzed hazards associated with a crane.

Transuranic Waste Operations: LANL has not performed transuranic waste drum venting since the November 2008 drum deflagration that occurred during remote drum venting operations in Area G. The remote drum venting operation was performed in a tent containment enclosure inside of Dome 33. In April, LANL plans to begin drum venting operations in a robust enclosure that will be provided by a subcontractor. The same enclosure unit was used for drum venting operations at the Savannah River Site. The Joint Evaluation Team met this week to discuss the plans for evaluating readiness for this activity and will recommend a laboratory RA to the site office. LANL estimates that between 1,000 and 3,000 drums (including both above and below ground drums) will require installation of filtered vents using this system.

Weapons Engineering Tritium Facility (WETF): Last week, LANL declared a TSR violation based on exceeding the combustible loading limits for two WETF rooms. LANL also declared a Potential Inadequacy in the Safety Analysis (PISA) due to inadequate documentation for calculations associated with combustible loading limits (this issue was later declared a positive unreviewed safety question). These issues resulted from evaluation of issues identified during a site office safety system oversight review. In accordance with the Limiting Condition of Operation (LCO) action statement and based on previously identified issues with the fire suppression system, WETF was placed in warm standby and a fire watch patrol was established every hour (the LCO requires a fire watch patrol every two hours).

The combustible loading limit LCO also requires WETF to comply with the limits within one week (due Thursday of this week) or to begin actions to place the facility in cold standby mode (i.e., all but residual quantities of tritium removed from process areas). The actions required to comply with the combustible limits could not be completed by Thursday of this week (a TSR revision will likely be needed). In addition, placing the facility in cold standby would require movement of tritium in systems that are not currently operable and require readiness activities to restart. As a result, LANL submitted a Justification for Continued Operation that allows a 60 day extension for the completion time of the LCO action statement (i.e., coming into compliance with the combustible loading limits). The JCO requires WETF to remain in warm standby mode and to continue hourly fire watch patrols. LANL also committed to providing a path forward for resolving this issue within 30 days. On Thursday, the site office completed a Safety Evaluation Report that approved the LANL JCO.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 19, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 19, 2010

Transuranic Waste Operations: There have been three glovebox glove breaches or failures at the WCRR repackaging facility in the last two weeks. Prior to this series of events, unplanned glovebox glove openings had been infrequent at WCRR. The most recent event, which occurred on Wednesday, resulted in a glovebox worker receiving skin contamination (1600 dpm/100 cm²) with subsequent nasal smears positive for low levels of alpha radioactivity (42 dpm). Facility management has responded by suspending WCRR glovebox operations while glovebox glove inspection protocols are strengthened.

Transuranic Waste – Sort, Segregate, Size Reduction and Repackaging (SSSR): Late last year, the site office approved a safety basis change for Area G to support SSSR operations in five structures (e.g., TA-54-412 and dome structures). The safety basis change included material-at-risk limits for open waste of 12.5 PE-Ci equivalent combustible waste for all of Area-G and 2.5 PE-Ci for each individual SSSR operation. During development of the Area G Basis for Interim Operation, LANL identified a defense in depth control for separation distance between metal and non-metal transuranic waste containers and the SSSR operations to help prevent fire propagation. This week, LANL submitted a safety basis change that will include the separation distance control in the current Area G safety basis (site rep weekly 8/7/09).

Radioactive Liquid Waste Operations: This week, LANL declared the Waste Management Risk Mitigation tank farm operational as a radiological facility to receive low level waste during emergency conditions. This action provides 250,000 gallons of storage capacity that could be used for the following three entry conditions: 1) RLWTF is operable but overflow of the influent storage tank is imminent (e.g., large low level liquid influent due to fire deluge system operation at a generator facility), 2) RLWTF is not operable and overflow of the influent tank is imminent (e.g., major equipment failure) and 3) lab-wide evacuation (site rep weekly 10/30/09).

Weapons Engineering Tritium Facility: In February, LANL requested a temporary safety basis change to allow introduction of low-pressure inert gas into portions of the tritium systems in order to calibrate instruments and to verify compliance with safety basis requirements (i.e., hazardous material protection and pressure safety programs). LANL also requested an extension for a Justification for Continued Operation associated with exceeding the Maximum Allowable Working Pressure for two Standard Tubs (this issue will not be resolved prior to when the JCO expires). This week, the site office approved the temporary safety basis change and the JCO extension. The JCO now expires in March 2011 or when processing is complete, whichever is sooner.

The site office also approved a temporary safety basis change to address facility combustible loading issues that resulted in a TSR violation and Unreviewed Safety Question. This temporary safety basis change will remain in effect until June 30, 2010 or until the safety basis combustible limits are changed permanently based on appropriate engineering analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 26, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 26, 2010

Transuranic Waste Operations: Facility management declared a TSR violation at the WCRR repackaging facility this week. During an emergency exercise involving the Los Alamos County Fire Department (LAFD), emergency responders opened the WCRR vehicle access system barriers to gain entry to the scene of a simulated event. Opening the vehicle access system barriers while material-at-risk was present inside the WCRR facility perimeter violated a Specific Administrative Control. LAFD personnel never received any indication that opening access barriers presented a problem for the facility; they were acting in accordance with their pre-incident plan and alerted the WCRR operations center that they were opening barriers. On the facility side, a number of opportunities to identify and prevent the safety basis impact from this exercise were missed, including participation in exercise planning and the final exercise plan being subjected to the unreviewed safety question process.

In response to this event, facility management will now require all final exercise plans for transuranic waste facilities to require approval by the Facility Operations Director. Conducting exercises at nuclear facilities across the site are an important part of continuing to improve the coordination between LANL and LAFD. Since proper planning and control of these on-going exercises are critical to ensuring that nuclear safety hazards are not inadvertently introduced and safety basis controls are not compromised, broadening the corrective action requiring FOD approval of exercise plans to apply to all nuclear facilities may warrant consideration.

Sitewide Seismic Hazards: This week, the site office approved removal of a number of facilities, or facility segments (Chemistry and Metallurgy Research Building - Vault and Storage Wells, TA-55 Interim Radiography Tunnel, Radioactive Liquid Waste Treatment Facility, Weapons Engineering Tritium Facility, WCRR repackaging facility and the RANT shipping facility) from the Seismic Analysis of Facilities and Evaluation of Risk (SAFER) Justification for Continued Operation (JCO). LANL evaluated safety systems that are required to perform a seismic safety function for each of these facilities against the updated probabilistic seismic hazards analysis and concluded that system performance during a seismic event is consistent with that credited in facility safety bases. The seismic evaluation basis for each of these facilities and systems was reviewed by an external peer review team. Although the SAFER JCO for the Plutonium Facility is currently scheduled to expire at the end of May 2010, it is likely that LANL will request an extension to complete the evaluation.

Plutonium Facility – Safety Basis Implementation: LANL has completed the 3rd phase of the 2008 DSA implementation effort at the Plutonium Facility including completion of Implementation Verification Reviews. In February, the site office approved extending the implementation period for this DSA from the end of March to the end of May. In the 4th and final phase of implementation, LANL will complete actions to achieve a safety class fire suppression system for non-seismic fire scenarios. The final phase also includes implementation of controls on material-at-risk and transient combustible loading, as well as, several safety management programs (e.g., fire protection and glovebox transient combustible programs) and safety design features (e.g., glovebox support stands). The site office continues review of the Plutonium Facility's 2009 DSA annual update submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 2, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 2, 2010

Plutonium Facility – Seismic Hazards: This week, LANL requested an extension for completing the seismic analysis of the Plutonium Facility against the updated probabilistic seismic hazard assessment. The existing Justification for Continued Operation (JCO) that addresses this issue will expire on June 30, 2010 for the Plutonium Facility. LANL's preliminary evaluation of the facility indicates the need to perform a more sophisticated probabilistic analysis. The new schedule to complete analyses for the facility structure and key safety systems is December 2010. The completion date also includes evaluation of portions of the ventilation system and the fire suppression system against performance category-3 criteria. This information will be needed to make decisions on safety system upgrades to improve the facility safety posture for challenging seismically-induced accident scenarios. The proposed JCO would expire in March 2011 (the additional time would be used to complete and seek approval for any required safety basis changes).

Plutonium Facility – Safety Basis: This week, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) based on a discrepancy between a TSR material-at-risk (MAR) limit and the supporting analysis in the DSA. The MAR limit, which controls the amount of dispersible Pu-238-enriched heat source plutonium (HS-Pu) allowed in individual gloveboxes, excluded several forms of HS-Pu, including sintered oxide pellets. Although these material forms are not highly dispersible, the DSA does not discuss or justify a basis for excluding them from the glovebox MAR limit in the TSRs.

In response to the PISA, the affected material forms will be counted toward the glovebox MAR limit until a Justification for Continued Operations or DSA page change is submitted and approved. Also, facility personnel have confirmed that no gloveboxes currently exceed their MAR limit when the previously excluded forms are added to the glovebox MAR inventory calculation.

Plutonium Facility – HS-Pu Containerization: In FY09, LANL personnel overpacked into safety class containers 60 of the roughly 160 HS-Pu-bearing Russian Product Containers (RPC) stored in the vault water bath. The campaign to overpack the remaining RPCs, which is required to be complete by the end of June 2010, has been on-hold awaiting the procurement and testing of a new, more robust safety class container. This new container successfully completed a series of burst tests recently that demonstrated it far exceeds the performance criteria required of safety class containers. NNSA is now reviewing a LANL request to begin using these new containers to overpack the remaining RPCs prior to the completion of a series of drop tests that are not expected to challenge the extremely robust construction of the new container (Board Letter dated 4/7/09).

Plutonium Facility – Isotopic Fuel Impact Test Facility: The site office approved resumption of testing operations this week based on satisfactory closure of all pre-start findings and approval of corrective action plans for post-start findings identified during the NNSA Readiness Assessment for the Isotopic Fuel Impact Test Facility. LANL plans to begin hot operations next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 9, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 9, 2010

Both site representatives were offsite this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 16, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 16, 2010

This week, staff members R. Arnold, F. Bamdad, C. Butch, D. Eyler, P. Fox and R. Oberreuter were onsite to review the Radioactive Liquid Waste Treatment Facility – Upgrade Project. In particular, the staff evaluated the resolution of issues identified in the Board’s March 2008 and February 2009 letters, with a specific focus on NNSA efforts to improve federal oversight, the integration of safety into the facility design and the adequacy of the project’s 60% design package.

Plutonium Facility: On Tuesday, a machine tool head associated with the robotic lathe for the ARIES process disengaged from the lathe and briefly pinned a worker’s hand. The worker was tightening a locking mechanism on the lathe and had his hand extended into the glovebox where the lathe is located. Personnel in the area responded to free the worker’s hand and contact radiological protection personnel. No glove breach occurred and worker was taken to occupational medicine with only minor injuries. LANL evaluation of the event concluded that the tool head moved beyond the end of the tool track while the worker was tightening the locking mechanism, which allowed the tool head to disengage from the lathe. No mechanical end stop was present to prevent disengagement. Corrective actions include installation of an end stop for this particular lathe and evaluation of other machining operations at the Plutonium Facility to ensure end stops are installed, where appropriate.

Radioactive Liquid Waste Treatment Facility (RLWTF): During low level waste operations at RLWTF, a worker identified a spill that appeared to have come from the raw daily feed sample line. The worker donned personal protective equipment (booties), entered the area and concluded that the spill did not appear to be growing. After exiting the area, the worker contacted the shift operations manager. The spill was evaluated by radiological protection personnel and samples indicated approximately 60 nCi/L contamination with a pH of 7.5. Facility personnel subsequently cleaned up and decontaminated the area. RLWTF personnel are developing a plan to identify and correct the source of the leak. Other corrective actions include creating a spill response team (similar to the team implemented at the Plutonium Facility) and issuing a lesson learned notice reminding workers of appropriate spill response protocols.

Transuranic Waste Facility Project: Transuranic Waste Facility Project personnel recently submitted a Conceptual Safety Design Report (CSDR) for NNSA review and approval. The current project scope includes six segregated storage buildings intended to accommodate a total of 1,240 drum equivalents and a concrete pad to house drum characterization trailers. Open drum remediation and size reduction activities are not part of the project’s scope. The CSDR postulates ten design basis accidents that can involve up to 27,300 Pu-equivalent Ci of material-at-risk. The CSDR identifies six safety class structures, systems or components to prevent or mitigate these accidents. Safety class controls include vehicle barriers to prevent a vehicle accident with resulting pool fire, controlled space with few or no combustibles around storage buildings to prevent thermal insults from wildfires or propagation of fire from one building to another, and a seismic switch to de-energize electrical equipment to prevent a seismically-induced fire. The storage building structures and fire suppression systems are designated safety significant and seismic design category 2.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 23, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 23, 2010

Weapons Engineering Tritium Facility (WETF): LANL continues actions to restart tritium gas transfer and handling operations to support current plans to unload tritium containment vessels that may exceed their maximum allowable working pressure and to support tritium material-at-risk reduction efforts. WETF restart plans now include performance of both a Contractor Operational Readiness Review and an NNSA Operational Readiness Review, currently planned for late-May and late-June, respectively. WETF personnel also plan to perform several function test activities to support an important programmatic need this summer. Restart of the tritium function test system was planned to occur after the initial restart that will be covered by the readiness reviews. To ensure support for this programmatic deliverable should the current restart schedule slip, WETF personnel are evaluating options that will allow safe and timely restart of the function test system as a priority.

Transuranic Waste Operations: This week, the Facility Operations Director declared a potential inadequacy of the safety analysis (PISA) at the WCRR repackaging facility. The PISA resulted from a discovery that the safety significant WCRR drum lift fixture was not anchored to the floor slab and therefore could not perform its credited safety function of preventing a transuranic waste drum drop during a seismic event. A 2007 seismic analysis of the drum lift fixture that included a Seismic Qualification User Group (SQUG) walkdown and another analysis performed in 2009 to support the SAFER project both concluded that this system could perform its seismic safety function based on an incorrect assumption that the drum lift fixture was securely anchored to the floor. As a result of the PISA, facility management has prohibited the introduction of material-at-risk into the WCRR facility until a Justification for Continued Operations is approved by the NNSA site office.

Glovebox Safety: The WCRR repackaging facility has had six glove breaches associated with its Waste Characterization Glovebox in the past two months, including several that resulted in personnel contamination and one that resulted in positive nasal smears. Prior to this series of events, glove breaches had been infrequent at WCRR. In response to this adverse trend, facility personnel engaged subject matter experts from the lab's Institutional Glovebox Safety Committee. Based on recommendations from the committee, WCRR will begin using longer cut and puncture resistant gloves over glovebox gloves to provide greater protection against objects that could cause breaches. The committee also recommended that protective over-gloves be worn whenever operators have their hands in the Waste Characterization Glovebox. Current WCRR procedures require the use of these over-gloves when active waste sorting and processing operations are being conducted, but do not require use of protective over-gloves during subsequent glovebox clean-out and wipe-down activities where latent hazards that could challenge unprotected glovebox gloves may exist.

WCRR personnel have also strengthened their glovebox glove receipt inspection protocols. Using the new more stringent inspections, facility personnel have rejected high percentages of gloves received from the Plutonium Facility's quality component warehouse. Typical rejection rates have been around 10-15%, but one recent lot approached 90% rejection. Based on this and other data, institutional quality assurance receipt inspections for glovebox gloves from the affected manufacturer have recently been increased from 20% sampling to 100% inspection.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 30, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 30, 2010

Chemistry and Metallurgy Research (CMR) Building: LANL recently began construction activities for the Permacon structure in Wing 9 that will support the Confinement Vessel Disposition project. This project will provide the capability to initially perform gross removal of transuranic material from the 6' confinement vessels (one at a time) with follow-on activities to reduce contamination such that the vessels can be dispositioned as low level waste. Construction activities are expected to continue through this year followed by startup and readiness activities (at this point, contractor and NNSA operational readiness reviews are expected). The first vessel is scheduled to be processed in late-2011.

Safety Basis: This week, LANL resubmitted the CMR Documented Safety Analysis and Technical Safety Requirements that will support post-2010 operations. The resubmittal is expected to resolve previous site office comments provided in March. An NNSA Safety Evaluation Report is expected in late-May followed by LANL implementation confirmed via Implementation Verification Reviews to be completed by the end of calendar year 2010.

Other key safety basis documents for LANL nuclear facilities are pending submittal. A revised DSA and associated TSRs for the Plutonium Facility are scheduled to be submitted for NNSA review and approval in mid-May. These documents will serve as an Annual Update to the 2008 safety basis that is in the final stage of implementation at the Plutonium Facility. Additionally, a Basis for Interim Operations (BIO) and supporting TSRs for Area G are scheduled to be submitted to NNSA in June. Area G is currently operating under a DSA that was approved in 2003.

Plutonium Facility: This week, Plutonium Facility personnel resumed the campaign to retrieve ²³⁸Pu-bearing Russian Product Containers (RPC) from the vault water bath and overpack them in safety class Fuel Storage Outer (FSO) containers. About 60 RPCs were overpacked in FY-09 before the effort was paused to allow testing, qualification and procurement of an even more robust safety class container known as the Next Generation FSO. Prior to resuming overpack operations this week, approximately 100 RPCs remained in the vault water bath. Program personnel intend to complete the RPC overpack campaign by June 30th, using a combination of FSO and Next Generation FSO containers (Board letter dated 4/7/09).

Work Control: LANL recently completed a project execution plan for moderate hazard research and development safety improvements in response to a January site office letter that expressed concerns about recent safety incidents at the laboratory. The plan defines the approach for achieving hazard identification and evaluation that appropriately engages workers, operates within a defined safety envelope with well-understood risks for each experiment and accommodates the dynamic nature of research and development activities. Twelve baseline sub-projects have been identified with completion dates through the end of this fiscal year including plans to improve subject matter expert and peer review involvement in work control/hazard identification, pre and post-job briefs, hazard analysis training and lessons learned (site rep weeklies 3/5/10, 1/22/10).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 7, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 7, 2010

The site representatives were at DNFSB Headquarters in Washington, DC. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 14, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 14, 2010

Weapons Engineering Tritium Facility (WETF): LANL continues actions to resume tritium gas handling operations at WETF to support tritium containment vessel unloading, material-at-risk reduction and to support programmatic testing needs (i.e., function test operations). Recently, LANL recommended the following two options to restart function test operations, which is necessary to support important programmatic deliverables: A) complete contractor and NNSA operational readiness reviews (ORRs) for phase 1 (i.e., unloading and low pressure gas handling/glovebox systems) followed by a contractor readiness assessment to support function test operations or B) if the schedule for option A cannot be maintained, then seek an exemption to DOE Order 425.1C, *Startup and Restart of Nuclear Facilities*, in order to conduct a contractor readiness assessment for function test operations (and required gas handling/glovebox systems) solely to support the execution of a series of function tests required for programmatic deliverables. Last week, the site office approved option A as the preferred plan with preparations to execute option B as the backup plan. The site office directed LANL to obtain LASO approval if it becomes necessary to execute option B. LANL currently remains on the option A plan with a management self assessment being conducted this week and the contractor ORR scheduled to begin on May 24th.

LANL also recently submitted a safety basis strategy for WETF that details their plans to submit a safety basis annual update no later than July 31, 2010 and a new Documented Safety Analysis by the end of FY 2011. The safety basis strategy notes that current tritium inventory is higher than what is required to support the anticipated enduring mission at WETF and that material-at-risk reduction over several years is expected to reduce the tritium inventory from the current safety basis limit of 400 grams to approximately 100 grams.

Plutonium Facility: This week, facility management declared a potential inadequacy of the safety analysis (PISA) based on the recognition that hazards may not be fully analyzed for four metallic heat source plutonium (HS-Pu) items currently stored in shelf locations in the facility's vault. These Pu-238 enriched items were made in the late 1990's to support a programmatic activity that is now complete. One item contains greater than 100 grams of HS-Pu sealed in a welded inner container that is overpacked in a container with a filtered vent. The other three items, believed to involve small quantities of HS-Pu, are welded in sealed sample vials that are not contained in filtered overpacks. Facility personnel are evaluating these four items for potential container pressurization hazards related to high internal temperatures and helium buildup from the high specific activity of Pu-238. Management has prohibited handling these items pending the results of further evaluation.

Chemistry and Metallurgy Research Building (CMR): CMR personnel have transferred roughly 40 grams of non-dispersible Cm-244 from Wing 9 floor well storage locations to a hot cell for repackaging to support offsite disposition of this material. From a material-at-risk standpoint, this small quantity of curium represents greater than 40 kg of Pu-239-equivalent and required NNSA site office notification to introduce into the hot cells. LANL personnel intend to have all material out of floor well storage by the end of this calendar year. Material currently stored in floor wells that cannot be shipped to another on-site or off-site location will be staged in hot cells or the CMR vault.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 21, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 21, 2010

Staff member J. Pasko was onsite this week to attend the Integrated Nuclear Planning workshop.

Integrated Nuclear Planning: This week, LANL conducted an Integrated Nuclear Planning workshop with participation from NNSA Headquarters, service center and site office personnel. The focus of this workshop was on TA-55 programs, projects and facilities with particular focus on the path forward to address changing programmatic direction as a result of the Nuclear Posture Review. The workshop also covered the impact and integration of construction projects in the Pajarito Corridor (i.e., in and around TA-55).

Plutonium Facility - ARIES: LANL continues development and operation of the Automated Retirement and Integrated Extraction System (ARIES) to support the Pit Disassembly and Conversion Project (PDCP) and the MOX Fuel Fabrication Facility (MFFF). In March, LANL received certification as an approved supplier for MOX Services. This fiscal year, the baseline for ARIES is to produce and package 50 kgs of plutonium oxide with a stretch goal of an additional 50 kgs. The current commitment is to provide 2000 kgs of plutonium oxide to the MFFF by the end of 2018. LANL also continues support activities for the PDCP design authority.

Plutonium Facility – Safety Basis: Last week, LANL management requested an extension to complete full implementation of the technical safety requirements associated with the 2008 Documented Safety Analysis from May 31 to August 12, 2010. LANL requested the delay to allow additional time to complete (1) physical modifications to the fire suppression system in support of the new safety class designation for non-seismically initiated facility fires, (2) technical baseline documentation of glovebox support stands, and (3) final implementation activities related to the new software application to track and control facility material-at-risk limits.

This week, physical modifications to the fire suppression system began to address previously identified fire water flow density deficiencies. These modifications involve installing additional fire water riser piping to tie-in the laboratory floor and basement suppression system distribution lines to overcome hydraulic losses in the current facility configuration that cause flow density issues. Verification and validation of the actual software associated with the new computerized material-at-risk tracking program is complete. Work continues to configure and benchmark the software for reliable implementation at the Plutonium Facility.

Weapons Engineering Tritium Facility (WETF): On Monday, a NNSA facility representative noted that on two recent occasions WETF personnel failed to log performance of ceiling tile inspections as required by a Justification for Continued Operations (JCO). The JCO that included this compensatory measure was issued in response to deficiencies identified for a fire wall. Corrective actions included additional personnel training. For tritium gas handling restart, the contractor Operational Readiness Review, which was previously scheduled to begin next week, has been delayed to early-June; however, the schedule for the NNSA ORR has not changed (late-June).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 28, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 28, 2010

Plutonium Facility – Fire Suppression System: NNSA site office safety system oversight engineers, augmented by HSS personnel, are conducting an assessment of the TA-55 fire suppression system upgrades and implementation efforts to support the system's new safety class designation for non-seismic fire scenarios. This system is being upgraded as a part of the 2008 safety basis implementation, which is now expected to be complete in August. This week, site office personnel provided preliminary feedback that included the following potential issues: additional actions are required to meet some NFPA requirements (both system configuration and maintenance); the System Design Description has not been updated to reflect the new safety class function; some aspects of the fire hazard analysis do not appear consistent with the safety basis and; some technical assumptions require verification (i.e., supply tank level and diesel day tank volume). LANL plans to address these issues as they continue safety class fire suppression implementation. A gap analysis against the *Interim Guidance on the Design and Operation of Wet Pipe Sprinkler Systems and Supporting Water Supplies* that is associated with Board Recommendation 2008-1 is also planned. The NNSA assessment team plans to continue their review once implementation is nearing completion.

Plutonium Facility – Criticality Safety: A recent critique of a suspected criticality safety infraction at the Plutonium Facility highlighted issues associated with software quality assurance and methods of ensuring compliance with criticality safety limits. Last week, facility personnel implemented a change to the Plutonium Facility's material control and accountability software without satisfying all requirements specified in LANL's institutional software quality assurance procedure. This software change caused the mass of certain containerized items to be counted twice in inventory totals. When operators in the analytical chemistry group attempted to perform a material transfer, this double counting error led them to believe they had slightly more material in a glovebox than allowed by the criticality safety posting. Based on the information available at the time, a criticality safety infraction was declared. The software error was discovered in the process of investigating the criticality safety infraction. During the critique of this event it became apparent that the analytical chemistry group, which routinely deals with large numbers of low mass samples, was relying solely on the material accountability software to ensure compliance with criticality safety limits. This practice violates the Plutonium Facility's criticality safety procedure which prohibits sole reliance on accountability software for criticality safety purposes because the software does not have the quality assurance pedigree required for safety software. Facility management intends to perform an extent of condition review to identify any other groups relying solely on accountability software for criticality safety.

Transuranic Waste Facility (TRUWF) Project: LANL continues conceptual design activities to support a critical decision-1 (CD-1), *Approval of Alternative Selection and Cost Range*, for the TRUWF that will provide an enduring solid transuranic waste capability for the site. A joint NNSA/LANL design review of the CD-1 package is scheduled for early-June with a Technical Independent Project Review scheduled for mid-July. In addition, the site office is reviewing the recently submitted Conceptual Safety Design Report.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 4, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 4, 2010

Weapons Engineering Tritium Facility (WETF): LANL began the contractor Operational Readiness Review (ORR) to confirm readiness to resume tritium gas transfer operations on Thursday following line management declaration of readiness. All but two pre-start findings identified during the management self assessment have been closed and closure plans and schedules are in place for the two remaining findings. The NNSA ORR is scheduled to begin the week of June 21st.

Plutonium Facility: The Plutonium Facility Documented Safety Analysis (DSA) that was approved by NNSA in 2008 and is currently being implemented by LANL identified a suite of planned safety improvements that include seismic upgrades to a population of 'high risk' gloveboxes. The DSA criteria for high risk included gloveboxes that contain ignition sources or greater than 10 kg of material at risk. Because these glovebox upgrades play a key role in the facility's existing seismic safety strategy, the NNSA Safety Evaluation Report (SER) that approved the 2008 DSA included a Condition of Approval to accelerate the schedule for glovebox seismic upgrades such that all high risk gloveboxes meet performance category 3 seismic requirements by the end of 2011. LANL uses this commitment for future glovebox seismic upgrades to reduce the mitigated dose consequence for a seismically-induced spill scenario by a factor of 10 (i.e. a damage ratio of 0.1 is credited).

LANL intended to use Phase 2 of the line item TA-55 Reinvestment Project (TRP2) to complete seismic upgrades for all high risk gloveboxes. However, the expected cost of seismic upgrades to individual gloveboxes has risen from an original estimate of about \$80,000 per glovebox to a current estimate of approximately \$850,000. Concurrent with this order of magnitude cost increase, LANL personnel completed a comprehensive facility survey and identified 157 high risk gloveboxes, roughly twice as many as originally expected. The current scope of TRP2 would upgrade a total of 40 gloveboxes through 2014. LANL has not yet clearly defined the strategy and schedule for performing required seismic upgrades for the large population of remaining high risk gloveboxes that will not be addressed by TRP2.

Chemistry and Metallurgy Research Building (CMR): This week, the NNSA site office issued a SER approving the CMR DSA that supports continued facility operations after the current Basis for Interim Operations expires at the end of 2010. This new safety basis must be implemented by the end of the calendar year. The newly approved DSA includes a seismically-induced fire scenario with final mitigated consequences that exceed the DOE Evaluation Guideline by approximately 45%. In the SER, the NNSA site office accepts the risk associated with this scenario based on the low likelihood of the event and the limited life and needed mission of the facility.

Also this week, LANL recommended to the site office that an ORR be performed to confirm readiness for confinement vessel disposition (also known as Bolas Grande) operations in Wing 9 of CMR. Although the Joint Evaluation Team, which evaluates startup activities and recommends the level of readiness review, concluded that a readiness assessment be performed, LANL management determined that an ORR is a better vehicle for confirming readiness for this activity. Construction activities to support confinement vessel disposition are ongoing with startup planned for late-2011.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 11, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 11, 2010

Staff members Laake, Martin, and Von Holle were onsite this week to review implementation of DOE-NA-STD-3016, *Hazard Analysis Reports for Nuclear Explosive Operations*, at Los Alamos.

Weapons Engineering Tritium Facility (WETF): The Contractor Operational Readiness Review (CORR) to support resumption of programmatic gas transfer operations at WETF concluded this week. The final report is undergoing factual accuracy review by facility personnel, but preliminary findings were discussed at an outbrief on Friday. Roughly a dozen pre-start findings were reported at the outbrief, of which six were closed during the review. The follow-on federal ORR is currently targeted to begin the week of June 21st.

Chemistry and Metallurgy Research (CMR) Building: NNSA and LANL plan to continue performing mission-critical analytical chemistry operations in the CMR Building until the CMR Replacement (CMRR) Facility is constructed and commissioned. The recently issued Nuclear Posture Review targets transition from the existing CMR Building to the new CMRR Facility in 2021. The overarching strategy for operating CMR until CMRR is available is documented in the CMR Facility Consolidation and Risk Mitigation Program Execution Plan (CMR PEP). A central tenet of the operating strategy described in this document is to continuously reduce the amount of material at risk (MAR) associated with CMR operations over time. The CMR PEP establishes a series of activities designed to reduce the quantity of MAR required to perform key analytical chemistry operations in CMR. Relocating Pu-238 analytical chemistry operations and sample management operations to the Plutonium Facility are two important planned activities designed to enable MAR reduction at CMR over time. The implementation schedules for both of these relocation efforts have slipped significantly from their original completion dates meaning that the opportunities for CMR MAR reduction they will create will be delayed. Recently, LANL senior management has refocused attention on these relocation projects in recognition of the key role they play in supporting commitments to continuously reduce the MAR associated with CMR over time.

Transuranic Waste Operations: This week, facility management declared a TSR violation at the WCRR repackaging facility when a can of flammable liquid was discovered in WCRR while MAR was present in the facility. WCRR credits stringent combustible loading controls including a limiting condition of operation that prohibits the use or storage of flammable or combustible liquids or gases in the facility when MAR is present. A can of flammable spray paint was brought into the facility to support a painting evolution last weekend when the facility was in cold standby mode. The can of flammable spray paint was not removed when the painting work was completed and multiple surveillances credited to confirm that no flammable liquids or gases were present in the facility failed to identify and remove the can, as required, before the facility entered warm standby mode and introduced MAR.

Also this week, laboratory management authorized the startup of debris waste processing activities in Building 412 at Area G. These operations will use a glovebag inside a containment tent to remove WIPP-prohibited items from waste drums containing less than 0.52 ²³⁹Pu-equivalent Ci.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 18, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 18, 2010

Plutonium Facility: LANL recently completed overpacking all ^{238}Pu -bearing Russian Product Containers (RPCs) into safety class Fuel Storage Outer (FSO) containers. In response to a Board letter dated April 7, 2009, NNSA committed to complete the RPC overpacking effort by the end of June 2010. Over the next few weeks, LANL will complete radiography of the FSO container welds to verify adequacy. In addition, LANL is completing the FSO testing and qualification documentation for compliance with DOE M 441.1-1, *Nuclear Material Packaging Manual*.

This week, LANL also requested a revision to the Justification for Continued Operation (JCO) associated with the analysis and stabilization of miscellaneous vault water bath containers, which includes the RPC containers mentioned above and other miscellaneous ^{238}Pu -bearing containers. The revision addresses a RPC container that was identified in the vault water bath that had not been included in previous internal pressure calculations. The original JCO was submitted in May 2009 and since that time the majority of the non-safety class containers have been dispositioned by overpacking, repackaging or ensuring the containers are vented (inside glovebox lines). The JCO, which expires February 1, 2011, addresses the movement, handling, non-destructive assay, radiography, container opening and other incidental activities for non-safety class ^{238}Pu -bearing containers. The JCO also covers these activities for new containers receipts provided the approved internal pressure calculation indicates the containers have a usable lifetime that exceeds the JCO expiration.

Chemistry and Metallurgy Research (CMR) Building: LANL has now completed packaging approximately 40 grams of non-dispersible ^{244}Cm into appropriate containers that will be shipped to Area G to await ultimate disposition. Removal of this material represents a significant reduction in material-at-risk located at the CMR facility. Facility personnel also continue actions to restart the alpha box located in the Wing 9 hot cells for repackaging six dispersible ^{233}U and ^{237}Np items that are located in the floor wells. Facility preparation and readiness actions to use the alpha box are expected to be complete within the next two months to allow the repackaging campaign to be done by the end of September.

Weapons Engineering Tritium Facility (WETF): WETF personnel continued actions this week to close pre-start findings and develop corrective action plans for post-start findings associated with the contractor Operational Readiness Review (ORR). The NNSA ORR is scheduled to begin on Monday.

Transuranic Waste Facility (TRUWF) Project: This week, the site office provided comments to LANL on the TRUWF preliminary hazard analysis and the conceptual safety design report. The site office plans to issue a conceptual safety validation report in the near future. The Technical Independent Project Review for this project is scheduled for mid-July.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 25, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 25, 2010

Plutonium Facility – Safety Basis: This week, LANL re-submitted the 2009 annual update of the Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs) for the Plutonium Facility to the site office for approval. The DSA includes updated analysis of the seismic accident scenarios (both the seismically induced fire and spill events). Consistent with the previous submittal, LANL disaggregated the material-at-risk into the various physical forms (e.g., metal, oxide, solutions) with specific administrative controls for each form. In addition, this submittal includes further refinement of the different forms of heat source plutonium materials (e.g., fine powder, sintered) and the potential amount of molten plutonium that could be involved in the seismic accident scenarios. Based on the revised analysis, the offsite dose consequence for the postulated post-seismic fire scenario is significantly lower than the dose consequence in the DSA approved in 2008. However, the mitigated consequence remains above the DOE evaluation guideline (site rep weekly 12/4/10).

For the DSA and TSRs approved in 2008, LANL is currently conducting an Implementation Verification Review for the fourth and final phase of implementation. Last week, LANL also submitted a revision to the 2008 DSA/TSRs to resolve previous site office comments and conditions of approval. The submittal includes the following requirements for declaring a TSR violation for a design feature: 1) failure to perform an In-Service Inspection (ISI) within the required frequency is a TSR violation 2) if a design feature fails an ISI, that failure is new information, which shall be evaluated for initiation of the Potential Inadequacy of the Safety Analysis process (failure of an ISI is not automatically considered a TSR violation) 3) failure of a design feature to meet performance criteria, functional requirements, or safety function following return to service after planned or inadvertent modification is a TSR violation.

Weapons Engineering Tritium Facility (WETF): On Monday, the NNSA Operational Readiness Review (ORR) team began their review to evaluate resumption of tritium gas handling operations. This week, NNSA ORR field observations including conduct of an emergency drill were performed. The team plans to complete their review and provide recommendations and findings by next Wednesday. Following the initial restart of low pressure tritium gas handling operations, which is the scope of the ORR, LANL plans to perform a contractor readiness assessment in July to restart function test operations to support an important programmatic mission.

Plutonium Facility – Fire Suppression System: In September 2009, LANL declared the fire suppression system inoperable based on hydraulic calculations that indicate the system does not achieve the water density coverage required in the safety basis. A Justification for Continued Operation (JCO) including compensatory measures was approved and implemented while upgrades to resolve the flow density issue were completed. This week, LANL requested an extension to this JCO to September 17th (the previous JCO expires at the end of June) to allow completion of upgrades to resolve this issue.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 2, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 2, 2010

Weapons Engineering Tritium Facility (WETF) – Readiness: This week, the NNSA Operational Readiness Review (ORR) team completed their review and recommended to the startup authority (NNSA site office manager) that WETF be authorized to restart tritium gas handling operations following closure of pre-start findings and approval of corrective action plans for post-start findings. The team identified six pre-start findings and ten post-start findings (including two post-start findings associated with the site office). The team noted that the lack of a defined process to evaluate gaps in safety management programs and identify corresponding compensatory measures complicated the readiness review. The team also observed that there appeared to be weaknesses in both LANL and site office activities to demonstrate and verify readiness prior to the ORR. The ORR team also recommended that an integrated plan for overall startup (i.e., beyond the first phase of operations reviewed by the ORR) that is linked to safety basis and formality of operations improvements will help support future startup activities.

Weapons Engineering Tritium Facility – Safety Basis: This week, facility management declared a potential inadequacy of the safety analysis based on the discovery that safety significant tritium vessel storage racks could not perform their credited safety function. During a facility walkdown, an ORR team member identified that metal retaining plates used to position and secure tritium vessels in the storage racks were not mechanically fastened to the rack assembly. Original design calculations used to demonstrate the storage racks would meet required performance category (PC)-2 seismic criteria assumed the retaining plates were securely connected to the rack assembly. Without this secure connection, the racks cannot perform their seismic safety function.

In late 2009, an updated analysis of the seismic capacity of these storage racks performed in support of the Seismic Analysis of Facilities and Evaluation of Risk (SAFER) project also concluded that the racks could meet PC-2 criteria. Although current system drawings reflect a lack of connection between the retaining plates and the rack assembly, the SAFER evaluation used the original design calculation that assumes this connection as a key input. As a result, the conclusions of the SAFER evaluation suffer from the same faulty assumption found in the original calculation.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, the assessment lead outbriefed preliminary results from a Facility Centered Assessment (FCA) of the RLWTF. Unlike previous FCAs, this review was chartered at the Responsible Associate Director (AD) level rather than at the Laboratory Director level. The review was shadowed by representatives of the DOE's Office of Health, Safety and Security (HS-64) and the NNSA site office. Overall, the assessment team concluded that within the last year RLWTF has become the most improved and best operationally managed facility at LANL. This conclusion underscores the effectiveness of management restructuring and leadership changes at RLWTF, including a shift in AD and Facility Operations Director ownership and the addition of a highly experienced Operations Manager. It will be critical to sustain this high level of operational performance as the anticipated operating lifetime of the existing RLWTF continues to grow due to delays in the RLWTF-UP project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 9, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 9, 2010

Federal Oversight: This week, Don Winchell, NNSA Los Alamos Site Office manager, retired from federal service. NNSA has announced that Kevin Smith will replace Winchell as the site office manager. Roger Snyder, deputy site office manager, will serve as the acting manager until Smith reports for duty in late August. In the interim, NNSA headquarters has delegated safety basis approval authority to Snyder, but has retained startup and restart authorization authority at the NA-10 level.

Plutonium Facility: On Thursday, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) and initiated a hazardous material response based on the discovery of potentially explosive ammonium nitrate powder inside the facility.

For years, facility personnel had observed a white powdery substance being generated and accumulating between the first and second stages of high efficiency particulate air (HEPA) filters in the standby glovebox exhaust filter plenum that services the 200 Area of the facility. White powder has never been observed in any other Plutonium Facility HEPA filter plenum, including the primary 200 Area glovebox exhaust plenum. The powder was thought to be an inert oxalate salt and was considered benign. Two weeks ago, more thorough chemical analysis performed to support dispositioning several bags of this powder as waste concluded that the substance was actually 95% ammonium nitrate. Upon receipt of the analysis results, facility and safety basis personnel believed the ammonium nitrate to be a strong oxidizer and entered the New Information process to determine whether the unexpected presence of a strong oxidizer in a credited HEPA filter plenum was an unanalyzed hazard that represented a PISA. On Thursday, as part of processing this New Information, safety basis personnel consulted LANL explosives experts who judged that the ammonium nitrate should be considered a UN Class 1.1 explosive based on qualitative description of the powder. This prompted a PISA and a number of immediate actions.

A hazardous material response to recover and neutralize several bags of previously collected ammonium nitrate powder from the facility basement was initiated on Thursday and successfully completed on Friday. Access to the basement room containing the affected HEPA filter plenum, where powder continues to be generated, has been secured and controlled. A waste box in the basement containing removed HEPA filters believed to be contaminated with ammonium nitrate powder has also been isolated and handling of this box has been prohibited. Until the generation mechanism of the potentially explosive powder is better understood, facility management has suspended all aqueous processing activities in the 200 Area of the Plutonium Facility.

Weapons Engineering Tritium Facility (WETF): Prior to retirement, the NNSA site office manager authorized restart of certain tritium gas handling and transfer operations after pre-start findings from the recently completed Operational Readiness Review were confirmed to be closed by site office personnel. An additional contractor readiness assessment is scheduled for late July to authorize function tester operations required for an important programmatic deliverable.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 16, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 16, 2010

Andersen, Caleca, Hadjian, Kimball and Porter were onsite this week to discuss ongoing seismic and structural analyses for the Chemistry and Metallurgy Research Replacement Project.

Transuranic Waste Facility (TRUWF) Project: This week, a team sponsored by the NNSA Office of Project Management and Systems Support (NA-54) conducted an Independent Project Review (IPR) to support a request for Critical Decision-1 for the TRUWF Project. The IPR scope included evaluation of nuclear safety, safety basis, and risk management. The team intends to have a draft report prepared next week.

In advance of the IPR, the NNSA site office issued a Conceptual Safety Validation Report (CSVR) approving the TRUWF project's Conceptual Safety Design Report. In the CSVR, the site office states that its review identified two issues that could affect the ability of the project to proceed. One issue relates to a lack of effective controls to mitigate public and collocated worker consequences for a postulated aircraft crash scenario. The other issue deals with the use of non-conservative analytical assumptions for a seismic impact scenario and the potential for the seismic design category of TRUWF building structures to change if conservative assumptions are used.

The CSVR asserts that more refined analysis is needed to support dose calculations and to provide a basis for the selection of controls, but concludes that the project should be capable of proceeding to the next stage of design if these issues are addressed in a timely manner. To prompt timely resolution, the site office issued formal conditions of approval to address concerns with the aircraft crash scenario within 30 days and to re-evaluate the seismic impact scenario within 90 days.

Transuranic Waste Operations: In late June, LANL management submitted a new Basis for Interim Operations (BIO) for transuranic waste operations at Area G to the NNSA site office for review and approval. The existing Area G BIO was approved in 2003. The new BIO identifies four postulated accident scenarios (fuel pool fire from container leak, aircraft crash, wildland fire and seismically-induced fire) where effective safety class controls cannot be credited to mitigate offsite dose consequences to below the DOE Evaluation Guideline. The proposed BIO credits three engineered controls (safety class vehicle barrier systems at high-risk locations and safety significant transuranic waste drums and drum venting system) and eighteen specific administrative controls to prevent or mitigate postulated accidents.

Plutonium Facility: LANL personnel recently completed the fourth and penultimate Independent Verification Review (IVR) of Technical Safety Requirements associated with the 2008 Plutonium Facility DSA. The scope of the IVR included TSR controls related to the vault water bath, glovebox support stands, laboratory room and glovebox transient combustible loading, and special nuclear material containers. The review identified five pre-implementation findings. This IVR was also initially intended to verify implementation of important new material at risk (MAR) controls. However, due to delays associated with the newly developed MAR Tracker software used to implement these controls, verification of MAR TSRs will be deferred to the final IVR.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 23, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 23, 2010

Mr. Broderick was out of the office this week.

Radioactive Liquid Waste: This week, the site office issued direction to LANL on maintaining an enduring radioactive liquid waste processing capability. The Radioactive Liquid Waste Treatment Facility – Upgrade Project (RLWTF-UP), which is over 90% complete with design, was intended to replace the existing aging facility and provide capability for both transuranic and low level liquid waste processing. However, NNSA has concluded that the escalating project cost (currently estimated at approximately \$350M versus previous estimates of approximately \$100M) combined with out-year funding challenges (given other high priority projects) require NNSA to evaluate and pursue other alternatives. Therefore, the site office has directed LANL to 1) provide a recommendation for the most cost effective and efficient way to ramp down on the current RLWTF-UP design activities and 2) evaluate options to provide an enduring radioactive liquid waste capability (including upgrade and use of existing facilities and smaller scope new facilities). The site office requested a final recommendation on a preferred option within eight weeks.

Chemistry and Metallurgy Research Replacement (CMRR) Project: The Integrated Design Coordination Meeting for the CMRR project was conducted in Los Alamos this week and included representatives from NNSA, LANL and project subcontractors. For the CMRR Nuclear Facility, the project is completing the closure of issues identified in the Technical Independent Project Review that was conducted late last year. The CMRR Nuclear Facility final design contracts are expected to be awarded in October.

Plutonium Facility – Unreviewed Safety Question: This week, LANL concluded that the presence of potentially explosive ammonium nitrate powder identified on high efficiency particulate air (HEPA) filters represents an Unreviewed Safety Question. Previous actions to place the facility in a safe configuration remain in effect (e.g., aqueous operations the 200 area suspended and controlled access to the HEPA plenum room). LANL continues to investigate the source of the ammonium nitrate powder with samples from the in-service HEPA filters collected this week (site rep report 7/9/10).

Weapons Engineering Tritium Facility (WETF): LANL continues to pursue startup preparations for the function test capability at WETF. A management self assessment is scheduled to begin next week followed by a contractor readiness assessment planned for August 9th.

Plutonium Facility – Safety Basis: As noted last week, Plutonium Facility personnel are on the final phase of implementing the Documented Safety Analysis that was approved in December 2008. LANL recently requested an extension for completing this activity to October (previously scheduled to be complete in August). The extension is required to allow completion of fire suppression system modifications and implementation of the material-at-risk tracking system.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 30, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 30, 2010

Transuranic Waste Facility Project: This week, LANL responded to an NNSA site office condition of approval (COA) identified in the Conceptual Safety Validation Report that requested re-evaluation of the aircraft crash accident scenario. In particular, the COA requested LANL to provide documentation that the frequency of occurrence for this postulated accident is below the screening threshold of $1e-6$ per year or that consequence of an aircraft crash can be mitigated to a level that does not challenge the DOE evaluation guideline. LANL has decided to relocate the facility from Technical Area (TA)-52 to the adjacent TA-63 to increase standoff distance from the airport thus reducing the likelihood of an aircraft crash to less than $1e-6$ per year per DOE-STD-3014. Currently, Critical Decision-1, *Approve Alternative Selection and Cost Range*, is planned for mid-August. LANL also plans to conduct value engineering studies next month, in part, to resolve a site office COA on the adequacy of the seismic accident analysis.

Radioactive Liquid Waste Treatment Facility: Last week, LANL began the deinventory efforts for the sludge settling tank (TK-7) previously associated with Room 60/60A transuranic (TRU) liquid waste processing. TK-7 has a known leak site that required urgent action in 2008 to reduce the sludge level below the leak site. As part of Room 60/60A TRU processing equipment upgrades, a new sludge settling tank (TK-7A) was installed and has been used since TRU processing resumed in late-2009. However, a legacy heel of TRU sludge containing approximately seven Am-equivalent Ci remained in TK-7. LANL's plans to remove this sludge involve the potential for multiple phases. The first phase that began last week involves transferring sludge to TK-7A using the existing pumps and piping that historically removed sludge from the tank. However, given the state of the sludge and lack of in-tank mixing capability, LANL anticipated that this technique may not be capable of removing all legacy sludge. Therefore, a second phase was planned that would involve opening a port on top of the containment tank to insert temporary suction piping to establish a new transfer path to mobilize and remove residual sludge. As of Friday, LANL has removed approximately 75% of the sludge using the initial technique but expected to have to move to the second phase as early as next week to complete removal.

Transuranic Waste Operations: Earlier this month, the NNSA site office approved a page change to the Area G TSRs that authorizes open-drum sort, segregate, size reduction and repackaging (SSSR) operations involving up to 2.5 combustible equivalent Ci. Similar open-drum operations have been conducted at Area G for some time at the less than hazard category 3 level (i.e. less than 0.52 Pu-equivalent Ci) in the Dome 231 Permacon and inside a containment tent in Building 412. The page change increasing the MAR limit associated with SSSR operations allows a greater population of drums to be processed to achieve compliance with the Waste Isolation Pilot Plant (WIPP) waste acceptance criteria, allowing offsite shipment. New TSR-level controls establish a limit of 5 SSSR processing areas at Area G and set thermal separation distances between SSSR areas and staged waste containers. NNSA also issued a COA requiring establishment of TSR-level flammable liquid controls in SSSR areas. A contractor readiness assessment will be performed prior to beginning 2.5 combustible equivalent Ci SSSR operations at

Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 6, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 6, 2010

Plutonium Facility – Criticality Safety: This week, Plutonium Facility management identified that an activity conducted last month in a drop box was not analyzed or approved by the criticality safety group. Drop boxes are used for pass through of materials from the trolley line to gloveboxes; however, operations, especially related to waste processing, are analyzed and allowed in many of these boxes. In this case, a dry residue material was identified as waste and was being repackaged for disposition. Operators moved the material to the drop box and then repackaged and weighed the material believing they were in compliance with the criticality safety evaluation and posting that allowed waste operations. The first line manager became aware this week that the operation had been conducted in the drop box and contacted the criticality safety group. The criticality safety group concluded that the dry residue operation was not analyzed and a Level 1 non-compliance criticality safety infraction was declared. During the critique of this event, facility management became concerned that there may be a misunderstanding of what operations are allowed in drop boxes. As a result, all drop box operations were paused and a deliberate review and resumption process developed involving conduct of operations mentors and criticality safety.

This infraction highlights the importance of precise communications in defining activity scope and safety requirements. Over the last several months, there have been a number of criticality safety issues identified at the Plutonium Facility. Management has taken several actions to address these issues including stationing two members of the criticality safety group at the Plutonium Facility to observe and walkdown process operations. Plutonium Facility management will also conduct a briefing next week for all facility first line managers to discuss criticality safety issues.

Chemistry and Metallurgy Research Building (CMR): A number of high dose rate materials including Cm-244, Am-241, Np-237, and U-233 have historically been stored in heavily shielded floor wells in CMR's Wing 9. CMR personnel are aggressively working to disposition this material to reduce facility risk and to achieve compliance with new material at risk (MAR) limits in the approved CMR DSA that is required to be implemented before the end of December 2010.

Ten Cm-244 items account for nearly 99% of the MAR associated with the remaining material from the floor wells. These items have been retrieved from their floor well locations, transferred to Wing 9 hot cells and packaged into Type A shielded pipe overpack containers awaiting shipment out of CMR as waste. However, the ultimate disposition path for this material is currently in flux based on a request by the DOE Office of Fuel Cycle Technologies (NE-5) to provide interim staging of the curium items until April 30, 2011, to support possible programmatic reuse of this material. As a result, LANL management is investigating onsite and offsite options to provide interim storage outside of CMR where the 40 kg of MAR represented by the ten curium items would exceed the new DSA total facility MAR limit by almost a factor of 3.

Several remaining floor well materials contain Np-237 and U-233 in dispersible oxide forms that require repackaging prior to disposition. CMR personnel have restored the operability of an alpha box confinement system inside a hot cell to support dispersible material repackaging operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 13, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 13, 2010

Waste Operations: On Monday, LANL declared an Operational Emergency due to the potential release of red fuming nitric acid. Workers in Area L were in the process of over-packing three legacy containers for offsite disposition. After placing the third container into the overpack, workers noted fumes being released. The overpack container was latched closed and relocated to a spill pallet. The workers then contacted the operations center and protective actions were initiated (i.e., local evacuation and shelter in-place) along with contacting the emergency response organization. The overpack container subsequently ruptured and additional material was released. Emergency response personnel established an incident command for the event and the emergency operations center was manned. A re-entry and recovery plan was developed to stabilize the container and material. Hazardous material personnel performed multiple entries to place the area in a stable condition (the material was neutralized and repackaged into other containers). LANL plans to perform an investigation to identify opportunities for improvement and lessons learned from this event.

Criticality Safety: This week, Plutonium Facility personnel identified several additional criticality safety infractions where operations or activities were not consistent with criticality safety evaluations. These new discoveries were prompted by a significant effort on the part of facility management to refocus attention on criticality safety compliance in light of a string of recent issues. Senior management held a meeting with all first-line Plutonium Facility managers on Monday to discuss lessons learned from recent criticality safety infractions and to reinforce the importance of understanding and complying with criticality safety limits. The meeting also emphasized the need to pause operations if actual work activities depart from those analyzed in criticality safety evaluations or if there is ambiguity in the intent of criticality safety limits.

This week, the institutional Nuclear Criticality Safety Committee (NCSC) began a review at CMR to assess the facility's implementation of the LANL criticality safety program. The NCSC plans to conduct a similar review assessing implementation at the Plutonium Facility.

Transuranic Waste Operations: Operations to vent and filter sealed transuranic waste drums at Area G have been suspended since a hydrogen deflagration event occurred in November 2008. Several thousand legacy waste drums generated and stored at Area G require venting prior to offsite disposal at the Waste Isolation Pilot Plant. To improve the safety of drum venting operations required to support Area G closure, LANL has installed a new engineered drum venting system that is better equipped to mitigate the effects of a deflagration if one should occur. The NNSA site office is currently reviewing proposed revisions to the Area G TSRs to support resumption of drum venting operations using the new system. Area G personnel must also successfully complete a contractor readiness assessment prior to resuming drum venting operations (site rep weeklies 3/13/09, 11/28/08).

Transuranic Waste Facility (TRUWF) Project: Following an Energy Systems Acquisition Advisory Board review, the TRUWF Project received approval of Critical Decision-1, *Approve Alternative Selection and Cost Range*. LANL plans to perform value engineering studies later this month to evaluate parameters used in the safety analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 20, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 20, 2010

On Wednesday, staff members Pasko and Shuffler conducted a telephone conference call with LASO and LANL personnel to discuss the results of a recent review of the Chemistry and Metallurgy Research Building Documented Safety Analysis and plans for post-2010 operations.

Transuranic Waste Operations: This week, LANL began their contractor readiness assessment for open drum debris sorting operations with up to 2.5 combustible equivalent Ci in Area G. The review team is evaluating operations in both the Dome 231 Permacon and inside a containment tent in Building 412. This review is expected to be complete next week (site rep report 7/30/10).

Weapons Engineering Tritium Facility (WETF): LANL completed a management self assessment of function test operations at WETF this week. The team recommended that the activity proceed to a contractor readiness assessment following root cause determination and corrective action closure of pre-start findings. The team identified seven pre-start findings including issues with emergency management response (concerns with emergency response were identified during the NNSA operational readiness review for phase I operations). WETF personnel are working on closure of these findings and plan to begin the contractor readiness assessment on Monday.

Fire Protection Program: This week, NNSA completed a review of the LANL fire protection program with focus on overall program, fire hazard analyses, self-assessments, integration of fire protection with facility projects and fire department response and capabilities. The preliminary outbrief by the team noted a number of findings including issues with training and qualification of the fire protection staff, implementation of the fire system impairment program and self assessments. A final report for this review is expected in the next few weeks.

Plutonium Facility – Unreviewed Safety Question: As noted on July 23rd, LANL had declared an unreviewed safety question based on the presence of potentially explosive ammonium nitrate powder identified on high efficiency particulate air (HEPA) filters in a 200 area plenum. This week, sample analysis concluded that material found in a 400 area HEPA plenum is also ammonium nitrate. Based on these results, similar compensatory measures have been implemented in the 400 area (e.g., suspension of aqueous operations). Last week, LANL prepared an Evaluation of the Safety of the Situation (ESS) based on the information available concerning the ammonium nitrate in the 200 area plenum. The ESS noted that the material would not begin to approach an explosive hazard until one-half inch had accumulated (based on explosive expert evaluation). Further, the ESS identified that material accumulation was occurring very slowly. LANL proposed monitoring the material as part of the TSR Hazardous Material Protection Program and taking corrective actions if material reached one-quarter inch. Based on the results for the 400 area, LANL is revising the ESS to address the 400 area activities (site rep report 7/9/10 and 7/23/10).

Waste Operations: LANL has formed an investigation team to evaluate the Area L event involving red fuming nitric acid that occurred last week. The team will establish the event timeline, determine how the event occurred and identify recommendations for LANL management. The investigation is expected to be complete in early-September (site rep report 8/13/10).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 27, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 27, 2010

Waste Operations: This week, LANL identified that waste retrieved and stored in a container inside enclosure 1 at Material Disposition Area-B (MDA-B) exceeds the material-at-risk (MAR) limits for a radiological facility. The container (20 cubic yard capacity) is estimated to contain approximately 3 Ci Pu-239 equivalent, which is above the hazard category 3 threshold of 0.52 Ci for Pu-239. Facility personnel suspended waste operations at MDA-B and placed the facility in a safe and stable condition. LANL is performing waste retrieval and disposition operations at MDA-B as part of the American Recovery and Reinvestment Act activities at the laboratory. MDA-B was used to bury process waste from nuclear weapon and science activities in the mid to late-1940s. Previous characterization data indicated that the activity could be performed under the MAR limits for a radiological facility.

On Tuesday, MDA-B personnel completed the loading of the waste container in enclosure 1. Items retrieved during this operation included a pipe component (approximately 8" diameter, 2.5' length) that was noted to be highly contaminated. Field sample analysis of the waste in the container performed at that time indicated that the material retrieved had significantly higher MAR than expected. Subsequent sample analysis confirmed that approximately 3 Ci Pu-239 is present in the container. LANL is currently evaluating options to address the material. MDA-B retrieval operations remain suspended pending resolution of this issue.

Chemistry and Metallurgy Research Building (CMR): The site office directed LANL this week to move 10 curium-244 items (approximately 40 grams) from CMR to Area G for storage in a secured transportainer. These items had been stored in the Wing 9 floor wells but were recently repackaged into Type A shielded pipe overpack containers. LANL plans to store these items in Area G pending determination of whether a programmatic need exists. Removal of the curium-244 results in approximately 40 kg Pu-239 equivalent reduction in material-at-risk at CMR.

As part of the implementation plans for the recently approved Documented Safety Analysis (DSA) at CMR, LANL has been conducting in-service inspections of safety design features. While conducting these inspections this week, LANL noted deficiencies in several gloveboxes and in one hot cell that could prevent these design features from performing their safety function. The facility gloveboxes and the hot cells are credited as safety design features in both the current safety basis and the new DSA. LANL concluded that these issues represent a Potential Inadequacy in the Safety Analysis.

Weapons Engineering Tritium Facility (WETF): The contractor readiness assessment team completed their evaluation of function test operations at WETF this week and provided feedback to LANL and LASO management. The team identified six pre-start and four post-start findings. The review team recommends that the startup authority approve restart of this operation following satisfactory closure of the pre-start findings.

Transuranic Waste Operations: This week, LANL completed the contractor readiness assessment for open drum debris waste sorting operations at Area G. Two pre-start findings, both associated with training, and four post-start findings were identified by the review team. This team recommends

approval to start operations following closure of the identified pre-start findings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 3, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 3, 2010

Transuranic Waste Operations: Last week, the NNSA site office approved an activity at Area G involving the receipt, handling and storage of a shielded box containing approximately 0.5 g of Am-241. The box is currently staged at Sandia National Laboratories – Albuquerque (SNL-Albuquerque) and contains a legacy americium source that originated at the Lovelace Respiratory Research Institute. The material is thought to be in a dispersible form based on radiation protection alarms received during a previous attempt to open the shielded box. The box will be placed in robust Type B shipping cask at SNL-Albuquerque, transported to LANL, received at Area G, transferred from the cask to a Type A standard waste box, and staged in the Type A overpack in an Area G waste storage dome. Plans for retrieval and ultimate disposition of the americium are under development and will be reviewed and approved separately.

NNSA approval was required to support receipt, handling and staging of this item because LANL personnel performed an unreviewed safety question (USQ) evaluation against the Area G safety basis that resulted in a positive determination. The process step where the shielded box is removed from the Type B shipping cask and transferred to the Type A standard waste box caused the positive USQ. The Area G safety basis assumes transuranic waste at Area G is packaged in Type A containers of sound integrity. Since the shielded box is not a certified Type A container, this activity was assessed to increase the probability of an accident above the level evaluated in the safety basis.

Chemistry and Metallurgy Research Building (CMR): Facility personnel are in the process of implementing the Technical Safety Requirements (TSRs) associated with the Documented Safety Analysis that was approved by the NNSA site office in June 2010. One important improvement in the recently approved safety basis relates to the treatment of passive engineered controls that have been credited in the TSR document as Design Features. In the current safety basis, no periodic inspections or surveillances are prescribed to confirm that these safety class and safety significant Design Features continue to effectively perform their credited nuclear safety functions. Although the Department of Energy's hierarchy of controls gives preference to engineered over administrative controls and passive over active controls, DOE Directives do not require periodic surveillances for passive engineered Design Features, whereas surveillances are required for active controls.

Though they are not required by DOE Directives, LANL personnel included periodic in-service inspections for credited Design Features in the new CMR safety basis, as a best practice. As reported last week, when CMR personnel performed the initial in-service inspections on facility Design Features, they discovered a number of deficiencies that rendered some gloveboxes and one hot cell structure unable to perform their credited safety functions. These deficient conditions had persisted under the current safety basis, at least in part, because the TSR document did not require inspections on an appropriate frequency to identify and address degradation or inappropriate modification of credited passive controls. These discoveries underscore the importance and utility of performing periodic inspections to ensure TSR-level Design Features continue to effectively perform their credited safety functions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 10, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 10, 2010

Waste Operations: On Friday, the site office approved an Evaluation of the Safety of the Situation (ESS) for Material Disposal Area-B (MDA-B) that was submitted by LANL to address waste in Enclosure 1. As noted on August 27th, LANL sample analysis of waste retrieved and staged in Enclosure 1 indicates that approximately 2.9 Ci of Pu-239 equivalent contaminated soil and debris is present in the container, which exceeds the 0.52 Ci limit for the MDA-B radiological facility. The path forward detailed in the ESS includes 1) placing a contaminated pipe component that was retrieved into a 55-gallon drum, 2) removing this component from MDA-B, 3) returning the remaining soil and debris to the MDA-B pit and, 4) covering the contaminated soil with at least 4 inches of overburden. The ESS notes that these actions will reduce the MAR below radiological levels and render the site safe and compliant with existing safety analysis. The site office response included a condition of approval that precludes additional excavation activities at MDA-B until a robust radioactive material monitoring system can be demonstrated including site office concurrence.

Plutonium Facility: Last week, LANL management submitted a revised ESS related to the discovery of potentially explosive ammonium nitrate in two safety class HEPA filter plena in the Plutonium Facility basement. The revised ESS includes a discussion of the mechanism thought to be generating the ammonium nitrate. Both affected plena abut closed front maintenance hoods which are separated by metal doors that do not create air-tight seals. The plena and maintenance hoods are connected to different portions of the ventilation systems. The maintenance hoods that abut the two affected plena share a ventilation flow path with Plutonium Facility restrooms that are cleaned using products that contain ammonia. The ESS postulates that ammonia from the restrooms is being drawn into the filter plena from the maintenance hoods through the unsealed door, where it then reacts with nitric acid vapors being exhausted from process gloveboxes. This generation mechanism would explain why ammonium nitrate is only being created between the first and second stages of credited HEPA filters in the affected plena. The ESS proposes two new compensatory measures. First, sealing the interface between the HEPA plena and maintenance hoods to prevent ammonia intrusion and second, prohibiting work with heat or ignition sources inside the basement rooms housing the affected plena. The ESS also seeks approval to resume aqueous nitrate operations in Plutonium Facility that have been suspended since the ammonium nitrate was discovered.

Chemistry and Metallurgy Research Building (CMR): On Thursday, LANL personnel transferred ten drums containing approximately 40 g of Cm-244 from CMR to Area G. The shipment was significant because this small quantity of curium translated into roughly 40 kg of Pu-equivalent MAR, an amount about five times greater than all other MAR in the facility combined. This material will reside at Area G in pipe overpack containers staged inside a metal transportainer until it can be transferred to another programmatic user or disposed as transuranic waste.

Transuranic Waste Operations: On Monday, LANL began an outage at the WCRR repackaging facility to accomplish a number of important maintenance and safety improvements including 1) installation of fire suppression capability in the repackaging glovebox, 2) relocation of the oil-filled transformer to greater than 25 feet from the facility and 3) resolution of seismic anchorage issues associated with the drum lift. The WCRR outage is expected to last until late-October.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 17, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 17, 2010

Staff member J. Pasko was onsite this week for Conduct of Operations training.

Weapons Engineering Tritium Facility (WETF): The startup authority for the WETF function test activity authorized operations last week following satisfactory closure of pre-start findings identified during the contractor readiness assessment. WETF personnel successfully completed the first and most programmatically critical of a series of planned function tests earlier this week. In addition to the function test campaign, WETF personnel are also pursuing risk reduction activities that include shipping excess material-at-risk to the Savannah River Site and providing more robust confinement for roughly 75 tritium-bearing vessels that may or are known to exceed their maximum allowable working pressure and are not currently protected by any credited confinement barrier.

Waste Operations: Following NNSA site office approval of the Evaluation of the Safety of the Situation (ESS), Material Disposal Area-B (MDA-B) personnel returned the contaminated soil located in Enclosure 1 to the pit and covered the material with a 4 inch minimum overburden. LANL personnel also packaged a contaminated pipe that had been retrieved in a Type A container and removed this item from MDA-B. These actions reduce the material-at-risk (MAR) at MDA-B below radiological facility levels (i.e. 0.52 Pu-239 equivalent Ci). The site office approval of the ESS included a condition of approval that precludes additional excavation activities until LANL can demonstrate a robust radioactive material monitoring system. On Friday, LANL submitted a path forward for real-time excavation monitoring to identify high activity material prior to removal from the excavation pit. A low energy gamma detection monitor will be attached to the excavation boom to identify the high MAR material. These materials will remain in the pit and be covered with at least a 4 inch overburden. LANL contends that the new monitoring system will allow safe excavation of soil and debris from MDA-B.

Plutonium Facility: This week, facility personnel submitted a revised ESS related to the presence of ammonium nitrate in safety class high efficiency particulate air (HEPA) filter plena. The revised ESS augments the set of compensatory measures that were proposed in the previous submittal to replace HEPA filters affected by ammonium nitrate generation (i.e second stage glovebox exhaust HEPA filters) prior to resuming aqueous nitrate processing operations. Replacing these filters and removing residual ammonium nitrate from filter plena housings will eliminate any potential explosive hazard this material may present (site rep weekly 9/10/11).

Chemistry and Metallurgy Research Building (CMR): This week, two CMR laboratory personnel discovered contamination on their booties during routine monitoring activities. A Radiological Control Technician responded, confirmed the presence of contamination and provided replacement booties. Room surveys identified up to 1 million dpm removable contamination in an area below an open front hood where one of the operators was working. Subsequent isotopic analysis indicated that the contamination was Pu-238. No Pu-238 analytical chemistry operations have been performed in this laboratory room in recent history. CMR personnel decontaminated the room and continue to investigate the source of contamination.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 24, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B.P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending September 24, 2010

The site representatives were at DNFSB Headquarters in Washington, DC. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 1, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 1, 2010

Material Disposal Area (MDA)-B: Project personnel resumed excavation operations in all active enclosures, including Enclosure 1 where several weeks ago the material-at-risk (MAR) limit corresponding to the facility's less-than-hazard-category 3 status was exceeded. Prior to resuming excavation operations, LANL personnel implemented enhanced radioactive material detection capabilities to increase confidence that soil and debris involving higher levels of contamination can be identified and managed in compliance with the existing limit of 0.52 plutonium-equivalent (PE)-Ci for each excavation dig face.

Separately, LANL safety basis personnel are preparing a revised final facility hazard categorization, per DOE-STD-1027, that seeks to increase the less-than-hazard category 3 threshold from 0.52 PE-Ci to some larger value based on material dispersibility characteristics and energy sources associated with MDA-B.

Plutonium Facility – Fire Protection: Six fire-rated safes have been installed in the Plutonium Facility basement. These safes have been qualified to survive bounding Plutonium Facility accident scenarios and have been credited with a damage ratio of zero, meaning that material contained in these safes do not contribute to accident source terms.

LANL management has also submitted an evaluation documenting test results to support dramatically reducing the damage ratios of two types of special nuclear material storage containers commonly used in the Plutonium Facility. An outside laboratory performed furnace, open flame and drop tests on Conflat containers, often used to store plutonium metal, and a container sometimes referred to as an "espresso container," used to store Pu-238-enriched heat source plutonium. The tests used cerium oxide as a surrogate material for plutonium and containers were weighed before and after tests to determine how much material was released as a result of the test insult. The fraction of material released corresponds to the damage ratio of the container. Tests results indicate that both the Conflat and "espresso" containers have damage ratios very close to zero.

Plutonium Facility – Safety Basis: On Wednesday, LANL declared a Potential Inadequacy of the Safety Analysis (PISA) based on the use of non-conservative assumptions associated with calculation of dose conversion factors for plutonium chloride salts. Earlier this year, a PISA was identified at Hanford due to the use of Class-S (in accordance with ICRP-66) for plutonium materials subject to fire release scenarios. The Hanford PISA noted that the use of Class-S may not be conservative in all cases. Based on the information from Hanford, LANL safety basis engineers evaluated the assumptions used at LANL facilities and the Plutonium Facility in particular. Plutonium chloride salts are produced as part of pyrochemical metal production and purification processes used in the Plutonium Facility. For the Documented Safety Analysis approved in 2008 that is currently being implemented, the plutonium materials associated with certain pyrochemical processes are assumed to be molten plutonium metal that would oxidize during a fire with S-Class material type. LANL personnel concluded that the assumptions related to material class made in the safety basis may not be appropriately conservative in this case.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 8, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 8, 2010

Radioactive Liquid Waste: Last week, LANL provided an interim response to a July NNSA request to evaluate options for providing an enduring radioactive liquid waste capability. A joint NNSA/LANL strategy team evaluated options for sustainment/life extension of the existing capability and for providing a new capability. The team preliminarily assessed that it is not feasible or practical to provide a long-term capability with the existing Radioactive Liquid Waste Treatment Facility. However, the team also assessed that life extension upgrades to this facility could provide an interim capability for the next 10 to 20 years. For the enduring capability, the team identified and evaluated 37 separate options and proposed additional evaluation of two of these options. The first option involves updating mission requirements and reducing the scope of the current project plan. The second option involves some use of existing facilities along with separation of the processing capabilities (e.g., separation of low level and transuranic liquid waste processing). Progress on this study will be discussed during the upcoming Integrated Nuclear Planning workshop scheduled for early November. A final recommendation on the path forward for radioactive liquid waste capabilities is anticipated in late-December (site rep weekly 7/23/10).

Material Disposal Area (MDA)-B: On Tuesday, LANL submitted to the site office a revised Final Hazard Categorization for MDA-B that uses adjusted threshold quantities based on the specific materials and energy sources for the waste being retrieved. The LANL submittal would allow up to 5 plutonium-239 equivalent curies to be retrieved for the individual waste retrieval enclosures at MDA-B. The site office is currently reviewing the categorization to determine if the basis is adequate and whether it is compliant with DOE-STD-1027.

Plutonium Facility – Packaging: On Thursday, the site approved the final Safety Analysis Report for the Fuel Storage Outer (FSO) container in accordance with the requirements of DOE M441.1-1, *Nuclear Material Packaging Manual*. The FSO container is a welded safety class container that is used to robustly store plutonium-238 enriched materials at the Plutonium Facility.

Plutonium Facility – Evaluation of the Safety of the Situation (ESS): This week, the site office approved the ESS for the ammonium nitrate that was identified in the Plutonium Facility exhaust ventilation system. Following implementation of controls identified in the ESS (see site rep weeklies 9/10/10 and 9/17/10), LANL will be able to resume aqueous nitrate operations in the 200 and 400 areas.

Transuranic Waste Operations: LANL continues to pursue startup activities to allow venting of sealed transuranic waste drums at Area G. Drum venting activities have been suspended since a hydrogen deflagration event occurred in November 2008. A robust enclosure has been installed to improve the safety of this operation. This week, the site office approved Technical Safety Requirement page changes that cover drum venting operations. Currently, LANL plans to perform a laboratory readiness assessment prior to resumption of this operation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 15, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 15, 2010

Material Disposal Area (MDA)-B: This week, LANL personnel discovered that approximately 0.55 ²³⁹Pu-Equivalent Ci (PE-Ci) of material-at-risk (MAR) had been excavated from a retrieval pit and placed in a waste bin. This quantity of MAR exceeded the MDA-B MAR limit imposed to protect its designation as a less-than-Hazard Category 3 facility. In response, LANL management declared a potential inadequacy of the safety analysis and paused all excavation activity at MDA-B.

In late August, a similar MAR limit violation occurred at MDA-B. In response to the August event, excavation operations were suspended and the NNSA site office directed LANL to develop and implement enhanced radioactive material detection capabilities to provide higher confidence that important facility MAR limits could be protected via improved characterization of the quantity of MAR being unearthed during excavation. These new detection capabilities were in place this week and failed to prevent the MAR limit from being exceeded. Based on this recurrence, LANL senior management is evaluating options on how to resume and complete MDA-B environmental restoration activities in a compliant manner (site rep weeklies 10/8/10, 9/17/10, 9/10/10, 8/27/10).

Transuranic Waste Operations: Last Thursday, the LANL Associate Director for Nuclear and High Hazard Operations paused the conduct of a checklist contractor readiness assessment (CRA) required for startup of two heated transportainers at Area G based on the CRA team's discovery of several potentially significant safety basis-related findings.

Waste Isolation Pilot Plant (WIPP) waste acceptance criteria prohibit the presence of free liquids in transuranic waste drums. The heated transportainers are needed to ensure that any free liquids are in an unfrozen state prior to undergoing the radiographic characterization required by WIPP. The Area G safety basis restricts the aggregate amount of MAR allowed to be contained inside transportainers and within a 50 ft radius of their footprint. The CRA team found that the software program used by Area G to track inventory and ensure compliance with TSR MAR limits did not appear to effectively capture and account for MAR located inside a 50 ft radius of the heated transportainers. The CRA team also identified concerns related to the potential for hydrogen concentrations above the lower flammability limit to accumulate inside the heated transportainers. Area G engineering personnel had analyzed and ruled-out hydrogen deflagration hazards, but the CRA team found that key assumptions associated with transportainer drum loading and temperature from the engineering analysis had not been protected in operating procedures.

Plutonium Facility: This week, Plutonium Facility personnel recognized that sealed calibration standards containing ²³⁸Pu may present an over-pressurization hazard. There are more than 100 such standards in the Plutonium Facility and a smaller number of these standards in other LANL facilities. These standards were fabricated at the Mound Plant in the 1970's and documentation from that era indicates that the manufacturer only assured a five year safe operating life based on uncertainties related to material response to prolonged exposure to ²³⁸Pu. A great deal of relevant material response data now exists indicating that these sources are robust, but LANL is performing confirmatory analysis and is evaluating the situation through the New Information process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 22, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 22, 2010

Material Disposal Area (MDA)-B: This week, NNSA Headquarters approved a request submitted by the Los Alamos Site Office to exempt MDA-B operations from the requirements of 10 Code of Federal Regulations (CFR) 830, Subpart B, *Safety Basis Requirements*. This exemption request was prompted by two recent events where quantities of material at risk (MAR) were excavated at MDA-B that exceeded the facility's MAR limit. These events undermined confidence that MDA-B operations could be conducted without unearthing levels of MAR that exceed the hazard category 3 threshold (0.52 ²³⁹Pu-Equivalent Ci) that invokes 10 CFR 830 requirements to develop and implement a Documented Safety Analysis and Technical Safety Requirements.

The site office request stated that an exemption is necessary for MDA-B environmental restoration activities to complete prior to the deadline imposed by Consent Order agreement with the state of New Mexico. The request also asserted that the exemption is justified because the engineered and administrative control set implemented under the MDA-B Facility Safety Plan is essentially the same suite of controls that were originally derived in a 10 CFR 830-compliant safety basis prepared and approved when MDA-B was considered a hazard category 3 facility. The exemption covers MDA-B operations involving MAR up to the hazard category 2 threshold quantity of 56 ²³⁹Pu-Equivalent Ci (PE-Ci), but requires formal response actions if MAR exceeds 5 PE-Ci.

Prior to LANL resuming operations at MDA-B, the NNSA site office must issue a letter affirming that the Facility Safety Plan and associated procedures have been adequately revised and implemented to comply with the terms and conditions specified in both the site office exemption request and the headquarters approval. NNSA has also directed LANL to submit any future changes to the Facility Safety Plan and associated procedures that affect the MDA-B safety envelop to the site office for concurrence before implementing the changes.

Chemistry and Metallurgy Research Building (CMR): To continue operating, CMR is required to implement its new DSA and TSRs prior to January 1, 2011, when the current CMR Basis for Interim Operations and interim TSRs expire. This week, after extensive work by facility personnel to implement the new safety basis, an independent LANL team began the formal Implementation Verification Review (IVR) that is required before CMR can officially transition to the new DSA and TSRs. The IVR team immediately noted a number of potential issues related to time-intensive TSR-level surveillance requirements that have not been performed prior to the review, but are scheduled to be performed prior to declaring that the new DSA and TSRs are implemented. The IVR team intends to complete their assessment on November 1st and issue a final report on November 12th (site rep weekly 6/4/10).

Readiness: DOE Order 425.1D, the most recent revision of the directive governing verification of readiness to startup or restart nuclear facilities, was formally incorporated into the LANL Management and Operating contract in late September. This week, LANL management submitted for NNSA site office review and approval a revision to the laboratory institutional procedure on readiness verification that reflects changes and new requirements from the revised Order.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 29, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 29, 2010

The staff held a teleconference with NNSA and LANL personnel to discuss the design of safety class seismically-actuated electrical shutoff devices planned for use in the Plutonium Facility. Pasko was also onsite to observe a joint NNSA/LANL workshop to discuss the strategy and actions needed to effectively control postulated seismic events at the Plutonium Facility.

Transuranic Waste Operations – Readiness: This week, the NNSA site office issued a memorandum approving LANL's most recent Startup Notification Report. In the approval memo, the NNSA site office manager directs a change to the level of readiness review required to authorize transuranic drum venting operations at Area G from a contractor readiness assessment to a federal readiness assessment. Transuranic waste drum venting operations have not been conducted at Area G since a hydrogen deflagration occurred during a venting evolution in late 2008. The new drum venting operation will be performed by a subcontractor using a new engineered venting system that will be operated under new TSR-level controls.

Material Disposal Area (MDA)-B: On Wednesday, during excavation activities inside Enclosure 12, MDA-B personnel identified two buried drums that were significantly degraded. While trying to extract the drums in accordance with procedures, one drum released approximately 5 gallons of a clear liquid. The enclosure has the capability to monitor for volatile organic compounds (VOCs) and these instruments indicated a significant increase in VOC levels inside the enclosure. Industrial hygiene monitoring external to the enclosure did not indicate a significant release of VOCs. However, construction workers in a nearby area external to the enclosure later complained of symptoms (all were evaluated and ultimately released with no medical restrictions). Enclosure 12 operations were suspended. LANL continues to evaluate this event to determine appropriate corrective actions.

Weapons Engineering Tritium Facility (WETF): Earlier this month, WETF personnel noted an increase in the oxygen concentration in a portion of the Tritium Waste Treatment System (TWTS). Subsequent investigation identified that a leak in the Hot Inlet System (HIS), which is part of the Tritium Gas Handling System (TGHS), was introducing oxygen into the TWTS. The HIS is used to analyze the composition of gas mixtures for tritium samples (less than 2g) and effluent from this system is normally sent to the TWTS. The TWTS was declared inoperable (which precludes tritium processing activities) while this issue was investigated. In addition, the HIS was declared inoperable and effluent was directed to the stack to prevent additional oxygen introduction to the TWTS.

Late last week, LANL declared a Potential Inadequacy of the Safety Analysis and subsequently declared a positive Unreviewed Safety Question based on the potential for oxygen in-leakage into the TGHS/TWTS that could potentially lead to a deflagration. On Thursday, LANL submitted to the site office an Evaluation of the Safety of the Situation and Justification for Continued Operation (JCO) to support resumption of tritium processing operations. Compensatory measures proposed by LANL in the JCO include the following: 1) monthly surveillance of two influent isolation valves when the HIS effluent is directed to the stack, and 2) the HIS shall be directed to the stack unless an operator is stationed to continuously monitor the TWTS oxygen concentration during the evolution. The site office is reviewing the JCO submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 5, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 5, 2010

Plutonium Facility: Last Thursday, Plutonium Facility personnel lost control of radiological contamination during an operation to bagout material from a glovebox. The event occurred when one operator dropped a container to another waiting operator down an interface tube leading to the bagout port. When the container reached the second operator, the force caused his hand to pull down on the bagout assembly enough for the bag to detach from the glovebox port and breach the confinement boundary. Operators successfully re-secured the bag to the glovebox port with tape, and exited the area after continuous air monitors (CAMs) began alarming in their room. CAMs later alarmed in two adjacent rooms. The two operators and their attending Radiological Control Technician had contamination on their personal protective equipment and one operator had roughly 1100 dpm of alpha contamination on his skin. Nasal smears taken after all affected personnel doffed their respirators showed no detectable activity. This week, facility personnel performed a controlled re-entry to secure the bagged containers and decontaminate affected areas.

The design of the glovebox bagout port appeared to play a role in this event. Unlike most bagout ports found in the facility, this port lacks an engineered feature, such as a lip or raised nub, to help secure the bagout assembly to the port and prevent slipping. Also, this port included a long interface tube that required one operator to drop the container about 18 inches before it could be received and controlled by the other operator. Facility management has suspended all bagouts from gloveboxes with similar features until corrective actions can be developed and implemented.

Chemistry and Metallurgy Research (CMR) Building: A spill of greater than 5 gallons of contaminated liquid occurred in Wing 7 of CMR last Friday. There was no personnel contamination either during the spill or in subsequent cleanup activities. An analytical chemistry worker was disposing of approximately 2 liters of 2% concentrated nitric acid through the facility acid waste drain system. After pouring the acid into a hood drain, the worker opened a valve to the de-ionized water system to provide a flush of the acid drain line and exited the area. After the operator left the lab room, the acid drain line trap that connects to the hood drain separated and liquid from the trap and additional liquid from the de-ionized water system began to spill to the lab floor. The worker identified the spill upon return and contacted the Operations Center. The facility spill team was dispatched to the area to assess the spill and begin corrective actions. The emergency response organization was also contacted and responded to the facility. The de-ionized water was subsequently isolated and the spill was contained. During the event, the spill migrated to the basement and an uncontrolled lab corridor. Decontamination activities continued into this week. CMR personnel are developing corrective actions to reduce the likelihood of a similar event.

Plutonium Facility – Fire Suppression System: Last week, LANL requested site office approval to exit the Justification for Continued Operation (JCO) associated with deficiencies identified in the fire suppression system. The JCO was required because the system did not meet required flow densities in the most hydraulically remote 1500 ft² area. The request noted numerous improvements that have been made to this system including installation of additional risers (such that all areas have dual water sources) and relocation/installation of sprinklers to resolve coverage issues. The submittal also requests site office approval to use a 300 gpm hose stream allowance (500 gpm used previously). LANL notes that 300 gpm exceeds the NFPA 13 requirement (250 gpm) and is consistent with expected fire department response.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 12, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 12, 2010

Chemistry and Metallurgy Research Building (CMR): LANL management has submitted for NNSA site office review and concurrence a Safety Basis Strategy document that formalizes a new approach to controlling material-at-risk (MAR) at CMR. The new strategy would control MAR at a level that ensures offsite dose consequences for bounding postulated accident scenarios would not exceed the DOE Evaluation Guideline. To remain below the Evaluation Guideline, the total quantity of MAR allowed in CMR will be administratively controlled to a level 35% below the previously approved limit until the next annual safety basis update when the formal Technical Safety Requirement (TSR) MAR limit will be revised to capture the new approach. NNSA review of the Safety Basis Strategy is on-going.

CMR's two primary enduring missions involve performing programmatic analytical chemistry operations and recovering and dispositioning special nuclear material from a number of legacy confinement vessels. The most heavily loaded confinement vessels contain quantities of MAR that would consume a significant fraction of the total MAR allowed in the facility. Therefore, CMR will have to remove unneeded MAR, streamline transuranic waste disposition processes, and relocate to other facilities certain MAR-intensive operations in order to support processing these bounding confinement vessels without curtailing on-going analytical chemistry operations.

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a TSR violation associated with the Pressure Safety Program and a Potential Inadequacy of the Safety Analysis (PISA) related to internal fire barriers credited as part of the safety class facility structure Design Feature.

Management declared the TSR violation based on an issue identified by NNSA safety system oversight engineers. The TSR-level Pressure Safety Program requires post modification testing that involves leak testing at pressure conditions up to maximum operating pressure whenever a certain class of pressure-rated components are added to existing pressure systems. Roughly six assemblies containing this class of pressure-rated components were installed during the WETF restart effort, but were leak tested under vacuum conditions rather than the pressurized conditions required by the TSRs. In response to the TSR violation, WETF personnel will either perform required leak tests of the affected components, or produce documentation that these portions of the system had not leaked during use under pressure conditions equivalent to those required by the TSR-mandated tests.

The PISA was declared when two fire doors associated with fire barriers credited with a one hour fire rating were found to lack hardware required to ensure proper latching upon closure. Without latching hardware, the doors did not meet applicable National Fire Protection Association (NFPA) code requirements and represented noncompliant discontinuities in fire barriers credited to prevent fire propagation from one tritium storage or processing area to another. The discrepant condition was found during an in-service inspection (ISI) of the fire barriers by a fire protection engineer. The same ISI had been performed in the past but failed to identify the fire door deficiency, apparently because the inspection for this Design Feature assumed an adequate initial condition and only called for identification of degradation, wear, or unauthorized modifications. In response to the PISA, WETF management has instituted a fire watch for the affected areas when the facility is occupied and the application of door stops to maintain closure of the fire doors when the facility is unoccupied.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 19, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 19, 2010

Plutonium Facility: This week, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA) related to ^{238}Pu -enriched heat source plutonium (HS-Pu) items. This PISA involved the discovery of issues with several different classes of sealed HS-Pu items in the facility.

In mid-October, the Plutonium Facility cognizant system engineer for container systems identified a family of sealed HS-Pu items used as calibration standards that presented a potential over-pressurization concern. Although subsequent analysis demonstrated that pressures inside these standards would not exceed acceptable limits, an extent of condition review identified roughly 100 other sealed HS-Pu items that required evaluation for over-pressurization hazards. By this week, walkdown evaluations had discovered several sealed items that presented potential over-pressurization hazards, including one item that appeared to be slightly bulged. These discoveries prompted the PISA and immediate actions to place affected items in a safe configuration either by overpacking them in credited containers with a filtered vent or by introducing them into gloveboxes. LANL personnel are also taking action to evaluate the safety of several sealed HS-Pu calibration sources located at Area G and CMR.

In parallel with the walkdown evaluations of the roughly 100 suspect items, the cognizant system engineer was performing additional analysis on a type of encapsulated heat source that is credited as safety class in the Plutonium Facility DSA. This safety class encapsulated heat source is required to maintain confinement when subjected to the thermal insults associated with an evaluation basis facility fire. The new analysis indicates that units passed a certain age would not meet this performance criterion due to internal pressure increases associated with helium buildup from years of alpha decay. In response to this new information that is also covered under the PISA, facility personnel are locating units older than the threshold and ensuring they are appropriately overpacked (site rep weekly 10/15/10).

Readiness: Last week, the site office concurred with a revision to LANL procedure P115.0, *Verification of Readiness to Start Up or Restart LANL Nuclear Facilities, Activities, and Operations*. This revision incorporates the changes included in DOE Order 425.1D, which was added to the contract earlier this year. The site office provided six specific comments that will be incorporated into the procedure during the next update (within the next year). The NNSA site office plans to revise its startup procedure in the near future to align with the revised LANL procedure. Implementation of DOE Order 425.1D at LANL is required to be complete (including the revised site office procedure) by January 15, 2011. This week, representatives from NNSA Headquarters and the DOE Office of Health, Safety and Security were onsite to discuss LANL readiness and startup activities. Because of issues identified in this area (notably, the 2009 CDNS biennial review), compensatory measures were identified by NNSA Headquarters that require NA-17 to review and comment on readiness and startup decisions until a successful independent review is completed, either during the next CDNS biennial review or an independent follow-up review.

Chemistry and Metallurgy Research Building (CMR): The review team is finalizing the report documenting completion of the Implementation Verification Review for the new set of TSR controls that support post-2010 operation of CMR. The review identified eight pre-implementation findings and one post-implementation finding. Facility personnel have closed all but one pre-implementation finding.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 26, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 26, 2010

The laboratory was closed on Thursday and Friday in observance of the Thanksgiving holiday.

Plutonium Facility – Safety Basis: This week, facility management declared a TSR violation based on an NNSA Facility Representative discovery that a TSR-level surveillance to ensure compliance with material-at-risk limits had been performed without inspecting all required material locations.

Currently implemented Plutonium Facility TSRs require the quantity of ^{238}Pu -enriched heat source plutonium (HS-Pu) stored in each of the 60 locations in the vault water bath to be checked for compliance with approved limits on a quarterly basis. The limit on HS-Pu in vault water bath locations was derived to ensure the thermal loading from the total quantity of high-activity HS-Pu does not overwhelm the heat removal capability of the vault water bath leading to a rise in water temperature and eventual boiling. The NNSA Facility Representative discovered that the procedure used to execute the TSR-level surveillance only checked compliance in 51 of the required 60 locations in the vault water bath. The quarterly TSR surveillance had been performed five times using the inadequate procedure. This prompted Plutonium Facility management to declare a TSR violation.

In response to this discovery, facility personnel immediately checked the quantity of HS-Pu in the nine vault water bath locations that had been omitted by the surveillance procedure and each location was found to be in compliance with the TSR limit. The cause of the procedure inadequacy could not be immediately determined and continues to be investigated. Facility management identified corrective actions to strengthen expectations for verification and validation prior to procedure approval. Based on this and other discoveries of inadequate implementation of TSR-level surveillances and inspections, facility management is developing a plan to identify and address any similar issues. These implementation issues are also being evaluated to identify lessons learned that can be applied to the institutional Implementation Verification Review process that is intended to find and fix these issues.

Readiness: Recently, the site office provided conservative direction to LANL on the level of readiness review for startup activities identified in the FY 11 First Quarter Startup Notification Report (SNR). Because of the potential for substantial modifications, 15 planned startup activities at Area G, WETF and TA-55 were identified by the site office as potentially requiring federal Readiness Assessments in accordance with DOE Order 425.1D. The site office memo requests LANL to pursue project planning based on this direction. However, if LANL identifies additional information to indicate the startup activities do not involve substantial modifications, the laboratory should make appropriate recommendations in a future SNR revision.

For two startup activities, the site office memo directs that Operational Readiness Reviews be completed because of the hazards, complexity, and need to assess against all core requirements identified in DOE Order 425.1D. The first activity is startup of the Confinement Vessel Disposition Project in Wing 9 of the Chemistry and Metallurgy Building, which is scheduled for 2012. The second activity is the MOVER Project in Area G, which will conduct transuranic waste sort and segregate activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 3, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 3, 2010

This week, Board members Peter Winokur, Jessie Roberson, Joseph Bader, and John Mansfield were onsite along with staff members Timothy Dwyer, Matthew Moury, John Pasko and William Shields to meet with NNSA site office and LANL personnel.

Chemistry and Metallurgy Research Building (CMR): This week, the NNSA site office concurred with LANL's proposed safety basis strategy for CMR. NNSA's concurrence formalizes a new approach to managing and controlling material-at-risk (MAR) at CMR that ensures the DOE Evaluation Guideline will not be exceeded in bounding postulated accident scenarios. Under this new approach, CMR will administratively control MAR at a level approximately 35% less than the approved facility-wide limit. The Technical Safety Requirement (TSR) MAR limit will be changed to formally reflect the new approach in the next annual safety basis update.

CMR facility personnel are also nearing completion of their efforts to implement the DSA and TSRs that support post-2010 operations. Facility management is expected to declare implementation in mid-December and formally transition from the 1998 Basis for Interim Operations (BIO) and associated interim TSRs to the new modern DSA and TSRs.

Plutonium Facility: Historically, LANL tended to store low plutonium-content process residues in the vault rather than performing additional aqueous processing to recover and consolidate the special nuclear material. As a result of these legacy practices, roughly half of all items currently stored in the Plutonium Facility vault are residues. Additionally, greater than 1000 items or about 20% of the total vault holdings are items packaged in potentially vulnerable containers with taped slip-top lids rather than in robust safety-significant containers that include a HEPA-filtered vent. The presence of these slip-top containers requires respirator use whenever operators access the vault. In FY10, LANL made meaningful progress in addressing these legacy materials.

Last fiscal year, Plutonium Facility personnel robustly packaged or dispositioned almost 700 kg of plutonium-equivalent material. Of this 700 kg, about 25% was addressed using aqueous processing to recover plutonium (the significant ramp-up of aqueous processing was enabled by the restart of transuranic liquid waste processing capability in the Radioactive Liquid Waste Treatment Facility); approximately 40 % was shipped offsite or dispositioned as waste; almost 15% was repacked in robust containers; and another roughly 20% was packaged in welded 3013 containers.

Chemistry and Metallurgy Research Replacement (CMRR) Project: In September 2009, construction activities for the Radiological Laboratory/Utility/Office Building (RLUOB) were substantially completed. Since that time, LANL has been working to outfit laboratory and office space with necessary equipment. RLUOB is a radiological facility (limited to MAR less than 8.4g Pu-239 equivalent) that will provide approximately 19,500 ft² of laboratory space. RLUOB will also serve as a consolidated training facility, a centralized utilities and services building for the entire CMRR project (including the nuclear facility) and will accommodate 350 personnel. Turnover of office space is scheduled for October 2011 and radiological operations are planned for mid-2013.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 10, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B. P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 10, 2010

Safety Basis: Engineered controls credited in nuclear facility safety bases are implemented via Technical Safety Requirements (TSRs) as either Limiting Conditions for Operation or Design Features. In general, Limiting Conditions for Operation are used to implement active engineered controls and Design Features are used to implement passive engineered controls, regardless of functional classification. DOE Directives provide detailed requirements for Limiting Conditions for Operation, but provide few specific requirements for Design Features. In one example of this disparate treatment, DOE Directives provide guidance on what constitutes a TSR violation for Limiting Conditions for Operation but not for Design Features. This lack of specificity in requirements for Design Features appears to have contributed to variability in the treatment of Design Features across LANL's nuclear facilities.

The NNSA site office has taken action to drive a standard site-wide approach to Design Features as nuclear facility safety bases are updated. In the interim, the site office has issued supplementary direction describing when issues related to Design Features must be reported as TSR violations.

Transuranic Waste Operations – Area G: Last week, Area G personnel performed an in-service inspection for a TSR-level Design Feature on the last day of the required inspection period. Personnel completed the field portion of the inspection, which was found to be satisfactory, but could not formally complete the in-service inspection because a cognizant system engineer was not available to provide a required signature. As a result, the in-service inspection was not completed within the required time limit. The approved Area G TSRs provide criteria for declaring TSR violations associated with Limiting Conditions for Operation and Administrative Controls, but no criteria or requirements for declaring TSR violations for Design Features. However, based on the site office supplemental direction discussed above, facility management reported this failure to perform an in-service inspection within the required time limit as a TSR violation.

Transuranic Waste Operations – WCRR Repackaging Facility: This week, WCRR repackaging facility personnel were in the process of removing a 55 gallon drum from an 85 gallon overpack, when an operator noticed what appeared to be bulging of the vented 55 gallon drum. Operators immediately restored the lid to the 85 gallon overpack and all personnel evacuated the facility. Facility management called in a hazardous materials team from the LANL Emergency Response organization. The responders deployed a robot to enter the facility, remove the lid of the 85 gallon drum, and unscrew the vent on the 55 gallon drum to relieve any built-up pressure. Microphones mounted on the robot did not detect any acoustic evidence of overpressure relief and no CAM alarms activated after the vent was removed. Personnel ultimately made a controlled re-entry to the facility to survey for contamination and found none on the external surface of the affected drum or the surrounding area.

Today, the facility returned to normal operations and processed the affected 55 gallon drum. Inside, operators found a legacy 30 gallon drum that had been mostly reduced to powdery corrosion residue. This suggests that a highly reactive environment once existed inside the 55 gallon drum that may have caused the bulging noticed by WCRR operators.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 17, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 17, 2010

Staff members Caleca, Gibson, Hadjian, Kimball, Pasko and Shuffler were onsite this week to discuss the Chemistry and Metallurgy Research Replacement (CMRR) Project, walkdown the Plutonium Facility and to observe the peer review team meeting for the Plutonium Facility seismic evaluation.

Chemistry and Metallurgy Research Building (CMR): On Monday, CMR management declared implementation and began operating under the modern Documented Safety Analysis and Technical Safety Requirements that were approved by the NNSA site office in June. This action retires the 1998 Basis for Interim Operations, CMR's previous safety basis, which was set to expire on December 31, 2010. The new safety basis, in conjunction with a standing order that implements CMR's new policy for more tightly controlling material-at-risk (MAR), authorizes post-2010 operations using a quantity of MAR that ensures the DOE Evaluation Guideline will not be exceeded in bounding postulated accident scenarios.

Transuranic Waste Operations: This week, LANL resumed the readiness assessment for the startup of two heated transportainers at Area G. The heated transportainers are needed to ensure that any free liquids inside transuranic waste containers are in an unfrozen state prior to undergoing the radiographic characterization required by the Waste Isolation Pilot Plant waste acceptance criteria. In October, LANL started but then paused the review due to inadequate implementation of Technical Safety Requirements associated with tracking and limiting material-at-risk allowed inside the transportainers and within 50 feet. At the time, the review team also identified concerns related to the potential for hydrogen concentrations above the lower flammability limit to accumulate inside the heated transportainers.

These issues have now been resolved and the readiness assessment resumed on Thursday. Because of the work previously reviewed, the team expects to complete their review early next week.

Plutonium Facility: On Monday, the site office issued a letter to NNSA-Headquarters summarizing the completed near-term actions to reduce the probability and consequence of seismic accident scenarios. These actions included the following:

- Design of an automatic seismic shutdown of laboratory electrical equipment to reduce electrical ignition sources
- Removal or lock-out of glovebox ignition sources that are no longer needed
- Procurement and installation of six safes with adequate fire ratings to protect special nuclear material during a fire
- Testing of two container designs under fire conditions (testing completed supports a damage ratio of 1% for these containers)
- Establishment of project scoping for seismically upgrading the fire suppression system and key portions of the active confinement ventilation system
- Repair of deficiencies in the main Plutonium Facility fire barrier
- Robustly package or disposition special nuclear material (almost 700 kg Pu-239 equivalent was repackaged or dispositioned in FY 2010)

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 24, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 24, 2010

Transuranic Waste Operations: Thirty-one legacy confinement vessels that contain residual quantities of radiological material are staged on an outdoor asphalt pad at Area G. Late last week during a walkdown of the area, an NNSA Facility Representative noticed a number of vessel showed signs of possible degradation. Radiological surveys performed this week found external contamination on six of the thirty-one vessels (maximum of 17,000 dpm alpha) and on the ground beneath one of the vessels (900 dpm alpha). No routine contamination monitoring had been performed on these vessels, but they were subject to a quarterly TSR-level in-service inspection to identify leaks, corrosion, or damage. The latest quarterly inspection was completed and noted as satisfactory on the same day the Facility Representative raised concerns about vessel integrity.

In response to this discovery, facility personnel decontaminated the six affected vessels and applied tape to seal flanged ports that offer a potential leak pathway on all thirty-one vessels. Facility management also intends to add the vessels to a routine contamination survey program, review the adequacy of the applicable in-service inspection, and to move the vessels from the outdoor pad into a nearby waste storage dome.

Longer-term, LANL personnel need to take existing conceptual ideas on how to ultimately dispose of these items and mature them into well defined and executable dispositions plans. None of the Area G vessels are part of the baseline scope of the Confinement Vessel Disposition (aka Bolas Grande) Project that will be executed in CMR.

Plutonium Facility: This week, LANL management submitted for NNSA review and approval a Safety Basis Strategy (SBS) document that addresses the upcoming May 2011 Plutonium Facility DSA update that will include a major revision to analysis of the seismically-induced fire scenario. Whereas existing analysis assumes a seismic event could result in an intensely hot fire that engulfs an entire floor of the facility, the SBS proposes a new analytical approach intended to justify reducing the number and size of seismically-induced fires assumed in the scenario. This new approach would use published statistical data to determine the conditional probability of a given number of post-seismic fires occurring and updated facility combustible loading information to determine the maximum credible size and temperature characteristics of fires. The SBS then proposes using this refined seismically-induced fire scenario to re-evaluate leak path factors, airborne release fractions, and respirable fractions that are used in the accident analysis to calculate offsite dose consequences.

Federal Oversight: This week, the NNSA site office issued a letter that identified deficiencies with the laboratory's abnormal event investigation process and directed the contractor to develop corrective actions. In the letter, the site office asserts that: • some responsible managers are reluctant to hold formal critiques following an abnormal event; • some facilities have resumed operations prior to holding a critique to ensure all causes have been identified and all appropriate actions have been taken to prevent recurrence; and • some facilities have improperly categorized events. The letter requests that the contractor provide a report by January 15, 2011, that contains corrective actions to improve the laboratory's abnormal event investigation process, metrics for tracking these improvements, and a scheduled date for an effectiveness review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 31, 2010

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B.P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending December 31, 2010

The site representatives were out of the office this week. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 7, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 7, 2011

Plutonium Facility – Safety Basis: LANL continues to pursue implementation of Technical Safety Requirements (TSRs) associated with the Documented Safety Analysis (DSA) that was approved in December 2008. This safety basis represented the first major update to the Plutonium Facility safety basis in a decade. While most TSR controls have been implemented, upgrades and improvements to the fire suppression system and implementation of material-at-risk (MAR) controls have extended the implementation of this safety basis. Fire suppression system upgrades were completed last year, including installation of additional fire water risers and relocation/installation of sprinklers to resolve coverage issues. LANL also continues efforts to implement a new MAR tracking software system that will support TSR MAR controls. The Plutonium Facility is the first facility to implement this software. LANL plans to use this software at other nuclear facilities.

In early-November, LANL submitted a revision to the 2008 DSA to resolve site office comments on the fire suppression system limiting conditions for operation and to accommodate MAR associated with legacy confinement vessels stored on an asphalt pad outside the Plutonium Facility. LANL committed to complete implementation within 90 days of site office approval of this revision. The site office continues to review this document.

In December 2010, LANL submitted an annual update to the Plutonium Facility DSA. The 2010 DSA incorporates routine corrections/additions and inclusion of facility improvements and Unreviewed Safety Questions that have been identified since the DSA that was submitted in 2009. No site office action was taken on the 2009 DSA. In the submittal, LANL notes that a significant revision to the safety basis is planned for May 2011 to reanalyze seismic accident scenarios by “performing more thorough, realistic analyses.”

Plutonium Facility – PISA: This week, Plutonium Facility management declared a PISA related to two types of safety class controls used to contain ²³⁸Pu-enriched Heat Source Plutonium (HS-Pu). Certain completed heat source assemblies and robust containers for storing bulk HS-Pu oxide are credited in the Plutonium Facility DSA to survive the most severe accident scenarios postulated for the facility. Because these safety class assemblies and containers are credited to survive bounding accident conditions without releasing their contents, the HS-Pu they contain does not count toward facility MAR limits.

Facility personnel recently discovered that analyzed temperatures for glovebox fires exceed the temperatures that the safety class assemblies and containers are credited to survive. This discovery resulted in the PISA declaration. In response, facility management instituted a compensatory measure to begin counting the HS-Pu material inside the safety class assemblies and containers against glovebox MAR limits and to ensure all affected gloveboxes contained less than their allowed limits. Longer term, facility personnel intend to reevaluate the safety basis approach for analyzing and crediting these safety class controls.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 14, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 14, 2011

Plutonium Facility: This week, the NNSA site office conducted a workshop with LANL personnel to discuss the status of Seismic Analysis of Facilities and Evaluation of Risk (SAFER) project activities related to the Plutonium Facility; details of the conceptual design for upgrading the fire suppression system to seismic performance category-3 (PC-3); and the path forward and status of Recommendation 2009-2 deliverables. LANL personnel noted that the facility seismic evaluation was behind schedule and would not be complete, including peer review, until April (previous schedule was January). To accommodate this delay, Plutonium Facility personnel plan to request an extension to the SAFER Justification for Continued Operations associated with increased seismic hazard identified in the 2007 updated probabilistic seismic hazard analysis. LANL personnel asserted that the new schedule remains adequate to support the Documented Safety Analysis update scheduled for May (identified as a Recommendation 2009-2 deliverable) that will describe the proposed laboratory strategy for addressing challenging seismic accident scenarios.

The conceptual design for the fire suppression system upgrade to PC-3 has been submitted to the site office. NNSA plans to provide comments on the design this week. LANL noted that other Recommendation 2009-2 deliverables are on schedule including the conceptual design for PC-3 upgrades to appropriate portions of the confinement ventilation system.

Transuranic Waste Operations: Technical Safety Requirements (TSRs) for the WCRR repackaging facility include Limiting Conditions for Operation (LCO) associated with combustible loading. One of these combustible loading LCOs states that no combustible liquids shall be stored or used within the WCRR repackaging facility when inventory is present except combustible liquids found inside waste drums undergoing repackaging activities. There is a daily surveillance requirement associated with this LCO to verify that no combustible liquids are stored or used in the facility when inventory is present. Last week, facility personnel recognized that drum lift devices collocated with the waste characterization glovebox contain hydraulic fluid that is combustible. In response, facility management declared a potential inadequacy of the safety analysis. NNSA site office personnel have questioned whether this issue should have been categorized as a TSR violation rather than a PISA since the facility has operated for several years without complying with a combustible loading LCO and having performed TSR-level surveillances throughout this time affirming that no combustible liquids were used or stored in the facility when in fact combustible liquids were present.

This week, LANL submitted and NNSA approved a TSR change that only prohibits combustible liquids with a flammability rating exceeding a certain threshold, which hydraulic fluids do not exceed.

Radioactive Liquid Waste Treatment Facility (RLWTF): LANL recently submitted a Basis for Interim Operations (BIO) and new TSRs to the site office for approval. This Documented Safety Analysis was developed in accordance with 10 CFR 830. These documents update the previous safety basis submitted in September 2009 that had numerous comments from the site office. RLWTF is currently operating under a safety basis that was approved in 1995. The BIO supports hazard category 3 liquid waste operations with a material-at-risk limit of 55 Am-241 equivalent Ci, one safety significant design feature (transuranic waste tanks) and 10 safety management programs.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 21, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 21, 2011

Plutonium Facility - PISA: Several months ago, the Plutonium Facility received a shipment of Pu-238 in two containers from Lawrence Livermore National Laboratory. The material was packaged in nested inner and outer welded containers that met the specifications of DOE-STD-3013, but the Pu-238 inside was not stabilized in the manner required by the standard. The Plutonium Facility safety basis does not explicitly analyze the hazards associated with Pu-238 stored in this type of welded container configuration. As a result, Plutonium Facility management declared a potential inadequacy of the safety analysis (PISA).

In response, Plutonium Facility personnel are evaluating the two containers to determine whether they are appropriate for multi-year storage of Pu-238 until the material is needed to support programmatic activities. Also, personnel are assessing ways to strengthen the process used to review incoming shipments to ensure that received material meets Plutonium Facility requirements.

Weapons Engineering Tritium Facility (WETF): This week, the site office approved the inputs, methods and assumptions that will be used for the Documented Safety Analysis (DSA) update planned for WETF. Notably, LANL plans to reduce the material-at-risk limit for WETF to less than 250 g versus the current limit of 400 g. In September 2010, LANL submitted a resource loaded schedule for the DSA update that identifies a May 2012 target date for completion of this update.

Plutonium Facility – Safety Basis: This week, LANL submitted a revision to the Technical Safety Requirements (TSR) associated with the 2008 DSA to resolve site office comments on the limiting conditions for operation for the fire suppression system. This revision of the TSR requires that both the electric and diesel fire pumps be operable. LANL has committed to implement the TSRs associated with the 2008 DSA within 90 days of site office approval.

Next week, Plutonium Facility personnel plan to take an outage to install seismic shutdown switches that will isolate power to non-safety-related laboratory floor circuits on indications of a seismic event. Post modification testing will either occur as a part of this outage or during a subsequent outage. LANL plans to have this system operational by the end of February. Safety basis credit for this system will be included in the May 2011 safety basis update.

Plutonium Facility – Seismic Safety: The site office forwarded the conceptual design for the fire suppression system upgrades required to meet performance category-3 (PC-3) seismic requirements to NNSA Headquarters this week. This design is identified as a deliverable for Recommendation 2009-2 and, when implemented, will help improve facility safety for the challenging post-seismic fire accident scenario. The LANL analysis concludes that the following system upgrades are required to meet PC-3 requirements: for the main floor, a lateral support is required two-thirds down each branch line and an end support is needed; for the basement, axial supports are required for standpipes and lateral supports are needed for some piping sections and; for the pump houses, additional supports are required for supply lines.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 28, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 28, 2011

Electrical Safety: This week, Plutonium Facility management declared a near miss based on work performed in close proximity to 13,200 volt energized electrical lines without appropriate work control documentation or applicable hazardous energy controls. As a part of the Nuclear Materials Safeguards and Security Upgrades Project (NMSSUP), work was planned to install conduit, pull lines and tie into this 13,200 line. Two Integrated Work Documents (IWDs) were developed for these activities. The first IWD hazard analysis did not include work on or near energized electrical lines. In December, workers performed core drilling as part of the conduit installation within a few inches of the energized line using the first IWD. This activity was conducted successfully with no injury to workers or damage to the electrical line. A pre-job brief was conducted; however, workers noted that the IWD requirements were not discussed during this brief. In preparation for conducting the additional work under the second IWD, LANL personnel recognized that the drilling had occurred and notified Plutonium Facility management.

As a result of this near miss, LANL suspended NMSSUP construction activities while the requirements for conduct of pre-job briefs and actions needed if hazards and work controls are not appropriately included in IWDs were clearly communicated to project personnel and subcontractors. LANL is releasing specific construction activities following a review of work scope and work control documents. LANL also continues to investigate this event to develop lessons learned and to determine whether additional corrective actions are needed.

Transuranic Waste Operations: Transuranic waste drums in general waste storage arrays at Area G are restricted to less than 200 fissile gram equivalents by criticality safety limits. Drums that exceed this limit are segregated and stored in special arrays whose geometry is controlled to ensure criticality safety. Generator facility data is used to determine a drum's fissile gram equivalents until a valid assay is obtained by Central Characterization Project (CCP) personnel at Area G. Based on a 2007 technical study, the fissile gram equivalents value used for criticality safety purposes is the CCP assay result plus two times the uncertainty from counting statistics. This differs from the assay result plus the total measurement uncertainty used to determine whether a drum's fissile gram equivalents comply with the Waste Isolation Pilot Plant (WIPP) waste acceptance criteria. When a drum's fissile gram equivalents using the total measurement uncertainty exceed 200 g but its value using two times counting uncertainty does not, a Non-Conformance Report tag is applied to the drum and it is returned to a general waste array rather than a specially controlled array. As a result of these practices, there are currently about 200 drums in general waste storage arrays with NCR tags that identify them as drums with high fissile gram equivalents. Last week, the NNSA site office issued a letter to the contractor questioning the treatment of these drums.

This week, Area G personnel discovered that the configuration of a segregated array of high fissile gram equivalent drums violated the geometry restrictions specified by criticality safety limits. In response, facility management restricted access to the area and entered the criticality safety infraction process. Operations personnel and criticality safety engineers are coordinating to develop a recovery plan to address the infraction.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 11, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 11, 2011

Federal Oversight: All of the issues discussed in this report were initially identified and pursued by NNSA site office facility representatives and subject matter experts.

Transuranic Waste Operations – Criticality Safety: In response to concerns raised by NNSA site office personnel, a laboratory team recently reviewed the adequacy and implementation of criticality safety controls at Area G. This week, the team comprised of lab criticality safety engineers and institutional criticality safety committee members provided a briefing to site office and LANL management on the results of their review. The team concluded that Area G compliance with the institutional criticality safety program is immature. As a result of this immaturity, the team identified three criticality safety infractions during their review. Two infractions were declared because sludge and debris waste remediation operations at Area G had not been formally reviewed by criticality safety personnel, as required. Another infraction was declared because procedures governing the staging of drums for characterization activities did not ensure the segregation and special control of drums exceeding 200 fissile gram equivalents as required by established criticality safety limits (site rep weekly 1/28/11).

Weapons Engineering Tritium Facility (WETF): An ongoing NNSA site office review of facility status control evaluated a sampling of work packages used by facility personnel over the past year to make modifications to the safety significant Tritium Waste Treatment System (TWTS). Each of the packages reviewed were found to have various deficiencies, which taken together indicate significant weaknesses in conduct of operations and configuration management. Among other things, the review found that key documents, such as the System Alignment Checklist were not updated as required after new valves were installed; the required Return-to-Service checklist process was not used prior to restoring TWTS status to operable after modifications; and required material qualification certifications of credited components were not performed prior to installation.

Transuranic Waste Operations – Safety Basis: Yesterday, based on an issue identified by an NNSA Facility Representative, WCRR repackaging facility management reported a TSR violation based on a surveillance requirement that had not been successfully performed within its required frequency. The WCRR fire suppression system is credited as a safety significant control. WCRR TSRs include a surveillance requirement to perform a monthly valve alignment inspection to ensure an open flow path exists between water tanks and the facility fire suppression system. In performing this surveillance, facility personnel rely on affirmation from the institutional utilities group that three credited valves in the water distribution system are in the open position. The utilities group performs visual valve inspections on a nominally monthly basis, but execution of this work can and sometimes does slip beyond the frequency required by the WCRR TSRs.

When informed that the valve inspection by the utilities group had not been performed within the required interval, WCRR management had the valves inspected and all were found in the required open position. In response to this discovery, facility management intends to revise the WCRR surveillance procedure to require facility personnel to perform the credited valve inspection.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 18, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 18, 2011

Dunlevy was onsite this week for site familiarization activities.

Plutonium Facility – Seismic Safety: As part of the Plutonium Facility seismic safety improvements, LANL recently installed seismic shutdown switches that will isolate power to non-safety-related laboratory floor circuits upon indication of a seismic event. When operational, this system will help reduce the likelihood of post-seismic fire initiation. Last weekend, Plutonium Facility personnel successfully performed post installation testing of the switches. LANL plans to maintain the system in bypass mode for several weeks to review performance prior to declaring the system operational. Installation of the seismic switches is identified as an Implementation Plan deliverable for Recommendation 2009-2 (due April 2011). Safety basis credit for this system is expected to be considered for inclusion in the May 2011 Documented Safety Analysis update.

LANL also recently submitted the conceptual design for upgrading a portion of the Plutonium Facility confinement ventilation system to safety class including seismic upgrades to meet Performance Category (PC)-3 requirements. The design is based on input from the ventilation and support system backfit analyses, ventilation modeling and the Seismic Analysis of Facilities and Evaluation of Risk (SAFER) evaluation of system components. The design includes upgrades for the zone-2 bleed-off exhaust system, glovebox exhaust fans, the electrical distribution system, the uninterruptible power supply and a new control system. Based on the preliminary cost estimate for these upgrades (which cannot be finalized until SAFER analysis for the building structure is completed), LANL notes that a capital asset line item project subject to DOE Order 413.3 would be required to implement a safety class ventilation system that meets PC-3 seismic requirements.

Transuranic Waste Operations – Safety Basis: Recently, NNSA site office engineers questioned whether existing hydraulic calculations for the safety significant RANT fire suppression system accounted for the correct number of sprinklers in the most hydraulically remote area of the facility. After resolving discrepancies between system drawings and the actual as-found system configuration, laboratory personnel performed a new hydraulic calculation. The new calculation included one additional sprinkler in the most hydraulically remote area and concluded that the required water flow rate needed to ensure RANT fire suppression system operability is greater than the flow rate required by the TSR. Based on this new information, facility management declared a Potential Inadequacy of the Safety Analysis (PISA) this week.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Tuesday, a tubular ultra filter (TUF) connection assembly failed releasing approximately 20 gallons of low activity liquid waste from the low level waste processing system. Facility personnel responded appropriately upon discovery of the leak. TUF connection assembly failures have been a recurring problem at RLWTF. In response to previous failures, facility personnel implemented a remote shutoff capability that allowed operators to safely secure the system and limit the release during this event. Based on the known failure modes of the TUF, facility management has been pursuing replacement of this system with a series of more reliable pressure filters targeted for installation by the end of this fiscal year.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 25, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 25, 2011

Staff members Bamdad, Caleca, Gibson, Kimball, Moury, Pasko and Shuffler held a teleconference with LANL personnel this week to discuss the conceptual design for fire suppression system seismic upgrades at the Plutonium Facility.

Material Disposal Area (MDA)-B: This week, MDA-B management curtailed operations in an excavation enclosure when multiple glass jars were unearthed and found to contain beryllium fines. This operation will remain suspended until appropriate controls and training are implemented.

Overall, MDA-B continues to perform work under the approved 10CFR830 exemption that authorizes operations involving material at risk (MAR) up to 56 ²³⁹Pu-equivalent (PE)-Ci. To-date, the pace of excavation activities have outstripped the pace of material shipments, resulting in the accumulation of about 26 PE-Ci staged above ground in metal storage bins with secured lids. The bins are located in roughly 20 segregated waste container storage areas that are authorized and controlled in accordance with the NNSA-approved Facility Safety Plan. Laboratory personnel are attempting to ramp-up material shipments to accelerate deinventory of accumulated above ground MAR. In the meantime, LANL has committed to formally notify the NNSA site office if the total MAR inventory exceeds 28 PE-Ci and further committed to suspending active MDA-B excavation if MAR reaches 45 PE-Ci (site rep weeklies 10/22/10, 10/15/10, 9/10/10).

Readiness: This week, the NNSA site office formally requested that LANL review recent adverse indicators in the readiness review program and identify corrective actions to improve the execution of the readiness review and startup process. The request noted several examples of recent issues for startup activities at Area G and the difficulties in resuming operations at the Weapons Engineering Tritium Facility to support an important programmatic deliverable.

Chemistry and Metallurgy Research (CMR) Building: To improve safety and operational reliability at CMR, LANL plans to replace the four exhaust ventilation fans in Wings 5 and 7. Currently, one of the fans in Wing 5 has been replaced with system testing on-going. This fan is expected to be operable in March. Initial activities to support replacement of the first fan in Wing 7 have also started. LANL had also planned to replace the Wing 5 and 7 HEPA filters this year; however, quality assurance issues with the vendor may delay completion of this activity until 2012.

Transuranic Waste Operations – Criticality Safety: This week, LANL forwarded to the NNSA site office the final report for the assessment of the criticality safety management program at Area G (preliminary results noted in the 2/11/11 site rep report). Overall, LANL concludes that the activities at Area G comply with the safety margins required by ANSI/ANS 8.1. In addition, program improvements and maturity consistent with the nuclear criticality program safety improvement plan continue to be pursued at Area G. The assessment team also recommended that LANL management reconsider a 2007 decision to use new fissile gram equivalent values generated by Central Characterization Project personnel, once available and validated, to replace fissile gram equivalent data provided by waste generators. This recommendation is being evaluated.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 4, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 4, 2011

Pasko was onsite this week to attend a workshop on the conceptual design for potential seismic upgrades to portions of the Plutonium Facility ventilation system.

Transuranic Waste Operations - Readiness: This week, the contractor readiness assessment (CRA) team completed their review of drum venting operations at Area G and concluded that line management has not successfully demonstrated readiness to commence operations, meaning the CRA will need to be re-performed in the future. The team identified nine pre-start findings, one post-start finding and seven observations. Pre-start findings included inadequate technical bases to demonstrate compliance with functional requirements for two credited design features, an incorrectly written procedure, failure to follow procedures, inadequate operator training and failure to demonstrate adequate emergency response capability. LANL management intends to develop lessons learned based the results of this review. In addition, these issues will be factored into the response to the NNSA site office request on improving the startup process, which included several examples of startup problems at Area G (site rep weekly 2/25/11).

WCRR Repackaging Facility – Conduct of Operations: There have been a series of events over the past several weeks at the WCRR repackaging facility where personnel failed to initiate or properly execute procedures.

Two weeks ago, an operator was using a drum dolly to transfer transuranic waste drums out of the WCRR facility and onto a truck to prepare for onsite shipment. During the transfer evolution, the operator lost control of a waste drum which tipped over and fell on the ground. WCRR personnel did not initiate execution of an abnormal operating procedure as required in the event of a dropped or tipped drum. Last week, a glovebox glove was breached during WCRR operations. Upon detection of the breach, WCRR personnel did not use an abnormal operating procedure, as required.

This week, WCRR operations center personnel completed and filed the wrong checklist to effect a TSR mode change to allow waste processing operations. At the beginning of a shift, one operations center operator completed the appropriate checklist to transition from Warm Standby mode to Operations mode and pre-filled the checklist to change from Operations mode to Warm Standby mode that would be needed at the end of the day's operations. The operator inadvertently handed the wrong checklist to another operator who signed and filed it and the facility began waste processing operations. Later the same day, the error was discovered by an individual performing Senior Supervisory Watch when he was reviewing operations center documentation.

In response to the first two events, facility management conducted refresher briefings for operators on abnormal operating procedures and instituted a Senior Supervisory Watch for WCRR operations. After the latest event, management paused work to discuss conduct of operations issues with facility personnel. This negative conduct of operations trending has coincided with a significant increase in operational tempo at WCRR, which has moved to 12 hour a day, 7 day a week operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 11, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 11, 2011

WCRR Repackaging Facility – Safety Basis: Last week, facility management declared a Potential Inadequacy of the Safety Analysis (PISA) and subsequent positive Unreviewed Safety Question at the WCRR repackaging facility based on inconsistencies between the actual glovebox exhaust ducting configuration and assumptions made in the safety basis. The WCRR safety basis analysis on glovebox fire challenges to HEPA filter performance is based on a Plutonium Facility glovebox fire analysis and includes an assumption that the WCRR exhaust ventilation configuration is consistent with the Plutonium Facility glovebox ventilation configuration. Field observations identified that the WCRR glovebox exhaust consists of dual 2.25” exhaust pipes rather than a single 2” exhaust pipe assumed in the safety basis. The WCRR repackaging facility was placed in cold standby when the inconsistency was identified. LANL has completed an evaluation of the safety of the situation that includes new fire analysis with the correct exhaust configuration and concluded that the maximum temperature at the HEPA filters during a glovebox fire would be acceptable. LANL has requested site office approval to resume normal operations and plans to prepare safety basis changes to address this issue.

This week, WCRR facility management declared a TSR violation related to the uninterruptible power supply (UPS) system that is credited to ensure continued operation of the ventilation system in the event of loss of offsite power. The WCRR TSRs specify an annual surveillance requirement to test the ability of the UPS system to supply one hour of power to all required loads. The TSR violation resulted from the discovery that the UPS load test procedure did not call for the system to be tested in alarm mode. Since the alarm is a required load, the test did not comply with the TSR surveillance requirement.

Federal Oversight: Both the PISA and TSR violation discussed above were discovered by an NNSA site office safety system oversight (SSO) engineer. The site office engineer was shadowing a contractor team that was performing a vital safety system assessment of the WCRR ventilation system. The NNSA engineer brought the issues to the attention of facility management after the contractor VSSA ended with facility engineers failing to identify these problems. Site office personnel in general and this NNSA SSO engineer in particular have identified a significant number of recent PISAs and TSR violations at LANL nuclear facilities.

Electrical Safety: This week, LANL personnel provided an outbrief on the results of their investigation of a utility vault core drilling activity that occurred in December 2010. The core drilling activity was performed within inches of energized 13.2 kV electrical lines and this hazard was not identified and addressed in the Integrated Work Document (IWD). The team concluded that the event represented a significant safety concern with opportunities for work control improvements and lessons learned. Notably, and consistent with previous work control reviews at LANL, the team concluded that the implementation of Integrated Work Management needs improvement including use of IWDs during pre-job briefs and work execution, better scope definition in IWDs and enhanced assurance that only appropriately trained and qualified personnel are used for work execution. The results of this investigation have been provided as input to a broader review chartered by the LANL Deputy Director to develop a comprehensive understanding of obstacles and issues negatively impacting LANL’s Integrated Work Management implementation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 18, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 18, 2011

Plutonium Facility – Seismic Safety: This week, Plutonium Facility personnel placed the recently installed seismic shutdown switches on-line after monitoring system performance for several weeks. This system will isolate power to non-safety-related laboratory floor circuits on indication of a seismic event. An alarm response instruction and abnormal operating procedure have been developed for facility personnel to respond to initiation of this system. These switches will help reduce the likelihood of post-seismic fire initiation and is identified as a deliverable for Recommendation 2009-2.

Plutonium Facility – Safety Basis: Plutonium Facility management has submitted for NNSA site office review and approval a Justification for Continued Operations (JCO) related to sealed packages that contain ²³⁸Pu-enriched heat source plutonium (HS-Pu). Facility management has declared three recent PISAs related to the handling and storage of the large and diverse population of sealed HS-Pu containers housed in the Plutonium Facility. Because the existing DSA does not comprehensively analyze hazards associated with all sealed HS-Pu container configurations in the facility, which led to the PISAs, the JCO submittal attempts to address all activities involving all types of sealed HS-Pu containers in a holistic manner. NNSA office site review of the JCO is ongoing.

Readiness: On Monday, LANL responded to a recent site office request to review recent adverse indicators in the readiness review program and identify corrective actions to improve the execution of the readiness review and startup process. The review identified the following three causal factors: 1) LANL has failed to adequately implement requirements for timely planning and execution of readiness verification activities; 2) LANL has not used available planning tools to develop adequate assessment criteria for line management verification of readiness; and 3) LANL has not effectively executed appropriately objective and critical self-assessments prior to commencing readiness review activities.

Based on these issues, the response to the site office proposes several improvement initiatives including implementation of an institutional procedure on the conduct of line management readiness verification activities, use of a startup notification report affidavit that ensures programmatic input/concurrence and identification of a senior supervisory watch for Area G readiness activities (several recent readiness and startup issues have occurred at Area G).

Chemistry and Metallurgy Research (CMR) Building: As required by a condition of approval identified in the site office Safety Evaluation Report, LANL submitted an update last week on the status of the evaluation of designating the CMR electrical distribution system as safety significant. LANL plans to perform a system adequacy analysis on the system and establish the minimum requirements needed for the system to perform its safety function along with identifying appropriate surveillance and inspection requirements. The final evaluation of the system is scheduled to be complete in July 2011. The safety basis will be updated to reflect the safety significant designation during the next annual update following the July final evaluation.

Management: This week, LANL management announced an organizational change that elevates the manager responsible for large capital projects, including the CMR Replacement Facility, from the Associate Director level to the more senior Principal Associate Director level.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 25, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 25, 2011

WCRR Repackaging Facility: As reported on March 4th and March 11th, there have been a number of recent conduct of operations, engineering and safety basis issues at the WCRR repackaging facility. These issues prompted WCRR facility management to pause transuranic waste processing operations on February 28th. WCRR resumed operations on March 18th, after facility personnel executed a resumption plan that included some compensatory measures intended to mitigate identified deficiencies. This week, WCRR operations encountered a series of additional problems discussed below. Transuranic waste inventory has been removed from the facility and the WCRR building is currently in cold standby mode.

On March 20th, four transuranic waste drums were transferred into the WCRR facility without proper verification that they complied with TSR-level facility material-at-risk (MAR) limits. An operations center operator used data for the wrong set of drums to perform the required MAR calculation then failed to have the calculation independently verified, as required by the surveillance procedure. WCRR personnel later identified the issue and took appropriate action. Although the facility MAR limit was never exceeded, WCRR management reported a TSR violation for a surveillance requirement that was not successfully performed within the required frequency. (The operator who performed the surveillance was later transferred from the facility to the hospital for a medical issue, which may have contributed to the event.)

On March 21st, WCRR engineering personnel discovered that the facility procedure used to perform a surveillance on the credited fire suppression system did not adequately implement the TSR surveillance requirement to verify that an unobstructed flow path exists between the fire water supply tank and facility sprinkler heads. The implementing procedure failed to require inspection of one facility valve that could obstruct the fire water flow path if it were in the closed position. Although the affected valve was found in the open position, facility management declared a TSR violation based on the procedural inadequacy.

Also on March 21st, WCRR engineering personnel discovered that a key safety basis assumption stating that no transuranic waste would be stored or processed in the decommissioned size reduction glovebox enclosure (GBE) had failed to be carried forward as a TSR-level Specific Administrative Control, as required. This discovery led to the declaration of a Potential Inadequacy of the Safety Analysis.

This week, facility personnel also observed containers of potentially flammable liquid inside the GBE that had never been identified by daily TSR surveillances required to verify that no flammable liquids are present in the facility. WCRR personnel plan to make a controlled entry into the GBE to recover the suspect containers to determine whether they contain flammable liquids or are empty. Categorization and reporting for this discovery are on hold pending results from the GBE entry and container evaluation.

Although significant new issues continue to surface at WCRR, the recent series of problems were identified by laboratory rather than NNSA personnel. This appears to be due, in part, to increased LANL attention on previously identified problem areas and the implementation of compensatory measures such as the assignment of a Senior Supervisory Watch and enhanced engineering reviews of credited systems. However, based on the number and nature of recent problems, this week the NNSA Site Office Manager sent a letter to LANL management expressing concerns about WCRR. A LANL senior manager has now been assigned to evaluate WCRR corrective actions and determine when operations can be safely resumed.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 1, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 1, 2011

Plutonium Facility – Criticality Safety: This week, Plutonium Facility management declared a TSR violation based on the discovery that the material form of some plutonium items stored in two vault rooms does not comply with criticality safety requirements specified in a Justification for Continued Operations (JCO). Vault rooms B and I have been operating under a JCO since 2007 when laboratory personnel found that criticality safety limits for locations in these rooms were not adequate to prevent criticality under all normal and credible abnormal conditions. Criticality safety controls in the current JCO revision only provide approved material limits for plutonium metal and oxide items. On Monday, Plutonium Facility vault operators recognized that 22 plutonium residues and 9 plutonium compounds are currently stored in vault rooms B and I, in violation of JCO controls that only allow metal and oxide forms.

Plutonium Facility – Seismic Safety: The site office recently responded to the LANL analysis of options to achieve a seismically-qualified safety-class active confinement ventilation system and requested refinement of the baseline scope considering additional upgrade options. Upgrade and seismic qualification of the bleed-off subsystem and minimum power and controls is identified as the baseline scope. As the preferred alternative is refined, LANL plans to consider the following additional scope beyond the baseline: equipment and ducting downstream of the glovebox exhaust filter plenums; portions of the recirculation system; full ventilation control system upgrade; new diesel generator building (south of facility) versus reuse of the north-side generator building; and flywheel generators. The site office notes that a workshop would be an appropriate forum for evaluation of these different options.

Material Disposal Area-B (MDA-B): This week, the site office directed LANL to provide a path forward for aggressively reducing radioactive inventory at MDA-B. Early this month, LANL notified the site office that above ground inventory at MDA-B exceeded 28 PE-Ci. In accordance with previous correspondence, LANL is required to notify the site office when inventory is greater than 28 PE-Ci. The site office direction requests the current waste shipment schedule and the programmatic and operational drivers that require above ground inventories above 28 PE-Ci. The site office also directed LANL to provide additional notifications if inventory levels exceed 35 PE-Ci and again at 40 PE-Ci.

Safety Basis: Based on recent application of the new information process, the site office has directed that LANL review the site procedure as used in these recent applications and submit recommended improvements to the site office for concurrence. The site office notes that the LANL new information procedure appears to circumvent requirements for contractor actions upon discovery of a Potential Inadequacy of the Safety Analysis (PISA). For several recent issues identified at the WCRR repackaging facility, LANL followed the new information process and concluded these issues would not result in PISAs and exited the process. The site office concluded that for these issues, LANL use of the new information process went beyond determining if the information was credible and had a nuclear safety nexus, which possibly resulted in incomplete execution of the unreviewed safety question process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 8, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 8, 2011

Broderick was out of the office this week.

Plutonium Facility – Seismic Safety: On Tuesday, the staff held a teleconference with site office and LANL personnel to discuss the on-going seismic analysis of the Plutonium Facility structure, systems and components. This evaluation will support a path forward for the outstanding Justification for Continued Operation (JCO) associated with the updated probabilistic seismic hazards analysis and upgrade decisions in response to Recommendation 2009-2, *LANL Plutonium Facility Seismic Safety*. The seismic evaluation is scheduled to be complete in mid-May followed by review and comment from the peer review team resulting in a final product at the end of May. At that time, LANL also plans to submit an update to the Documented Safety Analysis (DSA) that includes a major revision to the bounding seismic accident scenarios.

Transuranic Waste Operations: On Thursday at the WCRR Repackaging Facility, operators identified a bulging 55 gallon inner drum after de-nesting the drum from an 85 gallon overpack drum. WCRR personnel responded appropriately and followed the abnormal operating procedure that required contacting the emergency response organization. After initial evaluation, the HAZMAT response team was also requested and responded to the facility. Portable HEPA filtered ventilation was moved in proximity to the drum and a robotic system was deployed to remove the vent from the 55 gallon drum to relieve any residual pressure in the drum. The vent was replaced and the drum was subsequently repackaged in the WCRR waste characterization glovebox. Limited contamination was identified on the portable ventilation system but no other facility contamination was identified.

Plutonium Facility – Safety Basis: Last week, LANL began the Implementation Verification Review for the fifth phase of the Technical Safety Requirements (TSRs) associated with the DSA approved in 2008. The primary focus of this review is on implementation of controls associated with the safety class fire suppression system. These controls are scheduled to be declared implemented by April 21st.

LANL has also requested site office approval to delay overall implementation of the 2008 TSRs from April 21st to June 3rd due to delays in development and deployment of the MAR Tracker software program that will be used to complete TSR MAR surveillances. LANL notes that implementation involves 4,000 material locations, multiple software database and program interactions and several Plutonium Facility organizations. Currently, a number of issues have been identified as a part of the software Validation and Verification process that require resolution prior to declaring TSR implementation.

Material Disposal Area-B (MDA-B): Based on a review of the MDA-B Facility Safety Plan in February, the site office requested that LANL revisit the institutional procedures and processes on facility chemical hazard categorization. The LANL response notes that the public and collocated worker protection criteria from DOE Standard 1189 will be used for future chemical hazard classification purposes. The revised methodology will be issued in a safety basis bulletin within 10 days of site office concurrence.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 15, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 15, 2011

Plutonium Facility – Seismic Safety: This week, LANL declared a Potential Inadequacy of the Safety Analysis (PISA) based on preliminary seismic evaluation results that indicate an increased likelihood of structural failure in some locations during postulated seismic events. In 2007, the Probabilistic Seismic Hazard Analysis for Los Alamos was updated and indicated increased seismic hazard for LANL facilities. A Justification for Continued Operations (JCO) for nuclear facilities was approved by the site office while the Seismic Analysis of Facilities and Evaluation of Risk (SAFER) project was initiated to evaluate the impact of the increased hazard. The SAFER evaluation of all LANL nuclear facilities except the Plutonium Facility was completed last year. The Plutonium Facility analysis has been ongoing and is now expected to be complete in May including independent peer review and resolution of comments.

Currently, SAFER preliminary results have identified nine Plutonium Facility issues where the anticipated seismic demand may exceed the structural capacity during the design basis seismic event. The potential failures may invalidate safety basis assumptions related to the facility's leak path factor in the 2008 Documented Safety Analysis (DSA), which is scheduled to be fully implemented within two months, and may impact assumptions in the yet to be approved 2010 DSA. As a part of the PISA declaration, LANL has identified a compensatory measure to develop and implement an emergency operating procedure to isolate the facility's exhaust stacks during certain seismic accident conditions to eliminate a potential unfiltered material release path that could result from two of the newly identified failure modes. The PISA is expected to result in an unreviewed safety question and safety basis personnel are developing an evaluation of the safety of the situation. Plutonium Facility management noted that facility upgrades to resolve these issues are being evaluated.

Weapons Engineering Tritium Facility (WETF): This week, the NNSA site office issued a letter to LANL senior management addressing WETF. In its letter, the site office notes numerous issues that have stemmed from WETF's existing nine year old safety basis, identified deficiencies in key safety management programs, and the existence of a significant population of legacy tritium containment vessels that need to be dispositioned to address safety concerns. The site office asserts that despite WETF safely restarting and conducting limited operations to meet national security requirements last year, the laboratory infrastructure and support for WETF has not been commensurate with what is required to sustain safe nuclear operations over the long term. Given this, NNSA requests for LANL to provide the following within 30 days: • an accounting of anticipated mission and readiness activities; • a perspective on hazards for current operations and continued storage of legacy items until they can be dispositioned; and • a risk-prioritized path-forward to address known gaps in safety management programs and the means that LANL will use to ensure any new gaps are identified and addressed in a timely manner.

As part of WETF's planned risk reduction activities, WETF personnel are also poised to begin a campaign to overpack a large number of legacy tritium containment vessels that may present over-pressurization hazards and lack the pedigree currently required for containing tritium. These legacy items will either be overpacked in credited tritium containment vessels or introduced into gloveboxes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 22, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 22, 2011

Transuranic Waste Operations – Safety Basis: This week, the discovery of new information related to the Area G Drum Venting System (DVS) prompted LANL management to declare a Potential Inadequacy of the Safety Analysis (PISA). Startup of the DVS is intended to reestablish the capability to safely vent the thousands of unvented drums currently stored above and below ground at Area G in preparation for final disposition. Earlier this year, LANL management declared implementation of the safety basis revision that covered DVS operations in advance of a Contractor Readiness Assessment (CRA), which ultimately failed to demonstrate adequate readiness to begin venting operations.

The implemented safety basis analyzes a drum deflagration event and the resulting overpressure challenges to DVS components. The analysis assumes the deflagration occurs in a drum with a 12% headspace gas concentration of hydrogen and also assumes the failure of internal DVS valves designed to contain blast pressure, allowing the deflagration overpressure to be vented into a greater volume. In the course of pursuing a question raised during the recent CRA, LANL personnel recognized that the assumptions related to hydrogen concentration and the failure of the blast valves may not be conservative. Higher hydrogen concentrations and actuation of the blast valves, both of which are credible, would lead to a more energetic deflagration confined to a smaller volume. This situation produces calculated pressure conditions inside the DVS chamber that are greater than those analyzed in the current safety basis, which prompted the PISA. LANL personnel are developing a path forward to address the PISA and evaluating the impact of these issues on the DVS startup schedule.

Integrated Work Management (IWM): Based on several events that occurred between late-2010 and early-2011 involving issues with work planning/execution and conduct of operations, the laboratory deputy director chartered a senior team to develop a comprehensive understanding of obstacles and issues negatively impacting LANL's IWM program. This team recently completed their review and identified the following four Judgments of Need (JON) along with recommendations for corrective actions to address these JONs: 1) LANL needs to accelerate full implementation of conduct of operations within craft and vendor work planning and execution; 2) LANL needs to strengthen the subcontractor technical representative program; 3) LANL needs to develop and implement an effective tool to evaluate operational performance that provides indicators for issues that require broad-based corrective actions; and 4) LANL needs to develop a mechanism to evaluate major organizational changes that may impact institutional IWM implementation. The team recommended nineteen specific corrective actions to laboratory senior management to address the identified JONs.

Seismic Safety: This week, the site office forwarded the Board's April 8th letter on issues with the computer software SASSI (A System for the Analysis of Soil-Structure Interaction) to LANL and requested a summary of the site's use of this code, information on code versions used, the basis for software quality assurance and any other information relevant to responding to the Board's letter. The site office directed LANL to respond to this request within three weeks.

Plutonium Facility – Seismic Safety: The site office memorandum discussed above also requests LANL to provide plans for identification and anchorage of critical equipment within Plutonium Facility gloveboxes

(e.g., furnaces that could contribute to post-seismic fire initiation). These plans will be included in the overall project execution plan for upgrades in response to Board Recommendation 2009-2.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 29, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 29, 2011

Plutonium Facility – Seismic Safety: Last week, LANL submitted an Evaluation of the Safety of the Situation (ESS) to the site office for the Potential Inadequacy of the Safety Analysis (which resulted in an Unreviewed Safety Question) based on preliminary seismic evaluation results that indicate an increased likelihood of structural failure in some locations during postulated seismic events. The ESS concludes that the potential consequences represent an acceptable risk and included one compensatory measure – a standing order to isolate the facility’s exhaust stacks during certain seismic accident conditions to eliminate a potential unfiltered material release path. This week, Plutonium Facility personnel issued the Emergency Operating Procedure that will replace the standing order and strengthen implementation of the compensatory measure. Facility personnel have also removed materials located in gloveboxes beneath mezzanines that were identified as seismically vulnerable. The site office has approved the ESS and the Plutonium Facility continues normal operations. Structural upgrade design efforts for some of the seismic issues have been initiated.

Emergency Preparedness: This week, laboratory management convened a meeting with all LANL Facility Operations Directors to discuss the state of emergency management and response planning and preparedness for challenging scenarios like an extended loss of offsite power and a large seismic event that could severely restrict all offsite utility services, communications and site access. The meeting was useful in indentifying specific areas where additional advance planning, drill activities, or investment in enhanced capabilities and equipment could improve the site’s safety posture and response in emergency conditions. Moving forward, each Facility Operations Director has been tasked to develop an Action Plan detailing areas they plan to pursue to strengthen emergency preparedness for their facilities.

Zero Liquid Discharge (ZLD) Project: Last week, an Energy Systems Acquisition Advisory Board reviewed the critical decision-3 package for the ZLD project and the acquisition authority (site office manager) approved start of construction activities. This project will provide capability to receive discharge from the Radioactive Liquid Waste Treatment Facility (RLWTF) and preclude the need for an evaporator unit operation or purified liquid discharge.

Plutonium Facility – Safety Basis: This week, LANL completed an Implementation Verification Review (IVR) for an additional phase of the Technical Safety Requirements (TSRs) associated with the safety basis approved in 2008. The IVR covered the following areas: Mode Change; criticality alarm system limiting conditions of operation (LCO); fire suppression system LCO; violations of TSRs; maintenance safety management program (SMP); procedures SMP and; the fire water supply and ion exchange resin (weapons grade) design features. Based on observation of activities and review of documentation, the team concluded that TSR controls reviewed were adequately implemented at the Plutonium Facility with the exception of 6 pre-implementation findings related to training, equipment availability to perform one surveillance and procedure issues. The primary remaining TSR control that has not been implemented relates to material-at-risk (MAR) limits. LANL continues to pursue adequate implementation of the MAR tracker software including software validation and verification. The site office recently approved an extension request that allows until

June 3rd for completion of this final phase.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 13, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 13, 2011

Davis was offsite this week.

The staff held a teleconference with NNSA and LANL personnel to discuss the site's response to the recent discovery of an increased likelihood of structural failures in certain portions of the Plutonium Facility during postulated seismic events.

Weapons Engineering Tritium Facility (WETF): In July 2010, WETF successfully completed an NNSA Operational Readiness Review allowing the facility to restart programmatic tritium gas handling activities after an extended operational suspension during which personnel worked to address significant pressure safety and safety basis issues. Soon after completing work to support an important national security deliverable in September 2010, WETF personnel discovered that small amounts of oxygen were leaking into a portion of the Tritium Gas Handling System called the Hot Inlet System where the air could potentially mix with tritium to form a flammable or explosive atmosphere. In October 2010, facility management declared a Potential Inadequacy of the Safety Analysis based on this issue and suspended tritium gas handling operations. In November 2010, the NNSA site office approved a Justification for Continued Operations (JCO) that would allow WETF to resume tritium gas handling operations upon implementation of a series of compensatory measures designed to address the potential deflagration hazard associated with oxygen ingress. The JCO compensatory measures have not been implemented and programmatic tritium gas handling operations remain suspended.

Since November, facility management has focused attention on the creation of a new set of hazard analyses that include comprehensive evaluation of deflagration hazards related to oxygen leakage into the Hot Inlet and Tritium Gas Handling Systems. In late April, LANL management submitted a revised JCO that incorporates the results of the new hazard analysis. The revised JCO, which was approved by the NNSA site office this week, credits additional engineered and administrative controls including a new material at risk limit of 100 g (and 52 g tritium processing limit) for the Tritium Gas Handling and Hot Inlet Systems.

The new hazard analyses will eventually serve as the foundation for a major revision to the facility's DSA and TSRs scheduled to be submitted in 2012. In the interim, LANL submitted and NNSA approved an annual update intended to be an incremental improvement to the facility's existing safety basis.

This week, LANL management also responded to formal NNSA direction to provide planning information for mission, readiness, risk reduction, and safety management program improvement activities. Safety-related priorities discussed in the response include •continued overpacking of non-pedigreed legacy tritium containment vessels into robust containers; •disposition of Early Storage Unit tritium vessels that are known to exceed their Maximum Allowable Working Pressure; and • installation of mercury traps required to remove trace amounts of mercury contamination from bulk tritium gas before this material can be shipped offsite.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 20, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 20, 2011

The site reps were offsite this week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 27, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 27, 2011

Management: This week, LANS announced that Charlie McMillan will replace Mike Anastasio as the Director of Los Alamos National Laboratory. McMillan had previously served as the Principal Associate Director for Weapons Programs and the Associate Director for Weapons Physics.

Plutonium Facility – Seismic Safety: LANL personnel have been aggressive in defining and pursuing necessary structural upgrades for the Plutonium Facility since discovering in late April that structural failures resulting from a seismic event are more likely than previously understood. This week, field construction activities began to install new support beams to address a high probability of failure vulnerability associated with glovebox ventilation filter plenum rooms. These upgrades are targeted for physical completion in early July. Next week, construction work is scheduled to begin to address vulnerabilities related to concrete shield walls located in the Pu-238 processing area.

Transuranic Waste Operations: This week, Area G management identified that construction work performed in support of high energy real time radiography (RTR) was conducted without electrical safety controls required by the Integrated Work Document (IWD). Because an electrical disconnect was open and locked out/tagged out, no personnel were exposed to hazardous energy during the construction activities. High energy RTR will provide LANL with the capability to adequately radiograph standard waste boxes that contain transuranic wastes in order to meet WIPP waste acceptance criteria.

The IWD that supports electrical and other construction activities identified the potential for the electrical hazard and required that a readily identifiable air-gap be in place to eliminate the hazard during this stage of construction activities. Recently, a separate LANL group was tasked with testing portions of the electrical system upstream from the tie-in to high energy RTR. In order to complete this testing, an upstream disconnect was opened and locked out/tagged out and the air gap was eliminated. However, this new configuration was not communicated to other construction personnel that were performing work under the IWD that required the air gap. Until this issue was identified earlier this week, high energy RTR construction activities were completed without the required air-gap. In addition, these construction workers did not have their own locks on the lock out/tag out that was providing hazardous energy protection as required by LANL procedures. High energy RTR construction activities are currently on hold because of this issue. Additional investigation of this event is planned to identify lessons learned and corrective actions.

Plutonium Facility – Safety Basis: LANL is currently in the process of conducting the final Implementation Verification Review (IVR) that covers Technical Safety Requirement (TSR) material-at-risk (MAR) controls. Notably, the team has questions with the configuration management and software quality assurance for the MAR tracker software that is used to perform the TSR surveillance in support of the MAR controls. The IVR team plans to outbrief the results of their review to facility and NNSA management next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 3, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 3, 2011

Plutonium Facility – Safety Basis: Today, Plutonium Facility management declared the set of Technical Safety Requirements associated with the 2008 DSA to be fully implemented. This declaration concludes a two and a half year effort to implement the new modern control set and to perform a series of independent assessments to verify the adequacy of implementation.

Plutonium Facility – Seismic Safety: This week, LANL personnel issued final seismic analyses performed as part of the SAFER project that describe the performance of the Plutonium Facility structure and key safety systems under the increased seismic loading associated with the site's updated Probabilistic Seismic Hazards Analysis (PSHA). Results from these analyses are critically important to understanding the Plutonium Facility's seismic vulnerabilities and in defining the scope of upgrades necessary to address these vulnerabilities.

LANL management declared a Potential Inadequacy of the Safety Analysis (PISA) in late-April based on preliminary SAFER results for the facility structure that indicated the failure of some structural components is more likely than previously understood. A Justification for Continued Operations (JCO) covering these issues with the facility structure is scheduled to be submitted on June 6th. Newly completed analysis focused on the seismic performance of facility safety systems indicates that some credited systems may also fail more frequently in seismic events than previously thought. These results are being evaluated using LANL's New Information process to determine whether an additional PISA or PISAs are necessary.

Weapons Engineering Tritium Facility (WETF): On Friday, WETF management declared a PISA based on the lack of updated seismic analyses for the two exhaust stacks associated with the facility. In 2007, LANL completed the 10 year update of the PSHA that identified higher ground motions for laboratory facilities. A positive unreviewed safety question was declared for multiple facilities including WETF and a JCO was approved by NNSA. The SAFER project was initiated to review facility performance against the updated PSHA. In 2010, LANL completed the SAFER analysis and exited the JCO for all facilities except the Plutonium Facility. During recent development of the Hazard Analysis to support an updated DSA for WETF, questions about stack seismic performance were raised. Upon investigation, WETF management discovered that the stacks were not evaluated via SAFER even though seismically-induced collapse could damage the safety-credited building. WETF is currently not processing tritium pending implementation of controls identified in the JCO associated with the hot inlet system (site rep weekly 5/13/11). An evaluation of the safety of the situation for the stack issue will be completed prior to resuming tritium processing activities.

Radioactive Liquid Waste Treatment Facility Upgrade Project: Last week, LANL provided their recommendation to the NNSA site office on the path forward for the Radioactive Liquid Waste Treatment Facility Upgrade Project. The recommended path forward includes separating the transuranic and low level waste processes into individual structures with use of the previous design details to the extent possible. LANL also recommends that the project scope include low level daily influent storage by upgrading and using the WMRM tanks. The site office is reviewing the proposed path forward for the upgrade project.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 10, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 10, 2011

Pasko was onsite this week to attend an Integrated Nuclear Planning workshop devoted to the Plutonium Facility. The focus of the workshop, which included LANL, NNSA site office and NNSA-Headquarters personnel, included the results of the SAFER seismic evaluation, the 2011 Documented Safety Analysis (DSA) update and the plans and priorities for safety upgrades.

Plutonium Facility – Seismic Safety: This week, LANL management submitted for NNSA approval a Justification for Continued Operations (JCO) related to the recent discovery that certain structural components are more likely to fail during a seismic event than previously believed. Seismic analysis that supports the JCO concludes that the failure of one identified vulnerability could lead to a cascade of other failures resulting in significant structural damage that could impact material at risk (MAR) in all areas of the facility. Based on this low probability failure mechanism, the JCO conservatively postulates a more severe seismic accident scenario than any previously analyzed for the Plutonium Facility. This low probability, worst case scenario has very large dose consequences that are constrained only by significantly reduced facility MAR limits that are imposed by the JCO as compensatory measures. The JCO also credits a number of other compensatory measures that provide varying degrees of additional protection against seismic accident scenarios. NNSA site office and Headquarters personnel are currently reviewing the JCO.

In parallel with JCO development, LANL management has been aggressively pursuing design and construction efforts to implement structural upgrades to permanently address the newly identified vulnerabilities. LANL engineers, in conjunction with LANS corporate partner resources from Bechtel, have developed a design concept for an upgrade to correct the structural deficiency that leads to cascading failures and the severe accident scenario analyzed by the JCO. LANL personnel currently estimate that this critical upgrade can be completed by the end of November 2011.

Plutonium Facility – Safety Basis: Last week, LANL submitted the 2011 DSA annual update that includes the latest safety basis analysis of seismic accident scenarios for the Plutonium Facility. This refined seismic analysis assumes that the structural upgrades have addressed the recently identified vulnerabilities and restored facility's ability to provide a measure of material confinement after a seismic event. Once approved and implemented, the JCO discussed above will provide safety basis coverage until upgrades return the facility to the previously credited level of confinement performance. The 2011 DSA update is identified as an Implementation Plan deliverable for Recommendation 2009-2, *LANL Plutonium Facility Seismic Safety*. The site office is evaluating this submittal, although NNSA priority is currently on review of the JCO.

Transuranic Waste Facility (TRUWF) Project: LANL has completed approximately 90% of the preliminary design effort for the TRUWF Project and is scheduled to submit the Preliminary Safety Design Report to the NNSA site office later this month. This project will provide an enduring capability for transuranic waste storage, staging and characterization after Area G closure and shutdown of the WCRR Repackaging Facility. Currently, a technical independent project review is scheduled for September followed by Critical Decision-2, *Approval of Performance Baseline*.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 17, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 17, 2011

Federal Oversight: This week, the NNSA Site Office Manager announced the selection of a new Assistant Manager for Field Operations whose responsibilities include management of Facility Representatives, Safety System Oversight engineers, and the readiness program. The selectee is a former Facility Representative of the Year who had been serving at the Plutonium Facility.

Weapons Engineering Tritium Facility (WETF): WETF management declared a TSR violation this week based on the discovery of two rupture disks installed in the safety significant Tritium Gas Handling System (TGHS) that did not comply with the WETF Pressure Safety Program. The two rupture disks rated to actuate at 16 psid were located adjacent to a portion of the TGHS equipped with pressure protection devices rated to actuate at 38 psid. In this configuration, accumulation of gas in the adjacent section that exceeded 16 psid could actuate the rupture disks and back-flow gas into a now unprotected part of the system making it vulnerable to over-pressurization and failure.

The two affected rupture disks were installed prior to WETF fully implementing the requirements of LANL's conduct of engineering program. Using the less formal prior process, relevant Piping and Instrumentation Diagrams (P&IDs) were not updated to reflect the presence and rating of the newly installed rupture disks. When WETF engineers verified Pressure Safety Program compliance as part of their phased restart process, these rupture disks were not identified as a problem because they were not shown on P&IDs. Also, since this section of the TGHS was part of the lowest priority restart phase, associated components were not subjected to the enhanced verification measures applied to higher priority sections needed to support earlier startup phases.

In response to this discovery, WETF management has declared the TGHS inoperable pending modifications to bring the system into Pressure Safety Program compliance and has initiated an extent of condition review to identify any similar issues within credited pressure systems.

Plutonium Facility: LANL management has submitted for NNSA site office concurrence a recommendation to perform confirmatory analysis that compares the results of deterministic soil-structure interaction (SSI) analysis with the results of the probabilistic soil-structure interaction analysis that served as the basis for LANL's SAFER evaluation of the Plutonium Facility.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week, RLWTF personnel used an upgraded rotary vacuum filter to transfer low-level waste sludge to a drum for disposition for the first time since 2007. Restoration of this drum-out capability will allow operators to begin removing large quantities of sludge from the low-level waste system that have accumulated over the years and prevented some key pieces of equipment from being operated as intended. RLWTF personnel are also making significant progress on replacing the failure-prone tubular ultrafilter system with more robust pressure filters. These upgrades will help improve the reliability and availability of the low-level waste processing system but do not reduce the need or urgency to construct a replacement facility. LANL and LASO continue deliberations on the path forward for the RLWTF-Upgrade project that is intended to provide this replacement capability.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 24, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 24, 2011

Plutonium Facility – Seismic Safety: Last week, LANL management submitted for NNSA site office approval an Evaluation of the Safety of the Situation (ESS) that addresses a positive Unreviewed Safety Question stemming from SAFER project results that show an increased probability of failure for safety significant systems and components in a seismic event. The previously submitted Justification for Continued Operations (JCO) that is currently under review by NNSA covers increased probabilities of failure for the safety class building structure and safety class systems and components. The ESS concludes that the increased likelihood of failures for safety significant systems and components does not increase the offsite consequences of bounding seismic accidents above those analyzed for building failures in the previously submitted JCO. The ESS does not propose any new compensatory measures; however, the ESS does commit to modify or upgrade affected systems and components to meet relevant seismic performance requirements, although the priority for resources will continue to be upgrades that focus on building structural integrity and confinement.

This week, Plutonium Facility Management declared a TSR violation based on a failure to comply with an operational restriction associated with the facility's cement silo appurtenance. SAFER project analysis concluded that if the silo is filled with cement above a certain level, it could fail in a seismic event and adversely impact the confinement integrity of the safety class building structure. In conjunction with JCO completion and submittal, Plutonium Facility management committed to implement an operational restriction to control the amount of cement in the silo to less than one-fourth capacity. To protect this operational restriction, operations personnel physically locked out a bucket hoist mechanism that they believed was the only means to add cement to the silo.

Roughly two weeks after the silo capacity operational restriction was declared, a delivery of cement ordered by programmatic personnel was received at the facility and added to the silo through a pneumatic fill tube that operations personnel were not aware of and was not locked out. The programmatic engineer who ordered the cement was cognizant of the silo capacity operational restriction and had calculated the size of the order to comply with the one-fourth capacity limitation. However, the programmatic engineer used the nominal density value for dry cement in his calculation and the process of transferring the material into the silo through the fill tube aerated the cement, lowering its density. As a result, the silo was found to be filled to nearly half capacity by the delivery. Facility personnel are planning an evolution to remove excess cement to restore compliance with the operational restriction.

Transuranic Waste Facility (TRUWF) Project: This week, LANL submitted a revision to the Safety Design Strategy to address changes in the TRUWF's design and safety strategy as the project approaches completion of preliminary design (Critical Decision-2 is planned for September). The revised strategy supports relocation of the facility from TA-52 to TA-63 to reduce the calculated frequency of design basis aircraft crashes. For the seismic accident scenarios, LANL continues to plan for Seismic Design Category-2 storage structures with a seismic switch to isolate power during a seismic event to prevent subsequent fires. The strategy also proposes vehicle barriers to protect the facility from external vehicle impacts. The Safety Design Strategy will be reviewed by the site office.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 1, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 1, 2011

The laboratory was closed this week due to the Las Conchas wildland fire. LANL declared an operational emergency on Monday, June 27th, and the Emergency Operations Center was activated and declared operational. Only one small (less than one acre) spot fire occurred on LANL property and was extinguished within one hour. All nuclear operations were suspended this week and nuclear facilities were placed in a safe-stable configuration with the exception of the Radioactive Liquid Waste Treatment Facility (RLWTF), which did perform low level waste processing operations this week to maximize lag storage space should an extended outage at RLWTF be required.

As of Friday, the Las Conchas fire has burned over 100,000 acres and is only 3% contained; however, the threat to LANL property and nuclear facilities has been significantly reduced by extensive firefighting efforts, preventative burns and fire breaks. During the week, LANL also performed extensive fire mitigation activities throughout the laboratory to reduce fuel sources (especially around Area G). Based on the reduction in threat to laboratory from the fire on Friday afternoon, LANL terminated the operational emergency and transitioned to recovery operations mode.

On Friday, the LANL emergency director approved the recovery plan that includes facility walkdowns (including the nuclear facilities) over the weekend by the Facility Operations Directors (FODs) to determine facility status and habitability. Restart of the laboratory will be phased over two days with management and programmatic walkdowns and restoration of site services on the first day. Provided there are no significant facility issues identified by the FOD or programmatic walkdowns, LANL will reopen to all personnel on the second day. Beginning the phased restart of the laboratory is dependent on repopulation of the Los Alamos town site.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 8, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 8, 2011

The laboratory re-opened on Wednesday after being shut down for more than a week due to the Las Conchas wildland fire. Last weekend, the Facility Operations Directors (FODs) conducted walkdowns to assess the status and habitability of LANL facilities. No significant issues were identified during these walkdowns. On Tuesday, a larger group of management and programmatic personnel conducted more detailed walkdowns of programmatic equipment and activities in advance of re-opening the laboratory. Other LANL personnel were onsite to restore key site services and support functions.

For the LANL nuclear facilities, restart of programmatic activities began on Wednesday following an all-hands briefing that emphasized safe, methodical resumption of work. As of Friday, there were no significant issues with nuclear facility restart activities.

Weapons Engineering Tritium Facility (WETF): This week, WETF personnel held a critique to discuss a situation involving the safety class Lightning Protection System (LPS) that was discovered before the Las Conchas fire. In March, craft personnel were performing maintenance work on the WETF roof. The Integrated Work Document (IWD) governing this activity allowed workers to remove certain kinds of roof hardware as part of this work. The IWD did not discuss removing roof-mounted air terminals associated with the safety class LPS and the negative Unreviewed Safety Question documentation for the IWD stated that the LPS would not be impacted.

During the course of the roof work, craft personnel realized that some air terminals would need to be removed in order to accomplish the task. The workers removed two air terminals, considering this to be work incidental to their maintenance task. On March 31st, this roof maintenance activity was paused to address an unrelated industrial hygiene question. When work was paused, the air terminals remained in the uninstalled configuration.

On June 18th, a WETF Duty Officer was on the roof to inspect ventilation equipment and noticed the uninstalled air terminals. Upon discovery of this condition, the LPS was declared inoperable. Subsequent evaluation by the Cognizant System Engineer and an LPS subject matter expert determined the system met National Fire Protection Association Standard 780 requirements, as credited in the TSR. Based on this evaluation, the LPS was declared operable, but impaired.

After the WETF Duty Officer noticed the air terminal modification, craft workers reinstalled the two affected air terminals. No new work control documentation was prepared to support this reinstallation evolution. WETF personnel are currently evaluating whether appropriate and pedigreed adhesive materials were used to perform this modification to the safety class LPS.

WETF management personnel are developing corrective actions to address the work control and work authorization issues evidenced by these events.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 15, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 15, 2011

Transuranic Waste Operations: Recently, LANL submitted updated Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs) documents for the WCRR Repackaging Facility to the NNSA site office for approval. Notably, the update increases the material-at-risk limit for the WCRR building from 300 combustible equivalent curies to 800 combustible equivalent curies to allow processing higher activity transuranic waste containers. Design basis accident scenarios have been updated, as appropriate, based on the higher material-at-risk limit.

As a part of the WCRR safety improvements that occurred late last year, a fire suppression system was installed in the waste characterization glovebox. The safety basis now credits this system as safety significant. Other significant changes in this submittal include clarification that the electrical distribution system is not a safety significant support system and removal of the transportainers and lightning protection system as safety design features. The specific administrative controls relative to transportainers usage and code requirements for inspection and maintenance of the lightning protection system remain. The site office is currently reviewing this submittal.

Plutonium Facility – Seismic Safety: Plutonium Facility personnel have completed physical installation work on steel support beams in glovebox exhaust ventilation plenum rooms in the facility basement. The newly installed beams address a structural vulnerability that could have caused roof members to fail and crush portions of the HEPA-filtered exhaust plena during a seismic event. Breaching the exhaust plena could have resulted in the creation of an unfiltered release path from the facility. The structural issue that the newly installed support beams are designed to address had one of the highest probabilities of failure of any vulnerability identified by the SAFER project.

Plutonium Facility personnel also plan to install seismic shut-off valves on natural gas lines that service support buildings around the periphery of the Plutonium Facility. Natural gas is not used in or plumbed into the Plutonium Facility itself. Among other buildings, the new seismic shutoff valves will be installed in the two redundant fire water pump houses that perform an important function as part of the safety class fire suppression system. The fire suppression system is currently credited for operational (i.e. non-seismically-induced) fires, but Plutonium Facility management intends to pursue upgrades to credit the system for seismically-induced fire scenarios as well. Adding seismic shutoff valves to natural gas lines in the pump houses will support this approach by reducing the likelihood of common cause earthquake failures rendering the safety class fire suppression system inoperable.

Additionally, this week LANL personnel removed a quantity of dry cement from the Plutonium Facility cement silo appurtenance. This evolution restores compliance with the TSR-level compensatory measure limiting the allowed amount of cement to one-fourth silo capacity. When at or below one-fourth capacity, the cement silo is not expected to fail in a seismic event and adversely impact the confinement boundary provided by the safety class Plutonium Facility building structure.

Radioactive Liquid Waste Treatment Facility: Facility personnel began work this week to install seismic shutoff valves to natural gas lines that service the Radioactive Liquid Waste Treatment Facility and the facility's treated effluent evaporator.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 22, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 22, 2011

Plutonium Facility: Late last week, the site office manager signed the Safety Evaluation Report (SER) that approves the Justification for Continued Operations (JCO) associated with the increased seismic risk identified by the SAFER analysis of the Plutonium Facility. LANL plans to complete structural upgrades to address these issues by the end of the calendar year. The SER includes six conditions of approval including a requirement to reevaluate seismic performance with the roof drag strut modification complete. An interim report is scheduled for September with a final report in December. This evaluation will determine whether additional upgrades are required.

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a TSR violation based on the discovery that TSR-level glovebox leak checks had been performed using uncalibrated equipment. WETF TSRs require gloveboxes to be leak tested after modifications or maintenance. The WETF implementing procedure for leak testing gloveboxes did not require the leak test to be performed using calibrated pressure transducers. WETF management is evaluating the extent of condition of this problem in response to this discovery.

Transuranic Waste Operations: Area G currently houses approximately 400 fiberglass-reinforced plywood boxes containing legacy transuranic waste that is too large to fit in drums or standard waste boxes. To remediate these boxes, LANL Waste Disposition Project personnel have been working to reconfigure the processing line in Building 412 at Area G that had originally been established to remove prohibited articles from low activity (i.e. less than 2.5 ²³⁹Pu-equivalent curies) transuranic debris waste drums. This week, after successful completion of a Management Self Assessment, LANL management authorized processing and size reduction of waste from boxes with contents whose activity does not exceed the DOE Standard 1027 Hazard Category 3 threshold (0.52 ²³⁹Pu-equivalent curies). On Thursday, Area G personnel processed the first in a campaign of 17 less than Hazard Category 3 boxes inside the Building 412 confinement tent. Upon completion of this campaign, LANL management will initiate a Contractor Readiness Assessment and NNSA Readiness Assessment to authorize box processing at the Hazard Category 3 level.

Work Planning and Control: This week, LANL began an assessment of the site's Integrated Safety Management (ISM) and Integrated Work Management Systems. The assessment is being shadowed and reviewed by site office and NNSA-Headquarters personnel. The criteria review and approach document includes criteria for each of the ISM five steps for performing work.

Chemistry and Metallurgy Research (CMR) Building: Recently, LANL submitted the 2011 update of the CMR Documented Safety Analysis (DSA) and associated Technical Safety Requirements. This update includes reduced material-at-risk limits that were previously captured as a standing order such that the offsite dose consequence for bounding postulated accident scenarios are below the evaluation guideline. In addition, the submittal addresses several conditions of approval and comments previously identified by the site office. The site office is currently reviewing the updated DSA and TSR submittal.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 29, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 29, 2011

Weapons Engineering Tritium Facility (WETF): For roughly nine months, WETF personnel have been working to develop and implement new TSR-level controls to address deflagration hazards resulting from the discovery that low levels of oxygen were leaking into a portion of the safety significant Tritium Gas Handling System. If not properly controlled, this oxygen could mix with hydrogen isotopes to create a potentially flammable atmosphere inside the system. After verifying successful implementation of a Justification for Continued Operations that included a number of additional controls, WETF personnel resumed programmatic gas handling operations this week.

Chemistry and Metallurgy Research Building (CMR): This week, CMR management declared two TSR violations based on the discovery that several recent TSR-level surveillances of the fire suppression system had failed to recognize readings that did not meet limiting conditions for operation and failed to initiate required response actions. At CMR, fire water risers associated with the safety significant fire suppression system are required to maintain pressures above certain values and riser pressure surveillances are performed weekly. This week, a team of safety system oversight engineers from the NNSA site office began an assessment of the CMR fire suppression system.

As part of the assessment, the NNSA team reviewed completed surveillance documentation and discovered that in one recent case pressure readings for two separate risers were less than pressure values required by the TSR, but were not identified as unsatisfactory results that would trigger required response actions such as initiating a fire watch. In response to the NNSA discovery, CMR personnel did a more exhaustive review of completed fire suppression system surveillance documentation and found another instance where recorded riser pressure values did not meet TSR limiting conditions for operation, but were not recognized and handled appropriately. Facility management is developing corrective actions to address the issues that led to these violations.

Federal Oversight: Last week, the NNSA site office formally transmitted to LANL a report documenting the results of an assessment of the laboratory's Cognizant System Engineer (CSE) program. DOE Order 420.1B, *Facility Safety*, establishes the requirements for a CSE program and stipulates that a CSE must be assigned to at least every active safety class and safety significant system in a nuclear facility to ensure these systems maintain their operational readiness and the ability to perform their credited safety functions. The site office assessment concluded that the LANL CSE program is not fully compliant with DOE requirements. One particularly notable assessment finding stated that the majority of qualified LANL CSEs are not knowledgeable of key safety basis parameters for their systems, including functional classifications, functional requirements and performance criteria.

In the course of their assessments, NNSA safety system oversight engineers continue to routinely discover Potential Inadequacies of the Safety Analysis and TSR violations that have not been identified by laboratory personnel (the most recent example related to CMR is discussed above). Strengthening LANL CSEs knowledge and understanding of nuclear safety bases and the critical nexus between the safety basis and their assigned system appears to be a key step to improving LANL's ability to self-identify PISAs and prevent TSR violations moving forward.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 5, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 5, 2011

Verhaagen was onsite this week to observe an ongoing LANL work control assessment.

Material Disposal Area (MDA)-B: LANL personnel are approximately 98% complete excavating the buried contents of MDA-B, which was used from 1944-1948 as a landfill for waste contaminated with radioactive material. Excavation activities performed within HEPA-filtered enclosures were originally authorized as less than hazard category 3 operations (per DOE-STD-1027) that were not subject to the safety basis requirements of Title 10 Code of Federal Regulations, Part 830 (10 CFR 830), *Nuclear Safety Management*, Subpart B. In two separate instances in late 2010, MDA-B operations excavated waste material whose total activity exceeded the hazard category 3 threshold of 0.52 ²³⁹Pu-equivlent curies (PE-Ci). Based on these events, future excavation of hazard category 3 quantities of waste material became anticipated. At the hazard category 3 level, MDA-B operations would be subject to the requirements of 10 CFR 830 Subpart B, including the requirement to perform work under a Documented Safety Analysis.

In response, the Los Alamos Site Office (LASO) requested, and NNSA Headquarters (NA-10) approved, an exemption from the requirements of 10 CFR 830 Subpart B for MDA-B. In approving the exemption, NNSA imposed a number of terms and conditions, including provisions requiring MDA-B operations to be conducted in accordance with a Facility Safety Plan (FSP) and requiring LASO to concur in any changes to the FSP or implementing procedures that affect the safety envelop at MDA-B. To comply with these conditions, MDA-B management implemented an Unreviewed Safety Question (USQ)-like process to determine which changes could affect the safety envelop. MDA-B operations resumed under the 10 CFR 830 exemption in October 2010.

After waste is excavated and loaded into bins inside MDA-B enclosures, the waste bins must be weighed to establish an accurate value of material-at-risk (MAR) for facility inventory purposes. Scales used to weigh waste bins were located approximately 90 feet outside the LANL-designated boundary of MDA-B. On a number of occasions since October 2010, waste bins containing greater than 0.52 PE-Ci, were transferred from MDA-B to these scales to be weighed. The LASO-concurred FSP mentions the scales but does not discuss their location or weighing operations.

On July 25th, a LASO facility representative recognized that greater than hazard category 3-quantities of material were being transferred outside of the MDA-B boundary to be weighed and questioned the safety basis coverage for these activities. The NNSA-approval of the 10 CFR 830 exemption is specific to MDA-B, but the boundary of MDA-B is configuration controlled by LANL. On July 28th, facility management used the LASO-concurred USQ-like process to evaluate a boundary change that expanded the MDA-B footprint to include the scales. The USQ-like evaluation concluded that the boundary change did not affect the safety envelop and therefore did not require LASO concurrence. The new MDA-B boundary that includes the scales went into effect on Monday. At LASO management's request, LANL is documenting a position on the safety basis coverage and 10 CFR 830-compliance of scale operations that had been conducted prior to the MDA-B boundary change. This position will be submitted for NNSA review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 12, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 12, 2011

Transuranic Waste Operations – WCRR Repackaging Facility: This week, LANL personnel recognized that waste processing operations have occurred for several weeks despite expiration of a Safety Evaluation Report (SER) approval of an Evaluation of the Safety of the Situation (ESS). On Thursday, the site office extended the SER approval to September 2nd to resolve this issue. In March 2011, LANL declared a Potential Inadequacy of the Safety Analysis because a Specific Administrative Control that prohibits staging or processing waste in the glovebox enclosure was not carried forward into the Technical Safety Requirements (TSRs). The control was implemented by standing order pending update and implementation of revised TSRs. In the March site office approval of the ESS, a condition of approval was identified that required LANL to submit safety basis and TSR page changes within 60 days. In addition, the SER identified that it would expire 90 days after approval (June 28th). LANL submitted the page changes in June but not within 60 days as required by the SER. The facility also continued to perform transuranic waste processing after the SER expired. This issue was complicated by the Las Conchas fire that started on June 26th and resulted in a laboratory shutdown for over a week.

Transuranic Waste Operations – Area G: The site office approved safety basis page changes last week that support operation of high energy real-time radiography at Area G. This operation provides characterization capability to support shipment of additional waste container types to WIPP. Because of previous readiness and startup issues at Area G, LANL management has decided to use outside personnel to review and ensure facility readiness prior to performing a management self assessment. The site office approval also requests LANL to provide a technical basis for concluding that the worker radiography hazard is a standard industrial hazard.

Plutonium Facility – Seismic Safety: Recently, LANL submitted a revision to the Justification for Continued Operations (JCO) associated with the increased seismic risk identified by the SAFER analysis of the Plutonium Facility. This revision resolves several site office conditions of approval including a requirement to identify TSR level controls for the marine doors that are credited to reduce the potential for an unfiltered release path following a seismic event. The JCO now includes a material at risk limit (MAR) for the glovebox line directly beneath roof girder drag strut (one of identified seismic vulnerabilities). A biweekly surveillance for this MAR limit will be implemented for this control. Facility upgrades to resolve the currently identified seismic vulnerabilities are ongoing and scheduled to be complete by the end of the calendar year.

Transuranic Waste Operations – RANT Repackaging Facility: Last week, the site office provided the SER approval to LANL for an updated safety basis and TSRs. This revision of the safety basis resolves several conditions of approval from the previous safety basis including re-analysis of the aircraft crash accident scenario, which now has a frequency of less than 1e-6/year. Implementation of the revised safety basis is scheduled to complete within 90 days. Because RANT is now considered an enduring facility, the site office has requested the next update to be a DOE-STD-3009 compliant documented safety analysis (previous safety basis analysis was in the form of a basis for interim operations).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 19, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 19, 2011

This week, Board members Peter Winokur, Jessie Roberson, Joseph Bader and John Mansfield were onsite along with staff members Timothy Dwyer, Matthew Moury and John Pasko to meet with NNSA site office and LANL personnel. The Board members also toured transuranic waste operations at Area G and seismic upgrades at the Plutonium Facility.

Plutonium Facility – Criticality Safety: A criticality safety infraction was declared last Thursday when a plutonium overmass condition was identified in a facility glovebox. In order to take pictures of several cast plutonium items in a glovebox, a plutonium worker removed the items from two separate slip lid containers in two different mass locations. The worker then collocated all of the items to take a picture. This resulted in a total mass that exceeded the criticality safety limit. An angle iron spacing delimiter that is a criticality safety engineered feature was also moved from its required location and used to prop up the items for the photographs.

A second plutonium worker entered the area and recognized the overmass condition. The first worker then moved the items back to their original location. This action is not consistent with criticality safety expectations and procedures, which require workers to back off and contact criticality safety personnel. Workers in the lab room were notified of the issue and the room was evacuated and facility management was notified. Subsequent evaluation by criticality safety personnel concluded that the current position of the items (i.e. after the worker returned the items to the separate locations inside slip lid containers) was safe and consistent with criticality safety requirements.

During the subsequent critique, additional issues with regard to the process for authorizing work (the glovebox owner was not aware of the activity) and timely and complete notifications were identified. Recognizing the significance of this event, Plutonium Science and Manufacturing Directorate management plan to pause work on Monday morning to conduct an all-hands briefing followed by breakout sessions at the group level to discuss the briefing and lessons learned. The brief will focus on conduct of operations, criticality safety requirements, work authorization and lessons learned from this and other criticality safety issues. Management will authorize individual group activities to resume after this training is complete. All Plutonium Facility personnel will be required to complete this training prior to being authorized to perform work.

Transuranic Waste Operations: In late July, an institutional Facility Centered Assessment (FCA) team issued a final report documenting their review of facility and programmatic operations at Waste Disposition Project (WDP) nuclear facilities – Area G, RANT, and WCRR. This independent assessment covered a broad range of functional areas and safety management programs and was conducted by representatives from LANL, NNSA's Los Alamos Site Office, and DOE's Office of Health, Safety and Security. The FCA report concludes that WDP nuclear operations are significantly non-compliant with requirements in the following functional areas: safety basis, engineering (particularly configuration management), fire protection, criticality safety, emergency preparedness, quality assurance, and management systems. LANL line management organizations have accepted the findings and are developing corrective actions.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 26, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 26, 2011

Weapons Engineering Tritium Facility (WETF): WETF Technical Safety Requirements (TSR) credit a containerization program that has specific provisions governing the labeling and allowed storage locations for containers that could exceed their rated design pressures under fire conditions. Pressure requirement compliance for individual tritium-bearing containers is tracked using a controlled spreadsheet that was designed to update container pressure conditions over time. This week, a WETF subject matter expert (SME) was reviewing the spreadsheet and recognized that a container known to exceed pressure requirements was now reflected as compliant. In investigating this situation, the SME identified an error in the spreadsheet algorithm used to calculate internal container pressure as a function of time. This error underestimated the amount of helium in-growth from tritium decay in a way that caused calculated container pressures to decrease rather than increase over time. Upon discovery of this issue, WETF personnel are systematically reassessing the pressure conditions of each tritium container in the facility. The extent of condition review continues. To date, one container has been newly identified as non-compliant with TSR containerization program requirements. As a result, WETF management declared a TSR violation.

Also this week, WETF personnel conducted an emergency exercise where an exercise controller fed simulated alarms into the WETF Integrated Control System in accordance with an Exercise Plan that had been approved and evaluated through the Unreviewed Safety Question process. All qualified WETF operations center operators evacuated the facility in response to simulated alarms. During the exercise-prompted evacuation, an actual high oxygen level alarm for the Tritium Waste Treatment System (TWTS) was received by the exercise controllers who remained in the facility. Receipt of a valid alarm was relayed to evacuated personnel and the exercise was suspended. However, before qualified personnel could return to the operations center, the unqualified operators observed conditions that they felt warranted action to introduce inert gas into the TWTS to dilute the oxygen concentration. After the unqualified personnel manipulated the system to initiate the dilution, qualified operators returned and oxygen levels fell and remained below alarm levels. In addition to evaluating issues related to unqualified personnel operating credited safety systems, WETF management is investigating both the cause and the safety basis implications of the unexpected influx of oxygen into the TWTS.

In response to these events, WETF management suspended container movements and gas handling operations, pending further investigation. The facility has been placed in Warm Standby mode.

Transuranic Waste Operations: This week, Area G management declared a TSR violation based on a failure to comply with minimum staffing requirements during transuranic waste operations. Area G TSRs require two technicians and a radiological control technician to be present when operations involving transuranic waste containers are performed inside waste storage domes. Recently, an NNSA facility representative observed a forklift operator transfer a standard waste box containing transuranic waste from one storage dome location to another without the required second operator. Area G management declared a TSR violation based on this facility representative observation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 2, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 2, 2011

Plutonium Facility: This week, LANL self-identified that a quarterly Technical Safety Requirement (TSR) surveillance for Pu-238 material-at-risk (MAR) was not performed within the required period (the surveillance should have been performed by August 13th). Facility personnel successfully completed the MAR surveillance on Thursday and verified that material inventory in the laboratory was within limits.

This TSR surveillance was one of the last controls implemented in early June to complete full implementation of the 2008 Documented Safety Analysis and associated TSRs. A Plutonium Facility worker performed the surveillance on June 2nd using an approved procedure; however, MAR inventory data from May 13th was used instead of the current inventory data called for by procedure. The facility surveillance tracking database in the operations center was tracking this quarterly surveillance based on the June date versus the May date. This week, facility personnel questioned the required time to perform the MAR surveillance, identified the discrepancy and reported the TSR violation. LANL investigation and development of corrective actions are ongoing.

Safety Basis: Last week, the site office provided direction to LANL on the processes used to manage safety system deficiencies. In particular, LASO requested the following actions within 30 days: 1) implement detailed requirements for declaring and reporting TSR violations; 2) update the New Information Process based on site office comments; 3) provide process flow charts that clarify the relations between the nonconformance reporting, new information and operability determination procedures (including draft changes to procedures, as needed); and 4) identify required training to implement these changes. When implemented, these changes should help clarify and improve site processes used to manage and resolve safety system deficiencies.

Work Planning and Control: Recently, the site office provided feedback to NNSA-Headquarters on the proposed standard for work planning and control developed by the Energy Facility Contractors Group. LASO asserts that the standard "...could be an appropriate guide or manual for maintenance work but should not be a required standard, particularly for the wide ranging research and development (R&D) and high-skill programmatic work that is the focus of [LANL's] national security and other scientific missions." LASO recommends that the standard be used as a non-mandatory guide for capturing best practices.

Transuranic Waste Operations: An unvented legacy container that holds a 0.5 g ²⁴¹Am source received from the Lovelace Respiratory Research Institute is currently staged at Area G inside a vented Standard Waste Box. LANL personnel intend to use a glovebag inside the Dome 231 Sort, Segregate, and Size Reduction (SSSR) permacon to open the legacy container and remove the ²⁴¹Am source for disposition. This week, the NNSA site office approved a one-time exemption to an Area G specific administrative control that normally prohibits opening unvented containers during SSSR operations. The exemption approval includes a number of compensatory measures to control hazards presented by hydrogen accumulation in the legacy container. LANL must also successfully complete a contractor readiness assessment, currently scheduled for September, prior to performing this work.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 9, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 9, 2011

Weapons Engineering Tritium Facility (WETF): At WETF, the safety significant tritium monitoring system is credited to detect high tritium concentrations and provide a local alarm to prompt worker evacuation. Last week, four tritium monitors that had recently been recalibrated at the LANL Calibration Laboratory had their TSR-level surveillances performed to confirm operability upon reinstallation. A step in the WETF surveillance procedure requires a qualified operator to verify the tritium high level alarm to be set at $7,000 \mu\text{Ci}/\text{m}^3$. The procedure then calls for the operator to verify that the high level audible alarm sounds at a tritium concentration less than $10,000 \mu\text{Ci}/\text{m}^3$, which is a TSR requirement. A qualified WETF operator performed the surveillance procedure and initialed completion of the set point verification and the audible alarm confirmation steps. During the course of testing, operations center personnel noticed unanticipated system responses and called in the Cognizant System Engineer (CSE) to investigate. The CSE discovered that although the TSR surveillance had been completed and documented as satisfactory, the tritium monitor set point had never been changed from the Calibration Laboratory default setting of $99,000 \mu\text{Ci}/\text{m}^3$, as required by the surveillance procedure, and therefore could not have audibly alarmed at a level below $10,000 \mu\text{Ci}/\text{m}^3$, as required by the TSRs. Upon discovery, WETF management entered applicable action statements for the tritium monitoring system Limiting Conditions for Operation (LCO), fixed the tritium monitor set point issue, and successfully re-performed the TSR surveillances. WETF management has taken other actions to address the significant procedure compliance issues associated with this event.

Plutonium Facility: This week, the site office completed a Safety Evaluation Report for a revised Justification for Continued Operation (JCO) associated with handling and storage of heat-source plutonium (HS-Pu) material containers. This revised JCO addresses three Potential Inadequacies of the Safety Analysis (PISAs) that were identified for HS-Pu between November 2010 and January 2011. The site office response also approves removal of previously identified operational restrictions following implementation of the revised JCO controls. The JCO identifies a specific administrative control implemented as a LCO that requires welded HS-Pu containers inside gloveboxes to meet the performance criteria at the glovebox fire temperature of 1800°F or have a limited time (two weeks) to be present in the glovebox (and count toward the applicable glovebox material at risk limits). The JCO is scheduled for implementation within 90 days.

Plutonium Facility – Seismic Safety: Recently, the site office submitted to NNSA-Headquarters the Project Execution Plan that includes strategy, cost, scope, schedule and identified funding sources to complete upgrades that ensure mitigated consequences for worst case seismic accident scenarios do not challenge the offsite evaluation guideline. This submittal is identified as a deliverable for Recommendation 2009-2. The plan includes the following: 1) upgrades to address deficiencies identified in the SAFER evaluation to meet facility performance assumptions 2) credit analyzed and approved fire-rated containers with reduced damage ratios 3) upgrade glovebox support stands to meet PC-3 requirements for gloveboxes that process plutonium in the molten state 4) upgrade the fire suppression system to meet PC-3 requirements and 5) upgrade appropriate portions of the ventilation and support systems to meet safety-class and PC-3 requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 23, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 23, 2011

Federal Oversight: Last week, the NNSA site office transmitted a series of letters to LANL that call for corrective actions in response to recent operational events and assessment results. The letters focus on issues related to criticality safety and conduct of operations at the Plutonium Facility, as well as, safety system and safety management program efficacy concerns at transuranic solid waste facilities (Area G, RANT, and WCRR). Collectively, the letters prompt LANL to take immediate actions to: • evaluate the adequacy and implementation of criticality safety controls for certain Plutonium Facility operations that rely heavily on conduct of operations to maintain criticality safety margin; • evaluate vital safety system operability concerns at transuranic solid waste facilities; and • evaluate whether safety management programs at the Plutonium Facility and transuranic solid waste facilities require compensatory measures. Longer-term, the letters call for LANL to examine the issues associated with the Plutonium Facility and transuranic solid waste facilities, determine causal factors, evaluate extent-of-condition across the site, and develop a comprehensive corrective action plan. The letters also drive LANL to develop a suite of performance metrics and leading indicators that can be used jointly by LANL and NNSA to track improvements in nuclear operations.

Plutonium Facility: In response to the NNSA site office correspondence discussed above, this week Plutonium Facility management suspended selected operations, pending review of the adequacy and implementation of criticality safety controls. One affected operation involves nitric acid-based plutonium recovery and purification. Close evaluation of this process based on NNSA concerns highlighted the fact that it is physically possible to transfer plutonium-bearing solutions from process tanks, through piping, into a bulk nitric acid tank that resides outside the Plutonium Facility's credited confinement boundary. This situation presents both safety basis and criticality safety concerns and prompted Plutonium Facility management to declare a Potential Inadequacy of the Safety Analysis.

Las Conchas Wildfire: Last week, the site office transmitted the Las Conchas Wildfire Final Emergency Report to NNSA-Headquarters consistent with the requirements in DOE Order 151.1C, *Comprehensive Emergency Management System*. The fire began on Sunday, June 26th at approximately 1300 roughly 12 miles southwest of LANL. An Operational Emergency was declared on Monday, June 27th due to a small (approximately 1 acre) fire on laboratory property that was quickly extinguished. LANL transitioned from an Operational Emergency to recovery mode on Friday, July 1st after the threat from the fire had been sufficiently mitigated.

As a noteworthy practice, the report identifies lessons learned and corrective actions developed after the 2000 Cerro Grande fire that included execution of a wildland fire management plan, construction of a new Emergency Operations Center (EOC), formalized training of Emergency Response Organization personnel, establishment of a 24/7 Emergency Operations Support Center and development of an enhanced drill and exercise program. The report identified opportunities for improvement in the areas of communication, management and staffing, EOC infrastructure, access control and accountability. The site office also reviewed the event and identified opportunities for improvement associated with LASO and DOE-Headquarters performance. The site office is developing a performance-based incentive for FY12 to drive improvements in the identified areas.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 30, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 30, 2011

Broderick was out of the office this week.

Plutonium Facility – Seismic Safety: This week, NNSA-Headquarters formally submitted the Project Execution Plan for structure, system and component upgrades to ensure worst-case accident scenario consequences do not exceed the DOE evaluation guideline. The plan is identified as a deliverable for Recommendation 2009-2, *LANL Plutonium Facility Seismic Safety*, and includes the initial strategy, cost, scope, schedule and funding sources for the proposed upgrades. A key proposed upgrade, safety-class, performance category-3 active confinement ventilation has a current schedule for completion in fiscal year 2020; however, the forwarding letter notes that NNSA is reviewing this project to determine if the schedule can be accelerated. NNSA also commits to updating the Project Execution Plan in January to include any additional input from the Plutonium Facility Seismic Analysis of Facilities and Evaluation of Risk (SAFER) analyses. Based in part on input from the Board staff, LANL is currently evaluating the impact from the facility service chase roof cold joint and the performance of corridor columns after other upgrades are completed. These evaluations may identify the need for additional facility upgrades to address worst-case seismic accident scenarios.

As a part of the Justification for Continued Operation associated with the increase in seismic risk identified by the SAFER project, LANL included a compensatory measure to containerize a significant quantity of heat source-plutonium (HS-Pu) into safety-class fuel storage outer containers. This week, LANL reported to the site office that 1.2 kg of HS-Pu from the laboratory floor has been packaged in safety-class containers. Because of the high specific activity for HS-Pu, this represents a significant quantity of plutonium-239 equivalent material.

Safety Basis: Recently, LANL responded to site office direction on management of safety system deficiencies related to declaring Technical Safety Requirement (TSR) violations, the new information process, the non-conformance report process, integration of these procedures and required training. With input from the site office, LANL has developed a standing order that defines the conditions for declaring a TSR violation. This definition will be incorporated into safety basis documents as part of the annual update process. In addition, the NI and NCR procedures have been revised to address site office comments and ensure process integration. LANL plans to perform a training needs analysis to determine appropriate training content, target audience and best method to deliver training material to the target audiences.

Formality of Operations: Earlier in September, LANL responded to a July 2011 NNSA-Headquarters request to analyze the site's issues and weaknesses in formality of operations, identify common contributing factors and corrective actions and describe "best in class" practices in this area. The site office response notes that while formality of operations procedures adequately address DOE requirements, uniform and compliant implementation of these procedures and processes remain a problem at LANL as evidenced by facility centered assessments, readiness review results and site office oversight activities. Specific issues that need to be addressed are identified for conduct of operations, engineering, maintenance and training. The site office notes that LANL continues their "maturation" of formality of operations; however, full compliance is expected to take several more years to complete.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 7, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 7, 2011

Weapons Engineering Tritium Facility (WETF): This week, LANL submitted to the NNSA site office an Evaluation of the Safety of the Situation and revised Justification for Continued Operation (JCO) to address hazards and controls associated with the potential for oxygen in-leakage into WETF tritium systems. In October 2010, LANL identified an unreviewed safety question associated with potential oxygen in-leakage through the Hot Inlet System. A hazard analysis was performed to evaluate deflagration hazards due to oxygen in-leakage and a JCO was submitted and approved by the site office. Subsequently, during an emergency exercise in August 2011, an increase in oxygen concentration in the Tritium Waste Treatment System (TWTS) was noted after repositioning a three-way valve. In response, the three-way valve was returned to its previous position and the system was purged, which reduced the oxygen concentration. Facility operations were also placed in warm standby and restrictions on introduction of flammable gases into tritium systems were implemented by standing order. This issue was declared an unreviewed safety question due to the potential increase in frequency for oxygen in-leakage into the TWTS.

The revised JCO, which is based on a new hazard analysis, identifies additional controls including blanking off the connection from the TWTS to the three-way valve discussed above. LANL contends that the newly identified controls along with previous JCO controls ensure the facility can be operated safely and requests approval of the JCO until January 30, 2012. The site office review is ongoing.

Plutonium Facility – Seismic Safety: LANL reported to the site office this week completion of several key upgrades that address seismic/structural issues identified by the Seismic Analysis of Facilities and Evaluation of Risk project. These upgrades included the Zone 1 plenum column to wall and column to ceiling separation and the Zone 1 fan pad modifications. These improvements help reduce the potential for an unfiltered release during and following a seismic event.

Transuranic Waste Operations: This week, a LANL team completed a checklist Contractor Readiness Assessment (CRA) of high energy real-time radiography (RTR) operations at Area G. The startup of high energy RTR operations is necessary for LANL to certify that transuranic waste directly loaded into Standard Waste Boxes meets the waste acceptance criteria specified by the Waste Isolation Pilot Plant. At the outbrief, the CRA team leader noted that the high energy RTR operations reviewed during this CRA demonstrated a higher degree of readiness than other recently reviewed transuranic waste startup activities. This conclusion indicates that steps taken by LANL management to improve the preparation and state of readiness for transuranic waste-related startups are having a positive effect.

The CRA team did identify three pre-start findings. One of these pre-start findings reflects a damage ratio value used in the approved safety analysis that is a factor of ten lower than the value dictated by DOE-STD-5506, *Preparation of Safety Basis Documents for Transuranic Waste Facilities*. Since dose consequences are linearly proportional to damage ratios, using a damage ratio value that is consistent with DOE-STD-5506 would increase the consequences from postulated accident scenarios by an order of magnitude. LANL management intends submit a safety basis page change to the NNSA site office for approval to address this issue prior to beginning high energy RTR operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 14, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 14, 2011

Plutonium Facility: This week, the NNSA site office approved revision 1 of the 2011 Plutonium Facility Document Safety Analysis (DSA) and its associated Technical Safety Requirements (TSR). This is the first major Plutonium Facility DSA update to be approved by NNSA since December 2008. The approved DSA presents mitigated doses that are below the DOE Evaluation Guideline for all postulated accident scenarios, including the bounding seismically-induced fire scenario. The approved DSA also addresses NNSA comments generated during prior reviews of the never-approved 2009, 2010, and 2011 revision 0 DSA annual update packages. The NNSA approval letter requests for LANL to provide an implementation plan for the updated set of TSRs within 30 days.

The approved update includes a completely revised accident analysis for the bounding seismically-induced fire scenario. The reanalyzed scenario in the 2011 DSA is significantly different from the 2008 DSA seismically-induced fire scenario in a number of respects. First, the 2011 DSA provides a basis to assume that post-seismic fires will be confined to four laboratory rooms rather than using the 2008 DSA assumption that a post-seismic fire would engulf the entire laboratory floor. This collection of four smaller fires provides less energy to drive released material out of the building than a large floor-wide fire, resulting in a leak path factor of 0.18 in the 2011 DSA down from 0.40 in the 2008 DSA. The 2011 DSA also limits the total amount of material at risk (MAR) allowed on the laboratory floor to approximately 50% of that allowed by the 2008 DSA. Finally, unlike the 2008 DSA that assumed all MAR was present in a single extremely dispersible form, the 2011 DSA disaggregates the MAR based on the various physical forms of material that are actually found in the facility and assigned dispersibility values based on each specific form. The aggregate effect of reduced MAR, dispersibility (i.e. airborne release fractions and respirable fractions), and leak path factor values result in a mitigated offsite consequence for the seismically-induced fire in the 2011 DSA that is below the DOE Evaluation Guideline and is two orders of magnitude lower than the 2008 DSA consequence.

Importantly, the revised seismic accident analysis in the 2011 DSA assumes that an earthquake does not cause the facility to collapse and does not breach the confinement integrity of the building structure. In April, results of the SAFER seismic analysis for the Plutonium Facility identified a number of structural vulnerabilities that could cause facility collapse or loss of confinement integrity in the event of an evaluation basis earthquake. This new information prompted the development and approval of a Justification for Continued Operation (JCO). This JCO remains in force while NNSA and LANL aggressively pursue structural upgrades to address the identified vulnerabilities. One key upgrade milestone occurred last weekend as concrete was placed to form a heavily reinforced strengthening member on the Plutonium Facility roof to address the one currently known vulnerability that could lead to facility collapse in a severe earthquake. This week, Plutonium Facility management also completed formal implementation of all compensatory measures included in the seismic JCO after performing and resolving issues from an independent Implementation Verification Review.

Presently, the 2008 DSA, its associated TSRs, and the seismic JCO remain the Plutonium Facility safety basis of record. The 2011 DSA and TSRs can be implemented to supersede the 2008 documents, but some version of a seismic JCO must remain in place until the seismic performance of credited controls (e.g. no building collapse or confinement breach) conforms to assumptions made in the DSA.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 21, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 21, 2011

This week, staff members T. Cutler, J. Deplitch, M. Helfrich and J. Pasko were onsite to review the LANL emergency management program.

Material Disposal Area-B (MDA-B): In September, LANL completed the retrieval of waste buried at MDA-B, a six acre legacy waste disposal area that received radiological and chemical waste in the late-1940s and is only meters away from public areas. At present, approximately 85% of the 116 plutonium-239 equivalent curies (PE-Ci) that were retrieved have been shipped away from MDA-B for disposal. The shipment of all remaining excavated waste from MDA-B is currently scheduled to be complete in early 2012. Permanent removal of this legacy waste, which included significantly more radioactive material inventory and total waste volume than anticipated, will represent a significant achievement in reducing the hazards at Technical Area-21.

LANL also recently submitted the safety basis strategy for retrieval of sludge waste from the two "General's Tanks" located in Material Disposal Area-A in Technical Area-21. Sample results obtained recently indicate approximately 150 PE-Ci are contained in these tanks. The strategy notes that sludge removal from the General's Tanks will be conducted as a hazard category 2 nuclear activity using a Documented Safety Analysis and Technical Safety Requirements developed in accordance with DOE-STD-1120, which is a 10 CFR 830 safe harbor methodology for developing safety basis documentation for environmental restoration activities.

Transuranic Waste Operations: Laboratory personnel plan to use a glovebag inside of a permacon structure located at Area G to access a legacy Am-241 source and either retrieve it for future programmatic use or package it for disposal as transuranic waste. Historically, this source had been used for experiments at the Lovelace Respiratory Research Institute. Available assay data indicates the source contains approximately 0.56g of Am-241 which represents 1.7 PE-Ci (about three times greater than the hazard category 3 threshold of 0.56 PE-Ci found in DOE-STD-1027).

The Am-241 was originally contained in a glass ampoule that was placed inside a copper-shielded steel box. The integrity of the glass ampoule is now suspect and LANL personnel are planning for the presence of dispersible americium oxide based on a continuous air monitor alarm received the last time the box was opened in 2007 at a Sandia National Laboratories – Albuquerque facility. The steel box containing the americium source is currently overpacked inside a Standard Waste Box (SWB) and staged in a transportainer at Area G. Lab personnel plan to transport the SWB to a permacon structure in Area G, remove the steel box and insert it into a glovebag inside the permacon, open the steel box the access the americium source, and either package the material for shipment to the Plutonium Facility if the source is recoverable or package the material for disposal as transuranic waste if the source is not recoverable.

This week, a LANL review team issued their final report documenting completion of a checklist Contractor Readiness Assessment (CRA) for this activity. The report identifies four pre-start findings. Lab personnel plan to perform this evolution upon successful resolution of these findings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 28, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending October 28, 2011

Mr. Broderick was out of the office this week.

Transuranic Waste Operations – Area G: On Tuesday, LANL waste personnel successfully repackaged the americium-241 item received from Sandia National Laboratories – Albuquerque (see last week’s report). After opening the copper-shielded steel box, LANL personnel identified contaminated lead and plastic but not the americium-241 item that was expected. The contaminated materials including the glovebag used for this operation were collapsed and packaged in a standard waste box for disposition as transuranic waste.

In July, LANL began processing fiberglass-reinforced plywood boxes containing legacy transuranic wastes that are too large to fit in drums or standard waste boxes. This operation is being performed in the waste processing line in Building 412 at Area G. To date, 17 boxes that contain less than Hazard Category 3 threshold material (0.52 plutonium-239 equivalent curies) have been processed. An additional approximately 400 boxes remain that exceed the Hazard Category 3 threshold and need to be repackaged prior to shipment to WIPP.

This week, waste disposition project personnel completed line management activities to support startup for the higher activity boxes. The site office also approved the Plan of Action for the initial startup of this operation. A contractor readiness assessment is scheduled to begin next week followed by a federal readiness review in November. Lessons learned and operator training from processing operations with the less contaminated boxes has been used to help ensure readiness to process the higher activity waste boxes.

Transuranic Waste Operations – WCRR Repackaging Facility: Earlier this year, LANL submitted revised safety basis documents for the WCRR Repackaging Facility that support an increase in the material at risk limits from 300 to 800 combustible equivalent curies to allow processing higher activity transuranic waste containers. The submittal also clarified that the electrical distribution system is not a safety significant support system. Based on site office comments, the safety basis was resubmitted in September. This week, the site office provided an additional comment that identifies the need for the electrical distribution system to be safety significant. The site office letter notes that this system supports the safety significant confinement ventilation system and, therefore, should have the same safety classification.

Radioactive Liquid Waste Treatment Facility (RLWTF): Earlier this month, LANL submitted a safety basis strategy for completing a DOE standard 3009 compliant Documented Safety Analysis (DSA) and Technical Safety Requirements for the existing RLWTF. LANL had previously submitted a Basis for Interim Operation in December 2010; however, in July 2011 the site office directed development of a DSA because of the potential for delays in the replacement project. The strategy notes that approximately 18 months will be required to develop the new DSA for RLWTF. The facility is currently operating under a 1995 safety basis document with interim Technical Safety Requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 4, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 4, 2011

Plutonium Facility – Seismic Safety: In October, LANL personnel installed a large strengthening member on the Plutonium Facility roof. This upgrade was significant because it was designed to address the one known structural vulnerability whose failure could have caused the facility to collapse in a large earthquake. A key aspect of post installation testing for this important upgrade involved destructively evaluating concrete samples to ensure they met strength specifications. Although the 28 days of cure time required by the code have not yet elapsed, recent tests of the still curing concrete indicate that it already meets the acceptance criteria for compressive strength.

Readiness: This week, LANL provided a set of corrective actions to the site office in response to the recent NNSA annual assessment of the laboratory readiness review program. The assessment was completed in September with a final report issued on October 3rd. Overall, the review concluded that the LANL readiness program met the requirements identified in DOE Order 425.1D. Seven findings and six observations were identified by the review team.

A notable finding identified during the NNSA review was the lack of “consistent performance demonstrating Line Management’s capability to achieve readiness to operate preceding Readiness Reviews.” This issue has been identified as a lesson learned for a number of LANL startup and restart activities. The laboratory corrective action notes that the site has issued procedure P119.0, *Process for Management Self-Assessment (MSA) of Startup and Restart of LANL Nuclear Facilities*. This procedure describes the actions that are required prior to declaring readiness to begin a formal readiness review. This procedure also provides guidance for the execution of systematic self-assessment activities that will assist line management in confirming that nuclear activities are ready to safely begin operations. Poor performance by line management in readiness preparation before commencing the formal readiness review and verification process has been a recurring problem at the laboratory.

Integrated Work Management: In September, the laboratory declared that Integrated Safety Management (ISM) and Integrated Work Management (IWM) are adequately implemented for research and development (R&D) and programmatic work at LANL. This week, the NNSA site office concurred with this declaration based on the results of a recently completed LANL assessment. The laboratory assessment was extensively shadowed by NNSA personnel and the federal shadow team concluded that this review was sufficient to demonstrate that ISM and IWM are adequately implemented for the types of R&D and programmatic activities that have resulted in safety problems in the past. Notwithstanding the overall conclusion, a number of weaknesses were identified during the assessment including the need for better application of conduct of operations principles in some detailed operating procedures, a need for improvement in computerized job hazard analyses and the need to ensure that all relevant hazards and controls are incorporated into technical procedures when these documents are used in lieu of Integrated Work Documents.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 11, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 11, 2011

The Board staff held a conference call with site office and LANL personnel this week to discuss the status and safety strategy for the Transuranic Waste Facility, which will provide an enduring laboratory capability to stage and ship transuranic solid waste after Area G closure.

Federal Oversight: The Performance Evaluation Plan (PEP) is a key tool used by the site office to incentivize contractor performance. The Fiscal Year 2012 PEP includes roughly \$45M in at-risk fee for subjective and objective performance measures with approximately 80%, 10% and 10% identified for essential, stretch and multi-site incentives, respectively.

The award term incentive, which would extend the contract period, includes a mandatory measure for the improvement and integration of formality of operations at the Plutonium Facility (PF-4). Other measures associated with the award term are 1) reduction in the safety basis offsite dose consequence to less than 25 rem for all PF-4 accident scenarios; 2) meeting national security mission requirements; 3) sustaining LANL's science and technology leadership; and 4) meeting goals related to detection and characterization of nuclear and radiological signatures. LANL must achieve success in the mandatory measure and 3 of the 4 other measures in order to meet the criteria for the award term incentive.

The PEP also includes the following performance incentives and measures (this is only a partial list of Fiscal Year 2012 incentives):

- Capability Sustainment and Transition – relocation of sample management from the Chemistry and Metallurgy Research (CMR) building to PF-4; improvements in disposition of newly generated waste
- Capability Risk Reduction – materials disposition and PF-4 vault work-off; Integrated Nuclear Planning for waste operation continuity
- Environmental Management Mission – disposition of newly generated and legacy transuranic waste; environmental planning and execution
- Project Management Performance – CMR Replacement and site-wide project execution performance
- High Hazard Operations – integrate and execute mission and safety commitments (including PF-4 seismic upgrades and criticality safety improvements); formality of operations implementation; nuclear safety improvements (including submittal of safety basis documents); correct fire protection deficiencies; execution of confinement vessel disposition activities at CMR; mature conduct of operations
- Emergency Operations – implement emergency accountability system; improve emergency operations center facility and communication systems
- Excellence in Operations – conduct of operations, safety basis, operational readiness for facility startup and restart, credited safety management programs and vital safety system program improvements

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 18, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B.P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending November 18, 2011

The Board held a public hearing in Santa Fe this week to discuss seismic safety for the Plutonium Facility, emergency preparedness, and the safety of existing facilities and planned replacement facilities. Board members P. Winokur, J. Roberson, J. Bader and J. Mansfield conducted the hearing with testimony from senior NNSA and LANL personnel.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 25, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending November 25, 2011

Federal Oversight: In September, the site office requested LANL to provide a status report on the adequacy and implementation of criticality controls at the Plutonium Facility, safety system operability issues for transuranic waste facilities, and the adequacy of safety management programs for both facilities. LANL provided an initial response in October and was scheduled to provide a comprehensive report on planned actions and performance tracking metrics by the end of November.

In a letter to the laboratory last week, the site office noted significant progress and management focus on criticality safety improvements at the Plutonium Facility but stated that the comprehensive report should fully address issues identified by a recent criticality safety committee review and actions to improve conduct of operations. For the transuranic waste facilities, the site office noted that LANL responses to safety system operability issues appear to justify the status quo and not actions required to “bring about the significant step-improvement in transuranic waste operations that is needed.”

To ensure the LANL response on improving the safety of nuclear operations at these facilities includes the appropriate depth of analysis and adequate corrective actions, the site office letter directed the laboratory to delay their comprehensive report until December 19th.

Plutonium Facility – Safety Basis: Last week, LANL submitted a revised Justification for Continued Operations (JCO) associated with the increased seismic risk identified by the SAFER analysis. The revised JCO takes credit for completion of upgrades to the Plutonium Facility roof such that collapse scenarios during a seismic event are no longer credible. LANL does identify that reevaluation of the facility performance with the roof upgrade in place is ongoing. Any issues that result from this evaluation will be dispositioned using the appropriate site procedure (e.g. unreviewed safety question). Compensatory measures for the previously identified seismic issues remain largely unchanged. The identified expiration date for this JCO is May 11, 2012. LANL continues to pursue facility upgrades to resolve other identified vulnerabilities.

This week, the site office approved a LANL request to close the outstanding Potential Inadequacy of the Safety Analysis (PISA) associated with miscellaneous vault water bath containers. Six “K2” containers remain in the vault water bath that do not meet the safety class performance criteria described in the Documented Safety Analysis (DSA), which caused initial declaration of the PISA in December 2009. However, these containers and safety basis are now appropriately described in the 2011 DSA that was approved in October 2011. Facility implementation of safety controls for the K2 containers is not required. The site office approval letter requests a schedule for disposition of the remaining K2 containers within 90 days.

Radioactive Liquid Waste Treatment Facility: In October, LANL requested site office concurrence with a safety basis strategy for developing a compliant DSA and Technical Safety Requirements for this facility in 18 months. Last week, the site office disagreed with the 18 month schedule and directed the laboratory to submit compliant documents by September 2012.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 2, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 2, 2011

Transuranic Waste Operations: The Area G safety basis includes TSR-level inventory limits on the curie content of both transuranic waste and tritium. The TSRs require a quarterly surveillance to confirm that the Area G tritium inventory remains below the approved limit. The quarterly surveillance is performed by querying a computer database that tracks the quantity of tritium at Area G and comparing the current inventory value to the TSR limit. During a recent surveillance, an Area G operator recognized that the tritium inventory value reported by the tracking software had not changed from the previous surveillance even though tritium material moves had been made. Subsequent evaluation revealed that there was an error in the tritium inventory tracking software.

Per the LANL institutional software quality assurance program, requirements for software change control and verification and validation are graded based on the importance of the software. Area G inventory tracking software is rated at the highest level of safety-related software subjecting it to the most stringent change control requirements. In 2010, a change was made to the inventory software that caused it to report incorrect tritium inventory values. This error was not identified during required software change verification and validation activities. As a result, TSR-level surveillances were performed for roughly two years using invalid tritium inventory values. This week, Area G management declared a TSR violation based on this discovery.

Also this week, operators at the WCRR repackaging facility cracked a glovebox window when a tool they were using to remediate the contents of a drum slipped and the tool handle impacted the glovebox glass. No contamination was released in this event, but cracking glovebox windows with tools has been a recurring problem at WCRR. In response, facility management is emphasizing the need to use the right tool for job when removing the contents of transuranic waste drums inside the WCRR glovebox.

Radioactive Liquid Waste Treatment Facility (RLWTF): This week during low level waste processing operations, an equipment failure caused an RLWTF operator to be sprayed in the face with 25% sodium hydroxide solution resulting in localized second degree burns to his lips. The operator was adjusting the setting of a caustic solution addition pump when the failure occurred.

Maintenance of the caustic addition system had been performed the day before the event. The maintenance activity required the normal valve line-up for the caustic addition system to be changed. The maintenance work package called for the valves to be repositioned according to operations personnel instructions upon completion of the evolution, but the work was completed after hours when no operations personnel were present. The valves were left in an abnormal line-up and valve position status was not effectively communicated to operations personnel. The next day facility personnel did not perform a procedurally required pre-operational valve alignment check prior to beginning low level waste processing activities. As a result, the caustic addition system was not in the expected configuration when it failed and sprayed the operator. The exact cause of the equipment failure is being investigated by facility personnel.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 9, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 9, 2011

Weapons Engineering Tritium Facility (WETF): The WETF safety basis credits combustible loading limits as a TSR-level control and requires monthly and annual surveillances for transient and permanent combustibles, respectively. WETF uses a detailed software spreadsheet to track the quantities of combustibles present in the facility and to compute the combustible loading (in units of lbs/ft²) for WETF rooms that have defined limits. A summary spreadsheet then imports the computed combustible loading values from the detailed spreadsheet and operators use the data from the summary spreadsheet to perform the monthly TSR surveillance.

On Thursday, a WETF operator performed the monthly combustible loading surveillance, documented that the combustible loading for all rooms complied with TSR limits, and turned in completed surveillance paperwork to the Operations Center. A post-surveillance review by Operations Center personnel discovered that for one WETF room, the documented combustible loading value from the summary spreadsheet exceeded the TSR limit by roughly a factor of four, but had been recorded as satisfactory during the surveillance.

Follow-up investigation showed that the combustible loading in the affected WETF room actually complied with TSR limits. However, a recent change to the summary combustible loading spreadsheet had introduced an error that caused it to import data from the wrong fields in the detailed spreadsheet. WETF combustible loading spreadsheets are graded as the second highest level of safety-related software, but required change control and verification and validation (V&V) protocols failed to identify this error. Several recent events have highlighted failures of existing change control and V&V protocols to identify errors introduced to safety-related software spreadsheets by changes. WETF declared a TSR violation in August based on a container pressurization spreadsheet error and last week Area G declared a TSR violation based on a tritium inventory tracking spreadsheet error.

Plutonium Facility: On Thursday, the site office issued the Safety Evaluation Report (SER) that approves revision 2 of the Justification for Continued Operation (JCO) for seismic issues associated with the Plutonium Facility. This JCO reflects completion of facility upgrades and implementation of compensatory controls. The Kardex unit has also been added as a component that will be upgraded. The site office SER directs implementation of additional controls for mezzanine loading within 30 days. The JCO expires on May 11, 2012. LANL continues to work on additional analyses of building seismic performance to address concerns identified by the Board's staff and independent peer reviews.

Transuranic Waste Operations: This week, the federal readiness assessment team completed their review of the box repackaging line in Area G's Building 412 and briefed their results to site office and LANL management. The team recommended that LASO authorize startup following resolution of the one pre-start finding (a carryover finding from the contractor readiness assessment) and approval of corrective actions for the two post-start findings identified by the federal review team. As a noteworthy practice, the team noted that the project team and personnel demonstrated a visible nuclear safety awareness and focus on eliminating or mitigating challenges to safe and reliable operations. Results from recent laboratory readiness reviews and this review indicate significant improvements in line management readiness and startup performance for waste disposition programmatic activities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 16, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 16, 2011

Staff members J. Pasko and C. Shuffler were onsite this week to review the design and safety basis for the Transuranic Waste Facility Project. In addition, staff members A. Hadjian, J. Kimball and Z. McCabe were onsite Thursday to discuss the status and results of ongoing seismic-structural analyses of the Plutonium Facility. LANL presented the results from a sensitivity analysis that re-evaluated the performance of key facility roof features and discussed the path forward for performing an important static non-linear analysis of the Plutonium Facility.

Plutonium Facility: The NNSA site office has approved an implementation plan for the 2011 Plutonium Facility Documented Safety Analysis (DSA) and associated Technical Safety Requirements (TSR). The approved plan calls for an Independent Verification Review to confirm implementation of the 2011 DSA and TSRs by May 25, 2012. Notably, the 2011 DSA and TSRs cannot take effect as a stand-alone safety basis (i.e. they must be accompanied by a Justification for Continued Operation that covers seismic issues) until Plutonium Facility structural upgrades have been completed to prevent seismically-induced collapse or loss of confinement integrity.

Transuranic Waste Operations: Area G currently stores about 300 Fiberglass Reinforced Plywood (FRP) boxes that contain transuranic waste. These FRP boxes house contaminated gloveboxes, equipment, and debris removed from the TA-21 Plutonium Facility (predecessor to the current TA-55 Plutonium Facility) when it was decommissioned in the mid-1970's. Area G FRP boxes vary widely in both size and material-at-risk content. LANL personnel are establishing multiple processing lines to open FRP boxes, remove their contents, size reduce large items, and repackage the resulting waste in Standard Waste Boxes for shipment to WIPP.

In July, LANL personnel began processing FRP boxes that contained less than 0.52 ²³⁹Pu-equivalent Ci (i.e. less than the Hazard Category 3 threshold) inside a confinement tent in Area G's Building 412. After a campaign to process low activity FRP boxes in Building 412, LANL personnel successfully completed a recent NNSA readiness assessment to begin remediating FRP boxes that contain Hazard Category 3 quantities of transuranic waste. This week, the NNSA site office formally authorized Hazard Category 3 FRP box processing in the Building 412 confinement tent.

LANL transuranic waste personnel also intend to establish FRP box processing lines in Area G's Dome 231 and Dome 375. The existing Dome 231 Permacon will be reconfigured with upgraded fire suppression, ventilation, and electrical systems to support Hazard Category 3 FRP box processing. Dome 375 will be outfitted with a new Permacon structure to process large FRP boxes and boxes that contain a larger quantity of material-at-risk, including the roughly 10 boxes containing inventory that exceeds the Hazard Category 2 threshold of 56 ²³⁹Pu-equivalent Ci.

Federal Oversight: This year, NNSA established a Performance Based Incentive (PBI) for LANL to develop and use a set of metrics to demonstrate the continuous improvement and maturity of Formality of Operations. Yesterday, the site office rejected the initial LANL deliverable in part because the proposed metrics did not represent leading indicators as required by the NNSA PBI.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 23, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending December 23, 2011

Plutonium Facility: Laboratory and NNSA management are focusing sustained attention on improving criticality safety and conduct of operations practices at the Plutonium Facility. The site office has heavily emphasized these improvements in FY12 contractual Performance Based Incentives (PBI) and LANL management is making meaningful progress in implementing changes to processes and training designed to improve criticality safety and conduct of operations performance.

In August, a troubling criticality safety infraction occurred at the Plutonium Facility that increased management concern over criticality safety and conduct of operations and highlighted the pressing need to address shortcomings and improve performance in these areas. In the August event, a researcher, who was a certified fissionable material handler (FMH), wanted a photograph of the results of a recent plutonium casting operation. The FMH accessed material in a glovebox that he was not authorized or released to work in and violated posted criticality safety limits by taking plutonium metal rods from two separate material locations and bringing them together in a single location. During this evolution, a second certified FMH entered the area and recognized the plutonium mass in the glovebox location significantly exceeded posted limits. The two certified FMHs then violated requirements for dealing with criticality safety infractions by re-accessing the affected glovebox and moving the rods back to their original locations.

In response to the significance of the August event and in reaction to prompting from the NNSA site office, LANL management is taking serious action to improve criticality safety and conduct of operations compliance. At the outset, LANL senior management re-assigned a highly experienced Plutonium Facility manager to work full-time on developing, coordinating, and executing improvement efforts. This dedicated manager and his working group began by drafting major revisions to the procedures that govern criticality safety program implementation and fissionable material transfers at the Plutonium Facility. The revised procedures provide much greater clarity in the roles, responsibilities, and requirements that apply to operators and supervisors during glovebox work and fissionable material transfers.

More recently, the dedicated improvement manager led an effort to completely overhaul the Plutonium Facility's FMH certification process. The new process involves classroom training with an exam, a performance demonstration, and an oral board. The new classroom training is well structured and well taught using many practical examples from Plutonium Facility operations and experiences to illustrate relevant criticality safety and conduct of operations concepts. The new performance demonstrations and oral boards are significantly more rigorous than anything required by the old certification process.

Taken together, it appears that the new FMH certification process is a more credible approach to instilling and then testing required knowledge and understanding than has been used in the past at the Plutonium Facility or is typically used elsewhere at the laboratory. All Plutonium Facility FMHs and their supervisors are currently undergoing recertification using the new process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

December 30, 2011

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: B.P. Broderick and R.T. Davis

SUBJECT: Los Alamos Report for Week Ending December 30, 2011

This report is filed for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 6, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 6, 2012

Transuranic Waste Operations: In 2005, the Department of Energy/National Nuclear Security Administration (DOE/NNSA) and the New Mexico Environment Department (NMED) entered into a formal Compliance Order on Consent (Consent Order) that set legally-binding schedule milestones for environmental remediation and restoration activities at LANL. A key Consent Order milestone results in the termination of activities and closure of Area G, which drives a need to remove all above-ground and retrievable below-ground transuranic waste from Area G and complete all necessary environmental corrective measures by the end of 2015.

This week, DOE/NNSA and NMED jointly issued a new Framework Agreement that describes a realignment of environmental priorities at LANL. The Framework Agreement differentiates between different types of Area G transuranic waste based on the relative risk of the material being released or dispersed in accidents, including wildland fires. On this basis, above-ground non-cemented transuranic waste receives a higher priority for disposition than cemented or below-ground transuranic waste. The Framework Agreement includes the following DOE/NNSA commitments:

- Complete removal of all non-cemented above-ground legacy transuranic waste at Area G by June 30, 2014;
- Complete removal of all newly generated transuranic waste that is received at Area G in FY12 and FY13 by December 31, 2014; and
- Develop, by December 31, 2012, a plan and schedule for the removal of retrievable below-ground transuranic waste at Area G.

Although all parties to the Consent Order endorse the Framework Agreement, it is not legally-binding and the existing Consent Order remains in force. In conjunction with this week's joint issuance of the Framework Agreement, DOE/NNSA publically acknowledged that it is not possible to meet the current Consent Order milestone to complete Area G clean-up activities by the end of 2015. The Framework Agreement notes that DOE/NNSA and NMED will meet at an appropriate time to consider Consent Order changes.

Federal Oversight: In September, the site office requested LANL to evaluate Plutonium Facility and Waste Disposition Project nuclear safety issues; determine deficiencies, causal factors and the extent of problematic conditions across the site; and provide a comprehensive report on planned actions and a suite of performance metrics to monitor conditions and progress. In December, LANL responded to this request and submitted the LANS Nuclear Safety Culture Analysis and Improvement Plan, which details the site's plans for review and causal analysis of nuclear safety issues. A project team has been assigned to execute this plan and LANL intends to implement corrective actions as they are identified by the team. In addition, an initial set of performance metrics, which will be refined as the project progresses, have been identified to track improvements in nuclear safety. At this point, the LANL submittal only provides an initial plan for identification of nuclear safety improvements in Fiscal Year 2012.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 20, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 20, 2012

Transuranic Waste Operations: The site office recently provided comments to LANL on Area G Documented Safety Analysis and Technical Safety Requirements (TSRs) changes associated with minimum shift staffing requirements and drum venting operations. LANL plans to resubmit these changes later this month to resolve site office comments.

In October, LANL requested site office approval to revise the safety basis minimum shift staffing requirements that preclude working alone for certain activities not involving transuranic waste operations at Area G. The revised TSRs require a Shift Operations Supervisor, an Operations Center operator, and a nuclear operator with a fire watch operator on call (i.e. able to respond within 2 hours) for operations when material-at-risk is present and transuranic waste operational activities are being performed. The safety basis also requires all of these personnel to be on call when material-at-risk is present but transuranic waste operational activities are not being performed. Transuranic waste operational activities are defined as active waste handling (e.g. waste container movement, characterization and processing). The LANL request noted that the changes will ensure that minimum staff are available to perform TSR actions when required and are consistent with the NNSA Technical Bulletin on minimum staffing.

In November, LANL also requested changes to the Area G safety basis to support drum venting using the Area G Drum Venting System (DVS) in a remote configuration (i.e. with operator standoff requirements during key venting operations). Startup of this operation without the remote configuration failed in 2011 when questions arose during the contractor readiness assessment about non-conservative hydrogen deflagration assumptions in the safety basis (see 4/22/11 site rep report). The safety basis changes are based on controls required for previous remote venting operations, the planned DVS operations and the updated analysis to support the Area G Basis for Interim Operation. LANL has not performed drum venting operations since the deflagration event that occurred in November 2008 during previous remote venting operations.

Federal Oversight: As a part of the fiscal year 2012 performance based incentives, the site office included a measure for the contractor's ability to integrate and execute mission and safety commitments. Based on feedback from NNSA on a previous submittal, LANL recently provided a proposed list of milestones to measure success in this area that included the following:

- Plutonium Facility – Conduct of Operations improvements, criticality safety improvements, seismic safety improvements and material stabilization progress
- Safety Basis – High quality, on schedule safety basis submittals, and a schedule for safety basis annual updates
- Transuranic Waste Operations – RANT shipping facility safety basis submittal, readiness for 231 Permacon box line and drum venting operations, de-inventory MDA-B, ship 22,500 PE-Ci offsite from Area G, implement DOE Order 426.2, reduce NCR closure times and submit corrective action plan for initial nuclear safety culture causal analysis (last item due 3/12/12)
- Chemistry and Metallurgy Building – Improve Fissile Material Handler training and certification, and complete scheduled vital safety system assessments
- Weapons Engineering Tritium Facility – Startup gas transfer operations from the function tester through the load out and high pressure gloveboxes

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

January 27, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending January 27, 2012

Plutonium Facility: This week, Plutonium Facility management declared a TSR violation based on the failure to perform a required In-Service Inspection (ISI) on a safety significant design feature. The Plutonium Facility safety basis requires the use of credited containers for all operations that could produce molten plutonium metal. These containers provide a confinement barrier for molten plutonium in the event of a process or furnace upset. Recently, Plutonium Facility personnel discovered an infrequently used process that creates molten plutonium metal. The containers used in this process are made of the correct material for molten plutonium processing, but the containers had not been subjected to the applicable ISI as required by the TSR.

Chemistry and Metallurgy Research (CMR) Building: The CMR safety basis credits shielding associated with CMR's Waste Assay Facility (WAF) as a safety significant design feature to protect workers from radiation produced by radiation generating devices inside the WAF. The CMR TSRs require an ISI to be performed on the WAF shielding every two years. Personnel must be qualified to perform this inspection by completing a computer based self-assessment and a performance demonstration of the ISI procedure. During a Vital Safety System Assessment, CMR personnel recognized that the most recent WAF shielding ISI was performed by an individual who had completed the self-assessment, but not the required performance demonstration and was therefore not qualified to perform the inspection. This discovery prompted facility management to declare a TSR violation based on the failure to satisfactorily perform an ISI within the required frequency. In response to this violation, facility personnel are performing an extent of condition review to identify any other TSR-level inspections or Surveillance Requirements that may have been performed by unqualified personnel.

Transuranic Waste Operations: Recently, LANL consolidated all Fiberglass Reinforced Plywood (FRP) boxes into a single dome in Area G that has an operable fire suppression system. This action improves the safety posture for these transuranic waste forms in the interim as Area G personnel continue to disposition these items. The FRP boxes contain legacy contaminated equipment and debris from decommissioning the TA-21 Plutonium Facility in the 1970s. LANL is currently processing FRP boxes in Building 412. This year, LANL plans to startup FRP processing lines in the Dome 231 Permacon and in Dome 375. FRP processing activities at less than 2.5 PE-Ci are covered under the Area G safety basis for sort, segregate and size reduction activities. For a small number of large FRP boxes, LANL plans to perform processing activities (i.e., waste removal, size reduction and repackaging) in-place, using confinement tents erected around the large boxes; however, this activity is not scheduled for 2012.

Safety Basis: This week, the site office approved a proposed revision to the LANL Unreviewed Safety Question (USQ) Procedure to incorporate changes to DOE Guide 424.1-1B, *Implementation Guide for Use in Addressing Unreviewed Safety Question Requirements*. The revision also provides improved linkage between the USQ and new information processes, includes required actions times in response to a potential inadequacy in the safety analysis, and adds an expert-based USQ screening process (the last will be piloted and reviewed during the next year). The site office approval notes that the LANL new information process needs to be substantially improved or discontinued and requests detailed contractor review of the process. A report on lessons learned and the advantages/disadvantages of continuing this process is requested by May 1, 2012.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 3, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 3, 2012

Plutonium Facility: The Plutonium Facility safety basis credits the criticality alarm system as a safety significant control for worker protection. Plutonium Facility TSRs require a quarterly channel function test to ensure the system will produce an alarm when detector heads in the vault indicate radiation levels at or below 75 mR/hr. A quarterly channel function test of the criticality alarm system was performed in December. During this test all four detector channels in the vault were recorded as producing alarms at 80 mR/hr. Personnel performing the test and subsequent reviewers did not recognize that these results failed to meet the acceptance criteria and documented the surveillance as being completed satisfactorily. This week, the cognizant system engineer for the criticality alarm system was reviewing completed surveillance documentation and recognized the error. Plutonium Facility management declared a TSR violation based on this discovery. Facility personnel have reperformed the channel function test and all four vault detector heads were found to produce alarms at or below 75 mR/hr, as required.

Weapons Engineering Tritium Facility (WETF): Personnel at WETF measure the composition of gas mixtures using a Hot Inlet System that contains piping to route gas samples through various diagnostic instruments. In October 2010, facility operators discovered that small amounts of oxygen were leaking into the Hot Inlet System where under uncontrolled conditions it could potentially mix with hydrogen isotopes to form a combustible atmosphere. Since this situation presented a deflagration hazard that had not been analyzed in the WETF safety basis, facility management declared a Potential Inadequacy of the Safety Analysis (PISA) and in July 2011 implemented a Justification for Continued Operations that contained controls to prevent a deflagration from Hot Inlet System oxygen in-leakage.

After successfully operating under this JCO for approximately one month, facility personnel discovered another oxygen in-leakage pathway that affected the safety-significant Tritium Waste Treatment System (TWTS). This discovery prompted another PISA and the JCO was revised to include new controls to address the TWTS in-leakage. Before the revised JCO was implemented, facility management submitted a safety basis page change package that updated the WETF Final Safety Analysis Report and TSRs to include oxygen in-leakage hazards and controls. In the Safety Evaluation Report approving this package, the NNSA site office explicitly identified the Hot Inlet System as a safety significant control. In response, LANL management submitted another safety basis page change that was intended to present a technical justification to remove the Hot Inlet System as a safety significant control.

This week, the NNSA site office disapproved the proposed safety basis change concluding that the entire Hot Inlet System serves a safety significant function by protecting workers from tritium releases and deflagrations. In response, WETF personnel are preparing a revision to the oxygen in-leakage JCO for NNSA review and approval that will address the Hot Inlet System until the functional classification issues are resolved. The facility remains in warm standby mode with programmatic tritium gas handling operations suspended pending approval and implementation of the revised JCO.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 10, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 10, 2012

This week, staff members Hadjian, Kimball, McCabe, and Pasko met with NNSA-Headquarters, site office, and contractor personnel to discuss completed and ongoing analyses of the Plutonium Facility seismic response including plans to perform a static non-linear analysis, which is scheduled to be complete in June and may identify the need for additional structural upgrades.

Plutonium Facility: On Tuesday, Plutonium Facility personnel discovered a leak in the safety class fire suppression system when operators observed water on the floor of a laboratory room used for pit manufacturing. Upon discovery, personnel isolated the affected portion of system piping, entered the applicable TSR Limiting Condition for Operation and instituted a fire watch. The system was repaired, confirmed to be operable and returned to service by the end of Tuesday.

The leak developed at an elbow joint in the fire suppression system piping. The failed joint fitting was installed during system modifications performed in 2005. Preliminary evaluation of the failed fitting suggested a hairline crack may have developed due to over-tightening of the tapered threaded connection during installation. Results of more detailed metallurgical evaluation are pending. In response to this event, facility management has directed engineering personnel to develop a plan to inspect system piping and components as part of an extent of condition review. The extent of condition inspections will focus on other components that were installed during the 2005 system modification, but will also involve a sampling of older components.

Weapons Engineering Tritium Facility (WETF): LANL recently submitted a revised Justification for Continued Operations (JCO) that includes compensatory measures for the Hot Inlet System. As discussed last week, the site office disapproved a proposed WETF safety basis change to downgrade the Hot Inlet System from safety significant noting that the system protects workers from tritium releases and deflagration accidents. The revised JCO includes compensatory measures that establish an engineering and maintenance work package to identify and repair Hot Inlet System leaks. In addition, maintenance and modifications to this system will be performed in accordance with Management Level 2 requirements, which is consistent with expectations for a safety significant system. Programmatic tritium gas handling operations remain suspended pending site office approval and implementation of the revised JCO.

Radioactive Liquid Waste Treatment Facility (RLWTF): In November 2011, the site office disapproved a LANL safety basis strategy for developing a 10 CFR 830 rule compliant Documented Safety Analysis (DSA) over 18 months and requested the safety basis be submitted by September 2012. The disapproval noted that the facility is not complex, hazards are well understood, basic controls to ensure safe operations are established, and much of the required DSA information is contained in the existing Final Safety Analysis Report (FSAR). This week, LANL submitted a plan for upgrading the safety basis consistent with DOE Standard 3009 and for addressing outstanding site office comments. RLWTF is currently operating under a FSAR that was approved in 1995.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 17, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 17, 2012

Chemistry and Metallurgy Research Replacement (CMRR): This week, NNSA-Headquarters provided direction to LANL on the CMRR-Nuclear Facility (CMRR-NF) noting that, consistent with the President's budget, no funding is requested for the facility and construction of the CMRR-NF is deferred for at least five years. The budget request includes \$35M to accelerate actions to optimize storage capacity in the existing Plutonium Facility vault. The NNSA-Headquarters direction notes that the budget request will require optimized use of existing infrastructure to maintain continuity of programmatic activities. LANL is requested to provide an interim briefing in 30 days and a final plan in 60 days that include the following elements:

- A plan to substantially complete CMRR-NF design by the end of FY 2012 including design close-out activities to ensure project documentation is available for potential future use.
- An orderly phase out of NNSA program activities at the existing Chemistry and Metallurgy Research Building concluding in approximately 2019 (following completion of the Confinement Vessel Disposition project in Wing 9).
- Plans for continued analytical chemistry capabilities to support mission needs that include maximum use of the Radiological Laboratory, Utility and Office Building (RLUOB).
- Capability to safely and securely move material between RLUOB and the Plutonium Facility and address sample preparation at the Plutonium Facility.
- Consider options at other NNSA sites to address residual analytical chemistry needs.
- Maintain required material characterization capabilities using the Plutonium Facility and Building 332 at Livermore as a Hazard Category 2, Security Category 3 nuclear facility.
- Minimize nuclear material at the Plutonium Facility by processing, packaging, and shipping excess materials including a plan and estimated timeline to stage bulk quantities at the Device Assembly Facility.

Plutonium Facility: This week, LANL requested site office review and approval of an Evaluation of the Safety of the Situation (ESS) for a potential criticality safety issue for the Confinement Pressure Vessels (CPVs) stored at TA-55. In January, LANL identified that no existing criticality safety evaluation (CSE) exists to support storage and movement of these vessels contrary to statements in the TA-55 Hazard Analysis. Immediate actions were taken to ensure the CPVs were not moved and this issue was evaluated and determined to be an Unreviewed Safety Question. The ESS concludes that there is essentially no potential for an inadvertent criticality as long as the CPVs are not moved. The ESS states that the compensatory measure on movement will remain in place until LANL develops CSEs that support storage and movement at TA-55. LANL plans to transfer and disposition these vessels during the Confinement Vessel Disposition Project at CMR.

Federal Oversight: The NNSA office issued a letter to LANL this week noting ten operational events in the last month that indicate potential issues with control and integration of work activities. The letter requests LANL evaluate the events and identify common cause and systemic issues. The laboratory also continues actions associated with the LANS Nuclear Safety Culture Analysis and Improvement Plan that responds to a September 2011 site office request on improving nuclear safety.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

February 24, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending February 24, 2012

Plutonium Facility: The approved, but not yet implemented, 2011 annual update to the Plutonium Facility DSA asserts the mitigated offsite dose for the bounding postulated facility accident involving a seismically-induced fire is 23 rem, a value just below the DOE Evaluation Guideline. The 2011 DSA relies on two key elements to support this significant reduction of consequences compared to previous safety analyses: (1) an assumption that all structural features of the safety class building that could fail in an evaluation-basis earthquake and cause facility collapse or loss of confinement will be identified and fixed prior to implementation of the 2011 DSA, and (2) refined assumptions and analysis associated with the seismically-induced fire scenario that reduce the material at risk (factor of ~2), the airborne release fractions and respirable fractions of materials (factor of ~30), and the leak path factor (factor of ~2).

Laboratory personnel are in the process of performing an important static non-linear analysis scheduled to complete in June that will determine whether additional structural vulnerabilities exist that could lead to facility collapse or loss of radiological confinement. In parallel, LANL and NNSA have aggressively pursued and completed upgrades to repair known structural vulnerabilities. These upgrades include plenum room beam-to-column connections (complete July 2011), glovebox exhaust fan pads (complete October 2011), plenum room captured columns (complete August 2011), concrete shield wall connections (complete November 2011), roof drag strut (complete November 2011), laboratory ceiling beams (complete December 2011), and mezzanine upgrades. Last week, Plutonium Facility personnel finished field work on the last of five mezzanines that required modifications. This marked physical completion of all currently planned facility upgrades pending results of the static non-linear analysis.

Analytically, the 2011 DSA reduced the material at risk by imposing more stringent limits on the amount of inventory allowed on the facility's laboratory floor. Dispersibility parameters were reduced by disaggregating the material at risk and analyzing the dispersibility characteristics of each specific form of material (e.g. metals, oxides, and solutions). The leak path factor was reduced based on revised fire analysis that concludes a seismic event will cause a number of individual lab room fires rather than a large floor-wide fire, as previously assumed. Smaller fires with lower overall thermal output contribute less motive force to drive aerosolized material out of the building and result in a reduced leak path factor.

The revised fire analysis concludes that the new seismically-induced fire scenario should assume one "probabilistic fire" and three "deterministic fires." The probabilistic fire is based on statistical analysis of 80 years of seismically-induced fire ignition data from Alaska and California for all structures in the "generally built environment," that is, all residential, commercial, and industrial structures. The deterministic fires are postulated to occur in lab rooms that operate high temperature furnaces that intentionally take plutonium metal to a molten state. Last week, LANL management submitted a DSA revision for NNSA review and approval that includes additional technical discussion of the revised fire analysis and how it was used in developing the new seismically-induced fire scenario in the DSA. The DSA revision provides new justification to support the assumption that only furnaces that produce molten plutonium metal, rather than all high temperature furnaces, present an increased probability of seismically-induced fire ignition in relation to the generally-built environment. The DSA revision also provides a technical argument that the new leak path factor analysis is conservative because its final calculated value assumes four lab room fires in each half of the building for a total of eight room fires.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 2, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 2, 2012

Staff members T. Cutler, E. Elliott and J. Pasko were onsite this week to observe an NNSA-Headquarters review of the LANL criticality safety program.

Transuranic Waste Operations: This week, RANT shipping facility management declared a Technical Safety Requirement (TSR) violation based on a failure to comply with the Vehicle Access Control specific administrative control (SAC). This SAC credits the control of vehicle access features, such as gates and bollards to reduce the probability of vehicle impacts and subsequent fuel pool fires that could impinge on transuranic waste.

Last Friday, a LASO Facility Representative arrived at the RANT shipping facility and discovered a vehicle access gate open and unmanned. The Facility Representative alerted facility management and the gate was closed, the RANT facility yard was inspected for unauthorized vehicles (none were present), and the RANT operations crew was briefed on the need to maintain control of vehicle access features. RANT shipping facility procedures address gate control when transuranic waste is being moved into or out of the facility or yard, but not all vehicle access gate openings are procedurally controlled. In this case, a vehicle access gate was opened to allow the passage of a forklift and operators forgot to restore the gate to a closed position.

Material Disposal Area-B (MDA-B): Early this week, LANL completed removal of all material at risk that was excavated from MDA-B in Technical Area-21. MDA-B is a six-acre legacy waste disposal area that was used to bury radiological and chemical waste in the late-1940s and is close to public areas. Removal of this legacy waste represents a significant achievement in reducing the hazards at Technical Area-21.

Transuranic Waste Operations – Safety Basis: On Thursday, the site office approved the Area-G Basis for Interim Operations (BIO) and TSRs that were submitted in January 2012. This safety basis was developed and approved in accordance with 10 CFR 830 and represents the first major revision to the Area-G safety basis since 2003. The site office identified the following three conditions of approval: 1) elevate the current requirement for overburden (currently an element of a safety management program) to a specific administrative control or design feature; 2) elevate the requirement to use non-sparking tools as a control for certain deflagration accident scenarios and; 3) analyze hazards associated with acetylene, derive appropriate controls, and incorporate these controls into the BIO and TSRs. All of the conditions of approval are due in 90 days.

As part of the next annual update for Area-G, the site office requested that LANL re-evaluate hazard and accident analyses without taking specific risk reduction credit for safety management programs (with the exception of the criticality safety program). In addition, the site office directed that the accident analysis dose consequences be re-calculated using atmospheric modeling that does not use plume meander. The site office approval letter directs the laboratory to submit an implementation plan for the new safety basis within 30 days that reflects full TSR implementation at Area-G within 6 months.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 9, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 9, 2012

Management: This week, LANL senior management announced the selection of two key contractor positions. First, Jeff Yarbrough was selected as the Associate Director for Plutonium Science and Manufacturing replacing Carl Beard, who is now the Principal Associate Director for Business and Operations. Second, Charles Anderson was identified as the Associate Director for Nuclear and High Hazard Operations. Mr. Anderson has been acting in this position for approximately 8 months.

Chemistry and Metallurgy Research Building (CMR): The CMR TSRs credit a flammable gas control to limit the quantity of flammable gases such that the lower flammability limit (LFL) cannot be exceeded in a storage volume if the entire contents of a gas source are released. On February 15th, CMR personnel discovered a small propane bottle in an unmarked and nondescript plumber's kit stored in a cabinet. This source and storage configuration did not comply with the requirements of the flammable gas control in the CMR TSR document. In response, facility management entered the applicable TSR action statements, relocated the propane bottle to a compliant storage location, and initiated an extent of condition review to identify any similar problems elsewhere in CMR.

This week, as part of the extent of condition review, CMR personnel discovered another propane bottle in an identical plumber's kit that was stored in a location where the LFL could be exceeded if the bottle released its entire contents. In response, facility management again took appropriate response actions and declared a TSR violation. The extent of condition review will continue until all required areas of the facility have been searched for inappropriately stored flammable gases.

Weapons Engineering Tritium Facility (WETF): Facility procedures require WETF gloveboxes to be leak tested by drawing a vacuum on the affected glovebox and measuring the pressure rate-of-rise and then pressurizing the affected glovebox and measuring pressure rate-of-fall. This week, WETF personnel were performing the vacuum portion of the leak testing procedure when oxygen alarms annunciated inside affected glovebox sections. Operators immediately terminated the test and purged the glovebox sections with nitrogen, forcing the oxygen into the Low Pressure Receiver (LPR) intake section of the Tritium Waste Treatment System. Oxygen readings inside the glovebox sections reached a maximum of about 5.5%, but oxygen readings inside the LPR remained well below 1%.

The WETF safety basis includes a Specific Administrative Control (SAC) that is designed to reduce the probability of forming a deflagrable mixture of gases inside the LPR. This SAC is applicable to open glovebox maintenance (e.g. maintenance that requires a glovebox window to be removed) and other operations that could intentionally introduce enough oxygen into the LPR to challenge the limiting oxygen concentration (LOC) for combustion. When applicable, this SAC requires material at risk to be "segmented" within affected glovebox sections by closing and tagging valves. During a critique for the oxygen alarm event, facility management recognized that the LPR oxygen concentration never approached the LOC of 5% in this instance; however, upset conditions during glovebox leak testing could credibly challenge the LOC in the LPR. The ability to challenge the LOC in the LPR would invoke SAC requirements, including segmentation. Since MAR was not formally segmented during the glovebox leak testing evolution, facility management declared a TSR violation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 16, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 16, 2012

Emergency Preparedness: This week, laboratory, NNSA and Los Alamos County personnel participated in an emergency exercise that simulated an earthquake followed by a wildland fire. The exercise scenario involved a magnitude 5.6 earthquake that initiated a small wildland fire in Technical Area 52. Transportation routes and communications were assumed to be impacted, but no catastrophic structural failures or material releases were postulated for nuclear or high hazard facilities. This is first time in recent years that the laboratory has performed an exercise involving a sitewide rather than facility-specific event. Exercise evaluators are compiling information about performance during the exercise and will issue a report that includes lessons learned and opportunities for improvement. Lab management intends to continue improving emergency response planning and execution for sitewide events by exercising increasingly challenging scenarios over time.

Plutonium Facility: Radiological material is authorized to be staged in several locations within the protected area outside of the Plutonium Facility. Containerized transuranic waste can be staged on an outdoor asphalt pad and material associated with the Offsite Source Recovery Project (OSRP) can be staged in an outdoor transportainer. The Plutonium Facility safety basis credits a specific administrative control (SAC) that prohibits vehicle refueling activities from being conducted within 100 feet of the transuranic waste pad or OSRP transportainer. The intent of this control is to prevent liquid fuel fires from directly impacting the transuranic waste containers or OSRP material.

Recently, an NNSA Facility Representative questioned whether other refueling operations that did not involve vehicles were being conducted near the waste pad or OSRP transportainer that could create the opportunity for liquid fuel fires and violate the intent of the SAC. In evaluating this concern, facility personnel recognized that an underground diesel fuel tank that supplies a pump house for the safety class Plutonium Facility fire suppression system is located approximately 40 feet away from the transuranic waste pad. This roughly 580 gallon tank is refueled about every six months and these operations create the possibility of initiating a liquid fuel fire that could directly impact the containerized transuranic waste staged on the pad. This week, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis in response to this issue.

Transuranic Waste Operations: The NNSA site office recently approved a revision to the RANT shipping facility Basis for Interim Operation (BIO) and Technical Safety Requirements (TSRs) to incorporate updated details and hydraulic calculations for the fire suppression system (FSS). An assessment of the FSS concluded that the field conditions did not align with system drawings that were used for the hydraulic calculations. The site office approval letter directs LANL to submit an equivalency to National Fire Protection Association (NFPA) Standard 13 within 90 days to resolve a non-compliance with requirements for minimum sprinkler spacing. The BIO notes that the FSS meets NFPA 13 minimum flow density requirements (0.2 gpm/ft^2) despite the non-compliance.

In February, an NNSA Facility Representative identified conflicting requirements in the RANT TSRs for critical lift plans for transuranic waste container handling. The NNSA approval letter also directs a change to the SAC for hoisting and rigging to clarify when critical lift plans are required.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 23, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 23, 2012

Staff members F. Bamdad, T. Chapman, C. March, J. Pasko and R. Verhaagen were onsite this week to review the 2011 update of the Plutonium Facility Documented Safety Analysis (DSA) and Technical Safety Requirements (TSRs).

Federal Management: Recently, NNSA announced the selection of Juan Griego as the LASO Deputy Site Office Manager. Mr. Griego has been acting in this role since August 2011 and was previously the Assistant Manager for National Security Missions.

Plutonium Facility – Safety Basis: LANL continues activities to implement the 2011 DSA and TSRs, which are currently scheduled to be complete by May 25, 2012. The laboratory has also submitted two minor revisions (revision 1.1 and 1.1a) to this safety basis to clarify and correct the DSA and TSRs and to resolve site office comments. In addition, the facility is operating under the Justification for Continued Operations (JCO) for seismic-structural vulnerabilities that will expire on May 11th. LANL has requested site office approval to extend the JCO expiration date to align with the DSA and TSR implementation schedule. All physical upgrades identified in the JCO have been completed and controls on Mezzanine loading and cement silo level are included in the new safety basis. The site office is reviewing the minor safety basis changes and JCO extension request. LANL and subcontractor personnel are also completing a static non-linear analysis of the facility to determine if additional facility upgrades are required.

Weapons Engineering Tritium Facility (WETF): In November 2008, LANL identified a Potential Inadequacy of the Safety Analysis (PISA) because certain tritium containment vessels may exceed their maximum allowable working pressure (MAWP) under accident conditions (i.e. fire). A number of 1980s-vintage tritium-bearing components are stored for surveillance at WETF in credited containment vessels known as Standard Tubs. As a credited containment vessel, the MAWP of Standard Tubs is required to be defined and protected. Since 2008, the WETF facility has been operating under a JCO associated with these containment vessels.

WETF personnel now plan to disposition these vessels by packaging them in Flanged Tritium Waste Containers (FTWCs) and shipping them to Area G for disposal. Earlier this month, LANL requested an extension to the JCO for the Standard Tubs to April 20th to allow completion of the overpacking activity. The activity will include loading, closure, leak checking and over-packing the FTWCs for transport to Area G for disposal. WETF personnel have procured the required equipment, developed procedures and trained operators. A management self assessment was recently completed and WETF personnel plan to begin a contractor readiness assessment on Monday. In addition, the laboratory has completed a system adequacy analysis of the FTWC and requested a safety basis change to use these containers to package existing tritium containment vessels with vulnerabilities (including the Standard Tubs).

To support shipment and disposition of the tritium-bearing Standard Tubs inside FTWCs at Area G, LANL has also completed waste disposal reports and a risk analysis.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

March 30, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending March 30, 2012

Area G: The Area G TSRs credit overburdens as design features to protect low level waste in disposal pits from accident conditions that could cause the material to be dispersed. The design feature requires, “6 inch minimum fill material overburden on exposed low level waste pit layer – operational cover for active pit.” Last week, a site office Facility Representative questioned why an exposed portion of an active low level waste pit at Area G was not covered by an overburden.

Area G personnel had historically interpreted language from the accident analysis in the Area G DSA to conclude that the overburden design feature was only applicable when greater than 500 PE-Ci of low level waste was exposed in an active waste pit. Since far less than 500 PE-Ci was exposed in the pit observed by the Facility Representative, Area G personnel did not believe the overburden was required. This week, upon evaluation, Area G management concluded that the 500 PE-Ci applicability interpretation did not comply with the TSRs as written and suspended low level waste operations until a revision to the TSRs can be reviewed and approved by NNSA.

Radioactive Liquid Waste Treatment Facility – Upgrade (RLWTF-UP) Project: This week the site office provided NNSA-Headquarters a path forward for development and selection of safety basis controls for the RLWTF-UP Project. In July 2010, NNSA provided direction to LANL to re-evaluate options for this project to reduce cost. LANL subsequently recommended separating the transuranic and low-level waste processes into individual structures. The project path forward that includes separate facilities was accepted by NNSA in 2011. The low-level processing operations and common utilities would be located in a less-than-hazard-category 3 facility planned for completion in 2017. The transuranic processing operations would be located in a hazard category 3 nuclear facility planned for completion in 2020.

The path forward notes that LANL will be directed to identify anticipated engineered and administrative safety controls for the transuranic processing facility as part of the safety design strategy. The site office letter also notes that the quantity of transuranic liquid waste that requires processing has been low recently (averaging 6 to 9 Ci/year since 1994). Based on this low processing need, NNSA will also request LANL to perform an engineering study and make recommendations on alternate locations for the transuranic liquid waste processing portion of this project that considers expected mission need along with improved nuclear safety, waste minimization and life-cycle costs. This study may obviate the need to collocate hazard category 3 and radiological operations.

Plutonium Facility: This week, LANL transmitted a positive Unreviewed Safety Question determination to the site office associated with the refueling of an underground diesel fuel tank that supplies a pump house for the safety class Plutonium Facility fire suppression system. The following compensatory measures remain in place for this issue: refueling of the underground diesel fuel tank only when required, refueling operations will be performed under a work package that includes a fire watch and traffic control, training for personnel that perform the refueling operation and ensuring refueling vehicles meet safety basis requirements.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 6, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 6, 2012

Area G – Safety Basis: The Area G safety basis includes a TSR-level control to ensure the inventory of exposed low level waste in active disposal pits does not exceed 500 ²³⁹Pu-equivalent curies (PE-Ci). Surveillances are required to be performed quarterly to verify compliance with this low level waste inventory limit. In September 2011, Area G management declared a TSR violation based on a failure to satisfactorily perform the low level waste inventory surveillance within its required periodicity. The September 2011 violation was based on a discovery that the implementing procedure for the low level waste inventory surveillance directed operators to obtain inventory data from a database that was no longer being updated with real-time low level waste inventory information. The TSR violation resulted from the credited surveillance being performed using inaccurate inventory data. In response to this violation, Area G management identified a corrective action to revise the surveillance procedure to query a different data source that contained accurate low level waste inventory information.

This week, Area G personnel discovered that the key corrective action from the September 2011 TSR violation had not been effectively implemented. Although the low level waste inventory surveillance procedure had been revised, it continued to direct operators to obtain inventory data from the same database that is not updated to reflect accurate low level waste inventory information. As a result, the last two credited quarterly surveillances were again performed using inaccurate inventory data. This discovery prompted Area G management to declare another TSR violation. Based on the repeat nature of this violation, Area G management intends to evaluate its existing corrective actions and issues management process to identify and address weaknesses.

Plutonium Facility - The NNSA site office issued a Condition of Approval for the 2008 Plutonium Facility DSA that required LANL to establish a process to evaluate criticality safety controls for inclusion in the DSA, per DOE-STD-3007. As LANL personnel developed modern and compliant criticality safety evaluations, they have used criteria from the Standard to identify a set of criticality safety controls that will be formally credited in the next annual update of the DSA and TSRs.

This week, LANL personnel performing their annual criticality safety process review discovered a safe storing fissile material that did not appear to comply with the requirements of its Criticality Safety Limit Approval (CSLA) document and associated posting. The CSLA requires the safe to remain upright in a seismic event. Additionally, the safe's ability to remain upright in a seismic event was deemed important enough to be credited as safety significant (per DOE-STD-3007) in the next annual update of the DSA and TSRs. The safe is currently mounted on rolling casters and this configuration has not been analyzed to survive a seismic event without toppling. This discovery led to the declaration of a criticality safety infraction and facility management initiated an extent of condition review to identify any similar situations that may exist in the Plutonium Facility. This issue has also been entered into the New Information process to determine whether a Potential Inadequacy of the Safety Analysis exists. As part of this review, facility personnel will evaluate whether a seismic vulnerability for this safe is covered under existing supplementary safety basis documents that address known Plutonium Facility seismic vulnerabilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 13, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 13, 2012

Staff member R. Verhaagen was onsite this week.

Plutonium Facility – Fire Suppression System: This week, LANL began construction on upgrades to a portion of the fire suppression system sprinkler piping to meet Performance Category-3 (PC-3) seismic requirements. In response to Board Recommendation 2009-2, NNSA developed a Project Execution Plan (PEP) to complete a set of Plutonium Facility upgrades that ensure mitigated offsite dose consequences do not challenge the DOE Evaluation Guideline. The fire suppression system upgrades are a key component of this effort and are scheduled to be complete in Fiscal Year 2013. The initial upgrades that have started will help LANL validate cost estimates while designs to upgrade other portions of the system continue development. LANL is also developing design packages and upgrade plans for electrical components that will be used to support the safety class/PC-3 active confinement ventilation capability consistent with the PEP submitted to the Board.

Plutonium Facility – Safety Basis: As reported last week, Plutonium Facility personnel recently discovered a material storage safe equipped with rolling casters that was required by its Criticality Safety Limit Approval to remain upright and in position during a seismic event. In accordance with DOE-STD-3007, the safety function of the safe to remain upright in a seismic event has been deemed sufficiently important to criticality safety to be elevated to the TSR-level in the next annual update of the Plutonium Facility safety basis. Facility personnel have identified three other safes that are currently in-service and storing material that have similarly important seismic requirements that are not yet implemented. This week, Plutonium Facility personnel determined that the situation represented by these safes is not explicitly covered under existing supplementary safety basis documents that address known seismic vulnerabilities for safety class and safety significant controls. In response, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis and implemented compensatory measures to physically restrain the movement of one safe and to prohibit metal storage in the other safes to limit the reactivity of any configuration that could be caused by physical rearrangement of stored materials due to seismic upsets.

Chemistry and Metallurgy Research (CMR) Building: LANL identified a potential criticality safety over-mass condition for a transuranic waste drum at CMR this week. The waste drum was loaded and stored at the facility several years ago with plutonium content recorded by the generator that exceeds the criticality safety limit. During preparations to ship drums to Area G for disposition, facility personnel noted that the generator data for the drum in question identified a plutonium content that exceeded the WIPP waste acceptance criteria but did not initially recognize the potential criticality safety concern. Non-Destructive Assay (NDA) at CMR to evaluate the drum contents indicated significantly lower plutonium content than the generator data. A CMR criticality safety engineer subsequently recognized the potential over-mass condition during a review and appropriate actions were taken to isolate the drum and evaluate the situation. Other corrective actions include the development of a recovery plan to examine and repackage the drum contents and to reconcile the difference in generator data and NDA results.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 20, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 20, 2012

Plutonium Facility: The Plutonium Facility safety basis credits a TSR-level material at risk (MAR) limit of 7500 g Weapons-Grade Pu (WG-Pu) equivalent for individual containers outside of gloveboxes. Plutonium Facility personnel use a software program called MAR Tracker to perform this and other required MAR limit surveillances in the facility. This week, a system engineer discovered an error in MAR Tracker that caused only a small subset of applicable facility containers (roughly 1700 out of 13000 containers) to be checked during the required annual MAR surveillance. This week, facility management declared a TSR violation based on this discovery.

In response to this TSR violation, normal operations have been terminated and the Plutonium Facility has been placed in Standby Mode. Facility personnel have revised the surveillance procedure to allow compliance with container MAR limits to be verified manually, rather than automatically using MAR Tracker, and teams of individuals are working to perform surveillances on all 13000 applicable containers. To date, fifteen containers, all housed in the facility's vault, have been identified with contents that exceed the MAR limit of 7500 g WG-Pu equivalent.

The MAR Tracker error was introduced during software development. To perform surveillances, MAR Tracker imports data from the laboratory's Material Control and Accountability (MC&A) inventory database. The MAR Tracker error resulted from a miscommunication between software developers and security personnel over how to recognize inventory data that corresponded to containers in the MC&A database.

Transuranic Waste Operations: Area G management identified a concern this week with the completion of a TSR surveillance requirement for receipt and placement of low level waste in disposal shafts. The surveillance requires verification that exposed waste inventory is less than 1200 plutonium equivalent curies prior to placement of new waste in a shaft. This surveillance is implemented by a procedure that requires documentation of completion in the waste inventory log book. Although Area G operators noted that the surveillance was completed prior to placement of waste, no log book entries have been made for the surveillance since 2010. As an immediate action, Area G personnel confirmed that all shafts contained less than the inventory limit. The inventory procedure is being revised to address this issue and another low level waste inventory issue identified earlier this.

This week, LANL completed the "red team" review for drum venting operations in Dome 33 of Area G. Red team reviews, which include a senior team of subject matter experts, have been successfully used recently at Area G to assess and improve the state of readiness for startup and restart of activities prior to moving forward with contractor and federal readiness assessments. LANL plans to resume drum venting at Area G later this year in a remote configuration using a containment structure and operator standoff requirements during key venting operations. Drum venting at Area G has not been performed since 2008. The red team completed a thorough review and identified a number of concerns and recommendations in the areas of nuclear safety, operations, maintenance, training and qualification, emergency management, engineering and other areas. Contractor and NNSA readiness assessments are scheduled for May and July, respectively.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

April 27, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending April 27, 2012

Transuranic Waste Operations: Last week, Area G management discovered that criticality safety controls had not been implemented for Fiberglass Reinforced Plywood (FRP) boxes, as required by the Area G Criticality Safety Program. A Criticality Safety Limit Approval (CSLA) for transuranic waste receipt and staging required FRP boxes with greater than 325 Fissile Gram Equivalents (FGE) to be specially controlled. Area G personnel identified five above-ground FRP boxes and one other oversized container that each held greater than 325 FGE, but did not comply with applicable criticality safety controls. In response, Area G management declared a level 3 criticality safety infraction (indicating a total loss of the safety parameter for mass control) and restricted access to areas where the high FGE containers were staged.

To address this discovery, LANL criticality safety personnel analyzed the existing configurations of the over-massed containers and concluded that no special action was necessary to segregate or isolate the affected containers. Area G management removed access restrictions based on this criticality safety analysis. Also as part of the response to this discovery, laboratory personnel found that the CSLA for FRP box processing operations in Building 412 did not evaluate the potential for FRP boxes to have FGE inventories in excess of 1000 g, which is a known condition for the bounding FRP box. The discovery of this CSLA deficiency prompted facility management to declare a Potential Inadequacy of the Safety Analysis (PISA).

Weapons Engineering Tritium Facility (WETF): This week, LANL identified concerns with the performance of a semi-annual TSR surveillance for the safety significant Halon fire suppression system at WETF. As part of this surveillance, WETF personnel verify that the squib actuator valves have not exceeded their service life (five years). Recent performance of this surveillance indicated that the squib valve had potentially exceeded five years and that the previous surveillance recorded the incorrect manufacturer qualification date, which is the basis for evaluating the service life. Although subsequent information indicated that the squib valve was not beyond its service life, the issue highlighted concerns with the conduct of this surveillance. WETF management is developing corrective actions to improve the procedural performance of this TSR surveillance.

WETF recently transitioned from warm standby to operations mode to support the disposition of four tritium containers (Standard Tubs) that may exceed their maximum allowable working pressure under accident conditions. These containers are being overpacked into Flanged Tritium Waste Containers (FTWCs) that will be transferred to Area G for disposal. Currently one FTWC has been loaded and successfully leaked checked to support transfer to Area G.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 4, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 4, 2012

Plutonium Facility: Plutonium Facility management has submitted for site office review and approval a temporary safety basis modification that would allow three types of containers to be credited with damage ratios of less than one. The temporary safety basis modification package requests that the functional classification of Hagan, SAVY-4000, and 3013 containers be upgraded from their current designation of safety significant to safety class and that damage ratios of 5%, 1%, and 0%, respectively, be credited for these containers based on the results of thermal and mechanical insult testing. Upgrading these container types to safety class with damage ratios much less than one will allow facility personnel to address the recent discovery of 17 containers stored in the vault that exceed the TSR-level individual container material-at-risk limit. Many of these 17 items are already stored in Hagan, SAVY-4000 or 3013 containers, and all but one of the remaining items (a 55-gallon drum) can be overpacked into one of these containers to restore compliance with the TSR limit. LANL personnel intend to capture these three container types as safety class in the 2012 DSA Annual Update and retire the temporary safety basis modification.

Weapons Engineering Tritium Facility (WETF): As discussed last week, LANL is overpacking four Standard Tub containers into Flanged Tritium Waste Containers (FTWCs) for disposal at Area G. Although all containers have now been overpacked, only one of three FTWCs has passed the required leak test. Based on discussions with the vendor, WETF personnel have increased the torque used on the container and will re-perform the leak check on one of the remaining FTWCs early next week.

This week, WETF management declared a Technical Safety Requirement (TSR) violation based on the failure to appropriately perform a TSR surveillance for the battery associated with the safety significant Halon fire suppression system. Based on questions from an NNSA facility representative, WETF personnel concluded that the recently completed surveillance for the battery discharge test was not performed consistent with the description of the surveillance in the bases section of the TSR. In February, WETF completed implementation of a safety basis update that included changes to the TSR bases for this surveillance. The revision includes requirements for a 24 hour discharge period followed by a five minute full fire alarm load test. Previously (and during the most recent surveillance), facility personnel performed the battery discharge test using an accelerated discharge device consistent with a site-wide preventive maintenance procedure. WETF is revising the surveillance procedure to be consistent with the TSR description and developing corrective actions for this issue.

Safety Basis: During last year's Las Conchas fire, aircraft were used as part of the overall wildland firefighting and containment effort. This week, LANL management responded to an NNSA site office request by submitting an evaluation of aircraft crash probabilities for firefighting aircraft. Laboratory analysts concluded that crash probabilities did not exceed 10^{-7} per fight directly over a nuclear facility and therefore no additional controls are necessary to protect LANL nuclear facilities from firefighting aircraft crashes.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 18, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 18, 2012

Weapons Engineering Tritium Facility (WETF): This week, LANL successfully transferred three Flanged Tritium Waste Containers to Area G for disposal. This action reduces the material at risk in WETF and eliminates four containers that were the subject of a November 2008 Potential Inadequacy of the Safety Analysis (PISA) due to overpressure concerns during a fire accident scenario.

Radioactive Liquid Waste Treatment Facility (RLWTF): Last week, RLWTF management declared a PISA based on the discovery that the actual configuration of a portion of the transuranic liquid waste receipt and distribution system did not match the configuration described in the facility's safety basis. Transuranic liquid waste is received from the Plutonium Facility into one of two tanks in an underground reinforced concrete vault adjacent to the RLWTF. According to the RLWTF safety basis, the two transuranic liquid waste receipt tanks would overflow to a sump in the concrete vault and a manually operated pump could be used to transfer liquid from the sump to a portion of the system normally used to receive low level liquid waste. Facility personnel recently discovered that contrary to the safety basis description, the transuranic waste receipt tanks were plumbed to route overflowed material directly into a low level waste receipt tank and that the sump pump in the concrete vault would automatically (vice manually) transfer liquid from the sump to the low level waste receipt system. This configuration could result in an unplanned discharge of transuranic liquid into the low level liquid processing portion of the system.

In response to this discovery, RLWTF personnel have completed physical modifications to cause the two transuranic waste receipt tanks to overflow into the concrete vault sump, as described in the safety basis. Personnel are also in the process of modifying the vault sump pump and associated piping to manually transfer overflowed liquid into the transuranic rather than low level portion of the system.

Transuranic Waste Operations: On Tuesday, LANL submitted the Evaluation of the Safety of the Situation (ESS) to address criticality safety issues for Fiberglass Reinforced Plywood (FRP) box processing operations at Area G. Last month, LANL identified several above-ground FRPs (and one other oversized container) that exceed 325 Fissile Gram Equivalents (FGE) and were not specially controlled in accordance with the applicable Criticality Safety Limit Approval (CSLA). The ESS was written to address credible upset limits for the potential processing of these boxes in Building 412, which was not adequately addressed in the CSLA. The path forward identified in the ESS includes 1) not transferring containers to the processing line (a standing order has been issued) 2) a specific criticality safety evaluation will be performed prior to processing containers with greater than 325 FGE and 3) one box with uncertainty in the assay data that indicated greater than 1000 FGE will be re-evaluated (generator information indicates approximately 350 FGE).

Plutonium Facility: Last week, LANL submitted the ESS for safes that were not anchored consistent with criticality safety requirements. The ESS notes that all safes have now been anchored as required and that the safety basis will be updated to include requirements to anchor these safes in the next annual update.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

May 25, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending May 25, 2012

Staff members A. Hadjian, J. Kimball, J. Pasko and C. Shuffler were onsite this week to discuss the seismic analysis of the Plutonium Facility structure, systems and components.

Plutonium Facility – Seismic Safety: This week, NNSA and LANL personnel discussed the status and plans for completing the static non-linear seismic analysis of the Plutonium Facility. Following the completion of the Seismic Analysis of Facilities and Evaluation of Risk (SAFER) project review of the Plutonium Facility, LANL completed a series of facility upgrades to address identified vulnerabilities. NNSA and LANL also decided to perform a static non-linear seismic analysis to determine if other upgrades are required to support the safety function identified in the Documented Safety Analysis (maintain confinement integrity) and to identify whether additional collapse mechanisms need to be addressed. The staff expressed concern over certain inputs for this analysis and the details for modeling the service chase roof slab. LANL plans to perform testing this summer to better characterize the seismic performance for the service chase roof slab.

The site office also provided direction to LANL this week noting that the non-linear modeling needs to be completed expeditiously to determine if there are other deficiencies that need to be addressed in the near term. The letter requests a final report on the analysis by September with preliminary results in July and that NNSA be promptly notified if issues arise that delay this schedule. The letter also directs LANL to update the Plutonium Facility Seismic Project Execution Plan to include any additional out-year testing and analyses that are needed to address facility seismic concerns. While it is important to complete this work in a timely manner, NNSA and LANL need to ensure the results adequately evaluate the Plutonium Facility seismic performance to ensure any needed upgrades are identified and pursued.

Plutonium Facility – Safety Basis: On Friday, LANL requested and received approval of a one month delay in the schedule for implementation of the 2011 Documented Safety Analysis and associated Technical Safety Requirements (TSRs). The previously approved schedule for completion of this effort was May 25th. LANL identified issues and concerns with the implementation of the MAR tracker software, which is used to implement TSR controls for material at risk inventories.

Plutonium Facility – K2 Container Disposition Plan: Earlier this year, LANL provided NNSA with a disposition plan for the K2 containers that contain Plutonium-238 material received from Mound in the 1980's. Six of these containers are currently located in the vault water bath. The site office requested a disposition plan for the K2 containers as part of the closeout of a Potential Inadequacy of the Safety Analysis associated with miscellaneous vault water bath containers late last year. This material is particularly difficult to handle and repackage because of the high dose rates involved. LANL provided two options for disposition of this material as transuranic waste at WIPP. The first option would use existing pipe overpack containers to ship the material as contact handled waste. The second option would ship the material as remote handled transuranic waste and requires development of a shielded container. LANL plans to pursue both of these options in parallel with a schedule for completion in the 2018 timeframe. The site office requested LANL to include these plans in the safety basis during the next annual update and to pursue funding for this activity beginning in 2014.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 1, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 1, 2012

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a Potential Inadequacy of the Safety Analysis (PISA) due to non-conservative oxygen readings for the Oxygen Monitoring System (OMS). The safety significant OMS is used to monitor oxygen concentrations in the Tritium Waste Treatment System Low Pressure Receiver (LPR) and the Tritium Gas Containment System (i.e. gloveboxes). During a review of a 2010 calculation last week, WETF management identified that OMS readings are dependent on pressure at the oxygen sensor and would indicate non-conservative values (i.e. less than the actual oxygen concentration) if the pressure at the sensor fell below the calibration pressure (the OMS is calibrated at atmospheric pressure).

For the LPR, a sample loop that includes a back pressure regulator is used to monitor LPR contents; however, the regulator failed several years ago and has not been repaired or replaced. A manual bypass valve that bypasses the regulator has been used to maintain a back pressure on the oxygen monitor since that time, but there is no surveillance for this pressure and the oxygen monitor's pressure dependence is not addressed in the safety basis. In addition, the setpoint calculation for the OMS does not address pressure uncertainty. Evaluation of this pressure, which is periodically recorded by a facility control system, indicates that the pressure at the sensor has routinely been well below atmospheric pressure. After this issue was recognized last week, the OMS was declared inoperable for both the LPR and glovebox systems and appropriate TSR Limiting Conditions for Operation were entered.

Transuranic Waste Operation: As part of Area G closure activities, LANL plans to startup Fiberglass Reinforced Plywood (FRP) box processing operations in Dome 375 and in the Dome 231 Permacon later this year (box processing is currently performed in Building 412). LANL has constructed a new larger Permacon containment structure in Dome 375 and plans to revise the safety basis to include processing greater than Hazard Category (HC) 2 quantities of waste in this Permacon. Area G personnel plan to perform a concurrent contractor readiness assessment in October for both the Dome 231 and Dome 375 operations prior to processing FRP boxes with greater than hazard category 3 quantities. A federal readiness assessment will be conducted for HC 2 operations in Dome 375.

Safety Basis: Last week, NNSA NA-1 Supplemental Directive Guide 1027, *Guidance on Using Release Fraction and Modern Dosimetric Information*, was formally added to the prime contract for management and operation of LANL. Among other things, this Supplemental Directive uses updated dose conversion factors to modify the threshold inventory values used to determine when a facility must be classified as an HC 2 or 3 nuclear facility, which requires the development of a Documented Safety Analysis. The new inventory threshold values generally allow more radiological material to be present in a facility before it must be classified as HC 2 or 3 (for example, under the new guidance, a facility can contain up to 38g of Pu-239 or 26g of weapons-grade Pu and remain below the HC 3 nuclear facility threshold, up from 8.4g or 6g, respectively). The NNSA site office has requested that laboratory management submit an implementation plan for applying the Supplemental Directive before any changes are made based on the new guidance. Ultimately, several LANL facilities including the Radiological Laboratory and Utility Office Building are expected to attempt to invoke the new inventory threshold values to allow a greater quantity of material to be present in the facility while remaining less than HC 3.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 8, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 8, 2012

Plutonium Facility: On Friday, Plutonium Facility management formally declared the 2011 Documented Safety Analysis (DSA) and associated Technical Safety Requirements (TSR) to be implemented. Prior to declaring implementation, facility personnel closed all pre-implementation findings from an independent Implementation Verification Review (IVR) conducted in May. Chief among the recent actions to close IVR findings was completion of verification and validation activities for changes to the safety-related Material at Risk (MAR) Tracker software and successful performance of all TSR-level MAR surveillance requirements using MAR Tracker. This week's implementation of the 2011 DSA and TSRs retires the 2008 DSA and TSRs and the 2011 Justification for Continued Operation that addresses seismic vulnerabilities of the facility structure.

Federal Oversight: This week, the office of the NNSA Chief of Defense Nuclear Safety (CDNS) completed their biennial review of the Los Alamos Site Office. The CDNS team noted significant improvement in overall performance since the prior review in 2009 with objectives met in all functional areas. Findings were identified in a number of areas; however, significant previous issues identified in 2009 for Maintenance and Startup and Restart of Nuclear Facilities were judged to be adequately resolved. The team also noted that contractor weaknesses in several areas indicate a need for continued strong performance by the site office.

Area G – Safety Basis: This week, the site office responded to the Evaluation of the Safety of the Situation (ESS) and Unreviewed Safety Question Determination (USQD) for criticality safety issues associated with Fiberglass Reinforced Plywood (FRP) box processing and storage at Area G. In April, LANL identified several above-ground FRP boxes that exceed 325 Fissile Gram Equivalents (FGE) and were not specially controlled in accordance with the applicable Criticality Safety Limit Approval document. The USQD performed by LANL was determined to be negative; however, the site office response does not agree with this result because they believe this information could “increase the probability of occurrence of an accident previously evaluated in the facility's documented safety analysis.” The site office concurs with the ESS and requests that LANL re-evaluate the USQD. Consistent with the ESS, LANL will perform a specific criticality safety evaluation prior to processing containers with greater than 325 FGE.

Transuranic Waste Operations: This week, the 1,000th shipment of LANL-generated transuranic waste was sent to the Waste Isolation Pilot Plant in Carlsbad, NM. Also, LANL work to support the Framework Agreement between NNSA and the New Mexico Environmental Department is currently proceeding ahead of schedule in terms of volume shipped, ²³⁹Pu-equivalent curies shipped, and total shipments. To support near-term Framework Agreement work scope, LANL personnel expect to complete field work this month on the installation of a new large Permacon structure in Dome 375 and upgrades to a smaller existing Permacon structure in Dome 231, both at Area G. These Permacons will house FRP box processing lines similar in nature to the processing line currently operating in Building 412 at Area G. This month, LANL personnel also plan to resume drum venting operations in Dome 33, using drums that contain less than Hazard Category 3 quantities of material (i.e. less than 0.52 ²³⁹Pu-equivalent curies).

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 15, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 15, 2012

Technical Area-35 (TA-35): This week, LANL identified a number of fuel rods in TA-35 Building 27 that are not consistent with the criticality safety evaluation for the facility. Operations at this building had previously been suspended in late-May due to the discovery of three fuel rods that were not in the facility or institutional tracking systems. Operations remain suspended pending development and implementation of corrective actions, including site office approval of these actions.

TA-35 Building 27 is categorized as a radiological facility per DOE Standard 1027 and conducts detector experimental activities. In 2011, LANL responded to concerns about the hazard categorization of this building because the amount of material inventory exceeds the Standard 1027 threshold based on criticality safety concerns. LANL concluded that the “nature of the process” for activities conducted in Building 27 precludes criticality consistent DOE supplemental guidance for Standard 1027. A criticality safety evaluation and criticality safety limit approval were developed to describe facility activities related to criticality safety and capture the “nature of the process” argument.

Earlier this year, site office personnel identified concerns with the implementation and basis for these conclusions at TA-35. LANL subsequently developed a programmatic improvement plan to address criticality safety implementation for Building 27. However, these latest issues and concerns indicate the need to revisit the building mission, hazard categorization, or strengthen the “nature of the process” arguments for the building. Programmatic operations at TA-35 Building 27 will remain suspended until LANL develops a corrective action plan that is approved by the site office.

Transuranic Waste Operations: The Area G senior readiness review board reviewed closure of Management Self Assessment pre-start findings and recommended start-up of drum venting operations for less than hazard category 3 quantity drums this week. Contractor and federal readiness assessments are scheduled to be performed prior to conducting operations at greater than hazard category 3 quantities.

Radioactive Liquid Waste Treatment Facility (RLWTF): On Wednesday, LANL submitted the Evaluation of the Safety of the Situation (ESS) to the site office for the Potential Inadequacy of the Safety Analysis (PISA) associated with the configuration of the transuranic liquid waste receipt and distribution system. LANL’s evaluation concluded that this issue does not represent an Unreviewed Safety Question. The ESS notes that LANL has completed physical modification to eliminate potential interactions between the transuranic and low level waste systems. Based on submittal of the ESS, RLWTF management will remove operational restrictions that were identified as part of the PISA.

Area G – Safety Basis: This week, the site office approved a revision to the Area G Documented Safety Analysis and Technical Safety Requirements. This revision, which was submitted last week, includes clarifications for the material at risk for exposed waste in pits and shafts and overburden requirements for buried waste. The site office approval identifies a concern with the exposed radioactive waste inventory in active shafts and pits and requests LANL to evaluate using the new information process.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 22, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 22, 2012

Staff members Dunlevy, Futrell, Johnson, Pasko and Sharpless were onsite this week to review the Area G Basis for Interim Operation that is scheduled to be implemented by September 30, 2012.

Transuranic Waste Operations: This week, facility management discovered a significant breakdown in inventory control and material at risk (MAR) tracking for several locations in Area G. The facility uses a software database to track the physical location of transuranic waste inventory and to protect TSR-level MAR limits for defined areas and facilities inside Area G. When moving transuranic waste from one location to another, Area G operators use hand-held barcode scanners to update the location of inventory in the software database to ensure that applicable MAR limits will not be exceeded. A recent inquiry by an NNSA facility representative prompted the discovery of significant discrepancies between inventory information in the database and the actual inventory present in several locations including Pad 10 characterization facilities and the waste storage dome used to house material awaiting characterization on Pad 10. Facility management also discovered that historical inventory records extracted from the database indicate that a TSR-level MAR limit for a characterization facility had been violated on multiple occasions within the past several months. This information led Area G management to declare a TSR violation.

In response, facility management suspended MAR movements within Area G and initiated walkdowns to re-establish an accurate physical inventory of transuranic material in all affected areas. The walkdowns did not identify any instances where the actual MAR in a location exceeded TSR limits. Area G management has allowed MAR movement to resume under a modified inventory tracking and control system that requires positive confirmation that the database was successfully updated after every barcode scanner transaction, as well as, the use of a redundant paper-based tracking system. Using this modified approach, issues have been identified where a barcode scanner indicates that information has been sent, but the inventory database is not updated. Area G personnel continue to investigate the root causes of the inventory control breakdown.

Quality Assurance: The Area G inventory control issue discussed above is the seventh TSR violation in the past 10 months that involve issues with software databases used to implement TSR-level controls in LANL nuclear facilities. The following is a summary of the recent database-related TSR violations: • August 2011 - WETF containerization program pressure limit, • September 2011 – Area G low level waste MAR limit, • December 2011 – Area G tritium MAR limit, • December 2011 – WETF combustible loading limit, • April 2012 – Area G low level waste MAR limit, • April 2012 – Plutonium Facility MAR limit, • June 2012 Area G transuranic waste MAR limit.

Weapons Engineering Tritium Facility (WETF): This week, LANL submitted a Justification for Continued Operation (JCO) to address non-conservative oxygen readings for the Oxygen Monitoring System (OMS) at WETF. In late-May, WETF identified that the OMS readings are dependent on the pressure at the oxygen sensor and declared a Potential Inadequacy of the Safety Analysis. The JCO includes a weekly surveillance to verify that the pressure at affected OMS sensors is within the required range and an annual surveillance to calibrate the pressure instrumentation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

June 29, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending June 29, 2012

Staff member R. Tontodonato was onsite this week to attend an Integrated Nuclear Planning workshop. During the workshop, personnel from NNSA and LANL discussed the progress and plans for transuranic waste operations and, in particular, the 3706 m³ campaign to disposition higher risk (i.e. combustible and/or dispersible) above-ground transuranic waste at Area G.

Chemistry and Metallurgy Research Building (CMR): Laboratory personnel have been working for years to design, test and install equipment in Wing 9 of CMR to safely retrieve and disposition radiological material from nine large metal confinement vessels currently staged at the Plutonium Facility. Project personnel have now fielded all Confinement Vessel Disposition project hardware in Wing 9, including a Permacon enclosure equipped with fire suppression and HEPA-filtered ventilation, a seismically-qualified confinement vessel support stand, a glovebox workstation that will be mated to confinement vessels, and a robotic arm that will be used to remotely remove material and decontaminate the interior of confinement vessels.

This week, laboratory personnel issued a final report documenting the results of an Implementation Verification Review (IVR) whose primary purpose was to validate the implementation of Confinement Vessel Disposition-related Technical Safety Requirements (TSRs). The IVR identified three pre-implementation findings, all of which were addressed and closed during the review. After successful completion of the IVR, Confinement Vessel Disposition project management had intended to begin formal startup activities including a Management Self Assessment, contractor Operational Readiness Review, and federal Operational Readiness Review. However, these required startup activities appear likely to be deferred to FY13 due to funding issues.

Safety Basis: LANL management has submitted, for NNSA site office concurrence, a technical justification to continue using a deposition velocity of 1 cm/s for accident analysis calculations of unfiltered/unmitigated releases at LANL facilities. The LANL justification argues that non-conservatism associated with the 1 cm/s deposition velocity is offset by over-conservatism in the default values for dispersion coefficients (σ_y and σ_z) used in the MELCOR Accident Consequence Calculation System, Version 2 (MACCS2) computer code employed to calculate χ/Q values.

Weapons Engineering Tritium Facility (WETF): This week, the site office responded to the Evaluation of the Safety of the Situation (ESS) and Justification for Continued Operation (JCO) for non-conservative oxygen readings associated with the Oxygen Monitoring System (OMS). The site office approved the ESS but did not approve the JCO. The LASO letter directs LANL to revise the WETF TSR document so that the low-pressure receiver remains in warm standby until the OMS is declared operable. LANL was also directed to submit a TSR revision that clearly defines the conditions for OMS operability, which should account for pressure sensitivity. The low-pressure receiver will remain in warm standby until the TSR revision is approved and implemented at WETF.

LANL also submitted a revision to the WETF safety basis strategy this week that defines the plan for submittal of an upgraded Documented Safety Analysis and TSRs. The strategy states that the upgraded safety basis will be submitted to the site office for approval by August 15, 2012.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 6, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 6, 2012

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF management identified that the semi-annual Oxygen Monitoring System (OMS) surveillances are performed after replacement and calibration of the oxygen sensors, which may not be consistent with the Technical Safety Requirements (TSRs). Performance of the surveillance after a new sensor is calibrated does not provide information on the performance of the previous sensor. The TSR surveillance identifies that operators should “VERIFY” OMS performance, which does not allow operator manipulation. Upon discovery, WETF management conservatively concluded that this issue represented a TSR violation and plans to critique the issue on Monday.

Technical Area-35 (TA-35): Last week, LANL submitted a corrective action plan to the site office for recovery from recent criticality safety issues identified at TA-35, including the discovery of three unaccounted for fuel rods in May and identification of fuel rods with active lengths that may exceed the length identified in the criticality safety evaluation in June. The plan includes compensatory actions and a path forward to ensure proper accounting and disposition of the fuel rods; however, it did not incorporate actions required to respond to a recent site office memo on the TA-35 criticality safety issues. The LASO memo requests that LANL evaluate the following three options: 1) deinventory sufficient fuel rods to preclude criticality concerns; 2) upgrade the hazard categorization of certain facilities in TA-35 to hazard category 2; or 3) improve the “nature of the process” arguments that allow these TA-35 facilities to be radiological (i.e. less than hazard category 3) facilities per DOE Standard 1027. The site office did not take action on the LANL corrective action plan and instead requested that LANL incorporate the actions and path forward into a recovery plan that adequately addresses all LASO requested actions. Programmatic operations associated with these fuel rods remain suspended pending LANL development and site office approval of a recovery plan.

Nuclear Safety: This week, the Laboratory Director provided a final response to a September 2011 NNSA site office letter requesting action to improve nuclear safety and operations. In this response, the Director provides the results of laboratory causal analysis of four key identified problem areas: • Why are Technical Safety Requirement (TSR) violations occurring? • Why are criticality safety infractions occurring? • Why are issues and deficient conditions, which should be discovered by LANS personnel, being found by NNSA Facility Representatives and other outside groups? • Why do personnel have difficulty executing procedures and work packages? The LANL analysis rolls up identified deficiencies and causal factors into five judgments of need related to: 1) Strengthening management emphasis on Nuclear Safety Culture, self-discovery, reporting free from fear of retaliation, and continuous improvement; 2) Improving clarity and understanding of roles, responsibilities, authority, and accountability; 3) Enhancing issues management with corrective actions directed at causes rather than symptoms to support continuous improvement; 4) Elevating management attention on the training and qualification program; and 5) Improving effectiveness of technical procedures as tools for workers. In the response, the Director also announced the establishment of a Senior Executive Committee on Nuclear Safety that will be chaired by the Associate Director for Nuclear and High Hazard Operations. This committee will be responsible for addressing the five identified judgments of need and directing future improvements to nuclear safety and operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 13, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 13, 2012

Software Quality Assurance: This week, LANL provided the site office with a plan to evaluate issues and develop an improvement plan for recent software quality assurance issues related to Technical Safety Requirement (TSR) violations. As noted in the June 22nd weekly report, there have been 7 TSR violations in the past year that involve issues with software databases used to implement TSR-level controls at LANL nuclear facilities. The LANL plan includes gathering and evaluating historical data by July 20th and developing an improvement plan by August 17th.

Weapons Engineering Tritium Facility (WETF): This week, WETF management declared a TSR violation related to the facility's credited Pressure Safety Program. WETF TSRs state that components of the safety significant tritium waste treatment system are required to comply with pressure safety provisions in the LANL Engineering Standards Manual. In a number of cases, formal variances to the manual's pressure safety requirements were issued to establish interim compliance while system modifications could be executed to achieve full compliance. Each pressure safety variance has an expiration date and the institutional engineering organization that administers the program issues tags to hang on systems that indicate when variances expire. However, when a single system has multiple pressure safety variances, the variance tag for that system is issued with an expiration date that corresponds to the last expiration date of any individual variance. At WETF, engineers relied on the expiration date on the tag to track compliance with variances. This week, personnel recognized that although they had not reached the expiration dates reflected on any variance tags, at least one individual variance had expired. As a result, the tritium waste treatment system did not comply with TSR-level pressure safety requirements. Facility personnel are conducting an extent of condition review and working to improve the variance tracking and tagging system.

Plutonium Facility: On Tuesday, a Plutonium Facility worker was discovered to have alpha contamination on his left wrist (2,000 dpm) and wrist watch (10,000 dpm) after performing maintenance activities in an Automated Recovery and Integrated Extraction System (ARIES) glovebox. After completion of maintenance activities for the day, the worker alarmed the hand and foot monitor when exiting the room. The responding radiological control technician identified the personnel contamination, contamination on the personal protective equipment of another worker and contamination in the room. Appropriate actions were taken to respond to the personnel contamination and to isolate the lab room.

Plutonium Facility procedures require workers to monitor their hands and arms for contamination after removal from glovebox gloves. The particular glovebox where the maintenance was being performed is equipped with two newer cordless contamination monitoring devices. During the critique for this event, it was identified that these cordless probes are powered by a capacitor that maintains power for a limited time after being removed from the charging cradle on the glovebox. Workers for this maintenance activity had removed the probe and placed it on a nearby table to perform hand monitoring after exiting from the glovebox and were not aware that the probe would become de-energized and inoperable if not returned to the cradle. LANL management is developing corrective actions and plans to communicate a complex-wide lessons learned to ensure other sites are aware of the limitations for this type of cordless contamination monitor.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 20, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 20, 2012

Staff member R. Verhaagen was onsite this week.

Technical Area-35 (TA-35): This week, the site office approved a recovery plan to address the discovery of fuel rods at TA-35 Building 27 and the identification of fuel rods with active lengths that may exceed the length identified in the criticality safety evaluation. The LANL plan details a two phased approach to ensure adequate implementation of the criticality safety program at TA-35 Buildings 2 and 27 including improvements to the “nature of the process” arguments and controls consistent with recent direction from the site office. Phase 1 of the recovery plan includes 1) performing a wall-to-wall inventory of materials and sealed sources in Building 27; 2) ensuring fuel rods are included in accountability and tracking systems; and 3) verifying that the inventory meets criticality safety requirements. LANL is scheduled to have a corrective action plan for Phase 1 by August 13th.

The 2nd Phase of the recovery plan details LANL’s actions to ensure adequate and sustainable implementation of the nuclear criticality safety program at TA-35 Buildings 2 and 27. This effort includes updating the Facility Hazard Categorization and criticality safety evaluation documents, creating a systematic approach to operator training, and implementing improved inventory and access controls. LANL is scheduled to have a detailed implementation plan for Phase 2 by November 22nd. The site office approved the recovery plan subject to several comments, one of which states that programmatic operations involving fuel rods in racks and operations with sources underwater are precluded until completion of Phase 2 activities.

Transuranic Waste Operations: The safety basis for the RANT shipping facility credits a pre-action dry pipe fire suppression system (FSS) as a safety significant control. Preventive maintenance on this system has historically been performed using a generic maintenance work instruction that did not account for differences between RANT’s pre-action dry pipe FSS and more common wet pipe FSSs used elsewhere at LANL. In 2010, personnel using the generic work instruction inadvertently caused the RANT FSS to charge with water during a preventive maintenance evolution. In response, facility management defined a corrective action intended to prevent recurrence. When this corrective action was ultimately implemented in June 2012, facility personnel used an operator aid posting to capture several system manipulation steps necessary to ensure the RANT pre-action system is properly aligned to support maintenance. Personnel involved in developing and posting the operator aid were not aware that the Conduct of Operations Manual prohibits the use of operator aids to alter or contradict procedures. Additionally, one of the steps in the operator aid was incorrect and would actually cause a valve misalignment.

Last week, personnel performing preventive maintenance on the RANT FSS followed the steps on the operator aid and the resulting valve misalignment charged the system with water. In response to this event, facility management had the operator aid removed, directed that appropriate procedures and work instructions be revised to appropriately account for features specific to the RANT FSS, and chartered the development of continuing training to strengthen Conduct of Operations awareness and understanding for transuranic waste operations personnel and management.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

July 27, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending July 27, 2012

Staff member R. Verhaagen was onsite this week.

WCRR Repackaging Facility – Safety Basis: This week, WCRR repackaging facility management declared a Technical Safety Requirement (TSR) violation based on the failure to perform a required surveillance within its prescribed frequency. The WCRR TSRs require a weekly combustible loading surveillance to be performed in and around outdoor transportainers used to stage transuranic waste drums awaiting processing or shipment. This surveillance requirement, which came into effect in January 2012, is implemented as a part of the performance of facility rounds. Prior to January 2012, all of the TSR-level surveillance requirements implemented via rounds applied only to the interior of the WCRR building and no rounds-based surveillances were tied to the outside transportainers or the yard. As a result, operations personnel had historically not performed rounds when material at risk was removed from the WCRR building because no rounds-based surveillances were required when the building was in cold standby mode.

Problems with the WCRR drum lift have caused facility operations to be suspended and the building to be placed in cold standby mode for much of the last six weeks. Following past practice, operations personnel did not perform rounds while the WCRR building was de-inventoried and in cold standby mode. However, material at risk was present in the transportainers, meaning the associated combustible loading surveillance was required to be performed. This resulted in the weekly transportainer combustible loading surveillance to be missed on several occasions in June and July. In response, facility management is evaluating the extent of condition and developing corrective actions.

Weapons Engineering Tritium Facility (WETF): In July 2010, WETF successfully completed an NNSA Operational Readiness Review allowing the facility to restart programmatic tritium gas handling activities after an extended operational suspension. WETF personnel had been pursuing restart of the balance of the facility in a phased approach and planned to perform both contractor and federal readiness assessments in September and October 2012, respectively, to support tritium gas transfer operations from the function tester glovebox to the load-in glovebox. However, based on the time elapsed since the last gas transfer and function test operations (over 1 year), LANL is now proposing to include these operations as part of the upcoming readiness assessments. The LANL Joint Evaluation Team met this week to discuss the readiness plans for these operations and recommended both federal and contractor readiness assessments. LANL is revising the readiness assessment Plan of Action to be consistent with this approach. WETF management plans to resume programmatic tritium operations in November following successful completion of the readiness assessments.

Area G - Readiness: On Tuesday, the site office approved the LANL Plan of Action for the performance of the drum venting contractor readiness assessment that is scheduled to start on Monday. The site office manager has been delegated as the startup authorization authority for this activity. In June, Area G personnel completed a management self assessment and began venting drums with less than hazard category 3 material quantities. The readiness assessment team will observe venting operations with these type drums next week. A federal readiness assessment is also scheduled to be performed in September prior to beginning hazard category 3 operations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 3, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 3, 2012

Mr. Broderick was out of the office this week.

Federal Oversight: On Wednesday, the site office sent a letter to LANL management on nuclear safety culture and operations. Earlier this month, LANL identified that the static gauge pressure for the fire suppression system at the RANT shipping facility drops below the Technical Safety Requirement (TSR) lower pressure limit (i.e. the surveillance requirement) under certain conditions of domestic water usage. Facility management entered the New Information Process to evaluate whether this issue constitutes a Potentially Inadequacy in the Safety Analysis; however, no compensatory actions were taken to preclude pressure drops and normal operations continued. The site office letter notes that allowing conditions such as this to continue can lead to “normalization of deviation” and that lack of immediate action is not consistent with LANL commitments to nuclear safety culture. As noted on July 6th, the laboratory recently established a senior executive committee on nuclear safety that will be responsible for directing improvements in nuclear safety and operations.

Weapons Engineering Tritium Facility (WETF): Last week, LANL submitted a significant update to the WETF Documented Safety Analysis (DSA) and TSRs along with the Fire Hazards Analysis, Upgrade Safety Basis Strategy and the Inputs, Methods and Assumptions document. Although LANL has revised and updated the previous WETF safety basis, this update represents a significant revision to the WETF DSA and TSRs. The revised safety basis document includes an inventory limit of 250 grams of tritium (including holdup) and the following safety class structures, systems and components: DOT Type B shipping package, facility structure, pressurized gas flow restrictors, qualified containment vessels, oxygen monitoring system and the wet pipe sprinkler system. The site office is currently reviewing this submittal package. LANL will develop an implementation plan within 30 days of the site office approval of the DSA and TSRs.

Facility Hazard Categorization: LANL recently requested site office approval to use NA-1 SD G 1027, *Guidance on Using Release Fraction and Modern Dosimetric Information Consistently with DOE STD 1027-92* for the Technical Area-48 RC-1 building, which is a radiological facility (i.e. material quantities less than hazard category 3 per DOE STD 1027-92). The submittal includes a revised facility hazard categorization document to demonstrate that RC-1 remains below hazard category 3 quantities using the NNSA guidance document. Consistent with direction from the site office, LANL has completed an impact assessment and programmatic implementation plan for use of this guidance. Site office approval of this request will allow LANL to increase material inventories in support of increased throughputs for the LANL Medical Isotope Program. LANL plans to pursue use of the NNSA guidance for other radiological facilities on a case-by-case basis with site office approval when there is a mission need.

Area G – Readiness: On Monday, LANL began the contractor readiness assessment for the drum venting system at Dome 33 in Area G. Field observations including conduct of an emergency drill were completed this week. The team plans complete their review and outbrief the results to site management next week. A federal readiness assessment is scheduled for September.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 10, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 10, 2012

Plutonium Facility: On Thursday, Plutonium Facility management declared two Potential Inadequacies of the Safety Analysis (PISAs) associated with the 2011 Documented Safety Analysis (DSA) post-seismic accident scenario. The first PISA is associated with the potential for a post-seismic fire in the facility basement. As part of the DSA evaluation, LANL performed a probabilistic analysis to determine the likelihood of a fire following a seismic event based on historical information. The evaluation identified a probability of a post-seismic fire per facility square foot. When using this value for the Plutonium Facility, the DSA only used the laboratory area and did not include the basement area.

The second PISA is associated with the leak path factor used for the accident scenario. The software calculation used as the technical basis for the leak path factor included material involved in both a spill and a fire that provides an integral result; however, the DSA uses different leak path factors for the contribution from a fire and spill. Both of these issues were identified by the Board's staff during a review of the DSA earlier this year and communicated to NNSA by Board letter on June 18, 2012.

Safety Basis: This week, the site office provided direction to LANL on use of deposition velocities for nuclear facility safety basis calculations. Previously, LANL recommended continued use of 1 cm/sec despite this value being non-conservative (the site specific calculation for the Transuranic Waste Facility Project was 0.4 cm/sec) because of other conservatism in safety basis calculations. The site office directed LANL to use a deposition velocity of 0.4 cm/sec for the Transuranic Waste Facility Project and to submit a resource loaded plan to identify reasonably conservative dispersion parameters for other facilities and projects in December.

Sealed Sources: Building 214 in Technical Area 36 is a radiological (i.e. less than Hazard Category 3) facility used to perform instrument calibration activities. A number of sealed sources are not counted against Building 214's radiological material inventory for facility hazard categorization purposes based on the sealed source exclusion provision of DOE-STD-1027. This week, facility management discovered that two cesium sources and one americium-beryllium source may not meet all applicable requirements to be excluded from the facility's inventory because these sources have exceeded their manufacturer-specified recommended working life. Adding these previously excluded sealed sources to the facility's inventory caused the Hazard Category 3 threshold to be exceeded. In response, facility management suspended affected operations and began executing proceduralized actions to address the inventory limit violation.

The Building 214 issue was discovered as part of an on-going extent of condition review that was prompted by a similar discovery in a Technical Area 16 facility in late May 2012. In response to the Technical Area 16 event where a facility exceeded its material inventory limit (and the Hazard Category 3 threshold) because two sealed sources were found to no longer meet inventory exclusion requirements, laboratory management took positive action to perform a systematic and thorough extent of condition review and to evaluate laboratory processes for tracking and managing sealed sources. This week's discovery at Building 214 underscores the importance of both successfully completing the extent of condition review and ultimately improving the laboratory's process for managing sealed sources that are excluded from facility inventory limits.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 17, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 17, 2012

This week, Board members Peter Winokur, Jessie Roberson, Joseph Bader and John Mansfield were onsite along with staff members Timothy Dwyer, Daniel Ogg, Richard Schapira, Matthew Duncan, John Pasko and Richard Verhaagen to meet with NNSA site office and LANL personnel. The Board had detailed discussions with site personnel on the Plutonium Facility, the Chemistry and Metallurgy Research Building, Transuranic Waste Operations (including Area G closure activities), the Weapons Engineering Tritium Facility, LANL design and construction projects and emergency preparedness. The Board also toured the Radiological Laboratory, Utility and Office Building and the Plutonium Facility. Mr. Broderick was out of the office on Thursday and Friday.

Weapons Engineering Tritium Facility (WETF): This week, a WETF subject matter expert identified a non-conservative error in the software spreadsheet used to complete the monthly Technical Safety Requirement (TSR) surveillance for combustible loading in the facility. As a part of calculating the average combustible loading for a series of rooms, the spreadsheet does not include combustibles from one of the required rooms. The TSR surveillance limit is not exceeded if the combustibles for that room are correctly included in the combustible loading calculation. WETF management declared a significance category 2 management concern for this issue in part because a software quality issue was identified for this same spreadsheet in December 2011 and corrective actions did not identify the additional error (see site rep weekly 12/9/11).

Both software spreadsheet errors (i.e. the one identified this week and the one in December 2011) were caused by a change that occurred in November 2011. The combustible loading spreadsheet is graded as the second highest level of safety-related software; however, verification and validation (V&V) reviews failed to identify either error. In addition, extent of condition reviews performed in December 2011 that included additional V&V of the software spreadsheet did not identify the additional error introduced in November. WETF management identified corrective actions that include a line-by-line review of combustible loading spreadsheet calculations and an evaluation of the WETF software quality assurance program. As noted on July 13th, LANL is also reviewing recent software quality assurance issues related to TSR violations across the site and is scheduled to submit an improvement plan to the site office this month.

Plutonium Facility: This week, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis (PISA) based on structural/seismic issues with shelves and racks in two vault rooms. During performance of the In-Service Inspection (ISI) for design features in the vault, the system engineer identified a number of missing and loose bolts and screws. During evaluation of these issues, the system engineer identified that the SAFER seismic analysis of four vault rooms was not consistent with the actual field configuration. Subsequent seismic evaluations identified structural issues in two rooms that represent a PISA and need to be resolved. Three locations in these two rooms will require minor structural upgrades to resolve this issue. Plutonium Facility management is also reviewing the SAFER analyses to determine why these issues were not identified during the seismic review.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 24, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 24, 2012

Chemistry and Metallurgy Research (CMR) Building: On Tuesday morning, CMR personnel identified a significant amount of liquid on the floor in the basement of Wing 5. Appropriate actions were taken to contact the operations center. CMR Industrial Hygiene and Radiation Protection personnel responded to isolate the area and evaluate the situation. Based on the size of spill, the facility incident command was established and LANL Emergency Response personnel were called to respond. CMR management also suspended all activities involving liquids in Wing 5 laboratories. Hazmat and facility personnel were able to contain the spill area and confirmed that actions to cease liquid activities stopped the source of the leak. No personnel contamination occurred during this event and spread of contamination outside of controlled areas has not been identified. Cleanup activities commenced on Tuesday and have continued throughout the week.

CMR uses acid drain lines that transfer low-level radioactive liquid waste from individual laboratory rooms to a collection system in the basement that then routes the liquid waste to the Radioactive Liquid Waste Treatment Facility in TA-50. The acid drain line system is known to have significant material condition issues that have resulted in leaks and contamination of basement areas in the past. Although investigation continues, CMR personnel believe that a backup of liquids in a portion of this system caused the leak into the basement. In 2009, facility personnel systematically wrapped and bagged all system flanges because of leak and contamination issues. In addition, CMR management planned to perform periodic surveillances on the bagged flanges. Based on discussion with CMR personnel, these periodic inspections have not been performed as was intended; however, facility management noted this week that they plan to re-evaluate the need to inspect the wrapped flanges (see site rep weekly 2/27/09).

Plutonium Facility: This week, the site office provided additional direction to LANL on the performance of seismic static non-linear analysis for the Plutonium Facility. The letter identifies that additional seismic evaluation is required to address 1) the impact if the service chase roof joints are released and 2) the effect of modal-based loading versus common direction loading currently being used. LANL is directed to perform additional sensitivity runs at the next opportunity that does not delay current efforts and to obtain LASO concurrence with any work-scope that extends into FY 2013. The laboratory is also directed to include longer-term analytical and upgrade work-scope in the Project Execution Plan associated with Recommendation 2009-2, which is scheduled to be updated in November. The Board's staff will continue to review modeling and analysis work to ensure that technically defensible seismic analysis is completed and used for safety basis evaluations and potential upgrade decisions.

Transuranic Waste Operations: This week, the contractor readiness assessment team reported the results of their review of the Drum Venting System in Area G. The team identified three pre-start items in the areas of operations, engineering and safety basis and two post-start findings for Environmental, Safety and Health. Area G personnel are developing corrective action plans for these issues. The federal readiness assessment that was to start next week has now been delayed to late-September.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

August 31, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: B.P. Broderick and R.T. Davis
SUBJECT: Los Alamos Report for Week Ending August 31, 2012

Brett Broderick completed his assignment as a site representative at LANL this week. DNFSB staff member Richard Verhaagen will report to LANL in September.

Los Alamos Neutron Science Center (LANSCE): On August 24th, LANL personnel identified beta-contamination on the skin and clothing of a worker in a LANSCE experimental area. Subsequent surveys conducted by radiological control technicians on August 25th identified significant contamination at multiple locations at the Lujan Center experimental area. Based on the extent of contamination, the LANSCE facility operations director requested assistance from LANL emergency management and the Radiological Assistance Program (RAP) was notified. At approximately 1630 on Saturday afternoon, the emergency management incident command declared an operational emergency and the Emergency Operations Center was activated.

Surveys performed by LANL and RAP team personnel identified beta-contamination, Technetium-99 (Tc-99), outside LANL property at multiple homes and automobiles and on the skin and clothing of personnel who had worked in these areas. Additional RAP team support was requested and deployed to complete survey and decontamination efforts in multiple offsite locations. LANL and RAP team monitoring of LANSCE personnel that may have been in the area of the contamination continued throughout the week. All affected personnel will perform a special bioassay.

Based on the type of contamination and all information available, LANL management has stated that the contamination does not pose health risks to workers or the public. A senior level investigation was initiated by the laboratory director this week. In addition, NNSA NA-1 directed establishment of an Accident Investigation Board (AIB) in accordance with DOE Order 225.1B that will investigate the event “identifying all relevant facts, determining direct, contributing, and root causes of the event, developing conclusions, and determining the judgments of need to prevent recurrence.” The AIB investigation will start on Tuesday and provide a final report to NA-1 by the end of September.

Plutonium Facility – Seismic Safety: On Wednesday, Plutonium Facility management declared a Potential Inadequacy of the Safety Analysis (PISA) based on static non-linear seismic analysis of the Plutonium Facility. The results indicate that the probability of failure for certain structural components do not meet the performance goals identified in the safety basis. LANL will evaluate this information using the Unreviewed Safety Question process to determine the safety basis impact and the need for additional controls.

Engineering: This week, the engineering services division identified that most concrete used at LANL since May 2011 did not meet the ASTM C33 specification requirements for coarse aggregate. Concrete placements were suspended pending resolution of this issue. Non-conformance reports have been issued for concrete used during this period. Notably, the drag strut repair at the Plutonium Facility was performed during this period and LANL is evaluating the potential impact.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 7, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 7, 2012

Los Alamos Neutron Science Center (LANSCE): On Tuesday, the NNSA Accident Investigation Board (AIB), in accordance with DOE Order 225.1B, received an in-brief from LANL personnel and began their investigation into the recent LANSCE contamination event involving Technetium-99. The investigation will continue next week and the team will provide a final report to NA-1 by the end of September.

LANL also continued recovery plan activities this week. All known areas of contamination outside of Technical Area-53 have been decontaminated. Detailed surveys are being conducted for the Lujan Center Experimental Area and other contaminated areas at LANSCE to develop and execute decontamination plans.

Plutonium Facility – Seismic Safety: This week, LANL concluded that the Potential Inadequacy of the Safety Analysis (PISA) identified last week based on the results of the static non-linear analysis did represent an Unreviewed Safety Question. LANL is preparing an Evaluation of the Safety of the Situation for submittal to the site office for this issue. The static non-linear analysis has also been communicated to the peer review team. LANL personnel will be meeting with this team later this month to discuss the results and any peer review comments.

Chemistry and Metallurgy Research (CMR) Building: CMR management declared a Technical Safety Requirement (TSR) violation this week based on an obstructed sprinkler head in the Wing 9 basement. The obstructed sprinkler head was identified in October 2011 and a non-conformance report was written for the issue; however, no operability determination was performed at that time. After the issue was recognized by the CMR engineering manager earlier this week, an immediate operability determination was performed and the sprinkler head was determined to be inoperable. Appropriate actions were taken to enter the TSR Limiting Condition of Operation for the affected area. A work order was written to remove the obstruction and CMR management exited the Limiting Condition of Operation following execution of the work.

CMR personnel conducted an extent of condition review and concluded that other non-conformance reports did not impact TSR Limiting Conditions of Operation. In addition, the LANL procedure for non-conformance reports has changed recently to drive evaluation of potential safety basis impacts that should help preclude similar issues in the future.

Transuranic Waste Operations: LANL recently submitted a safety basis change to the site office to allow an increase in the material at risk (MAR) for sort, segregate and size reduction (SSSR) activities at Area-G. The change will increase the MAR limit from 2.5 to 18 plutonium equivalent curies (PE-Ci). In addition, the safety basis change does not include plume meander in the consequence evaluation consistent with comments from the site office. Approximately 70 above-ground waste containers at Area G that cannot be remediated at the WCRR repackaging facility (e.g., fiberglass reinforced boxes and large metal containers) exceed the 2.5 PE-Ci SSSR MAR limit. The safety basis change will allow LANL to process approximately 2/3 of the 70 transuranic waste containers.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 14, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis
SUBJECT: Los Alamos Report for Week Ending September 14, 2012

Electrical Safety: In the last week, there have been three separate electrical safety issues at LANL. First, a Physical Chemistry and Applied Spectroscopy post-doctorate employee received two minor shocks from a metal mounting rod last Friday. The employee was evaluated by occupational medicine and released with no restrictions. Subsequent investigation identified a mixer located on the same mounting rod with an intermittent line voltage short that caused the issue. LANL also determined that the mixer was not listed by a Nationally Recognized Testing Laboratory or approved for use as required by LANL procedures. As part of the extent of condition review, other chemistry division electrical equipment is being reviewed to ensure they are either listed or approved per LANL procedures.

Second, during installation of an oven at Technical Area-55 last weekend, two LANL employees received a minor shock. The two employees were evaluated by occupational medicine and released with no restrictions. The electrical safety officer subsequently identified that one of the three phases from the 480 volt line connection had shorted to the oven during the installation process. Finally, a LANL worker in Technical Area-16 opened a 480 volt disconnect and verified zero energy without the required Lock-Out/Tag-Out and personnel protective equipment. No personnel were injured during this activity; however, these activities were not covered by a work package and were not consistent with LANL hazardous energy control requirements. These three events highlight the need to maintain NNSA and LANL focus on work control and electrical safety.

Weapons Engineering Tritium Facility (WETF): On Tuesday, WETF management declared a Technical Safety Requirement (TSR) violation based on the expiration of a pressure safety variance in December 2011. In January 2012, the variance in question was replaced by three separate variances that effectively resolved the issue at that time. The expiration of the variance was identified by WETF engineering as part of the extent of condition review for previously identified TSR violations due to variance expirations. The extent of condition review for these type issues is now complete at WETF.

Radioactive Liquid Waste Treatment Facility (RLWTF): In 2009, LANL completed a low level liquid waste connection to the Waste Management Risk Mitigation (WMRM) tanks to provide 250,000 gallons of emergency storage capacity. Earlier this year, LANL decided to use a portion of this storage capacity for low level liquid waste influent storage to replace ageing RLWTF tanks that do not meet regulatory requirements. Physical modifications to support this configuration are expected to be complete later this month. RLWTF management plans to conduct appropriate readiness activities and begin using the WMRM tanks later this year.

Facility Hazard Categorization: This week, the site office approved a LANL request to use NA-1 SD G 1027, *Guidance on Using Release Fraction and Modern Dosimetric Information Consistently with DOE STD 1027-92* for the Technical Area-48 RC-1 building. The approval is contingent on validated implementation of key facility controls in the hazard analysis. The site office also directed LANL to obtain site office concurrence for use of this guidance for other LANL radiological facilities.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 21, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending September 21, 2012

Plutonium Facility: This week, LANL submitted the Evaluation of the Safety of the Situation (ESS) to the site office for the Unreviewed Safety Question associated with the Plutonium Facility structural performance (see site rep weekly dated 8/31/12). Recent static non-linear seismic analysis indicates that the probability of failure for certain structural components do not meet the Documented Safety Analysis (DSA) performance goals (i.e. probability of failure of 1.4×10^{-4} versus 1×10^{-4}). The ESS references DOE-STD-1020 that permits “using natural phenomena hazard exceedance probability of twice the value specified for new design” (i.e. 2×10^{-4}) for existing structures that are close to meeting the criteria. LANL recommends site office approval of continued operations at the Plutonium Facility under this ESS, and intends to update the performance goal in the DSA to 2×10^{-4} .

No operational restrictions are identified in the ESS; however, the document does acknowledge that this probability of failure applies not only to loss of confinement (the safety basis credited function) but also to potential facility collapse mechanisms. Facility collapse could result in offsite dose consequences well in excess of that postulated in the DSA. LANL plans to develop engineering designs to brace and strengthen Plutonium Facility structural elements. The designs will be prioritized based on capacity margin calculations and cost of proposed upgrades. Conceptual designs will be summarized and submitted to NNSA as part of the Recommendation 2009-2 Project Execution Plan update in early November. The site office is currently reviewing the ESS.

The seismic analysis peer review team met with LANL personnel early this week to discuss comments and questions on the recently completed analysis. Comments will be incorporated into the final report and drive follow-up evaluations, as appropriate. In addition, LANL will perform additional analysis in FY 13 to ensure the seismic results are appropriately bounding as directed by NNSA.

Software Quality Assurance (SQA): This week, LANL submitted a SQA improvement plan to the site office to address weaknesses identified through an analysis of SQA issues related to Technical Safety Requirements (TSR) violations (see site rep weekly dated 7/13/12). The analysis identified 11 instances of SQA issues causal to TSR violations that occurred from August 2006 to the present. The improvement plan identified five SQA areas of concern, including: requirements determination; configuration management; validation and verification; software interfaces; and training. Additionally, the team that conducted the analysis concluded that knowledge of software quality management policies and procedures, including roles and responsibilities, is a weakness that directly contributes to these five areas of concern. The improvement plan includes a number of action items that will be implemented at LANL nuclear facilities and will be monitored and managed by LANL’s Associate Director for Nuclear and High Hazard Operations.

Transuranic Waste Operations: The site office completed the closure verification for all pre-start issues and approved the corrective action plan for post-start issues identified in the contractor readiness assessment for the Area G drum venting system this week. Based on these activities, the site office transmitted the notice to proceed memorandum for conduct of the federal readiness assessment. The review is expected to start on Monday.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

September 28, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending September 28, 2012

Performance Execution Plan (PEP): On September 11, 2012, LASO and LANL jointly approved the Fiscal Year 2013 Strategic PEP for management and operation of LANL. Consistent with direction from NNSA HQ, this new PEP is radically different than previous years' plans in that it is shorter, more subjective, and contains considerably less detail and specificity. Objective performance measures have been replaced with both critical factors and applicable site specific outcomes that will be assessed in the aggregate to establish performance ratings for each objective.

The LANL strategic PEP contains five performance objectives supported by 12 site specific outcomes, some of which are identical to outcomes in other NNSA site PEPs. Some site specific outcomes unique to Los Alamos include: mature the NNSA Plutonium (Pu) Strategy and effectively implement funded FY 2013 elements; successfully execute Pu Oxide production efforts and achieve Surplus Fissile Materials program objectives; achieve program commitments negotiated under the January 2012 Framework Agreement including disposition of 1,800 m³ of Area G legacy waste; complete seismic/structural analyses, and any necessary facility upgrades, for the Plutonium facility in accordance with an NNSA list to be approved no later than the end of the first quarter; and demonstrate long-term site planning activities to enable a sustainable and viable National Laboratory. Of note, LANL must achieve a rating of "very good" or better in each performance area and experience no significant safety or security incidents during the performance period in order to earn the award term incentive.

Transuranic Waste Facility (TWF) Project: This week, NNSA conducted an Independent Project Review of the TWF Project to determine if requirements for critical decision-2, *Approve Performance Baseline*, have been met. The review focused on the following areas: technical; cost, schedule and risk; management and acquisition; environment, safety, health and quality assurance; and commissioning. The team concluded that the project has achieved 90 percent design as defined by NNSA guidance and LANL engineering standards; however, several comments and recommendations were identified that require project action prior to critical decision-2, including resolution of nuclear safety issues identified in the Board letter dated June 11, 2012. The TWF project is scheduled to submit a revised safety basis strategy and Preliminary Documented Safety Analysis to the site office for approval in early October. Currently, approval of critical decision-2 is planned for December.

Weapons Engineering Tritium Facility (WETF): In July, WETF personnel declared the Tritium Gas Handling System interlock inoperable and entered the appropriate safety basis limiting condition of operation. This interlock remains inoperable and the safety basis would have required the facility to enter cold standby for the affected area on September 30th. The site office approved a LANL request for a temporary safety basis change this week to eliminate the requirement to enter cold standby for the affected area. In August, the site office agreed that cold standby (versus warm standby) is not always the safest operational state and directed LANL to revise the safety basis to eliminate the cold standby mode. This revision is scheduled for submittal in October. WETF personnel continue facility restart activities to support resumption of programmatic work. Currently, contractor and federal readiness reviews are scheduled in December 2012 and January 2013, respectively.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 5, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 5, 2012

Radioactive Liquid Waste Treatment Facility – Upgrade Project (RLWTF-UP): Last week, LANL submitted a revision to the Safety Design Strategy (SDS) for the RLWTF-UP to the site office for approval. In 2011, NNSA approved a contractor proposal to separate the transuranic and low-level waste processes into individual structures. Low-level liquid waste processing will be conducted in a radiological facility (i.e., less than hazard category 3) planned for completion in 2017. Transuranic liquid waste processing will be conducted in a hazard category 3 nuclear facility planned for completion in 2020. The updated SDS reflects this separation and also incorporates previous comments from the site office. LANL is currently conducting a siting study for the transuranic facility to determine the optimum separation from the radiological facility. Critical decision-2, *Approve Performance Baseline*, is currently planned for December, 2012, for the low-level waste portion of the project.

Work Planning and Control. There have been several issues with LANL work planning and control this week. Two of the more significant failures to properly control work included:

At PF-4, construction personnel removed the automatic closing mechanism from an operable safety class confinement door while reinstalling trim. The PF-4 safety basis requires the confinement doors to be capable of closing automatically via this automatic door closure device. The trim work had not been authorized on the plan of the day and had not been released by the PF-4 operations center. Contributing to this unauthorized maintenance, the integrated work document for door modifications did not specify a sequence to complete door restoration and operability testing.

At the Chemistry and Metallurgy Research facility, electricians preparing to perform corrective maintenance on an elevator installed their lockout/tagouts (LO/TO) on the incorrect power isolation. An independent verifier (IV) identified the breaker specified on the LO/TO did not match the current location of the LO/TO. Instead of stopping work and informing management as required, the electricians removed their LO/TO to reinstall it on the specified circuit breaker. The electricians once again hung their LO/TO on an incorrect power isolation, but this time the IV did not identify the discrepancy when he reviewed the LO/TO. No work was performed on energized equipment before the discrepancy was discovered. Contributing to this issue, instructions in the integrated work document did not direct workers where to install the LO/TO, but rather relied on an attachment to communicate this important information.

Area G Drum Venting System (DVS) Federal Readiness Assessment (FRA). On Thursday, the FRA team presented their outbrief for the DVS readiness assessment. In total there were 18 pre-start findings, 14 post-start findings, and 48 observations. The FRA team concluded that the contractor had not successfully demonstrated readiness for hazard category 2/3 drum venting operations in Area G. This conclusion was based in large part on the number and severity of the findings. Many of the findings were attributed to inappropriate TSR control selection and development, and a reliance on specific administrative controls vice engineered controls. The final assessment report is expected to be issued next week.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 12, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 12, 2012

Area G 3706 Campaign: In FY 2012, LANL removed 920 m³ of the highest risk above ground solid transuranic (TRU) waste from TA-54, Area G, under the first year of the 3706 campaign. This inventory included 23,075 PE-Ci of TRU waste and exceeded the performance goals of 800 m³ and 22,500 PE-Ci. The FY 13 performance goals are to remove a campaign cumulative volume of 2600 m³ and a campaign cumulative 33,739 PE-Ci. Achieving these goals will keep the project on pace to meet the framework agreement commitment to remove the 3706 m³ of above ground TRU waste by June 30, 2014.

In order to achieve the FY 2013 performance goals, the box lines in domes 375 and 231, and the drum venting system (DVS) in dome 33 will have to be fully operational. Fire suppression system upgrades and a federal readiness assessment (FRA) are required prior to commencing operations in dome 375. Fire suppression system upgrades, ventilation system commissioning, and a contractor readiness assessment are required prior to commencing box line operations in dome 231. Corrective actions from the DVS FRA (see 10/5/12 weekly) will have to be identified and closed prior to commencing Hazard Category 2/3 DVS operations in dome 33.

Work Planning and Control: LANL continues to experience problems with work planning and work control as noted in last week's report. For example:

At a radiochemistry laboratory, a known previously contaminated cask located outside of the building was intentionally opened with a forklift without a specific integrated work document or radiological work permit in place. The work was done in the open air outside of a controlled area because it was believed that the cask was clean based on one individual's recollection from nearly 20 years ago. The lid was replaced when the radiological control technician detected the presence of contamination inside the opened cask.

At an environmental, safety and health analytical laboratory, workers removing ducting from a furnace were exposed to ash containing perchlorate and nitric acid. The development of the work scope for this job did not identify these contaminants as a potential hazard, and as such no controls (i.e. respirator protection) for this hazard were employed.

The Associate Director for Nuclear and High Hazard Operations has recognized this trend of poor performance in planning and controlling work, and is emphasizing this as a focus area with his facility operation directors.

Criticality Safety Improvement Plan: On September 28, 2012, LANS submitted a revised, *Los Alamos National Laboratory Nuclear Criticality Safety Program Improvement Plan*, to the site office for review and approval. This is the sixth revision to the document since it was issued in March, 2006. This most recent revision updates the status of program implementation at important facilities and updates progress on planned nuclear criticality safety evaluations.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 19, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 19, 2012

Staff members T. Chapman, J. Deplitch, M. Helfrich and J. Pasko were onsite this week to review the LANL Emergency Management Program. The staff conducted field walk-downs of emergency response capabilities and plans at the Plutonium Facility, the Chemistry and Metallurgy Research Building, Area G and the Weapons Engineering Tritium Facility.

Plutonium Facility – Seismic Safety: On Thursday, the site office directed LANL to complete an addendum to the Plutonium Facility safety basis to address the Unreviewed Safety Question (USQ) associated with the facility structural performance. The site office did not take action on the LANL submission of an Evaluation of the Safety of the Situation (ESS) for this USQ. Instead the site office requested that a safety basis addendum be developed and submitted for approval that addresses the steps identified under *Exigent Circumstances* in the DOE memorandum dated September 17, 2012, concerning *Adequate Protection*. These steps were identified by DOE for “an unusual situation ... where no viable control strategy exists to prevent or mitigate the consequences in one or more of the accident scenarios from exceeding the EG [Evaluation Guideline].” The site office also provided specific comments on the ESS to be addressed in the safety basis addendum and requested completion of this action concurrent with submittal of the seismic project execution plan (due November 7th) provided there was no schedule impact and no later than November 14th regardless.

Plutonium Facility – Criticality Safety: This week, Plutonium Facility management declared a Potential Inadequacy in the Safety Analysis (PISA) based on criticality safety concerns for vault rooms B and I. These rooms had been operating under a Justification for Continued Operations (JCO) since 2007 because criticality safety evaluations included a neutron poison (boron) with inadequate documentation that the boron was present. Without the poison, criticality safety controls were not adequate to prevent criticality under all normal and credible abnormal conditions. In September, LANL completed a new criticality safety evaluation that did not include the boron and exited the JCO; however, a separate calculation for the interaction between floor and drawer locations was identified this week that assumes the presence of boron. Plutonium Facility management suspended operations and entered mode 2 for these vault rooms pending resolution of the PISA. Identification of this issue was prompted by questions from site office personnel.

Weapons Engineering Tritium Facility (WETF): WETF management declared a Technical Safety Requirement (TSR) violation based on the failure to meet overpressure protection requirements for the Tritium Waste Treatment System (TWTS), Tritium Gas Handling System (TGHS), and the Hot Inlet System (HIS). The failure to meet the TSR requirements stemmed from inadequate historical calculations of over-temperature setpoints for these systems that did not include uncertainty calculations in their determination. TWTS over-temperature setpoints were found not to comply with the ASME Boiler and Pressure Vessel Code as required by the TSRs for overpressure protection. TGHS and HIS over temperature setpoint calculations could not be shown to comply with institutional engineering standards applicable at the time these calculations were made. Updated setpoint determinations that included uncertainty calculations revealed that the original setpoints were not protective of a credited operating parameter contained in the deflagration limit calculation.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

October 26, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending October 26, 2012

Los Alamos Neutron Science Center (LANSCE): In August, LANL identified a release of contamination at the Lujan Center experimental area at LANSCE and the subsequent spread of contamination to multiple offsite locations (see 8/31/12 report). LANL and other response teams aggressively responded to the spread of contamination, retrieved contaminated items and performed decontamination as required. Although the contamination levels found offsite exceeded DOE's release criteria, NNSA and LANL management have stated that contamination did not pose health risks to the workers or public. Based on the significance of this event, NA-1 directed establishment of an Accident Investigation Board (AIB) in accordance with DOE Order 225.1B. The AIB completed their investigation in September and NA-1 recently released the report.

The AIB concluded that LANSCE personnel lost positive control of a Technetium (Tc-99) sample from January 2012 until the time of the event. The investigation indicates that the Tc-99 sample container was re-used in August 2012 (likely on August 20th), which caused the initial spread of contamination. The AIB report notes that the accident "was (and its recurrence is) completely preventable." The team identified 14 Judgments Of Need (JONs) including the following: 1) establish effective engineering and administrative controls to ensure radioactive samples are identified and controlled; 2) establish clear roles and responsibilities for controlling samples and participating in experiments; 3) establish formal processes for managing material in radiological storage cabinets; 4) ensure personnel understand and comply with management processes; 5) revise work control process to ensure that work remains consistent with the reviewed and approved scope; and 6) address inadequacies in both site office and LANL oversight activities.

LANL plans to implement phased corrective actions with the first phase focused on the Lujan Center and the second phase to include other LANSCE facility areas. For the first phase (Nov 2012 to Feb 2013), LANL will implement interim corrective actions that address the JONs identified by the AIB for a portion of the Lujan Center flight paths (experimental flight paths in the area of most significant contamination will remain shut down). The scope and implementation of these corrective actions will be assessed by an independent laboratory committee. The second phase will include permanent corrective actions at LANSCE for the 2013 run cycle (July 2013).

Area G Drum Venting System (DVS): The site office transmitted the final report for the federal readiness assessment (FRA) of Area G, Dome 33 DVS operations (see 10/5/12 weekly). The review team concluded that the project had not demonstrated readiness to commence Hazard Category 2/3 operations based on the volume and severity of the findings. The site office has requested a corrective action plan be submitted by November 1, 2012, and a report on the immediate actions taken and the performance improvement approaches selected to close the prestart findings by November 19, 2012. In response to the report, Area G management has entered the New Information process to evaluate whether: the Technical Safety Requirements (TSR) protect the drum venting material at risk limits; the DVS chamber can be credited as a blast-mitigation device; the Unreviewed Safety Question process has been effective in ensuring TSR controls are properly implemented; and certain specific administrative controls apply to unvented drums that are overpacked. Following the completion of the corrective action plan, LASO plans on conducting a limited scope FRA to evaluate closure of the prestart findings.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 2, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director

FROM: R.T. Davis and R.K. Verhaagen

SUBJECT: Los Alamos Report for Week Ending November 2, 2012

The site representatives were out of the office. This report is submitted for continuity purposes only.

DEFENSE NUCLEAR FACILITIES SAFETY BOARD

November 9, 2012

MEMORANDUM FOR: T. J. Dwyer, Technical Director
FROM: R.T. Davis and R.K. Verhaagen
SUBJECT: Los Alamos Report for Week Ending November 9, 2012

Board member S. Sullivan and Board staff member R. Tontodonato visited the Los Alamos National Laboratory to discuss current operations and to walkdown select defense nuclear facilities.

Weapons Engineering Tritium Facility (WETF) – Disciplined Operations: WETF continues to experience issues with formality of operations as restart preparations move forward. Over the past few weeks a number of engineering and safety basis issues have been discovered by both facility personnel and the NNSA Facility Representative (FR) assigned to oversee WETF operations, including:

- Facility engineering personnel discovered two new pressure safety Technical Safety Requirement (TSR) noncompliances.
- A TSR violation was declared when the FR identified approximately 20 WETF procedures that had been approved and issued without having been evaluated through the Unreviewed Safety Question process against the currently implemented Documented Safety Analysis.
- The FR identified that a Limiting Condition for Operation action statement had not been entered within the required timeframe.
